## 1. A SYSTEMATIC APPROACH FOR ANALYSING INNOVATIONS AND CULTURAL CHANGE: THE BONE ARTEFACTS OF THE MIDDLE STONE AGE OF SOUTH AFRICA.

*Stolarczyk, Regine - (Research project "The role of culture in early expansions of humans" of the Heidelberg Academy Of Sciences And Humanities, Senckenberg Research Institute, Senckenberganlage 25, D-60325 Frankfurt/m., Germany) regine\_stolarczyk@yahoo.de*

The middle stone age (MSA) of southern Africa is an interesting period for analysing innovations, because of its essentially modern and cognitively and behaviourally complex artefacts. In the context of an ongoing DFG (Deutsche Forschungsgemeinschaft) project the material remains of the MSA of South Africa and Lesotho are analysed. The goal is to reconstruct past behaviours on the basis of artefacts, because innovations can be detected in various aspects of object behaviour, like material, function, technology of production or the cognitive complexity (Haidle & Bräuer 2011). The class of bone artefacts seem to be innovations of this period and region and are therefore of special significance for a detailed insight into the innovative behaviour.

A systematic approach was designed to analyse the organic artefacts, both qualitatively and quantitatively. The data is acquired based on ROAD, the data base of ROCEEH (the role of culture in early expansions of humans), a project of the heidelberg academy of sciences and humanities, and the current literature. Through quantitative analyses of the different types of artefacts it is possible to reconstruct cultural change during this period and to identify new artefact types. By using effective chains and cognigrams, two methods developed by Haidle (2012; Lombard & Haidle 2012), the object behaviour and its cognitive foundation can be coded and illustrated in a systematic way. In doing so, a variety of aspects of the tool behaviours are acquired. These can be evaluated by comparative analyses regarding their innovativeness.

Within the class of bone artefacts of the middle stone age of South Africa, various innovations can be detected. Beside new tool types like awls and arrow heads, diverse aspects of the reconstructed tool behaviours, like new production techniques or complementary tool sets, seem to be innovations of this period and region.

During the MSA of South Africa new problem-solution-concepts seemed to be developed, which are most likely based on evolvments of cognitive abilities.

## 2. THE NORTH AFRICAN MIDDLE STONE AGE DURING MARINE ISOTOPE STAGE 5

*Scerri, Eleanor - (University of Bordeaux) eleanor.scerri@u-bordeaux.fr*

*Drake, Nick (Kings College London) nick.drake@kcl.ac.uk*

*Groucutt, Huw (University of Oxford) huw.groucutt@wolfson.ox.ac.uk*

*Jennings, Richard (University of Oxford) richard.jennings@rlaha.ox.ac.uk*

North Africa during Marine Isotope Stage 5 (MIS 5, ~130-75 thousand years ago) is linked with the emergence of regionally distinctive stone tool (lithic) industries and complex material culture. However, the structure and variation of these lithic industries remains unclear and their articulation with human dispersals, while debated, is not well understood. Here, we present the results of an integrated multivariate analysis of 300,000 attribute measurements of 'Aterian', 'Nubian Complex' and 'Mousterian' assemblages from across North Africa. We first compared discrete stages of stone tool manufacture while accounting for the effects of differential raw materials, site function and mobility strategies. We then integrated these results with a palaeoclimate model of North Africa during MIS 5. The results of our multivariate analyses first revealed the presence of a number of distinct, spatially defined technological clusters, which did not correlate with traditional industrial nomenclatures. Similarly, our climate model showed that the Sahara was not uniformly green during MIS 5, as has been stated. Instead, variable environmental and hydrological resource gradients structured a patchwork of ecological bottlenecks and corridors, which we were able to link with the distribution of arid/wet palaeofauna. Final integration of the multivariate results with the climate model demonstrated that the spatial organization of the technological clusters correlated with the modelled palaeobiomes. The degrees of similarity between technological clusters were such that they decreased with distance except where connected by palaeohydrological networks. These results provide a new framework for understanding the lithic technology of North Africa during the Late Pleistocene and indicate for the first time how dispersal may have taken place across the Sahara during periods of environmental amelioration in MIS 5.

ORAL

### 3. GARBA III (MELKA KUNTURE, ETHIOPIA): RE-ANALYSIS OF THE SPACE PATTERNING AND DWELLING STRUCTURES OF AN EARLY MSA SITE

Mussi, Margherita - (Università di Roma Sapienza) [margherita.mussi@uniroma1.it](mailto:margherita.mussi@uniroma1.it)

Altamura, Flavio - (Università di Roma Sapienza) [flavio.altamura@uniroma1.it](mailto:flavio.altamura@uniroma1.it)

Melis, Rita T. (Università di Cagliari) - [rtmelis@unica.it](mailto:rtmelis@unica.it)

Spinapolice, Enza E. - (Max Planck Institute for Evolutionary Anthropology, Leipzig) [enza\\_spinapolice@eva.mpg.de](mailto:enza_spinapolice@eva.mpg.de)

Garba III, in the upper Awash Valley of Ethiopia, is one of the many sub-sites of Melka Kunture, where the archaeological record starts with the Oldowan, continues with a rich Acheulean sequence, and also includes MSA and LSA industries. Garba III was excavated in the Seventies of last century, under the direction of Francis Hours who discovered in layers B2 and B3 lithic assemblages now recognized as belonging to the Early MSA (EMSA). Ever since the first publication, it was stated that it was “*un habitat in situ*” where the crushing and grinding of bones was going on. Small basins with vertical sides and flat bottoms were also described, together with space patterning in the distribution of stone tools and bone fragments. Garba III is one of the few EMSA sites that also yielded human fossils, which belong to archaic *Homo sapiens*. New investigations were started to update the record and assess if site patterning was part of the innovations related to the emergence of modern human behaviour.

In 2011 the original site was re-located and tested, the stratigraphy was re-established, site formation processes were studied, and the lithic collections were re-analysed. A grid allowing the spatial distribution of the original finds was also prepared. U-series dating of bones and a combination of ESR and U-series analyses on teeth were planned.

Complex site formation processes were evidenced, including cyclic phases of erosion and re-deposition of pre-existing soils and deposits, together with prolonged phases of stability when pedogenetic processes developed. The fossil fauna is derived from earlier deposits, while the accumulation of lithic implements in layers B2 and B3 is the outcome of other distinct processes. The lithic assemblages are coherent and relatively well preserved. No major differences were noticed in alteration patterns. Obsidian was mostly used, and is largely affected by a thick grey patina. Edges are generally well

preserved, which is not compatible with long distance fluvial transport, suggesting a limited degree of disturbance and displacement. Comparing B2 to B3, however, there are differences in assemblage composition and in knapping methods.

Overall, the analysis of post-depositional modifications does not show any apatial patterning. While bone and teeth fragments do not allow dating the lithic assemblages, circumstantial evidence suggests an age not later than an early phase of MIS 5e. The differences between the industry of B2 and B3 may be the outcome of diachronic changes and/or of differential water transport. Accordingly, Garba III possibly gives information on technological developments in lithic production and use at the time of the emergence of *Homo sapiens*, but not on space patterning.

ORAL

### 4. CONTINUITY AND CHANGE ? THE INITIAL BLADE TECHNOLOGY OF THE LATE MIS 3 OCCUPATION AT MOCHENA BORAGO ROCKSHELTER, PROVINCE WOLAITA, ETHIOPIA

Parow-Souchon, Hannah - (University of Cologne) [hp-arows1@uni-koeln.de](mailto:hp-arows1@uni-koeln.de)

An increase in technological variability and a decrease in artefact size of lithic inventories from the horn of africa towards the end of MIS 3 might give an important indication for the spread of modern humans from africa to eurasia, though its mechanisms are not well researched to date.

This paper presents a detailed comparative technological study of artefacts from the younger layers (~43.5-41 ka) of mochena borago rockshelter, province wolaita, ethiopia. The analysis was mostly concerned with the reconstruction of the *chaine operatee* and the secondary flaking characteristics.

In comparison to the older, mainly flake-based, inventories from mochena borago, the youngest (~41ka) already shows all the necessary technological capabilities required for a formal blade production. In contrast to this intra-site development towards an initial blade production, several aspects of these inventories remain quite constant through time and seem to form site-specific characteristics. The most important raw material used (obsidian) remains constant, as well as the uncommonly small size of the pieces recovered and the very low significance of the levallois concept.

This analysis provides first insights into the technological variability of the lithic inventories described; mainly environmental and climatic factors are suggested to have influenced these inventories as well as the climatically driven accessibility of the raw material source. A regional hypothesis will remain a task for the future, since comparative studies on other sites from the horn of africa are currently lacking. The analysis of the blade production in mochena shows the great analytical potential of this outstanding site, and highlights the complex task of thoroughly understanding the regional developments in the horn of africa towards the end of MIS 3.

## 5. CHARACTERIZING THE STRATIGRAPHY OF BIFACIAL TECHNOLOGY IN THE ASSEMBLAGES FROM THE DEEP SOUNDING AT SIBUDU CAVE, IN KWA-ZULU NATAL

*Conard, Nicholas J.- (University of Tübingen) nicholas.conard@uni-tuebingen.de*

*Schmid, Viola - (University of Tübingen) viola.schmid@student.uni-tuebingen.de*

*Zeidi, Mohsen - (University of Tübingen) mohsen.zeidi@ifu.uni-tuebingen.de*

*Porraz, Guillaume - (CNRS, UMR 7041, Paris X) guillaume.porraz@mae.u-paris10.fr*

Since 2011 a team from the University of Tübingen has conducted annual excavations at Sibudu Cave in Kwa-Zulu Natal, South Africa. This research has extended the cultural stratigraphic sequence at the site beyond the classic sequence defined by Lyn Wadley. Excavations in the Deep Sounding of the site document a strong signature of bifacial technology well below what was previously considered the base of the Still Bay. This paper presents the lower part of the stratigraphic sequence at Sibudu and tests the hypothesis that the Still Bay reflects a narrowly defined cultural stratigraphic unit in southern Africa.

## 6. INTRODUCTION TO BUSHMAN ROCK SHELTER IN SOUTH AFRICA

*Porraz, guillaume - (CNRS, IFAS / ESI, University of the Witwatersrand) guillaume.porraz@mae.u-paris10.fr*

*Val, Aurore - (ESI, University of the Witwatersrand) aurore\_val@yahoo.com*

*Douze, Katja - (ESI, University of the Witwatersrand) douze-katja@gmail.com*

*de la Pena, Paloma - (ESI, University of the Witwatersrand) paloma.delapena@gmail.com*

*Schmid, Viola C. - (Eberhard Karls University of Tübingen) viola.schmid@student.uni-tuebingen.de*

Over the last decades, Stone Age studies in Southern Africa have moved their attention from Later to Middle Stone Age contexts, with a specific interest towards the MIS4 and 3. Results have emphasized the antiquity of modern-type behaviors in this area, but uncertainties still surround the scenarios and mechanisms behind the appearance of these cultural changes. One direction of research is to look for a longer-term perspective and to compare the forms and rhythms of changes in different environments. With its 7 m thick deposits, Bushman Rock Shelter (BRS, Limpopo) represents one of the classic Stone Age sites in South Africa. Located in the margin of the great escarpment at about 1500 m a.s.l., its sequence contains well stratified deposits of Later and Middle Stone Age occupations with a good organic preservation. Though the site is well-referred in the literature, very few data contextualizing the archaeological collections have been published. In this communication, we summarize J.F. Eloff's excavations conducted in the 1970's, basing our observations on his unpublished field notes and on our own 2014 field campaign. We emphasize the meticulousness of these old excavations which in many ways conform to modern standards, and we position the sequence of BRS in the current southern African chronological framework. We develop further on the upper MSA deposits where bifacial pieces have been identified and confirm recent observations that the MSA bifacial technology is more diverse than previously thought.

ORAL

## 7. PATTERNS OF CHANGES OVER THE HOWIESONS POORT SEQUENCE AT KLIPDRIFT SHELTER (SOUTH-AFRICA)

*Delagnes, Anne - (PACEA-CNRS, France) a.delagnes@pacea.u-bordeaux1.fr*

*Douze, Katja - (ESI, University of the Witwatersrand) douze-katja@gmail.com*

*Wurz, Sarah (Department of Archeology, History, Cultural Studies and Religion University of Bergen, Norway) Sarah.Wurz@wits.ac.za*

*Henshilwood, Christopher S. (1Institute for Archaeology, History, Culture and Religion, University of Bergen, Norway) christopher.henshilwood@ahkr.uib.no*

*van Niekerk, Karen (Institute for Archaeology, History, Culture and Religious Studies, University of Bergen, Norway) Karen.niekerk@ahkr.uib.no*

The coastal site of Klipdrift Sheter (southern Cape region of South-Africa), currently excavated by C.S. Henshilwood and K.L. van Niekerk, contains a Howiesons Poort (HP) sequence characterized by rich assemblages of marine and terrestrial faunas, engraved ostrich eggshells, hearths and ash deposits, lithics. The lithic assemblages are typical of the Howiesons Poort complex, as documented in a number of sites within the same regional context, eg. Klasies River and Diepkloof. They evidence a number of combined raw material, technological and typological changes over the sequence which echoes the changes already described in the sites mentioned above. These patterns of changes allow to correlate the upper part of the sequence to the Intermediate and Late HP phases. The different time intervals covered by these HP sequences, as inferred from the available radiometric data, raise questions as to the validity of the chronological framework commonly used for the Middle Stone Age of southern Africa.

ORAL

## 8. THE LATE PLEISTOCENE MSA LITHIC TECHNOLOGY OF SIBUDU, KWAZULU-NATAL, SOUTH AFRICA

*Will, Manuel - manuel.will@uni-tuebingen.de (Department of Early Prehistory and Quaternary Ecology, University of Tübingen)*

*Bader, Gregor D - gregor.bader@uni-tuebingen.de (Department of Early Prehistory and Quaternary Ecology, University of Tübingen)*

*Conard, Nicholas J.- (Department of Early Prehistory and Quaternary Ecology, University of Tübingen) nicholas.conard@uni-tuebingen.de*

Studies of the African Middle Stone Age (MSA) have become central for defining the cultural adaptations that accompanied the evolution of modern humans. While much of recent research in South Africa has focused on the Still Bay (SB) and Howiesons Poort (HP), periods following these technocomplexes were often neglected. Yet, in order to track technological change in the southern African MSA, all of its phases must be studied with the same intensity.

Here we examine lithic assemblages from Sibudu that post-date the HP to further the understanding of MSA cultural variability during the Late Pleistocene. Sibudu

preserves an exceptionally thick, rich and high-resolution archaeological sequence that dates to ~58 ka, which has recently been proposed as type assemblage for the "Sibudan". This study presents a detailed analysis of the six uppermost lithic assemblages from these deposits (BM-BSP) that we excavated from 2011-2013. We define the key elements of the lithic technology and compare our findings to other assemblages post-dating the HP.

The six lithic assemblages provide a robust cultural signal, closely resembling each other in various technological, techno-functional, techno-economic and typological characteristics. While we observed several parallels with other contemporaneous MSA sites, the lithic assemblages at Sibudu demonstrate a distinct and so far unique combination of techno-typological traits.

These findings support the use of the name Sibudan as a working unit for structuring the Late Pleistocene MSA after the HP. The nature of the Sibudan stone artifact assemblages also refute assertions that modern humans living during this period possessed an unstructured and unsophisticated lithic technology. Our results illustrate the important contribution of research focusing on periods before and after the HP and SB to our understanding of the cultural evolution of *Homo sapiens* in southern Africa.

*Conard, Nicholas J.- (Department of Early Prehistory and Quaternary Ecology, University of Tübingen) nicholas.conard@uni-tuebingen.de*

In recent years, South Africa has gained increasing importance for our understanding of the evolution of “modern human behaviour” during the Middle Stone Age (MSA). A key element in this suite of behaviours linked with modern humans is heat treatment of materials such as ochre for ritual purposes and stone prior to tool production. Until now, there has been no direct archaeological evidence for the exact procedure used in the heat treatment of silcrete.

Through the analysis of heat-treated artefacts from the Howiesons Poort from two South African sites, Diepkloof Rockshelter and Klipdrift Shelter, we identified a series of technological markers that shed light on the processes used for heat treatment in the MSA. These markers include distinct fracture surfaces due to heat-induced non-conchoidal (HINC) fracturing that happened during heat treatment and a previously unknown tempering residue. This tempering residue, presenting itself as a black film on the silcrete surface, is an organic tar that contains microscopic fragments of charcoal. It formed during the direct contact of the artefacts with hot embers of green wood. We also observed numerous HINC-fracture-surfaces on the artefacts, resulting from heat-induced breakages that occurred during heat treatment in an environment producing rapid heating to high temperatures. Our results suggest that heat treatment of silcrete was conducted directly using an open fire, similar to those likely used for cooking.

While our findings add to the discussion about investment in time and resources necessary for the used heat treatment procedure, they especially highlight the intentional, innovative and systematic character of this transformative technology that was used in a number of Howiesons Poort sites from the Cape region of South Africa.

**1. GRASPING TEMPORAL VARIABILITY AND LANDSCAPE EVOLUTION: SPATIAL ANALYSIS OF SURFACE SCATTERS FROM THE NEJD PLATEAU, OMAN**

*Hilbert, Yamandu - (CNRS) yamandu.hilbert@mom.fr*  
*Usik, Vitaly (Ukrainian Academy of Science) vitaly.i.usik@gmail.com*  
*Marks, Antony E. (Southern Methodist University, Dallas, USA)*  
*Rose, Jeffrey I. (Ronnin Institut) jeffrey.i.rose@gmail.com*

For the past four years, the Dhofar Archaeological Project (DAP) has conducted survey and excavations across the Governorate of Dhofar, southern Oman. Numerous sites of different techno-complexes and lithic industries have thus far been reported. The majority of the discovered sites, however, are surface localities devoid of sediments and, therefore, lacking clear chronological attribution; or so one is taught to think.

Using three dimensional piece plotting, technological attribute analysis, and observations on the diverse patination states of artifacts found on the surface, we show that some degree of "horizontal stratigraphy" and, therefore, relative chronology can be established at many multi-period surface localities found across the Nejd Plateau in southern Oman.

Based on local geomorphology, we suggest that this horizontal stratigraphy is, to a greater part, associated with the availability of sheets of raw material, as its exposed face erodes through time. These low inselbergs are remnants of larger surfaces that are more resilient to the aggressive erosion to which the Nejd plateau is subjected. Across the quaternary, phases of erosion have occurred that, in turn, made available fresh raw material that, in turn, was exploited by diverse hominid groups that inhabited South Arabia.

Our methodology indicates the existence of a relative chronology that is re-enforced by data from stratified and dated sites. This methodology and theory can and may be applicable to other comparable geomorphological environments. Especially for Southern Arabia, phases of population influx, persistence and some degree of local adaptability by prehistoric groups can be seen.

ORAL

**2. GIS-BASED ANALYSIS OF VERTICAL AND SPATIAL LITHIC DISTRIBUTION PATTERNS AT THE EARLY MIDDLE PALEOLITHIC SITE OF MISLIYA CAVE, MOUNT CARMEL, ISRAEL**

*Kapul, Reuven - (Zinman Institute of Archaeology, University of Haifa) kapul1@walla.co.il*  
*Zaidner, Yossi - (Zinman Institute of Archaeology, University of Haifa, Institute of Archaeology, The Hebrew University of Jerusalem) yzaidner@research.haifa.ac.il*  
*Weinstein-Evron, Mina - (Zinman Institute of Archaeology, University of Haifa) evron@research.haifa.ac.il*

The Early Middle Paleolithic (250-160 kyBP) site of Misliya Cave, Mount Carmel, Israel, is characterized by the highest density of lithic artifacts (3000/M<sup>3</sup>) in the Levant. The site also contains rich faunal remains and a series of well-preserved hearths. No visible layers could be observed during the excavation, and the lithic assemblage is typologically homogeneous. We used a GIS program, to examine the distribution of lithic artifacts spatially and vertically in an attempt to differentiate layers and activity areas within the site. We entered into the program data on natural features such as rock falls, the hearths and the lithics, processed them and examined the interaction between the various elements. Our analysis reveals four distinct layers, two of which contain a hearth. We also identified an especially dense concentration of lithic artifacts in a central location of the site. This pattern recurs at approximately the same location among the four layers. Significantly, lithic concentrations were also less dense in proximity to the hearths, suggesting different activity areas. Together with various other data, this study highlights the complex nature of this early MP habitation site.

ORAL

**3. ARABIA AND THE EASTERN TRAJECTORY: BRIDGING THE AFRICAN AND EURASIAN LANDMASSES**

*Chu, Wei - (University of Cologne) wchu@uni-koeln.de*  
*Parow-Souchon, Hannah - (University of Cologne) h.parow-souchon@uni-koeln.de*  
*Hauck, Thomas - (University of Cologne) Thomas.Hauck@uni-koeln.de*  
*Richter, Jürgen - (University of Cologne) j.richter@uni-koeln.de*

While there is currently little doubt about the African origin of anatomically modern humans, there is only

limited understanding as to the timing, migration pathways, and environmental conditions of these prehistoric settlers once they entered Eurasia. It is still unknown which industries are indicative of the early groups of anatomically modern humans in Eurasia, and what subsistence strategies they used in different chronological and geographic phases of their exodus. While we know that anatomically modern humans crossed specific climatic and environmental zones on their way into Europe, the capacity of their cultural adaptation is still largely unexplored.

To answer these questions, we present recent data obtained from the Collaborative Research Center's "Our Way to Europe" project which combines new sedimentological, geomorphological, and archaeological work in key locations in the eastern Mediterranean region representing different ecozones and environments. These areas, including the recently excavated site of Wadi Sabra, Jordan, all form part of the hypothesized "Eastern Trajectory" that anatomically modern humans may have followed in their initial ascent towards Central Europe.

Our results suggest that different environmental factors encountered by anatomically modern humans may have influenced the nature and the timing of their movements into the Eurasian continent and that these in turn, are reflected in the nature of stone tool residues that they characteristically left behind.

The implications of these recent results may help us to understand how anatomically modern humans were able to thrive in the region while pre-existing hominin populations may, at least locally, have diminished. They may also help explain the origin of Upper Palaeolithic industries in Central Europe including many of the so-called "transitional" industries and their creators.

#### **4. LATE PLEISTOCENE SETTLEMENT DYNAMICS IN SOUTHERN ARABIA? CONTEXTUALIZING LITHIC TECHNOLOGY, PALEO-ENVIRONMENT AND GEOGRAPHY**

*Bretzke, Knut - (University of Tübingen) knut.bretzke@uni-tuebingen.de*

*Conard, Nicholas J. - (University of Tübingen) nicholas.conard@uni-tuebingen.de*

Southern Arabia is a focus region regarding movements of hominins into and out of Africa. The growing archaeo-

logical record from the Late Pleistocene of the region allows us to begin characterizing chronological and spatial patterns related to this process.

Of critical importance in this setting is the deep archaeological stratigraphy from Jebel Faya, UAE. Between 2009 and 2014 we excavated seven archaeological horizons containing in total 8690 lithic artifacts. This talk presents the variability of lithic technological systems captured in the archaeological sequence and contextualizes this information in a diachronic approach with paleo-environmental and geographic data to model settlement dynamics in Southern Arabia during the late Middle and Late Pleistocene. Given a strong relationship between settlement history in South Arabia and the potential for hominin dispersals through this area, we contrast our regional model with global models of hominin expansions out of Africa.

Our results indicate a complex pattern of connectivity between the Southwest and Southeast of Arabia during the late Middle and Late Pleistocene. This argues against simple conclusions about the role of Arabia for hominin dispersals out of Africa and calls for more regional studies to facilitate critical assessments of the competing models for human dispersals.

#### **5. NEW DISCOVERIES ON THE MIDDLE PALEOLITHIC FROM CENTRAL AND NORTHERN SAUDI ARABIA AND THEIR IMPLICATIONS ON DEMOGRAPHIC DISPERSALS**

*Crassard, Rémy - (CNRS UMR5133 Lyon) remy.crassard@mom.fr*

*Hieronymus Hilbert, Yamandú - (CNRS UMR5133 Lyon) yamandu.hilbert@mom.fr*

We present here new archaeological data from central and northern Saudi Arabia. Since 2010 we have conducted archaeological survey across the Al-Kharj region, 100 km south of Riyadh, and since 2013 expanded our research focus towards the north of the Kingdom of Saudi Arabia, into the Al-Jawf province. Survey activities have revealed a high number of surface sites as well as one stratified site with a well preserve sequence. The majority of these sites are attributed to the Arabian Middle Paleolithic based on the presence of Levallois blank production methods. As such, this period shows great regional diversity across the Saharo/Arabian arid belt and is central to questions involving late Pleistocene human dispersals.

Special consideration was given to the identification of Paleolithic sites during these survey activities. Specific loci within the research areas were sampled based on raw material availability and general topographic location. Archaeological sites that yielded sufficient indications of being pristine were sampled. Artifacts were analyzed using morphological, typological and technological parameters chosen deliberately to provide insightful account as to the assemblages' cultural affiliation and general categorization.

In central Arabia, technological analyses on cores retrieved from the Rufa graben (Al-Kharj region) have revealed specific reduction modalities used to produce flakes with predetermined shapes. The identified modalities, which are anchored within the greater Levallois concept of core convexity preparation and exploitation, correspond with those utilized during the Middle Stone Age Nubian Complex of northeast Africa and southern Arabia. The discovery of Nubian technology at the Al-Kharj sites represents the first appearance of this blank production method in central Arabia.

The Al-Jawf Quadrangle in northern Saudi Arabia, which thus far experienced only sporadic prehistoric investigation, provided data adding to debates on demographic movements across Africa and Arabia. Sites attributed to the Arabian Middle Paleolithic show diverse types of blank production systems of which the Levallois Method certainly holds a central role. Given the growing complexity of the Arabian Prehistoric record the sites from the Al-Jawf Quadrangle will be discussed, first in a regional frame and then in an extended intra-regional context.

Here we demonstrate how a rigorous use of technological and taxonomic analysis may enable intra-regional comparisons across the Arabian Peninsula and beyond. Given the geographical location of the Al-Jawf Quadrangle, close to the desert areas of southern Levant, Negev, Sinai, Nafud, and given the location of the Rufa graben, close to other important regions experimenting more systematic surveying such as southern Arabia, the archaeological record described here may greatly add to the growing body of data on Arabian Prehistory, and suggests new dynamics of population movements between the southern, central and northern regions of the Peninsula.

ORAL

## 6. THE EMERGING PICTURE OF THE ARABIAN MIDDLE PALAEOOLITHIC AND ITS RELATIONSHIP TO SURROUNDING REGIONS

*Groucutt, Huw (University of Oxford) huw.groucutt@rlaha.ox.ac.uk*

*Scerri, Eleanor - (Université Bordeaux) eleanor.scerri@u-bordeaux.fr*

*Jennings, Richard - (University of Oxford) richard.jennings@rlaha.ox.ac.uk*

*Petraglia, Michael - (University of Oxford) michael.petraglia@rlaha.ox.ac.uk*

The Arabian Peninsula connects some of the key areas discussed in hominin evolutionary studies, such as northeast Africa, the Levant and southern Asia. A number of recent analyses have suggested that lithic assemblages in Arabia demonstrate dispersal into the peninsula by Middle Palaeolithic hominins. Emerging evidence allows the testing of these initial hypotheses. As well as being an important route for hominin dispersal from and between more intensively studied areas, the biogeographical and environmental structure of Arabia – plus emerging archaeological evidence – suggests considerable complexity to demographic processes and that Arabia was not a passive conduit.

In this paper we: 1) report a number of newly discovered Middle Palaeolithic sites in Saudi Arabia, 2) describe a quantitative comparative study of Middle Palaeolithic assemblages in Arabia, Iran, the Levant, and northeast Africa. We use a variety of techniques of comparison, including Principal Components and Correspondence Analyses to objectively describe the nature of similarities and differences between assemblages, and therefore moves beyond debates on the typology of individual artefact forms and on industrial nomenclature.

Our findings demonstrate considerable diversity in Middle Palaeolithic technologies in Arabia as well as a complex pattern of similarities and differences with assemblages in surrounding regions.

Our results demonstrate how robust comparative studies are starting to elucidate the nuances of demographic and cultural relationships between Africa and southwest Asia in the Late Pleistocene.

ORAL

**7. WHAT IF ANYTHING DOES THE MIDDLE PALEOLITHIC OF WESTERN SYRIA TELL US ABOUT MOVEMENTS IN AND OUT AFRICA?**

*Conard, Nicholas - (University of Tübingen) nicholas.conard@uni-tuebingen.de*

*Bretzke, Knut - (University of Tübingen) knut.bretzke@uni-tuebingen.de*

In much of the Levant the record of technological changes from the late Middle Paleolithic through the early Upper Paleolithic documents a gradual transition from the dominant use Levallois systems of knapping to the production of laminar assemblages from platform cores. This general pattern is reflected in studies from the Syrian Desert, the Negev and the Mediterranean coast. The results from our excavations and surveys in the Damascus Province on the eastern side of the Anti-Lebanon Mountains do not fit easily into this pattern and suggest that the record of cultural change at the end of the Middle Paleolithic preserves more variability than is usually argued. Data from excavation at Wadi Mushkuna, Kaus Kozah, Baaz Rockshelter and the famous sites in Yabroud excavated by Alfred Rust suggest that this region reflects a different pattern of technological evolution. While the signal for the shift from the Middle to the Upper Paleolithic in western Syria is not yet ideally documented and the civil war in Syria has stopped fieldwork, we summarize what is known about this important transition and its implications for testing the various Out of Africa hypotheses.

**MODES OF HUMAN OCCUPATION AT THE OPEN-AIR MIDDLE PALEOLITHIC SITE OF NESHER RAMLA, ISRAEL**

*Shemer, Maayan - (Zinman Institute of Archaeology, University of Haifa, Haifa, Mount Carmel 3498838, Israel; Israel Antiquities Authority, P.O. Box 35, 10600 Nahlal, Israel) shemerma@hotmail.com*

*Weinstein-Evron, Mina - (Zinman Institute of Archaeology, University of Haifa, Haifa, Mount Carmel 3498838, Israel) evron@research.haifa.ac.il*

*Zaidner, Yossi - (Zinman Institute of Archaeology, University of Haifa, Haifa, Mount Carmel 3498838, Israel; 2Institute of Archaeology, the Hebrew University of Jerusalem, Jerusalem 91905, Israel.) yzaidner@research.haifa.ac.il*

A recently discovered eight-meter-thick open-air sequence at Neshar Ramla (Israel) provides new evidence regarding Levantine Middle Paleolithic adaptations during most of MIS 6 and 5 (OSL dates:  $167 \pm 11$  ?  $78 \pm 6$  ka). The site is located in a karst depression formed by gravitational deformation and sagging into underground voids. During the deposition of the archaeological sequence the formation of the site was primarily shaped by a cyclic mechanism of deposition of eroded soils, water-logging and pedogenesis. Such a geomorphological context and formation mechanism are profoundly different from Levantine Middle Paleolithic cave and open-air sites. Excavations at the site yielded rich lithic and faunal assemblages, combustion features, hundreds of manuports, hammerstones and anvils, and ochre. The eight-meter-thick archaeological sequence was divided into six stratigraphic units, in which several horizons and vertically distinct concentrations of lithics and bones were identified.

Lithic assemblages from two horizons from the upper Units I and II were studied. The studied assemblages are dated to  $115 \pm 9$  ?  $78 \pm 6$  ka, the same time span to which the Early Modern Human remains from Qafzeh and Skhul caves are assigned.

Both studied assemblages show close similarity in technological and economic features and suggest continuity in the use of the site throughout the period of their accumulation. Several reduction sequences were identified among which Levallois is the most common. The frequency of Levallois products, however, is not high (11% and 13% for the studied horizons), contrary to the Levantine cave sites in which Levallois products are much more frequent. The Levallois assemblage at the site shows no clear preference to either unipolar or centripetal methods of reduction, making it difficult to assign it to one of the recognized Levantine Middle Paleolithic chrono-stratigraphic stages, originally defined on the basis of differences within the Levallois technology. The mode of exploitation of raw materials points to complex technological organization with evidence of both curated and expedient behaviors. The evidence point at the existence of curated tool-kits composed of Levallois products, Mousterian points, convergent side-scrapers and composite tools all made of Eocene chert. The tool-kit was complemented by simple and cortical flakes, backed knives, notches and pieces with light retouch made on Campanian (Mishash Formation) chert. Campanian chert was knapped onsite, while Eocene chert shows no evidence for onsite knapping, except for some tool resharpening and maintenance.

. The technological and economic characteristic of the lithic assemblages presented here indicates that in many aspects of human behavior Neshar Ramla differs from other Levantine sites, thus contributing to our understanding of the processes that led to behavioral modernity in the Levant.

## 8. KURAN BUZAN VALLEY: NEW EVIDENCE FOR THE PLEISTOCENE HUNTER GATHERER OF THE CENTRAL ZAGROS, IRAN

*Alibaigi, Sajjad - (Department of Archaeology, University of Tehran, Iran) sadjadalibaigi@gmail.com*

*Niknami Kamal, Aldin - (Department of Archaeology, University of Tehran, Iran) kniknami@ut.ac.ir*

*Khosravi, Shokouh - (Department of Archaeology, University of Tarbiat Modarres, Iran) shokouh.khosravi@gmail.com*

*Nikzad, Meisam - (Department of Archaeology, University of Tarbiat Modarres, Iran) meisam\_nikzad@yahoo.com*

The Kuran Buzan valley is a long and narrow valley is located in the Central Zagros mountainous region comprising the eastern parts of *Lurestan* as well as the north-eastern parts of *Ilam*. The valley environment and the flow of *Saimareh* River in the centre of valley potentially have given the valley an ideal space to attract human occupation from the very earlier times. To locate the real sequences of human occupations and their distributions across the valley a systematic archaeological survey conducted in the area in spring 2010. Since the dam reconstruction in the area seemed to have threatened the archaeological sites and also because of the topography of the valley which would obscured the sites appearances, a full coverage and intensive gridded system of survey was applied to enhance the probability of finding not only the actual locations of sites but rather the of-sites which were assumed to be distributed everywhere in the valley. By such a technique in an area about 71 km<sup>2</sup> we were enabled to explore some 110 Palaeolithic seasonal sites as well as about 12 sites from the other archaeological periods. The abundance of Palaeolithic sites in tour study area may be related to the geophysical patterns of the area where so many outcrops of the chert and limestone raw materials (Amirn formation) were appeared by the erosions on the surface and made it possible that the Palaeolithic stone tool makers being able to have easy accesses to the abundant resources. Through a typological classification of the Palaeolithic assemblages we assigned 3 sites to have been occupied by the lower

Palaeolithic peoples while 107 of which were assigned to have been used by the Middle Paleolithic. The assemblages are consisted of Acheulian bifacial axes as well as large chopping tools, cores, scrapers and other Lower Palaeolithic tool types. They also comprise a variety of the Middle Paleolithic stone industry including the large tools which were generally made by the Levallois techniques. Considering the locational pattern of the sites as well as studying the frequency distribution of tools and their technological characteristics may account for the fact that the Kuran Buzan valley attracted the different groups of Pleistocene's hunter-gatherer to occupy the valley, since the resources were available here could reinforced the populations living struggles.

## 9. TECTONIC AND PALEOLITHIC OCCUPATIONAL RECORDS IN THE ZAGROS MOUNTAINS

*Heydari-Guran, Saman - (Department of Early Prehistory and Quaternary Ecology, University of Tuebingen, Germany) saman.heydari@ifu.uni-tuebingen.de*

*Michael Märker (Heidelberger Akademie der Wissenschaften Forschungsstelle: The role of culture in the early expansions of humans) michael.maerker@geographie.uni-tuebingen.de*

*Conard, Nicholas - (Department of Early Prehistory and Quaternary Ecology, University of Tuebingen, Germany) nicholas.conard@uni-tuebingen.de*

The Zagros fold and thrust geological zones have formed by collision in between two tectonic plates of Eurasian and Arabia. Recent geological studies across these mountains demonstrate that the collision is still active and resulting a high rate of deformations. For instance GPS measurements across this region show that the current rate of shortening in SE Zagros is at about 10 mm yr<sup>-1</sup> and in the NW Zagros is around 5mm yr<sup>-1</sup>.

Meanwhile, the geographical position of the Zagros Mountains in the middle of the Middle East proposes it as part of the probable migratory path of Homo from Africa to East and North Asia. Despite of strong archeological evidences from Later Paleolithic including late Middle, Upper Paleolithic and Epipaleolithic sites in the caves and rockshelters across the Zagros Mountains, this region has not yielded convincing Earlier Paleolithic records (Lower to Early Middle Paleolithic periods) either as open air or sheltered places compared to the adjacent regions, such as Levant. The lack these Paleolithic occu-

pational records across the vast region of the Zagros Mountains has raised questions among the paleoanthropologists concerning the interpretation early hominin migration from west to east Asia.

This paper examines the probable influence of the Zagros rapid orogeny phenomenon, including erosional and depositional activities as a result of uplifting, fault scarps and truncated folds on the early human occupational records. The research, which is part of the Tuebingen-Iranian Stone Age Research Project (TISARP), has the goal of creating geomorphological models for prediction the location of Lower and Early Middle Paleolithic sites in the Zagros Mountains. The following processes are reflected in the outline of the paper:

Background studies of the Zagros orogeny;

Synchronic and diachronic patterns of the Paleolithic records across the Zagros Mountains;

Geological setting of the known Lower and Early Middle Paleolithic sites in the Zagros Mountains;

Monitoring the areas with high probability of having Middle to Upper Pleistocene records.

Sambhar and Jogpura. Comparisons will be made with Arabia and North Africa to identify which aspects of Middle Palaeolithic technology appear within the Saharo-Arabian deserts, which present disjunct distributions, and whether commonalities across the region can be best understood as independent adaptations to similar ecological settings or relating to population dispersals.

### 10. THE PASSAGE TO INDIA: DISPERSALS AT THE EASTERN EDGE OF THE DESERT BELT

*Blinkhorn, James - (UMR 5199 PACEA, Université de Bordeaux) jblinkhorn@outlook.com*

The interface of Africa and Eurasia comprises the desert landscapes of the Saharo-Arabian belt, stretching from the Atlantic coast in the west to the Thar Desert of India in the east. While these regions are by no means homogeneous, they share a number of environmental and biogeographic features that stand in stark contrast to sub-Saharan Africa, the Oriental zone of India and SE Asia, or Palearctic central and northern Eurasia. The resumption of widespread humidity in the Saharo-Arabian belt during MIS 5 opened up habitable but uninhabited landscapes, providing the potential for hominin expansions from Africa (modern humans), west and central Eurasia (Neanderthals) and India (archaic *Homo*). This talk will focus on the eastern extent of the Saharo-Arabian desert belt, presenting the most recent evidence from the field for the Palaeolithic occupations of the Thar Desert in the Late Pleistocene, including excavations at Katoati,

## 1. GRADUAL POPULATION MOVEMENTS FROM ASIA TO EASTERN EUROPE

Otte, Marcel - (Université de Liège) [Marcel.Otte@ulg.ac.be](mailto:Marcel.Otte@ulg.ac.be)

This presentation focuses on the different forms of acculturation following the east-west axis of Eurasia. Movement of the new modern human population led to very different reactions depending on region and local Mousterian cultures. This is thus a long-term demographic process, in particular involving the modes of thinking that were encountered. The abrupt anatomic changes are due to the isolation of Europe where populations reproduced by endogamy, in contrast to the vast Asian continent where genetic changes were much more common and thus accentuated the gradual tendencies proper to all humanity throughout its entire history. Examples will be presented during the session.

## 2. THE LATE PLEISTOCENE SEQUENCE OF ROCCIA SAN SEBASTIANO CAVE (MONDRAGONE, CASERTA) IN SOUTHERN ITALY. CHRONOSTRATIGRAPHIC DATA AND TECHNICAL BEHAVIORS

Collina, Carmine - (Museo Civico Biagio Greco (Mondragone, Caserta-Italy)) [carmincollina\\_1972@libero.it](mailto:carmincollina_1972@libero.it)

Piperno, Marcello - (Museo Civico Biagio Greco (Mondragone, Caserta-Italy)) [m.piperno@tin.it](mailto:m.piperno@tin.it)

The cave of Roccia San Sebastiano is a cave of tectonic-karstic origin at the foot of the southern versant of Monte Massico, in the territory of Mondragone (Caserta) in Campania, in Southern Italy. Systematic excavation campaigns have been conducted here since 2001, under the direction of Marcello Piperno, leading to the partial exploration of an important Pleistocene deposit, extraordinarily rich in archaeological and paleontological remains. The cavity is divided into two distinct parts: a shelter, about 12 m long and 3 m deep, and a cave whose dimensions have not yet been ascertained because it is still partially obstructed by reworked sediments. The excavation campaigns carried out since 2001 lead to the exploration of the first *in situ* level, called C, over a surface of about 4 m<sup>2</sup>; furthermore, the stratigraphic sequence was tested in a 2 m<sup>2</sup> sounding, localized within the excavation area, to a depth of about 3 m.

The preliminary stratigraphic study evidenced an alternation of detrital productions and collapse episodes, spaced by concreting phases. Level C is characterized by a deposit of compact and cemented clays, containing collapse clasts of variable dimensions. A first date of this level, obtained on burnt bones, was carried out by G. Calderoni of the C14 Laboratory of the Sapienza University of Rome (Belluomini *et al.* 2007), and provided an age of 19.570±210 BP. The excavation of level C and of the stratigraphic sounding yielded a total of over 20000 lithic artifacts that still need to be analyzed in detail.

The deepening of the sounding evidenced a thick stratigraphic and cultural sequence. At the present state of the research, at least six major phases, from different Gravettian horizons to Aurignacian until the Final Mousterian level, have been recognized in the deposit, whose chronological framework is based on a series of C14 dates on the fauna included between 19.570±210 BP and 38.980±950 BP.

The gravettian deposit appears to be especially rich in lithic industry - microlithic backed points being especially abundant - and fauna, mainly consisting of numerous remains of horse, *Equus hydruntinus*, and red deer. The excavation of level C also yielded several fragments of the skeleton of a single human. These display alterations of the bone tissue indicating prolonged exposure to climatic agents. As regards symbolical manifestations, traces of cuts and incisions made with flint tools on bones may have had aesthetic purposes. A tooth of child attributed to Neanderthal has been found in the mustertian levels.

Thus, the evidence as a whole indicates that the cave-shelter of Roccia San Sebastiano hosted a complex set of activities centered on the production of lithic tools and the butchering of preys. In this paper we will present the chronostratigraphic data of the archaeological sequence and we shall take into consideration data from lithic assemblages attesting the variability of technical behaviors among the gravettian lithic assemblages and the techno-economic structures of Aurignacian and Mustertian phases.

ORAL

## 3. LIVING ON THE EDGE? A MULTIREGIONAL APPROACH FOR STUDYING THE BEGINNING OF THE AURIGNACIAN

Bataille, Guido - (Insitute of Prehistoric Archaeology; University of Cologne) [gbataill@uni-koeln.de](mailto:gbataill@uni-koeln.de)

*Tafelmaier, Yvonne - (Institute of Prehistoric Archaeology; University of Cologne & Neanderthal Museum, Mettmann) tafelmaier@neanderthal.de*  
*Weniger, Gerd-Christian - (Neanderthal Museum, Mettmann) weniger@neanderthal.de*

At the moment a geographical source area for the Aurignacian is not recognizable. To the contrary, assemblages yielding fundamental Aurignacian elements, such as specific bladelet cores (e. g. carinated & nosed endsrapers) and its end-products (e. g. unilaterally, bilaterally & alternately retouched bladelets & microblades), occur prior to the Heinrich 4 event within a vast region between the river Don in the East, the Atlantic shore in the West and the Mediterranean in the South.

In the present study the beginning of the Aurignacian is examined from a multiregional point of view. For that approach empiric data from Aurignacian assemblages of the Western and the Eastern margin of Europe were techno-typologically analyzed and compared with secondary information including assemblage composition, chronology and environmental data from Western, Central and Southern European Aurignacian sites.

Of special importance is the Proto-Aurignacian (stage 0) and Early Aurignacian (stage 1) dichotomy, suggesting a temporal succession reflecting the initial migration of AMH groups into and through Europe (Banks et al. 2013, Teyssandier et al. 2010). On the basis of empiric studies of lithic assemblages from Northern Spain (Labeko Koba & Ekain), the Middle Don region (Kostenki 14) and Crimea (Siuren 1) the integrity of the Aurignacian stages 0 and 1 is critically analyzed. On the one hand the study of the Labeko Koba sequence reveals a high share of common technological knowledge within the analysed assemblages. On the other hand investigations of Aurignacian assemblages of Eastern Europe show a mixture of Aurignacian elements belonging to different stages of the established Western European Aurignacian sequence. Inter-assemblage variability seems to reflect predominantly regional specific adaptation mechanisms. A high share of Aurignacian tool/core types within the lowest initial Upper Palaeolithic complex IVb1-2 of Kostenki 14 emphasizes an early multi-regional spread of specific adaptive elements. Moreover, a technological shift in the bladelet production of the Siuren 1 Aurignacian sequence in connection with a technological and typological continuity regarding tool composition and blade production militates in favour of a regional *in situ* development.

In the framework of the current study the Aurignacian is understood as a specific set of adaptive elements (*Model*

*of adaptive segments*) which plays a fundamental role in the onset of the European Upper Palaeolithic. In this context the present day favoured interpretation of the Aurignacian as physical output of an unilineal spread of AMH through Europe is challenged. In contrast to that, a model of multilineal information transfer, which allows for movements of ideas or human groups back and forth, is postulated. Thus, both regional similarities and differences can be explained.

#### 4. NEANDERTHALS AND MODERN HUMANS AROUND 40 KYR CALBP AT COVA GRAN (SOUTH-EASTERN PREPYRENEES, IBERIA)

*Martínez Moreno, Jorge - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistòria.UAB) jorge.martinez@uab.cat*  
*Benito Calvo, Alfonso - (CENIEH) alfonso.benito@cenieh.es*  
*Mora Torcal, Rafael - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistòria.UAB) rafael.mora@uab.cat*  
*de la Torre Sainz, Ignacio - (Institute of Archaeology. UCL) i.torre@ucl.ac.uk*

Appearance of the Upper Paleolithic across Western Eurasia is the subject of intense debate. Iberian Peninsula plays a fundamental role in these discussions, since it is considered one of the last refuges of Neanderthals during the spread of anatomically modern humans across Europe.

Cova Gran de Santa Linya contains Late Middle Paleolithic (LMP) and Early Upper Paleolithic (EUP) sequence which provides contextual, techno-typological and radiometric elements that contribute to the debate on the MP/UP transition.

We analyze the geometry, stratigraphy and resolution of the archaeological levels from Cova Gran. These contextual indicators lead us to discuss the role of syn/post depositional processes and their impact on the homogeneity of the archaeological levels.

Technology of the Middle and Upper Paleolithic levels is compared, with special emphasis on the lithic assemblage of the most recent LMP unit (S1B) and the first EUP level (497D). Finally, series of 14C AMS dates of the LMP and EUP archaeological units is presented and discussed within the Iberian regional context.

Cova Gran contributes to the debate on the MP/UP transition. Given the paucity of well contextualized transi-

tional levels in Iberia, Cova Gran record fills a gap in the regional sequence.

This sedimentary geometry of S1B/497D levels is particularly relevant to the discussion of the MP/UP transition. Limited thickness of the levels suggests that the archaeological assemblages are homogeneous entities and reveals no evidence of mixing between layers, either by percolation of materials, cryoturbation, or deficient recording of artifacts.

Between Middle and Upper Paleolithic a systemic technological rupture can be described with no elements of cultural continuity. Technical attributes ascribe levels S1B to the Middle Paleolithic, since they present similar features in other MP levels of Cova Gran to other nearby Mousterian sites.

Otherwise, level 497D lithics main characteristic is to obtain elongated products, from large blades to bladelets and flakes. Retouched artifacts, pieces with denticulate edges and side scrapers on flake predominate. However, retouched blades, end scrapers, burins, and truncations produced on blades, plus backed points and backed bladelets are represented.

Finally, Cova Gran LMP-EUP radiocarbon series show ambiguities usually affecting chronometric data from radiocarbon older than 30 kyr BP. Although these uncertainty, we sustain  $^{14}\text{C}$  data from S1B/497D are relevant in the discussion MP/UP Transition debate.

Cova Gran indicates clear disjunction between Middle and Upper Paleolithic. The archaeological record clearly defines two traditions that represent different technical behaviors. Cova Gran opens up interesting perspectives to analyze the emergence of the Upper Paleolithic in the Iberian Peninsula and to discuss the possible coexistence of Neanderthals and modern humans.

*Prieto, Alejandro - (Universidad del País Vasco), Rachel Wood - rachel.wood@anu.edu.au (The Australian National University)*  
*alejandroprieto@ehu.es*

The cave of Lezetxiki (Arrasate) has been excavated in two series of seasons. Between 1956 and 1968, José Miguel de Barandiarán, together with a number of collaborators, excavated a large area of the deposit (some 100m<sup>2</sup>), and since 1996 a new series of fieldwork has been carried out under the direction of Alvaro Arrizabalaga, in a much smaller area. Owing to the taphonomic circumstances of this deposit, the difficulties in obtaining a consistent geochronological framework for it, and the complex nature of the lithic assemblage, great confusion has arisen about the stratigraphic units that should be included in a discussion about the Middle to Upper Palaeolithic transition at Lezetxiki. Strictly speaking, the only level that can be attributed to this period is Level III, which is sub-divided into IIIa and IIIb, separated by an erosional contact. Sublevel IIIa, with abundant industrial remains, is dated in the Aurignacian, whereas Sublevel IIIb, in which hardly any lithic industry or remains of fauna associated with human activity were found, corresponds to a very late phase of the Mousterian. As a result of the circumstances in the initial series of excavations, mixing of some materials between the two sublevels may have taken place, although their original differentiation was made by José Miguel de Barandiarán, and these possible cases should be regarded as few in number.

### 6. ARRILLOR CAVE (ÁLAVA). CHRONOLOGICAL, PALAEO-ENVIRONMENTAL AND CULTURAL NOTES ON A LONG MOUSTERIAN SEQUENCE

*Iriarte-Chiapusso, María José (IKERBASQUE-Universidad del País Vasco)*  
*mariajose.iriarte@ehu.es*

*Wood, Rachel (Australian National University / University of Oxford)*  
*rachel.wood@anu.edu.au*

*Sáenz de Buruaga, Andoni (Universidad del País Vasco)*  
*andoni.buruaga@ehu.es*

Arrillor is located in the southern foothills of the Gorbea Massif (Murua, Álava). It has yielded evidence of several human occupations, alternating with times when the cave was abandoned. All these occupations are assigned

to the Mousterian except for the most recent level (Level La), which is only conserved in the cave in a small side-passage where the remains are attributed to the Magdalenian.

The changing climate that existed during the formation of the sedimentary deposit in Arrillor influenced a series of frost-weathering and fluvial phenomena. At the base of the sequence (Levels Cag, Blm, Car, Cglm and Clm), the effect of frost-shattering predominates, although layers with a fluvial origin (Lgj) are inter-bedded. Except for the last level, which is archaeologically barren, the small numbers of artefacts found in the other levels confirm that the first occupations in the cave took place in the Mousterian. The middle part of the sequence had a clearly fluvial origin, as a series of sandy layers contain different amounts of clay in their composition and display varying colours. The Amk and Smkl Levels are significant within this part of the sequence. The former is characterised by a Mousterian industry already displaying some leptolithic proto-forms. However, the raw materials still come from locations near the site. In this level, a 9-13 year-old child's deciduous second molar was found. These occupations took place in more benign climate conditions in which hazel and alder shared the tree cover with pine and birch at, or beyond, the limit of radiocarbon c.50 ka cal BP. The Mousterian assemblage in Level Smkl, where the Levallois technique has been identified, displays a certain preference for side-scrapers and points. Between this middle sequence and the upper levels, erosion affected part of the sedimentary record. The Smc (denticulate Mousterian) and Lmc Levels appear to coincide with two different times of climatic deterioration occurring prior to 45 ka cal BP. A change of strategy manifested above all in the provenance of raw materials is attested in Level Lmc. Now, in addition to local material, artefacts are found made from flint from Urbasa (Navarre), Treviño (Burgos) and Flysch (Biscay) outcrops. The Mousterian industry includes types with a leptolithic character.

ORAL

## 7. THE LOWER LEVELS OF THE ROCK SHELTER OF EL CUCO (CANTABRIA, SPAIN)

*Rasines del Río, Pedro (Junta de Patrimonio Monumental y Arte Religioso de Laredo.) prasines@hotmail.com*

*gaem@gaemarqueologos.com*  
*Morlote Expósito, José Manuel (GAEM Arqueólogos)*  
*gaem@gaemarqueologos.com*

The rock shelter of El Cuco is located next to the cave with the same name, in Castro Urdiales (Cantabria, a northern region of the Iberian Peninsula), at the foot of a cliff of limestone and massive calcarenite of the Early Cretaceous. This lies 350 m from the present coastline. It has a length of about 35 m and one small cave in both ends; the west one has also an archaeological site. On October and November 2005 we carried out two archaeological sondages. In one of them (2 x 1 m in area and 254 cm depth) we identified fourteen archaeological layers.

Lower levels provided a malacological series with *Patella*, which brings one of the first evidences of collection and consumption of these resources in the Atlantic Façade.

ORAL

## 8. COVALEJOS CAVE (PIÉLAGOS, CANTABRIA, SPAIN). NUMERICAL DATES AND ARCHAEOLOGICAL DATA IN THE LIMIT MIDDLE / UPPER PALAEO-LITHIC.

*Montes Barquín, Ramón - (A.I.CARP) rmontes@prehistour.eu*  
*Muñoz Fernández, Emilio - (CAEAP)*  
*gaem@gaemarqueologos.com*

Covalejos cave is located in Autonomous Region of Cantabria (Spain), next to Arce (Municipality of Piélagos), very near of Santander's Bay.

Although it was excavated from 1876 to 1969, the cave retains a large sequence of 380 cm in thickness (with an unknown thick at the bottom), even though the Upper Palaeolithic levels are practically disappeared.

A total of 15 archaeological levels have been discriminated recently. In the basis there is an interglacial level with lithic artefacts and skeletal remains of *Dicerorhinus kirstbergensis* dated in the OIS. 5. Above, 7 levels contain Mousterian evidences, alternating with sterile levels. Following to the top, levels 2 and 3 contain Aurignacian elements (Aurignacian 0 and classic Aurignacian). The level that currently is in the top of the sequences is a sterile level with some remains from the Upper Palaeolithic levels that the old Archaeological excavations destroyed completely. From 2002 to nowadays, we have obtained an important

Numerical dates batch, specially into the framework of the Radiocarbon dating program that is coordinated by Dr. J. Maroto.

In this paper, we present all the results (Chronological and Archaeological data) and we define the state of the question Neanderthal / Modern Human substitution in the Cantabrian Region, from Covalejos' data point of view.

*Higham, Thomas - (University of Oxford)*  
*thomas.higham@rlaha.ox.ac.uk*

The integrity and significance of the assemblage in El Castillo (Cantabria, Spain) unit 18, or Aurignacian delta, has been extensively debated for over two decades. Whilst some suggest that it is transitional between the preceding Mousterian and the later Aurignacian, others contend that it is a mixture of older and younger material.

We present new radiocarbon dates on ultrafiltered collagen from butchered bone and bone tools from units spanning the Middle to Upper Palaeolithic transition at El Castillo. Samples have been taken from both the modern and early 20<sup>th</sup> century excavations to explicitly test the chronological integrity of the purportedly transitional assemblage.

The data demonstrate that younger material, similar in age to the Aurignacian in Cantabria, exists within the early 20<sup>th</sup> century excavations. In contrast, all radiocarbon dates in level 18 from the modern excavation pre-date 42 ka cal BP, and the arrival of the Aurignacian in the region.

It is possible that the assemblage in unit 18 falls into a unique timeframe in the region, being later than other Mousterian units at sites such as Cueva Morin and Arriñor, and earlier than the Aurignacian and Châtelperronian.

Further dating of late Middle Palaeolithic assemblages in the region is required to test this conclusion.

### 11. DOES SIZE MATTER? LOOKING FOR PROXIES FOR AGE AND GENDER ACTIVITIES IN THE LATE MIDDLE AND EARLY UPPER PALAEOLITHIC OF SOPEÑA (NORTHERN SPAIN)

*Pinto Llona, Ana C. (c/o J. Villarías, ILLA CCHS-CSIC)*  
*acpintoll@gmail.com*

Lithic analyses is chiefly directed to the identification of culture "types" that are frequently equated to cognitive stages or/and human species. Such interest in tool types of necessity leaves behind the most abounding evidence, which is flaking debris. The analyses of operative sequences and others cover partially the gap, but are slow work that still does not include the whole assemblage in the analyses. Efforts to distinguish the inputs from different intra-population sectors, namely females and young, are rarer, and their observations are difficult to interpret. However the subject is vital since the very existence of any population depends on the status and role of the females and young in it.

Here I review the literature dealing with alternative lithic analyses and principally on material properties such as raw material, size and weight in relation to such variables, then offer the observations recorded on materials from the late Middle and early Upper Palaeolithic of

Sopeña (northern Spain), a new site with a fairly continuous *in situ* stratigraphic sequence from c. 60 Ky to c. 25 Ky, relatively well dated by absolute methods.

Distinct patterns are observed and an attempt is made to interpret these in relation with demographic change during the later millennia of the Mousterian and the first millennia of early Upper Palaeolithic material cultures established soon thereafter in this site.

ORAL

## 12. CHRONOSTRATIGRAPHY OF THE MP / UP TRANSITION IN GÜELGA CAVE. ASTURIAS. SPAIN.

*Menéndez, Mario - (UNED) mmenendez@geo.uned.es*

The cave of the Güelga is located on the bottom of a blind valley in the Eastern part of Asturias (Spain), 200 m above sea level and 15 km away from the coast. It currently comprises a group of caves that were occupied during the Middle and Upper Palaeolithic periods. In recent years we have been studying the sediments of the Zone D proposing a sequence for the MP/UP transition: Châtelperronian - Aurignacian-Mousterian. Namely, an aurignacian interstratification, which we review in this paper. We also provide new dates for the different levels. The materials studied are the lithic and bone assemblages obtained in archaeological excavations, as well as the fauna remains. A Neanderthal premolar tooth has also been found in mousterian occupation. Both, sedimentological and micromorphological analysis have been carried out at the different levels. All the data that is presented in this paper is AMS14C on bone, with ultrafiltration pretreatment.

The results that have been obtained so far can not confirm the theoretical assumption regarding the aurignacian interstratification. Sedimentological and micromorphological analysis, also according to the levels data, show a likely stratigraphic inversion of the Châtelperronian level (42/45 Ky calBP). This situation must be explained in future geoarchaeological studies. We also present cultural and chronological analysis of the Aurignacian (38 Ky calBP) and Mousterian (45/50 Ky calBP) occupation, as well as of the sterile layers that are between them.

The Güelga Cave is an interesting site for transition MP / UP studies. It shows an early Aurignacian and Mousterian long occupation. Between these two periods the cave was abandoned for about 7/10 ky. Future work must explain the inverted position of the châtelperroni-

an and increase the information about the Aurignacians and Mousterian levels.

*Fábregas Valcarce, Ramón (GEPN, Dpto. Historia I. Universidade de Santiago de Compostela) ramon.fabregas@usc.es*

The Iberian Peninsula has become a key region for the understanding of the Middle and Upper Paleolithic Transition in Europe. Several scenarios have been proposed, where the Cantabrian Rim seems to play a key role. From the Cantabrian point of view, NW Iberia becomes a *Finis-terrae*, but the coastline acts as a link between the Cantabrian and Atlantic regions, where several Late Middle Paleolithic sites have been identified. Recent research projects carried out in the Galician karstic formations have revealed the existence of two sites framed in this period.

We shall deal with the archaeological and chronological data from two caves located in the Eastern ranges of Galicia: Cova Eirós (Triacastela, Lugo) and Cova da Valiña (Castroverde, Lugo).

Cova Eirós has a 3.4 m thick sedimentary infill at the entrance. The archaeological works carried out since 2008 have only excavated the upper part (1.2 m deep), revealing the existence of several archaeological layers related to the Middle Paleolithic (Levels 4 and 3), Early Upper Paleolithic (Levels 2 and 1) and Late Upper Paleolithic (Level B). Their lithic assemblages, although based

on quartz, show diagnostic features of the Middle and Upper Paleolithic technocomplexes, respectively. The sedimentary analysis and the radiocarbon and OSL dating mark the existence of an erosive hiatus between the Levels 3 and 2, the latter dated *circa* 32.000 BP.

The radiocarbon dates from Cova da Valiña are nearly equivalent to those from the Level 2 of Cova Eirós. Nevertheless, its lithic assemblage, also dominated by quartz, is quite scanty and ambiguous. Initially ascribed to the Chatelperronian, recent reviews point to their Mousterian character. Besides, the accidental find of several bone sagaies in the 1960's adds to the uncertainty since they are interpreted as either belonging to the excavated occupation or considered as an evidence of a later Upper Paleolithic occupation.

The well preserved and dated stratigraphic sequence of Cova Eirós has greatly increased our knowledge about the Middle and Upper Paleolithic transition in NW Iberia. Its contextualization within the Cantabrian record will allow us to understand the Early Upper Paleolithic settlement in the region and the technological and behavioural strategies related to anatomically modern humans.

#### **14. ACROSS THE DUERO RIVER? ABOUT THE NEANDERTHAL OCCUPATION IN CENTRAL IBERIA: RESEARCHES IN "ABRIGO DEL MOLINO" SITE (SEGOVIA, SPAIN)**

*Álvarez-Alonso, David (UNED) dalvarez@gijon.uned.es*

*de Andrés-Herrero, María (Neanderthal Museum)  
mdeandres@neanderthal.de*

*Díez-Herrero, Andrés (IGME) andres.diez@igme.es*

*Rojo Hernández, Julio A. (UNED) julio.a.rojo@gmail.com*

Interior part of the Iberian Peninsula, specially the Southern part of the Duero basin, is an area with scarce archaeological information concerning human settlements during the Upper Pleistocene. There are few known and excavated Mousterian sites, and most of them are open air sites. About these last sites there is more information than in karstic deposits sites, but most of them have not quantitative chronologies.

This area, between Central System Mountain range and Duero's valley, has short evidences of Middle Palaeolithic deposits, and most of them consist in lithic industries in open air sites in fluvial deposits. Archaeological excavations of Pinilla del Valle's sites confirm the presence of

Neanderthal groups since the final part of Middle Pleistocene OIS 6-5, and the beginning of OIS 4; Jarama VI site contains evidences of settlement during OIS 3 and the last OIS 4; and other sites as Los Casares or Peña Capón confirm the Neanderthal presence in the Southern Central range in the same period. The recent discovery of Abrigo del Molino is dated in OIS 4, increasing Mousterian remains in karstic environments. With this information we can check that from the beginning of the Upper Pleistocene until the end of Mousterian, there is a continued presence of Neanderthal groups in this area. We present the results of this recent discovery, as well as other mousterian sites in Duero basin, that fill existing gaps.

Karstic archaeological sites provide us great information what is completed with lithic evidence recovered in Mousterian open air sites between Central System mountain range and the South of the Duero basin, that results very interesting for studying of Neanderthal occupation in the South of northern Iberian plateau, particularly in the Duero Valley.

A matter of prime importance is how the interior part of the Iberian Peninsula was populated and what the settlement model for the different Neanderthal populations was. The possible barrier imposed by the Duero and the inexistence of endo-karstic reliefs (great caves) in the interior of the northern plateau, makes that our vision is the product of a combination between open air sites in fluvial valleys and cave settlements in the limestone-dolomite border that is in the boundary by East and South of this great interior basin. This duality makes us to consider different models of Neanderthal settlements and another important question, how was the replacement of these human groups by the AMH in this area? Is required to take into account that the evidences of Early Upper Palaeolithic are scarce and they appear more late that in other regions of the Iberian Peninsula. Furthermore seems to be a gap in the population between the last Neanderthals and the first AMH. In this work we will consider these issues.

#### **15. JARAMA VI (GUADALAJARA, SPAIN): NEW CHRONOSTRATIGRAPHIC AND CULTURAL DATA ABOUT THE LATE NEANDERTHALS IN CENTRAL IBERIA**

*Jordá Pardo, Jesús F. (Laboratorio de Estudios Paleolíticos, Departamento de Prehistoria y Arqueología, Universidad Nacional de Educación a Distancia.) jjorda@geo.uned.es*

*Navazo, Marta (Área de Prehistoria, Departamento de Ciencias Históricas y Geografía, Universidad de Burgos.)  
mnavazo@ubu.es*

*Kehl, Martin (Institute of Geography, University of Cologne.)  
kehlm@uni-koeln.de*

*Burow, Christoph (Institute of Geography, University of Cologne), Alexandra Hilgers (Institute of Geography, University of Cologne) christoph.burow@uni-koeln.de*

*Pastors, Andreas (Neanderthal Museum)  
pastors@neanderthal.de*

*Weniger, Gerd-Christian (Neanderthal Museum) weniger@neanderthal.de*

*Wood, Rachel (Research School of Earth Sciences, The Australian National University) rachel.wood@anu.edu.au*

Jarama VI is located on the NW edge of the Guadalajara province (Castilla-La Mancha, Spain). It is a rock shelter partially filled up by sediments which were excavated between 1989 and 1994. The archaeological excavation shows a lithostratigraphic sequence formed by three Pleistocene sedimentary units (Jordá 2007) with thousands of archaeological remains. Initially, the two lower units were attributed to the Middle Palaeolithic while the upper unit were assigned to the Early Upper Palaeolithic. In 1992 we obtained three conventional radiocarbon dates which indicated that the lower units were situated between 41 and 30 ky cal BP while the upper unit was dated around 29 ka cal BP (Jordá 2007). In the last years we have reviewed the stratigraphy, the chronology and the lithic assemblages of the three units. We present here the results of these works.

The materials studied are the sediments of the three units, all of the technological lithic remains and two different groups of samples for dating. Sediments have been studied from samples obtained in 2010 for sedimentological and micromorphological analysis carried out at the University of Cologne (Germany) and the National Museum of Natural Sciences of Madrid (Spain). The lithic assemblages (2.346 items) have been analyzed at the University of Burgos. Concerning dating, 30 bone fragments with cut marks were screened for dating in 2008/2010 at the Oxford Radiocarbon Accelerator Unit (U.K.) and 6 samples of sediments were obtained in 2010 for luminescence dating at the the University of Cologne with the collaboration of the Neanderthal Museum (Germany).

The grain-size distribution, mineralogical composition, geochemical fingerprints and micromorphological observations corroborate the notion that the middle unit of the sequence is a fluvial deposit of superfloods which

did not experience significant postdepositional changes. The lower and upper units received sediment inputs by sheet-wash and cave spall and shows features of more frequent frost. The results of a comprehensive analysis and the review of the lithic technological materials confirm that the three units belong to the Middle Paleolithic. With respect to AMS radiocarbon dating, only three bones provided results, two of them with infinite ages greater than 47 and 50,2 ky BP, from the lower and upper units, and the third with a date of  $49,4 \pm 3,7$  ka BP for the middle unit (Wood et al. 2013). The IRSL results are coincident with the dates of ORAU and place the human occupations between 60 and 50 ka BP (Kehl et al. 2013). The results of new research carried out in Jarama VI allow us to asseverate that the archaeological remains of the three sedimentary units belong to the Middle Palaeolithic and its age is older than 50 ka BP. Therefore, these human occupations correspond to later Neanderthal populations who lived in central Iberia many years before the arrival of the first modern humans to this area.

#### ORAL

### 16. CHRONOLOGY OF ZAFARRAYA, SPAIN, AND ITS RELEVANCE TO THE DEBATE ON THE DISAPPEARANCE OF THE LAST NEANDERTALS IN THE SOUTH OF THE IBERIAN PENINSULA

*Cecilio Barroso Ruiz - Fundación Instituto de Investigación de Prehistoria y Evolución Humana, Lucena (Córdoba)  
cecilibarroso1@hotmail.com*

*Miguel Caparrós - Muséum National d'Histoire Naturelle, Département de Préhistoire, Paris - capmig@aol.com*

Neandertal human remains corresponding to a minimum number of 9 individuals with ages of between of 14 months and 30 years were unearthed in the cave of the Boquete de Zafarraya, Spain, during archaeological excavations led by Cecilio Barroso Ruiz (2003, 2006) in 1982-1983 and 1992-1994. These fossils were found in Mousterian stratigraphic levels with a significant lithic assemblage characterized by a large Levallois technology percentage with a typology including flakes, side scrapers, denticulates, Mousterian points, etc. These beds included also a substantial faunal record made up of large herbivores (*Capra pirenaica*, *Cervus elaphus*, *Sus scrofa*, *Bos primigenius*, *Rupicapra pirenaica*, *Equus caballus*, *Equus hydruntinus*), carnivores (*Panthera pardus*, *Cuon alpinus*, *Crocota crocuta*, *Ursus arctos*, *Vulpes vulpes*, *Lynx pardina*), lagomorphs (2 species), insectivores (5 species), chiropters (6 species), and avifauna (30 spe-

cies). These assemblages were found in a precise stratigraphic context with a rigorous excavation methodology.

The initial chronology attributed to the site, based on biostratigraphy, suggested that the Pleistocene sedimentary levels were late in their formation (inter Würm II-III or even Würm III) which, should it be true, reflected a late survival of Neandertals in Andalusia, Southern Spain.

Various dating techniques (Michel et. al., 2006) such as C-14, U/Th, ESR and RAA were utilized with the aim of finding a more reliable age of the late presence of Neandertals in Zafarraya (Hublin et.al., 1995). Recent dating results obtained by Michel (2013) and Wood (2013) are significant and shed new light on the debate related to the paradigm of the late survival of Neandertals in the site.

On the basis of recently published chronology studies, we suggest that the question of the "late survival of Neandertals" in other archaeological sites of the South of the Iberian Peninsula must be raised in order to clarify such an important issue in European human palaeontology and prehistory.

largely based on chronological data, since a reliable temporal framework is essential to interpret the Middle-Upper Palaeolithic boundary and the interactions between Neanderthals and Modern humans. As a consequence, radiometric data have been closely scrutinized, revealing serious problems related to the archaeological context of dated samples and the dating methods. Nevertheless, in recent years, various research groups and laboratories have prioritized efforts to obtain new reliable dates, essentially through radiocarbon, from well stratified contexts. At the same time, studies of both environmental and material culture in such contexts have increased. Our contribution is aimed to discuss new chronostratigraphic data and their derived interpretations.

**1. RECENT RESEARCH INTO THE NORTH AFRICAN MIDDLE/LATE STONE AGE**

*Bouzouggar, Abdeljalil - (Institut national des sciences de l'archéologie et du patrimoine (Morocco) and Institute of archaeology, Oxford University, UK) abouzouggar@yahoo.fr*

*Barton, Nick - (Institute of archaeology, Oxford University, UK) nick.barton@arch.ox.ac.uk*

In the nineteenth century the first Aterian pedunculate lithic artefacts were discovered in North Africa. Since then many other *North African Middle Stone Age (NAMSA)* sites have come to light, but so far little has been published on any of the associated human fossils or their stratigraphic relationship with clearly diagnostic *NAMSA* finds. A point that also needs emphasizing is that up until now the majority of *NAMSA* human remains have come from western Morocco in a restricted area of the coastal zone between Rabat (Dar es Soltane 2) and Temara (Contrebandiers Cave and El Harhoura I Cave). This is almost certainly connected with a focus of fieldwork in this area over the past fifty years. It does not detract from the view that human remains in *NAMSA* contexts are relatively scarce and that the understanding of their evolutionary relationship with human fossils found in the *NAMSA* and Upper Palaeolithic is still problematic and controversial.

Any scope for discussing the *NAMSA* is still severely limited by the paucity of secure dating evidence. Although well-known sites, including those with human fossils, have been recorded on the Atlantic coast, very little dating evidence exists for the sequences in these caves. This is a major gap in our knowledge which we are hoping to rectify with new stratigraphic studies that are now in progress.

If we accept the dating from some caves, it is clear that the very late record of the Aterian of 40-20,000 B.P. can certainly now be extended back well to MIS6.

Another area for discussion concerns the whole question of the nature and identity of the *NAMSA* technology which we feel is urgently in need of review and redefinition. Up until now it has largely been accepted that the *Mousterian/Aterian* lithic technology is characterised by a dominance of flake tools and the Upper Palaeolithic by a dominance of tools on blades and bladelets. This

definition, which was already questioned by early researchers, has now come under renewed challenge after recent studies of finds from sites in Eastern Morocco and the Atlantic coast.

In consequence, it is now increasingly clear that this technology is a very flexible one, which in addition to flake tools includes evidence for the use of "Middle Palaeolithic" blades and flake tools and even occasionally pebble tools. Much of the existing interest in the *NAMSA* has tended to concentrate on the very narrow issue of pedunculate tools, rather than considering a wider set of variables. Finally, we feel that more consideration should be given to non-lithic aspects of the technology such as the manufacture and use of beads.

Numerous recent and on-going excavations are providing new data on North Africa's Middle Stone Age archaeological record. However, significant uncertainty remains on the nature, timing and meaning of the cultural variability this record documents across the period from 160,000 to 30,000 years ago, so much so that archaeologists are still debating how to organize and what to call these industries (e.g. Dibble et al. 2013). What is clear, however, given the rich hominin fossil record of North Africa, is that all major cultural transitions during this period occurred within *Homo sapiens* populations (Hublin 2001).

The definition of the North African MSA (Mousterian/Aterian) is based on inadequate archaeological evidence, and far from being a homogeneous or stable cultural entity, the MSA shows successive typological and technological changes through time. In this paper we seek to address some of the issues concerning these industries including their definition and the variability within them. A major problem is that much of the information concerning the evolution of the North African MSA is based on the very narrow issue of pedunculated tools. Microwear analyses from Rhafas have shown that some pedunculates appear to have been used for a range of tasks including scraping and butchery. When discussing the Aterian and late MSA variability, a wider set of variables should be considered including blades and bifacial foliates as well as changes in the core and blank morphologies.

One of the main aims of this paper is to provide information concerning the validity and significance of the two so-called "facies" (Mousterian/Aterian) of the North African MSA as there is still uncertainty whether these two are in fact distinct or whether they should be recognized as one unit with internal variability. Further, if they are indeed separate units, it is unclear whether they are a result of population replacement or a cultural transition. In this paper we discuss the nature of cultural variability in the late MSA based primarily on new data coming from excavations in Rhafas Cave compared to other sites in the region with similar sequences (Bouzouggar et al., 2007). We present new information on chronological developments within a sequence that also documents evidence for personal ornaments and symbolic shell artefacts

### 3. QUELQUES CONSIDÉRATIONS TECHNO-COMPORTEMENTALES SUR DEUX SÉRIES LITHIQUES ET OSTÉOLOGIQUES DU PALÉOLITHIQUE MOYEN EN TUNISIE

*Aouadi Abdeljaouad, Nabiha - (Institut National du Patrimoine, Tunisie) aouadinabiha@gmail.com*  
*Belhouchet, Lotfi (Institut National du Patrimoine, Tunisie) lotfi\_belhouchet@yahoo.f*  
*Barton, Nick - (Institute of archaeology, Oxford University, UK) nick.barton@arch.ox.ac.uk*

Nous souhaitons présenter quelques considérations technico-typologiques et comportementales sur un certain nombre de sites tunisiens attribués au Paléolithique moyen et récemment fouillés (Oued el Akarit et Aïn el Guettar).

Dans le site de l'Oued el Akarit, les carcasses de grands ongulés ont été ramenées entières sur le site et dépecées en faisant appel surtout à de gros blocs de pierres présents *in situ*. Le mode de subsistance des Préhistoriques et la présence de l'industrie osseuse sur le site suggèrent des activités liées à des *Homo sapiens* modernes. Des pièces pédonculées à débitage microlithique ont été découvertes tout le long de la séquence. Suite aux observations faites, l'Atérien semble représenter un faciès parmi tant autres appartenant à cette période.

Les modes de subsistance des hommes préhistoriques durant le Pléistocène supérieur en Tunisie sont en étroite relation avec les changements paléoenvironnementaux. Ces économies de subsistances montrent que l'Oued el Akarit est un site d'habitat avec une exploitation maximale des carcasses de *Ceratotherium* et d'*Equus mauritanicus* sur place alors que le site de l'Aïn el Guettar est un camp de boucherie saisonnier avec dépeçage des espèces particulières qui sont *Equus melkiensis*, *Equus algericus*, et *Alcelaphus buselaphus* avec transport sélectif des parties les plus nutritives hors du site.

### 4. THE LATE STONE AGE OF HAUJA FTEAH CAVE IN NORTHERN CYRENAICA, LIBYA: ORIGINS, CHARACTERISTICS AND LATE PLEISTOCENE TECHNOLOGICAL SHIFTS.

*Mutri, Giuseppina - (Department of archaeology, University of Cambridge, UK) gm461@cam.ac.uk*  
*Sacha Jones (Department of archaeology, University of Cambridge, UK) scj23@cam.ac.uk*

In the last decade, research in North Africa has revealed new and interesting data on the Middle Stone Age (MSA) to Later Stone Age (LSA) transition and chronology. In Morocco, the cave sediments of Taforalt present a clear

stratigraphical discontinuity between the youngest Aterian (MSA) and the oldest Iberomaurusian (LSA) levels, where these two horizons appear to be culturally unrelated. Currently, the Iberomaurusian at Taforalt, dated to 23000 BP, is the oldest dated LSA context in the Maghreb (Barton, R. N. E., et al. 2013). In North-east Africa, and particularly in Cyrenaica, the Dabban is considered the oldest LSA context, dated to between 40000 and 17000 BP (Douka et al 2014). At Haua Fteah, the Dabban is overlain by the Oranian, a backed bladelet lithic complex very similar to the Iberomaurusian.

While the Aterian and Iberomaurusian at Taforalt are argued to be culturally unrelated, the same cannot be said for the relationship between the Dabban and Oranian at Haua Fteah. Although certain technological criteria and differential artefact frequencies do distinguish these latter two industries, their technological commonalities unite them into a single technological system.

In Cyrenaica, therefore, the MSA to LSA transition needs to be sought earlier than in the Maghreb, and most probably in the late "Levalloiso-Mousterian" (McBurney 1967) levels at Haua Fteah. In this paper, we are going to address this problem through an assessment of the technological features of the Dabban lithic artefacts, highlighting elements of continuity with the Oranian and demonstrating its association with a LSA technocomplex.

Il existe très peu de sites préhistoriques connus dans la région de la Cheffia (sud-est d'El Tarf), et les vestiges ibéromaurusiens n'ont jamais été trouvés sous-jacents aux vestiges néolithiques. Une fouille de sauvetage a été récemment opérée au niveau du site préhistorique de Kef en-Naga. La découverte de ce site inédit a été favorisée par l'exploitation d'une carrière en grès dont les travaux ont tronqué une grande partie du site sur son profil transversal, ce qui a eu pour conséquence la disparition d'une grande partie du potentiel archéologique.

Le site de Kef en-Naga était un site de plein air protégé par une imposante falaise en grès qui dominait la vallée de l'oued Krenga à une altitude de 130 m, au milieu d'un massif accidenté revêtu d'une broussaille épaisse. L'aire fouillée se trouve sur un glaci-cône d'accumulation au pied d'un escarpement gréseux peu étendu et en pente forte. L'épaisseur de la formation observée au niveau de la coupe stratigraphique dégagée atteint 5 m d'épaisseur. La couche archéologique, couverte pas les alluvions, est constituée de sables fins argileux de couleur gris foncé. Elle est sous-jacente à une couche jaune marneuse 'intermédiaire' qui repose sur une assise d'argiles stériles.

La confrontation des analyses granulométriques et diffractométriques des sédiments prélevés au niveau de la couche archéologique, ainsi que l'analyse de leurs propriétés magnétiques a permis de conclure à la présence de deux types de dépôts sablo-argileux, non encore datés, qui se seraient formés distinctement et dans des conditions paléoenvironnementales différentes.

Les diverses analyses des sédiments confortent les résultats de l'examen des restes archéologiques.

En effet, le premier dépôt se rapporterait à l'Ibéro-maurusien et serait caractérisé par une industrie lamellaire à microburins, alors que le second, trouvé en position remaniée, contiendrait une industrie néolithique sur éclats associée à la production de la céramique.

**6. INDICES DU COMPORTEMENT MODERNE CHEZ LES HOMMES D'EL MNASRA (TÉMARA, MAROC) IL Y A PLUS DE 100 000 ANS.**

*El Hajraoui, Mohamed Abdeljalil - (Institut National des Sciences de l'Archéologie et du Patrimoine, Département de Préhistoire, Rabat, Maroc) maelhajraoui@gmail.com*

*Nespoulet Roland - (Muséum National d'Histoire Naturelle, Département de Préhistoire-UMR 7194, Paris, France) roland.nespoulet@gmail.com*

*Debenath, André - (Muséum National d'Histoire Naturelle, Département de Préhistoire-UMR 7194, Paris, France) andre.debenath16@orange.fr*

Située dans la région de Rabat-Témara, la grotte d'El Mnasra, dont les fouilles ont débuté depuis 1992, ne cesse de nous livrer de nouveaux indices archéologiques remarquables chaque année. Certaines de ces découvertes nous ont apporté énormément de renseignements sur le comportement moderne d'*Homo sapiens* au début du Pléistocène supérieur (Atérien). Outre leur très grande ancienneté, la présence simultanée de plusieurs indices dans les mêmes niveaux archéologiques nous amène à considérer que la grotte d'El Mnasra livre une documentation exceptionnelle.

Parmi les indices les plus représentatifs, nous retenons : Les foyers. Dans la couche 6, datée d'environ 110 ka, sept foyers ont été mis au jour sur une surface de 5 m<sup>2</sup>. Trois types de structures ont été identifiés : des foyers fermés, ouverts et enfin des foyers surcreusés. Ceci montre que la majorité des modes de construction d'une structure de ont été exploités, et que les atériens ont su maîtriser une large gamme de techniques liées à l'usage domestique du feu. Leurs fonctions présumées étaient la cuisson, la chauffe, la défense et l'éclairage. Des techniques d'entretien de la combustion a été mise en évidence dans les foyers creusés, indiquant un usage anticipé et répétitif de la même structure sur une assez longue période.

Les hématites. Les blocs d'hématite brute provenant des niveaux atériens d'El Mnasra sont de différentes variétés. Dans les couches 5 et 7, des blocs travaillés présentent des stries de raclage ainsi que des plages polies. Il s'agit, à notre connaissance, des premières découvertes de ce type dans l'Atérien du Maroc. Ces colorants sont accompagnés d'un galet de quartzite assez volumineux interprété comme une molette.

Les pièces en matières dures d'origine animale. Les niveaux atériens 5 et 6 d'El Mnasra ont livré 13 objets

façonnés en os. D'un point de vue fonctionnel, et comparativement aux outils lithiques, ces pièces indiquent qu'une même fonction, telle que racler et/ou percer, peut être accomplie avec des outils façonnés dans une matière première complètement nouvelle. Ceci témoigne d'une inventivité et d'une créativité permettant et se traduit par l'emploi et la maîtrise de plusieurs techniques, ainsi que l'utilisation de multiples outils pour accomplir des fonctions semblables.

Dans les niveaux 5, 6 et 7, 221 coquilles de *Nassarius* ont été recensées. Plus de 70 % d'entre elles sont perforées. Par comparaison avec des découvertes similaires dans des sites du Maroc, d'Algérie, d'Afrique du sud et du Proche-Orient, on peut considérer ces pièces comme des éléments artistiques et symboliques, puisque certaines perforations sont intentionnelles et présentent des traces d'usage de liens.

Avec ces trois types d'indices, nous pouvons conclure que l'esprit novateur, créateur, économe, social, prévisionnel, base du comportement moderne de l'Homme, se trouve bien documenté dans la grotte d'El Mnasra. Cette grotte constitue donc un jalon important de la question de la modernité comportementale des premiers *Homo sapiens* du Maghreb.

*Nespoulet, Roland - (Département de Préhistoire-UMR 7194, MNHN, Paris) roland.nespoulet@mnhn.fr*

The Témara area is located near Rabat on the Moroccan Atlantic coast. During the OIS 5, human occupations were related to high sea levels when the shoreline was near to the caves (Jacobs *et al.*, 2012; Stoetzel *et al.*, 2014).

This presentation is build on taphonomic and zooarchaeological analyses of meso and macrofaunal remains of El Mnasra Cave layers dated to the OIS 5.

The example of El Mnasra Cave indicates that diverse resources were consumed by Aterian populations: terrestrial resources on one hand, such as tortoises and several ungulates (gazelles and other bovids, wildpigs, equines and maybe elephants, rhinoceros and hippos), and marine resources such as shellfishes on the other hand. A complete reduction sequence of butchery of ungulates (mainly gazelles) is identified despite the rarity of cut-marks. Frequencies of butchery-marks are lower than in Europe archaeofaunal assemblages. Several phenomenon can explain this difference: the presence of unobservable surfaces (concretions, burnt portions); the use of a low magnification; the influence of climate on butchery practices or specific butchery practices (Campmas, 2012).

In addition to the butchery, evidence for multiple activities is seen through stone tool artifacts (including tanged tools), *Nassarius* shells beads (N>200), bone industry, used pigments and fire places (El Hajraoui *et al.*, 2012). These indexes show that El Mnasra was not a specialized site dedicated to one activity. The low density of material and the low number of exploited prey suggest short time occupations.

Thus this site could be interpreted as a short-term residential camp within a larger mobility system of "forager" type with a significant mobility of the residential camp, exploitation of local resources and without storage of food (Campmas, 2012).

This paper presents a synthesis of the results of the Archaeological Map Project in Northern Morocco, which has been carried out by researchers from the University of Cádiz, University of Abdelmalek Essaadi and Insap of Rabat.

There have been 4 prospecting archaeological campaigns in the region of Tetuán with excavations in the Cave of El Hafa and the Shelter of Marsa.

We provide data about the geomorphological context as well as explaining the kind of lithic resources used by the different human groups who had settled there. Moreover, the prospected areas and the settlement patterns studied in all of them are presented in this paper. We provide an updating of the relevant occupations corresponding to Palaeolithic hunter-gatherer societies, Neolithic tribal societies and also, of those ones corresponding to associated stages to Recent Prehistory.

The rockshelter of Benzú is located near the city of Ceuta, in North Africa. We have done an evaluation of geological, stratigraphic, chronological, and ecological data as well as of the different resources used by prehistoric societies.

We emphasize on technological data of the archaeological products and in lifestyles. Geological and paleoecological bases of the historical region of the Strait of Gibraltar provide great similarities between the European and North African shore.

The shelter of Benzú has a sequence of 7 archaeological levels with a clearly-defined technology belonging to Mode III concept. The similarities with the sets of the southern Iberian Peninsula are evident. We also emphasize the exploitation of marine resources by hunter-gatherer societies since the beginning of the Middle Pleistocene sequence.

## POSTER

### 10. TOOL USE AND HAFTING IN THE MIDDLE PALAEO-LITHIC OF NORTH AFRICA: PRELIMINARY RESULTS OF AN ON-GOING USE-WEAR ANALYSIS ON THE MOUSTERIAN/ATERIAN ASSEMBLAGES OF IFRI N'AMMAR (MOROCCO)

*Tomasso, Sonja - (Ulg/ Kaak-DAI) sonjatomasso@hotmail.com*

*Rots, Veerle - (Ulg) veerle.rots@ulg.ac.be*

The rock shelter of Ifri n'Ammar has a remarkable stratigraphy with alternating Mousterian and Aterian occupations within more than 6 meters of sediments dated from MIS 6 to 5a. The stratigraphy attributed to the Middle-Palaeolithic is divided in two units, separated by a calcareous crust, where upper and lower Aterian occupations can be identified.

Previous studies have characterised Aterian and Mousterian cultures on a typological and technological basis. Functional data on lithic industries from the Middle Palaeolithic in northern Africa is at present very scarce and detailed studies of the production, hafting and use of tools, particularly tanged pieces, have not yet been conducted.

Preliminary results of an on-going use-wear analysis of Middle Palaeolithic stone tools from the site of Ifri n'Ammar will be presented. Both low and high magnifications are combined for examining the macro- and microscopic wear traces on the stone tools. The interpretation of the archaeological material is based on comparisons with an experimental reference collection.

The long-term goal of the study is to understand how stone tools were used, whether hafted stone tools existed at the site and how these functional parameters compare to the typo-technological characteristics of the different assemblages and how they may have influenced assemblage variability.

Abdeljalil Bouzouggar - (Institut national des sciences de l'archéologie et du patrimoine, Rabat, Maroc) abouzouggar@yahoo.fr

Archaeological deposits at Grotte des Pigeons in Morocco document extensive evidence for human occupation during the Later Stone Age (Iberomaurusian) and incorporate numerous human burials representing the earliest dated cemetery in the Maghreb. Recent excavations have focussed on undisturbed burial deposits situated at the rear of the cave (Sector 10) and a deep well stratified sequence of deposits situated closer to the cave opening (Sector 8), where there is no evidence of funerary activity.

Sector 8 deposits document a marked change in the use of the cave during the Iberomaurusian, leading to the rapid accumulation of massive ashy midden layers known as the 'Grey Series' between 15,000 and 12,700 cal BP. Charred macro-botanical remains from these well-stratified deposits provide evidence for numerous edible or economically useful wild plants including acorns and pine nuts, juniper, terebinth pistachio, wild pulses and wild oats. The presence of rhizome fragments of esparto grass suggests that baskets could have been made and used to collect, store and process wild plant foods and other resources. The abundance of acorns and pine nuts points to deliberate selection of seeds with a high nutritional value that could have been stored and used as a staple food for most of the year.

The more rapid formation of cultural deposits after 15,000 cal BP points towards an intensification of activ-

ity involving more prolonged occupation periods or a larger population. Systematic harvesting and processing of wild food resources including plants and edible land snails may have supported a more sedentary lifestyle during the late Iberomaurusian than previously recognised. Direct dates on human bone samples from Sector 10 yielded age estimations between 15,077 cal BP and 13,892 cal BP, indicating that the allocation of a spatially demarcated area at the back of the cave for funerary activity coincided with the base of the Grey Series, and implying a simultaneous intensification of ritual and economic activities at Grotte des Pigeons.

Analyses of the adult dentitions revealed evidence of severely impaired dental function due to poor oral health, heavy tooth wear and cultural modification of the anterior dentition. The exceptionally high prevalence of carious lesions implies that most adults at Taforalt were infected by cariogenic oral bacteria. The shift towards a disease associated oral microbiota is likely to reflect regular consumption of wild plants rich in fermentable carbohydrates and processing of plant foods to increase their stickiness. The Iberomaurusian inhabitants Taforalt represent the earliest example of a hunter gatherer population with a high prevalence of caries, predating other high caries populations and the first signs of food production by several thousand years.

ORAL

### 13. OCCUPATION DE L'ESPACE ET COMPORTEMENT ANTHROPIQUE PENDANT LE PLÉISTOCÈNE (NORD-OUEST DU PLATEAU CENTRAL MAROCAIN)

*Mostapha Belhilali - (Département de géographie physique, Université Mohammed V-Agdal, Rabat, Maroc) belhilali@hotmail.com*

*Abdeljalil Bouzouggar - (Institut national des sciences de l'archéologie et du patrimoine, Rabat, Maroc) abouzouggar@yahoo.fr*

*Mohammed Tailassane (Département de géographie physique, Université Mohammed V-Agdal, Rabat, Maroc) tailamed2005@yahoo.fr*

*Abderrahim Watfeh (Département de géographie physique, Université Mohammed V-Agdal, Rabat, Maroc) abderrahimbenali@yahoo.fr*

La région étudiée est rattachée à la partie septentrionale du Plateau central marocain. Elle relie le palier intermédiaire (Amont) et le palier inférieur (Aval). C'est un espace naturel de transition verticale et horizontale. En effet l'amont fournit l'eau et les matériaux détritiques et cal-

caire (rôle du substrat géologique) et l'aval constituée par les fonds de vallées reçoit sa richesse en matière première. La région représente alors, une toposéquence dont la dynamique de transport des matériaux sur les versants est l'origine d'un apport essentiel pour les vallées d'une part, et offre de meilleures conditions de vie d'autre part.

Les fonds de vallées avec leurs terrasses alluviales, correspondent à des milieux très riches en matières premières lithiques indiquant l'intensité de l'occupation et l'exploitation anthropique.

En effet, la découverte de plusieurs sites archéologiques qui témoigneraient d'une occupation dense de la région au cours du Pléistocène. Le matériel archéologique est essentiellement composé d'objets lithiques abondants en coupes, sur les surfaces des terrasses et des plateaux. Les traces de l'homme enregistrées sur les terrasses et sur les surfaces des plateaux, explique les déplacements sans cesse de l'homme.

Ce genre de comportement, nous pousse à poser la question suivante : pourquoi l'homme a essayé d'occuper des espaces topographiques différents et très dispersés ? Est-ce à cause des crises environnementales ou pour chercher la matière première pour perfectionner ces outils ?

En effet selon les vestiges, l'homme a toujours essayé d'inventer de nouveaux outils de travail soit pendant les crises climatiques, soit pendant les périodes de stabilité pour répondre à ses besoins.

ORAL

### 14. LA DYNAMIQUE ET LE PEUPEMENT HUMAIN DANS LES PLATEAUX DE LA MESETA ATLANTIQUE AU COURS DE L'HOLOCÈNE

*Watfeh, Abderrahim - (Département de géographie physique, Université Mohammed V-Agdal, Rabat (Morocco) watfeh@gmail.com*

*Tailassane, Mohammed - (Département de géographie physique, Université Mohammed V-Agdal, Rabat (Morocco) tailamed2005@gmail.com*

*Nafaa, Rachida (Département de géographie physique, Université Hassan II-Mohammedia) nrachida2005@yahoo.fr*

*Malek, Farid (Laboratoire des recherches, d'analyses techniques et scientifiques de la gendarmerie royale, Témara (Morocco) larsbruus@hotmail.com*

*Laouina, Abdallah (Département de géographie physique, Université Mohammed V-Agdal, Rabat (Morocco))*

Les plateaux de la meseta côtière longent l'espace littoral entre kénitra et Casablanca et forment son arrière pays (figure 1). Ils se composent des grès marins et dunaires plio-quaternaires qui couvrent en discordance majeure les flyschs du socle Primaire, ainsi que la molasse et les marnes messéniennes. Ils se présentent en forme de cordons dunaires bio-détritiques consolidés, en prenant une disposition parallèle à la ligne du rivage.

La période de l'Holocène en Afrique du Nord a connu un développement accéléré des activités humaines. De telles innovations ont nécessité le recours à des méthodes scientifiques pluridisciplinaires pour les comprendre, telle que l'archéologie, les sciences humaines sociales et économiques afin de mieux analyser les héritages holocènes comme les sols, les différents dépôts, les trouvailles archéologiques et les restes osseux de la faune fossile. Cette approche qui peut nous aider à mieux appréhender la relation qui a pu exister entre l'Homme et son milieu, nous l'avons appliqué sur des coupes pertinentes selon les étapes suivantes:

a) description géomorphologique détaillée : ceci afin de préciser les types de sédimentation et leur localisation, leur proportion et par la suite choisir les échantillons qui seront soumis à des études sédimentologiques et chimiques au laboratoire. Cela pour but d'avoir d'après l'interprétation de leurs résultats des indications sur les paléo-environnements qui ont caractérisé les paléo-milieus holocènes déjà anthropisés.

b) Avoir recours à l'analyse archéologique, car les témoins matériels des activités humaines dans les sols ou dans d'autres dépôts peuvent fournir des indications sur la nature du peuplement humain, du milieu et les types d'exploitation des ressources de ce dernier.

c) Nous avons également eu recours aux datations radiométriques et essentiellement le  $^{14}\text{C}$  sur les charbons de bois et les coquilles terrestres, ce matériel est issu dans un premier lieu des profils de la Plage des Nations, de Fouarat, (Nafaa 2002) de l'embouchure de l'oued Cherrat (Tailassane 1999), et dans un second lieu ces méthodes ont également concerné les coupes de Harhoura et de Bir Jdid. (Watfeh et al. 2007), D'autres datations par OSL (Luminescence Stimulée Optiquement) ont essentiellement concerné la séquence de la grotte de Dar Es Soltane 1 (Rabat), d'El Mnasra (Témara) et des Contrebandiers (Témara) (Schwenninger et al., 2010 ; Bouzouggar et Barton, 2012).

L'ensemble des études s'accorde à attribuer un âge entre 6500 et 5500 ans BP pour dater l'optimum de la pulsation positive du mellahien. Les nouvelles recherches au niveau de la plage de harhoura au sud de la ville de Rabat réalisées par notre équipe depuis 2003 ont démontré que la transgression marine mellahienne correspond à deux pulsations marines :

- la première s'est produite vers  $6154 \pm 156$  ans BP correspondant au beach rock consolidé ;
- la seconde que nous avons identifiée récemment est représentée par un niveau marin plus haut que le précédent et qui l'a donc enfoui. Elle est datée de  $4888 \pm 139$  ans BP.

Les nouvelles recherches sur le littoral atlantique ont démontré que la transgression mellahienne s'est composée de deux phases principales et elles ont démontré que les traces de l'installation humaine sont devenues plus importantes au cours de l'Holocène.

*Hardy, Karen - (ICREA at Universitat Autònoma de Barcelona) khardy@icrea.cat*

The Mesolithic of the west coast Scotland is well known, principally for its shell middens and evidence for coastal exploitation. Camas Daraich is an open air Mesolithic site, currently the earliest in the Isle of Skye, Scotland, where it is located at the southernmost point of the island, at the Point of Sleat. It lies around 500m from the current coastline, facing a paleolake. Little evidence survives for resource exploitation, though micromorphology shows that the occupation layer was formed in situ with a high organic component which indicates animal consumption at the site, while some charred plant remains have also been recovered.

Early excavations in 2000, were followed more recently, by a new excavation campaign. Currently raw material characterisation, lithics analysis and spatial analyses are ongoing.

The recent excavations have revealed a large lithic assemblage, a series of small stone alignments and the outline of a structure. Raw materials suggest connections to the island of Rum 12 miles away and also to the north east part of the island.

Here we present the first results of the lithics analysis and spatial analysis of the occupied area. We offer our early interpretations of the occupation of the site.

ORAL

**2. COLONISATION OF THE UPPER MIERA AND ASON VALLEYS (CANTABRIA, SPAIN) EN THE LATE GLACIAL PERIOD AND THE HOLOCENE**

*Pérez Bartolomé, Mercedes - (UNED Univ, Nac. Educ. a Dist.) mercedesper@hotmail.com*

The colonisation of the upper valleys in the centre of Cantabria, the Miera and the Asón, in the late glacial period and the Holocene will be studied. The upper part of these valleys was affected by glaciation (glaciers in the Upper Miera valley, Valdició and Bustalviente). The moraines reached altitudes of 500m in the Miera and 340m in the Asón, where the glacier ablation zones were located.

The chronological sequence of occupation in altitudes of 300-700m will be presented. Although these are not great heights, owing to the geomorphology in this area with very steep slopes and karst landforms, the valleys are characterised by very rugged relief.

The settlement patterns will be considered together with the variables of absolute and relative altitude, distance from the coast and local topography. The settlement type, its relation with the landscape and the resources available in the different biotopes will also be assessed.

ORAL

**3. AFTER THE ICE: COLONISING ISLANDS**

*Woodman, Peter - (UCC) p.woodman@ucc.ie*

For hunter gatherers the process of colonising an island is not always easy. For archaeologists the identification of this process can also be difficult. Ireland represents a good case study where factors such as its size easy/difficult access, environmental or climatic differences or even a convenient substantial population presence at the start off point have to be weighed against each other. In terms of researching how and when colonising new island landscapes, there are two issues. 1) One might presume that the resources of the sea would play a major role yet the role of changing sea levels can present a major obstacle to finding evidence of coastal settlement. 2) One major question is whether, after arrival, significant changes take place and how rapidly does this process begin.

ORAL

**4. FROM HUNTER GATHERERS TO HUNTER GATHERERS AGAIN: SOFT COMPUTING PERSPECTIVE FOR UNDERSTANDING THE ARCHAEOLOGICAL GAP AND ITS IMPLICATIONS (8.6-6.2K BP) IN TIERRA DEL FUEGO (ARGENTINA AND CHILE)**

*Maximiano Castillejo, Alfredo - (III PC. Universidad de Cantabria) maximianoam@unican.es*

Topics related with Pleistocene-Holocene Transition (e.g. wildlife restrictions, changes in vegetation cover, temperature oscillations, reversals glaciers surfaces, sea level rise...) took place in Tierra del Fuego, and one more significantly: in ca. 8.2k BP the connection with American continent was broken (emerging Strait of Magellan) (Coronato et al 1999; Borrromei et al 2009) and providing a peculiar insularity context where terrestrial faunal and humans were trapped and forced to interact with a changing environment in a delicate equilibrium between social groups -as terrestrial hunters role-, and wildlife -as limit food resource-. This complex situation is an ideal social laboratory in terms of how people responded to those vicissitudes.

Among the earliest human occupations at Peninsula Tierra del Fuego (ca. 10.5k BP) (Massone 2003; Miotti & Salemme 2004; Salemme & Mioti 2008; Morello et al 2011) and stable ecological conditions at Island Tierra del Fuego, around 5.7k BP, there are a significant archaeological Gap (low and discontinuity presence of archaeological sites and radiocarbon dates: n=4). About these archaeological evidences, there are two plausible hypothesis: i) Human extinction or, ii) Endurance, and development new social strategies for survival in this isolation and changing medium. The archaeological data and local history course show us that it's far away from correlate first terrestrial hunters (Tres Arroyos site, ca. 10.2k BP and Narazzi 1 site, ca. 9.6k BP) with social complexity and variety detected in Middle Holocene (5.8k BP), where the archaeological record indicates specialization and diversification in coastal and terrestrial resources. In this sense, we are interested in try to fill this archaeological Gap (8.6k-6.2k BP) and elucidate social process in terms of extinction and subsequent a new maritime colonization of the Island (+- 6.5k BP), or survival and diversification process in different social groups (i.e. Shelk'nam, Hauss and Yámanas).

This communication is a theoretical dissertation about how to deal with diverse evidences relate with a multifaceted social process (extinction or survival), and know how we could find empirical and flexible solution for interpreting the population of Tierra del Fuego. In this situation we'll apply a powerful and flexible perspective: Soft Computing (Zadeh 1994) like epistemological and technological mediation to generate new and useful knowledge for this issue. Soft Computing is an effective and efficient resolution way in determinate scientific problems where data and information about phenom-

enology are fractional, complex and fuzzy; and our case is an excellent example for this perspective because if we want to understand the transition process and fill the archaeological Gap, we must work with partial and incomplete dataset (i.e. archaeological contexts in function of lithic technology, anthropological and archaeofaunal remains...), and variety sources (e.g. climatology, ecology, landscape evolution, maritime transgression sequence...) with fuzzy information levels.

This communication is a theoretical dissertation about *how to deal* with diverse evidences relate with a multifaceted social process (extinction or survival), and *know how* we could find empirical and flexible solution for interpreting the population of Tierra del Fuego. In this situation we'll apply a powerful and flexible perspective: Soft Computing (Zadeh 1994) like epistemological and technological mediation to generate new and useful knowledge for this issue. Soft Computing is an effective and efficient resolution way in determinate scientific problems where data and information about phenomenology are fractional, complex and fuzzy; and our case is an excellent example for this perspective because if we want to understand the transition process and fill the archaeological Gap, we must work with partial and incomplete dataset (i.e. archaeological contexts in function of lithic technology, anthropological and archaeofaunal remains...), and variety sources (e.g. climatology, ecology, landscape evolution, maritime transgression sequence...) with fuzzy information levels.

## 1. THE NATURE AND IMPORTANCE OF COASTAL ADAPTATIONS DURING THE MIDDLE STONE AGE OF SUB-SAHARAN AFRICA

*Will, Manuel - (Department of Early Prehistory and Quaternary Ecology & Senckenberg Center for Human Evolution and Quaternary Ecology, University of Tübingen, Schloss Hohentübingen, 72070 Tübingen, Germany) manuel.will@uni-tuebingen.de*

*Kandel, Andrew W - (Heidelberg Academy of Sciences and Humanities, ROCEEH - The Role of Culture in Early Expansions of Humans, Rümelinstr. 23, 72070 Tübingen, Germany) a.kandel@uni-tuebingen.de*

*Conard, Nicholas J - Department of Early Prehistory and Quaternary Ecology & Senckenberg Center for Human Evolution and Quaternary Ecology, University of Tübingen, Schloss Hohentübingen, 72070 Tübingen, Germany) nicholas.conard@uni-tuebingen.de*

The Middle Stone Age (MSA) of sub-Saharan Africa provides an exceptionally long record of marine resource exploitation and coastal settlements by modern humans. These adaptations to coastal landscapes feature prominently in current studies of the biological and behavioral evolution of *Homo sapiens*.

Here we present results on coastal settlement systems from our excavations at the site of Hoedjiespunt 1 (HDP1), Western Cape, South Africa. We also review recent advances in research on coastal adaptations of the MSA, with a focus on settlement patterns, lithic technology and economic behavior.

HDP1 dates to the last interglacial (MIS 5e) and demonstrates the simultaneous occurrence of flexible raw material use, anticipated long-distance transport of tool stones, systematic gathering of shellfish and use of ground ocher. The site's inhabitants executed scheduled movements to the coastline for exploiting shellfish during brief but repeated settlements. The three find horizons at HDP1 reflect a consistent pattern of technology and land-use that suggests stable adaptations of modern humans to coastal landscapes as early as MIS 5e. Recent other research has shown that coastal adaptations in sub-Saharan Africa date back as far as the late Middle Pleistocene (MIS 6). Studies from the western and southern coasts of South Africa, and from the Red Sea, demonstrate that coastlines provided important resources for occupations between MIS 6 and 4. These coastlines, however, represent diverse geographic, oceanographic and environmental settings.

Despite these dissimilarities, the available data suggest that early modern humans exploited marine resources in a comparable manner.

Mobile hunters and gatherers frequently integrated variable coastal landscapes and their resources into their settlement strategies during the MSA across more than 100 ka. The long-lasting and consistent nature of these behavioral innovations may have influenced human bio-cultural evolution during the MSA and the spread of our species along the African coast and beyond

## 2. THE CHANGING NATURE OF COASTAL RESOURCE USE IN WEST SCOTLAND

*Hardy, Karen - (ICREA at Universitat Autònoma de Barcelona) khardy@icrea.cat*

Evidence for coastal resource use, in the form of shell middens, can be found in many parts of the world. But the term 'shell midden' is used to define a wide range of different coastal sites, ranging from huge landscape-changing mounds, to small, barely visible, accumulations of shell or slow-accumulating deposits that can eventually fill up rockshelters.

Using a combination of radiocarbon-dated evidence and physical remains for different types of shell accumulations in Scotland, we explore how the nature of shell middens, and their patterns of accumulation, can contribute to an understanding of different ways coastal resources were used at different times in the past.

A closer look at the different types of shell middens from the Scottish west coast suggest that the way these have accumulated can help to distinguish different uses of the coastline and coastal resources in different periods. The fishing and collecting of coastal resources, as well as the accumulation of waste into shell middens occurred throughout the past in west coast Scotland. However, the evidence suggests that the way the coast, and the rockshelters where much of the evidence is located, were exploited, varied over time, with clear cut patterns of use at different times in the past. The archaeological evidence reflects this different use of the coastline and its resources.

Craig, Oliver (University of York) [oliver.craig@york.ac.uk](mailto:oliver.craig@york.ac.uk)

Maritime adaptations sustained South American pre-Columbian populations since the late Pleistocene and stable isotope studies reveal the crucial role of aquatic resources to several Holocene coastal groups, even during the intensification of food production. However these direct lines of evidence are strongly biased towards archaeological records along the western and south-eastern coast of South America. Here we have extended the information to the subtropical Atlantic rainforest coast of Brazil.

We performed an inter-disciplinary study on human, faunal and artefact remains from mid to late Holocene Brazilian archaeological sites (~6,700 to ~1,000 cal BP): Jabuticabeira II' Moraes, Piacaguera, Galheta IV. Stable carbon and nitrogen isotope analysis of bone collagen were performed along with stable carbon isotope analysis of single amino acid. We also investigated molecular and isotopic compositions of organic residue preserved in pottery.

Combined results indicate that the subsistence strategy was influenced by local resources. We also combined

our results with data available for the Atlantic coast of southern South America. Comprehensively, results suggest a long-term and large-scale protein-rich diet, based on marine and C3 terrestrial resources.

Our interdisciplinary results emphasize how the archaeological record offers a unique and exceptional opportunity to illuminate the longstanding trajectory of New World maritime adaptations, which still today play a pivotal role to coastal populations in Latin America.

Escobar, Manuel - (Universidad de Chile) [mem1074@gmail.com](mailto:mem1074@gmail.com)

The coast of the Atacama Desert in northern Chile is one of the most extreme environments of the Andean area.

It is nearly 1000 km long and presents a very narrow littoral platform flanked by the Pacific Ocean to the west, and the Cordillera de la Costa (ca. 2000 masl) and the absolute Desert of Atacama to the east. Despite extreme environmental conditions, the high productivity of the Pacific Ocean in this area facilitated the peopling of this territory as early as 12.000 cal BP, as well as a continual occupation by hunting-gathering-fishing communities throughout the Holocene.

During the late Second Millennium BC, the northern part of this arid coast began important transformations as coastal populations increased their contact and interaction with agropastoral societies from the Andean Highlands. By the First Centuries of the Christian Era, in this area the traditional way of life of the coastal hunter-gatherer-fishers had virtually disappeared, giving way to agromaritime economies and dramatic shifts in the settlement system. However, in the southern part of the arid coast, where ecological conditions are most extreme due to lack of permanent sources of fresh water except for small and often salty "springs", the traditional economy was not transformed in spite of growing interaction of local communities with agropastoral societies of inland oases. In this paper we explore the different responses of coastal hunter-gatherer-fishers to interaction with agropastoral societies during the Late Holocene. We will consider social and environmental variables in order to explain the unique case of the "Costa Arreica" -the southern part of the arid coast- where local communities were resilient to transformations in their settlement systems and overall economic organization, but at the same time underwent significant social changes due to interaction with agropastoral societies.

**1. EXCHANGE AND INTERACTION: THE IBERIAN MEDITERRANEAN BETWEEN THE VI AND THE III MILLENNIUM CAL BC.**

*Orozco Köhler, Teresa - (Universitat de València)*

*Teresa.Orozco@uv.es*

*Bernabeu Aubán, Joan - (Universitat de València)*

*jbauban@uv.es*

In Mediterranean Spain the first agropastoral economy begun around mid VI millennium cal BC. From this time, the archaeological record allows us to observe a development of the processes of interaction between groups. These are processes that have chronological and regional variety, the reading of which can be made from different materials, technologies and ideas.

In recent years the work is focusing on evaluating both forms of movement or methodologies that enable their identification but also trying to identify and define the social networks behind these processes.

The distributions show circulation, not only of materials but also of information or ideas, expressing contacts and relationships that can occur between neighboring groups, but also on a larger scale, between groups remote in space, showing some dynamic relationships that are built and which may vary over time.

Ongoing work to approach social phenomena involved in these interactions go through to take the perspective of networks and complex systems, which allows a better understanding of how these systems evolve, grow or become fragmented.

In this paper we present some examples of the central mediterranean region, approaching the movement of elements of different nature - lithic bracelets, symbols as eye idols and other- in a temporal framework that covers from VI to IIIr millenium cal BC.

Twenty years ago, based on the study of artifacts assemblages, structures, settlement patterns and preliminary environmental data and datings, both diffusionist and indigenist models were put into question (Oosterbeek 1994) and a series of hypothetical historic and dialectic models were proposed.

The main proposal was to understand the transition as a long process in which different communities intervened, some paying tribute to coastal spread of novelties and people but others being related to an inland dispersal, linking the Iberian Southeast and South to the West through the Guadalquivir, Guadiana and Tagus basins. Further initial arguments were later discussed by A. Cruz (1996) and L. Oosterbeek (1999). Until 2010, monographic studies on ceramics (Peng Fuying), lithics (Ana Graça, André Freitas), human bones (Sílvia Lopes, Tiago Tomé), animal bones (Nelson Almeida), vegetation dynamics (Cristiana Ferreira), rock art (Sara Garcês, Luís Nobre, Gioconda Abreu, Maria Fernando Carvalho), megaliths (Alexandra Figueiredo), climate (Luana Campos), geomorphology (Pierluigi Rosina, Hugo Gomes) and datings (Guilherme Cardoso) were produced.

Ongoing studies on ecofacts together with the accumulated research suggests that a mosaic of small communities shared the territory of the middle Tagus basin, from the mid-6th to the 4th millennium, within a single socio-economic system of economic intensification (with different strategies being pursued by each group, but all sharing similar social organization and patterns of

interaction). These communities may be clustered into two main groups, as anticipated in the 1990's, but those groups do not necessarily stand for a demic segregation. It is also apparent that a degradation of the environmental resources, possibly a consequence of the cold and dry oscillations of the 7th and 6th millennium, preceded any evidence of deforestation or agricultural activity.

### 3. WHITE-PAINTED POTTERY IN THE NEOLITHIC BALKANS AS A PROXY FOR HOMOGENEITY, DIVERSITY AND EXCHANGE

*Networks* Stojanovski, Darko - (UTAD) [stjdrk@unife.it](mailto:stjdrk@unife.it)

Pottery decorated with white-painted motifs is often associated with the second wave of migration of pottery-producing groups of farmers, moving generally from Anatolia towards Northwest. This event is presented as a massive and rapid migration process, that occurred at the end of the 7th millennium calBC (Özdoğan, 2011). In fact, the wide geographical distribution of this type of decoration in the Balkan Peninsula at approximately the same time is considered as an argument in favor of the migration theory.

Another viewpoint considers the role of the indigenous population more significant than the one of the Anatolian immigrants. In this view, the migrating groups were smaller than assumed and they simply transferred the know-how of the technological aspects of pottery production and agriculture. This practical knowledge was then adapted by the locals in the local context, and quickly spread through the already existing exchange networks of the pre-Neolithic Balkans (Thissen, 2005, 2009). The local varieties of the white-painted decoration, from which different Early Neolithic cultures were coined, certainly are in favor of this view. Their exact dating and synchronization is another question, to which ongoing and future researches will give the final answer.

Early Neolithic cultures with white-painted pottery are present throughout the entire peninsula. The incredibly high frequency of state borders has not helped the archaeological science in the past, in terms of scientific method, approach, terminology and dissemination "across the borders". One of the goals of this communication is to synthesize the information gathered so far from the different regions, relying mainly on published materials, but including also some information from the latest research campaigns in Macedonia. The assemblages are presented through the following aspects: their geo-

graphical distribution and cultural affiliation; the stylistic variation of the decoration patterns, with relation to the typological and technological attributes; their relative and absolute chronological position; the relation of the assemblages with similar ones outside of the Balkan Peninsula, namely SW Asia.

The results from this presentation should give a high resolution view of the Balkan communities in the Early Neolithic, their internal development and the nature of the relations among them.

The general goal of this communication is to give some final conclusions, which would concern the discussions over the emergence of pottery and agriculture in the Balkan Peninsula and the mechanisms behind this process.

---

ORAL

### 4. THE VOLCANIC CREATION OF LIPARI OBSIDIAN AND NEOLITHIC EXCHANGE NETWORKS IN THE WESTERN MEDITERRANEAN: IS THIS A COINCIDENCE?

*Tykot, Robert - (University of South Florida) [rtykot@usf.edu](mailto:rtykot@usf.edu)*

In the western Mediterranean, the long-distance movement of obsidian artifacts appears to coincide with early agriculture in the 6th millennium BC. The Aeolian island of Lipari, just north of Sicily, was a major geological source of high quality obsidian that was volcanically formed in the Late Mesolithic, while the obsidian sources on Melos, Palmarola, Pantelleria, and Sardinia were formed much earlier in time. Yet it appears that obsidian from all four Italian islands was not used during the Mesolithic, despite there being sites of that period on Corsica, Sardinia, Sicily, and elsewhere. Starting in the Early Neolithic, obsidian from Lipari was used to create stone tools found at archaeological sites as far away as southern France, northern Italy, Croatia, and Tunisia. But how and why does this seem to be coincidental with the introduction of the "neolithic package" of domesticated plants and animals and the use of pottery?

Since the introduction 50 years ago of chemical analysis for distinguishing obsidian sources and reconstructing trade and contact, I have conducted detailed geological research on the four Italian island obsidian sources, and analyzed more than 5000 obsidian artifacts from many prehistoric sites in the western Mediterranean. The ability to analyze such a large number has increased significantly in recent years with the use of a portable XRF, a

non-destructive method which allows analyses of large assemblages within museums and storage areas, providing statistically significant data sets for interpretation. I focus here on new analyses done with this instrument in 2008-2014 on obsidian from many neolithic archaeological sites in Sicily, southern Italy, Malta, and Croatia.

The data now available show that starting in the Early Neolithic multiple obsidian subsources were used on Lipari and the other islands. For Lipari, most obsidian has been assigned specifically to Gabelotto Gorge, but artifacts made from the Canneto Dentro subsurface have been found at multiple archaeological sites too. In southern/western Sicily, and on Malta, Pantelleria obsidian was also used, while in southern Italy some obsidian from Palmarola and even Sardinia have been found. These data are used to assess the regularity of long-distance mobility and the maritime transport involved; the selected use of certain geological subsources on Lipari and the other islands, based on quantity, quality, and accessibility; and regional and intra-site variation in source utilization.

The extensive obsidian information now available provides important perspectives on the socioeconomic nature of Neolithic societies, the initial use of obsidian in the western Mediterranean, and changes in source and subsurface usage over time. Obsidian use appears to be affected by such factors as the availability of other stone tool material, changes in territorial access to the sources, the development of local production centers for export, and the transport of other materials. Yet further research is needed in certain areas and especially for specific time periods. Integration of obsidian sourcing data with tool typology, usewear, other lithic materials, ceramics, and floral and faunal remains can produce a better understanding of the production and exchange networks for societies in Neolithic Europe.

ORAL

## 5. NEOLITHIC FLINT INDUSTRY FROM BULGARIA: RAW MATERIAL AND TECHNO-TYOLOGICAL PERSPECTIVE

*Gurova, Maria - (National Institute with Museum, Bulgarian Academy of Sciences) gurovam@yahoo.fr*

The paper focuses on the importance of raw material in the interpretation of flint assemblages. The general perspective and consideration of every prehistoric chipped stone industry should include an assessment of

the raw materials used, their availability, variability and the supply potential of the palaeoenvironment. Bulgarian prehistory is characterized by a remarkable abundance and diversity of flint raw materials. The main sources are located in the Lower and Upper Cretaceous limestones and cherts of the Moesian platform in northern Bulgaria. Some of them acquire a special prominence among the diagnostic characteristics of the flint assemblages. Typical is the case of 'Balkan Flint', which assumes considerable significance in the Neolithisation of the Balkans (and subsequently) in the context of the supra-regional Karanovo I-Star?evo-Cri?Körös cultural complex.

The paper aims to improve present day knowledge of the provenance and distribution of Balkan Flint, to highlight the decline of what for the Early Neolithic is an emblematic raw material during the subsequent stages of the Neolithic, and to examine the relation between raw material preferences and the typological repertoire of the flint industry through time.

The methods used to fulfill the research goals consist of techno-typological observation and analysis of a dozen flint assemblages from important Neolithic sites in Bulgaria studied by the author. The analytical approach to raw material investigations draws on interdisciplinary research done with geologists and petrographers using thin-section and LA-ICP-MS analyses.

A general shift in the flint industry from the Early to the Late Neolithic can be observed. The process includes a decline from the remarkable (Karanovo I, II) flint industry based on Balkan Flint and the diagnostic formal toolkit, consisting of approximately large blades with particular high and marginal to steep retouch, to a noticeable microlithization revealed by geometric microliths made of various raw materials (Karanovo III-IV and IV). The social dimensions and impacts of this phenomenon are still questionable and call for further research beyond the empirical patterns of the material culture.

ORAL

## 6. GALICIA AS A REGION OF EXCHANGE IN LATE PREHISTORY: POTTERY AS AN EXAMPLE

*Prieto-Martínez, M. Pilar - (University of Santiago de Compostela) mpilarprietom@hotmail.com*

*Lantes-Suárez, Óscar - (University of Santiago de Compostela) oscar.lantes@usc.es*

The north-west of the Iberian Peninsula has traditionally been considered as a key region for the connection of remote parts of the European continent. However, very little research has been carried out in detail on the available archaeological record, aimed at verifying this apparently obvious hypothesis. This idea was mainly supported by studying metals, especially from the later stages of the Bronze Age, in order to justify this importance.

We believe that if a detailed study is carried out of other elements of material culture, it could demonstrate the importance of the geographical location in a more specific manner. This is the case of this study, in which we present specific cases of pottery in which it is possible to document foreign influences in different scales of distance, thereby demonstrating the frequent mobility of people in the prehistory of this region.

Our aim is to attempt to verify this hypothesis based on a study of pottery using traditional archaeological research methods (the typology and operational sequence), and archaeometric methods (based on the physical and chemical analysis of clays).

Through the typological study, based on the manufacturing methods (the type of temper used) and the decorative techniques (such as the use of shells, the presence of stab-and-drag or "boquique" decoration, sgraffito or stamping), it is possible to document the influence of foreign traditions on prehistoric Galician pottery, as well as its possible points of origin. These influences can then be explored in greater detail through archaeometry. Studying the mineralogy of the pottery (using X-ray diffraction) in contrast with the mineralogical offer of the study areas has provided us with information on the most likely distances involved in providing the raw materials. Also, the geochemical study of the pottery and the geological samples in the surrounding area, using a multivariate statistical analysis, have allowed us to complement the calculation of these distances. Isotopic analyses were carried out of the Pb and Sr in these same samples, through which we hope to obtain an even more precise indication of the most likely sources.

Therefore, based on the typological studies and analytical results for the pottery, we will cover a period of some four thousand years, from the Early Neolithic through to the First Iron Age, although the best-documented stage is associated with Bell Beaker contexts.

The Postcardial Neolithic was known until recently as the Early Postcardial Neolithic Molinot type. The recent excavation of 4 episodes dated to the Postcardial Neolithic in Can Sadurní Cave has demonstrated that only the first of these episodes could be classified as Early Neolithic.

These same recent works in Can Sadurní demonstrated that during the Postcardial period (from the end of the first quarter to the last quarter of the 5th millennium BC), the community that dwelled in Can Sadurní cave acquired enough curve of experience and knowledge to start the exploitation of aluminium phosphates present in the Paleozoic basement of the Garraf Massif: variscite primarily, but also turquoise and chlorite minerals, of green colour and known as calaite. At the same time, the technology for the transformation of the raw material and the manufacture of ornaments was also developed. This took place in the 400 years before this community probably decided and specialized in the exploitation of these minerals in mines.

These same recent works in Can Sadurní demonstrated that during the Postcardial period (from the end of the first quarter to the last quarter of the 5th millennium BC), the community that dwelled in Can Sadurní cave acquired enough curve of experience and knowledge to start the exploitation of aluminium phosphates present in the Paleozoic basement of the Garraf Massif: variscite primarily, but also turquoise and chlorite minerals, of green colour and known as calaite. At the same time, the technology for the transformation of the raw material and the manufacture of ornaments was also developed. This took place in the 400 years before this community probably decided and specialized in the exploitation of these minerals in mines.

All this about 400 years before the community, and this is the hypothesis that we are currently working, possibly conditioned by the need to control the operation,

probably decided to move to the area of extraction and established themselves in Can Tintorer (Gavà, Barcelona), to specialize exclusively in the intensive exploitation of these mineralizations. Cipag is implementing a comprehensive program of genetic research one of the aims of which is to monitor the genetic Middle Neolithic I postcardial Can Sadurní population and its comparison with the population postcardial Can Tintorer i also Middle Neolithic II population.

In this paper we will explain how the community of Can Sadurní provided calaite to other Prehistoric settlements of the Northeast of the Iberian Peninsula. This can be confirmed by the materials that prove connections with these areas where beads have been recovered in chronologies that predate the foundation of Can Tintorer site.

## 8. RAW MATERIALS AND KNOWLEDGES CIRCULATION IN MIDDLE NEOLITHIC COMMUNITIES OF WESTERN EMILIA (ITALY)

*Garbasi, Francesco - (Università degli studi di ferrara)*

*francesco.garbasi@student.unife.it*

*Mazzieri, Paola - (independent researcher)*

*paolamazzeri@gmail.com*

*Dal Santo, Nicola - (independent researcher) santo-@libero.it*

The following paper offers an overview regarding the circulation of raw materials, finished products and technologies in Western Emilia during the middle Neolithic, with special reference to the marketplace of Gaione and to Ponte Ghiara, Pontetaro, Benefizio and via Guidorossi settlements, in order to point out changes within intra and intercultural exchange networks in SMP culture (5000-4300 b.C.). Raw materials are also analyzed in the perspective of a specific production chain with the aim of identifying differences between ordinary materials and materials with peculiar function or meanings.

A macroscopic analysis of lithic finds allowed the individuation of raw materials from several origins, which show contacts both with the Peninsula and the Alpine world. A diachronic observation of the Middle Neolithic lithic industries, from the beginning until the disappearance of SMP culture, allowed also to observe the development of some trends that characterize the period, identifying two distinct phases in which the external cultural contributions undergo a gradual increase.

The study of methods and chipping technology allowed

the identification of specific techniques probably meaning the importation of finished objects or the result of specialized crafts acquisitions.

The analysis of SMP lithic assemblages has allowed to understand the development of an increasing ideological and economic complexity that brought, during the final phase, the growth of networks with southern Italy and transalpine cultures.

Cultural exchanges are evident in the spread of exotic raw materials, in growing dimensions of the artifacts, in importation of finished products and in the introduction of peculiar technological innovations.

The analysis permitted to identify the different value attributed to every single raw material, from the identitarian meaning of flints from Biancone outcrops and of alpine green stones, to the ostentation of objects that denounce extra-cultural contacts, sometimes subtended over a wide-range (obsidian, rock crystal, Gargano flint and silex blond).

Exotic raw materials (french silex- blond, flint from Gargano's geological units, obsidian) are, sometimes, used as grave goods to increase the deceased consideration, replacing the employment of the Biancone's flint. The introduction of exotic raw materials coincides with the importation of specific chipping techniques, unrelated to ergology assets of Square Mouthed Pottery culture. During SMP culture there's also a growing tension to a marked macrolithism, perhaps resulting from deep relationships with Serra d'Alto culture (Peninsular Italy) and, nevertheless, to frame in a process which characterizes most of the 5th millennium european neolithic cultures.

Finally, data concerning to several craft specialization individuated in western Emilia sites are here presented, with particular attention to the manufacture of steatite, a local available rock from which personal ornaments were produced, which seems to be characterized by specific cultural and identitarian values.

## 9. EXOTICA, SKEUOMORPHS, AND THE PROBLEM OF MATERIALITY IN THE SOUTH EAST EUROPE CHALCOLITHIC

*Dragos, Gheorghiu - (National University of Arts Bucharest)*  
*gheorghiu\_dragos@yahoo.com*

The establishment in South Eastern Europe of trade routes during the Neolithic and Chalcolithic allowed the

circulation of a series of exotic materials from the south to the north of that region, which acquired a special value (i.e. social status) due to their rarity. Exotica was characterised by the quality of its material that was uncommon compared to the materiality of local objects.

As a consequence of their scarcity the exotic objects were copied in local materials, more frequently found, creating skeuomorphs. This phenomenon could have had two reasons: a need for a "mass production" of the rare items, or a replacement of the exotica when the trade routes failed to function.

One stage to approach the axiology of the prehistoric materiality is to identify the originals and their skeuomorphs and to find the qualities of the materials that were copied, as well as the differences in the aspect of the skeuomorphs, and their relationship with local materials.

Another stage could be the identification of the trade routes of the exotica, based on their presence in settlements, and on their decrease in dimensions.

The findings indicate that the dimensions of the exotica objects diminish as the distance from their origin increases, which implies that it was not the object, but its materiality that was important. It seems that the symbolism of this materiality had a strong social impact, being associated with "prestige", as the funerary finds show. One of the results discussed would be the identification of a standardised package of local and exotica materials in the Gumelnita-Karanovo Kodjadermen Chalcolithic tradition.

The Chalcolithic was characterized by the emergence of hierarchized societies as one can see from the changes occurring in material culture. In this process materiality (i.e. exotica and its simulacra under the form of skeuomorphs) played a significant axiological role.

### 10. TYPES AND GESTURES. THE JEWELLERY OF THE COPPER AGE IN THE ALPS IN A TECHNO-TYOLOGICAL STUDY

*Viola, Stefano - (Université de Genève)  
stefanoviola7@virgilio.it*

The contribute aims to compare jewellery objects coming from some northern Italy archaeological sites, datable to different periods of the Copper age. Through a techno-typological and functional study that takes into account several morphometric, morphological and spe-

cific trace parameters (indicators of workmanship activity and/or wear activity) the methods, techniques and tools are reconstructed and compared.

On one hand, with the typological analysis, jewellery has been looked at as a cultural marker, allowing to gather, from raw material, forms, and measures, information on different aspects of past life, such as style, territories, and traditions. On the other hand, with the technological analysis, interpretative hypotheses are proposed, based on the comparison between manufacture traces and experimental data, thus reconstructing, in part or completely, manufacture procedures and fabrication techniques.

Moreover, with a functional analysis allowed to distinguish wear traces from technological traces, and to recognize if the objects are used or not.

### 11. "SETTLEMENTS-HEAD" AND "SETTLEMENTS-TAIL" IN THE OBSIDIAN EXCHANGE NETWORK IN THE NEOLITHIC WESTERN MEDITERRANEAN

*Quero, Tania - (University of Trieste) taniaquero82@gmail.com*

The study of the obsidian circulation in the Western Mediterranean sea, during the Neolithic period, is very interesting, because of the important social and economic role that this volcanic glass played, testifying a long-distance trading.

I would consider this subject, reanalysing the Neolithic sites in Italy, in terms of the different participation to the exchange networks, according to their distance from the sources and the competition with other raw materials.

At S. Martino Spadafora, a site on the Northern coast of Sicily (South Italy) that was excavated in 2008, two occupation phases are attested, during the Early and Late Neolithic periods. The obsidian (Lipari source) covers the 98% of the whole lithic assemblage. There are almost all phases of the chaîne opératoire.

At the Granarolo Middle Neolithic site, in the central Po valley (near Bologna, North Italy), that was excavated in 2012, the lithic assemblage is obtained from local flint and the obsidian (unknown source for now) accounts for the 0,08% of the whole industry (only 10 small blades).

The study of obsidian industries from S. Martino Spadafora site allowed to draw a diachronic change in the obsidian exploitation, from the Ancient to the Late Neolithic, in a place close to the main source of Lipari island.

Instead, grace to the little investigation at the Granarolo site, it was possible to confirm a frequentation of the central Po valley, in the district of Bologna, during the Middle Neolithic period. In this moment, the SMP communities have many contacts with the Central and South Italy so that they could easily obtain some exotic materials, including the obsidian.

The obsidian exchange is still one of the most important example of the long-distance trade, during the Neolithic period, in Europe. Evidently, a raw material gained prestige and symbolic value, when the distance from the source increased. The case of Granarolo is significant because exotic raw materials (as obsidian and 'alpine' flint) arrived in a place where local flint was preferred.

Otherwise, S. Martino Spadafora site possibly was part of the Lipari obsidian networks of exchange, during the Neolithic period, and had an active role in the distribution, because of its strategic location on the coast, as a bridge to the Calabria and the Sicilian hinterlands.

POSTER

**12. THE IMPLICATIONS OF A EXTRA-REGIONAL TECHNICAL CHANGE IN THE AUTOCHTHONOUS GROUPS : THE EXAMPLE OF THE DIFFUSION OF COPPER METALLURGY FROM ITALY TO SOUTHERN FRANCE AT THE END OF THE NEOLITHIC PERIOD**

*Cauliez, Jessie - (CNRS) jessie.cauliez@gmail.com*

Au milieu du IV<sup>ème</sup> millénaire BC, la métallurgie du cuivre est en plein essor dans toute l'Europe où transitent dès lors les pratiques et les objets métallurgiques. Pour le sud de la France, archéologues et archéomètres s'accordent à dire qu'il faut rechercher l'origine de cette métallurgie en Italie, notamment en direction du Spilamberto de la plaine padane, du Remedello du nord de la Lombardie ou encore du Rinaldone de Toscane. Plus particulièrement, en Languedoc oriental, les données montrent que la métallurgie du cuivre aurait démarré modestement autour de 3100 BC, dans l'environnement culturel local du Ferrières, puis se serait déployée au moment du Fontbouisse aux environs de 2900-2800 BC. Pour autant, dans cette étape de plein développement technique, la Provence semble être restée en retrait (absence de site de transformation du minerai et rareté des

objets en cuivre), alors même qu'existeront au milieu du III<sup>ème</sup> millénaire BC des productions céramiques à fortes affinités Remedello et Rinaldone essaimées en Vaucluse, Drôme et Alpes-Maritimes, ainsi que des gravures d'armes comparables à celles données pour ces groupes en Hautes-Alpes.

Face à ce constat, trois questions se dégagent :

1. les groupes culturels de Provence ont-ils joué un rôle dans les filières d'échanges entre Italie et Languedoc ? Par l'analyse d'assemblages céramiques de différents faciès culturels provençaux de la séquence Néolithique final, est-il possible d'observer des influences italiennes au sein des identités culturelles régionales provençales qui traduiraient des voies potentielles de transit des produits et procédés métallurgiques, notamment via le nord des Alpes, ou a contrario des espaces frontières.

2. pour quelles raisons les groupes provençaux n'ont-ils pas adopté la métallurgie du cuivre, en dépit d'apports italiens connus (céramiques, mais aussi jadéites) et de l'existence avérée de gîtes cuprifères à l'est du Rhône ? Il s'agit ici de conduire une réflexion sur la mise en concurrence entre les grands centres producteurs de produits hautement valorisés au Néolithique final : la présence du centre de production des pièces de Forcalquier empêcherait-elle la diffusion des produits métalliques de la même manière qu'elle ne rend pas possible l'extension du réseau de diffusion des poignards pressigniens au cœur de la Provence ?

3. est-ce que la métallurgie entraîne des phénomènes de recomposition culturelle en Languedoc et en Provence au moment où elle se développe, suivant la réflexion de Roberts sur l'impact des changements techniques dans les structures de société ?

POSTER

**13. PALEOECONOMIC RECONSTRUCTION OF A NEOLITHIC COMMUNITY IN SARDINIA DURING THE FOURTH-THIRD MILLENNIA BC**

*Ucchesu, Mariano - (Università di Cagliari)  
marianoucchesu@gmail.com*

This study is part of an interdisciplinary research (Cultura visuale preistorica: le domus de janas/ Prehistoric Visual Culture: the Domus de Janas) started in 2011 under the scientific supervision of Giuseppa Tanda and funded by the Regione Autonoma della Sardegna. The main goal is to reconstruct different aspects of Neolithic societies with particular emphases on the understanding of the

emergence and development of agriculture in Sardinia. Archaeobotanical research in Sardinia is still at an early stage. Despite intensive archaeological work carried out in the island, data is still scarce and most published reports focus on random findings of plant remains which document the cultivation of free threshing wheats, naked barley, fava bean, lentil and pea since at least the Middle and Late Neolithic periods (5th-3th millennium BC cal.). Over the past years, there has been a systematic recovery and study of plant remains from numerous archaeological sites. Five sites are currently under study covering a wide chronological span from the Early Neolithic to the Chalcolithic period.

The sediment has been systematically floated using a flotation machine. Meshes were of 1mm inside the tank and of 0.25mm outside. Plant remains were sorted under a stereomicroscope and subsequently identified and counted. A total of 17 samples has been analyzed for this study.

The few samples studied from the late Neolithic levels of the Domus de Janas Molia have yielded two categories of cereals. The taxa identified comprise *Hordeum vulgare* var. *nudum* and *Triticum aestivum/durum* which are common elements in both other Sardinian sites such as Grotta del Guano and Canelles and also in different Neolithic sites of northern and southern Italy (Rottoli and Castiglioni 2009; Castaldi 1987; Trump 1983; Ucchesu in press). Cereals appear as an important resource which was probably supplemented by other plant categories from which evidence is still rather scarce. The limits of the available archaeobotanical data make difficult to explore in detail the type of subsistence practiced by the communities living during the 4th and 3rd millennium BC in Sardinia. It is clear that much more research into subsistence patterns is still needed in Sardinia to better understand the subsistence system of prehistoric communities. In fact, new analyses of plant macro-remains have been carried out on samples from square « ag » located at the wall E of the anti-chamber below some ceramic from Ozieri. The latter consisted of plates decorated with dotted lines. It is likely that these remains are leftovers from the offerings contained in plates deposited in the anti-chamber. It is also likely that the offerings were contained in vases from the grave goods. There are no human bones as they have not survived the acidity of the terrain.

**1. A GLIMPSE INTO SPATIAL SEX DISTRIBUTION AT THE MIDDLE NEOLITHIC COLLECTIVE NECROPOLIS OF THE BOM SANTO CAVE (PORTUGAL)**

*Gonçalves, David (Research Centre for Anthropology and Health) davidmiguelfgoncalves@gmail.com*  
*Granja, Raquel (University of Algarve) ragranja@ualg.pt*

*Alves Cardoso, Francisca (Centro em Rede de Investigação em Antropologia) francicard@fcsh.unl.pt*  
*de Carvalho, António Faustino (University of Algarve) afcarva@ualg.pt*

The assessment of the demographic profile of archaeological samples is critical to analyze and interpret funerary practices. In collective necropolises, composed of commingled secondary depositions, in which skeletons are rarely complete and many bones may present a poor state of preservation, the estimation of age at death and sex of the individuals is often impossible. Consequently, an accurate evaluation of funerary practices is often compromised. Therefore, aiming to resolve this problem and to assess spatial sex distribution, a sample-specific sex estimation method based on tooth measurement was used in the Bom Santo human remains.

Bom Santo is a burial cave located c. 30 km north of Lisbon. Systematic speleological surveys carried out in the 1990's allowed the identification of 11 different sectors within the cave. Presently, the estimated minimum number is of c. 121 skeletons. However, only one sector was partially excavated – Rooms A and B – so these are therefore preliminary results. All the data used here appertains to those rooms. The radiocarbon dates (3800-3400 cal BC), linked to a very homogeneous material culture points to a Middle Neolithic chronology, a period characterized by the “megalithic phenomenon” in which the Bom Santo population surely participated. Sex estimation was undertaken using the mean value of the buccolingual diameter of the lower canine, following the recommendations of Albanese et al. (2005) and Cardoso (2008). This method was used to sex discriminate 51 individuals, in a total of 73 canines. The sex estimations were then used to infer the sex distribution in those two rooms.

Although the sex ratio of the Bom Santo individuals was balanced (ranging from 1:1 to 1:1.7), spatial sex distribution suggests that the deposition of the remains in the cave may have been non-random. Estimated males were less represented in Room A ( $n = 4/N = 35$ ), when compared to Room B ( $n = 22/N = 36$ ), despite the fact that

the minimum number of individuals was similar in both rooms. As for estimated females, when compared to males their frequency was higher in Room A ( $n = 12/N = 35$ ), but sex inequalities were less pronounced in Room B ( $n = 13/N = 36$ ).

The use of a sample-specific odontometric method for sex estimation in contexts involving commingled remains may be a good alternative to more conventional methods in which human remains are poorly preserved and skeletons are incomplete. In the case of the Bom Santo Cave, this approach allowed us to detect a slight difference in sex distribution per Room. The spatial allocation of the individuals may have varied according to sex or to other unknown reason which resulted in different distributions of males and females in Rooms A and B. Similar research, in other Middle Neolithic sites, is necessary to infer if this was restricted to Bom Santo or if it was a common funerary practice amongst Middle Neolithic communities, and therefore culturally significant among the megalithic populations of central and southern Portugal.

**2. CULTURAL EVOLUTION AND BURIAL DISCONTINUITIES IN THE COLLECTIVE GRAVES: BURY (NORTHERN FRANCE, 4TH-3RD MIL. CAL. BC)**

*Salanova, Laure (CNRS) laure.salanova@mae.u-paris10.fr*

The Paris Basin provides more than 400 collective graves from various architectures, but all used between the second half of the 4th and the end of the 3rd millennia cal. BC. Few of them were precisely excavated until the innovative method of spatial analysis developed by A. Leroi-Gourhan in the 1960's. Excavated between 2001 and 2007 under the supervision of L. Salanova, the Bury grave (Picardie) is archetypal of the large gallery graves, which were used during the whole sequence of the collective graves in this region (3500 and 2100 cal. BC). The well-preserved burial layer, which provided 300 individuals, was the opportunity to develop a chronological approach of the burial practices in this type of monument. The excavation was orientated towards the understanding of both architecture evolution and burials succession. An important team was mobilised to detect, from the field, each individuals. The bones study has allowed reconstructing most of the skeletons and the stratigraphic order of the deposits. A programme of radiocarbon dating, which was completed since the excavation in the framework of a European project led by A. Whittle and A. Bayliss, has allowed the application of Bayesian

statistics. The both approaches made it possible the most precise chronology of the gallery graves from this region. The chronological frame has guided a biological study (stature, discontinuous morphological variations, activities markers), for understanding the social meaning of the collective deposits (family, village scale or broader social group).

This research has provided several major results. The first one is a discontinuous use of the grave, confirming the cultural gap observed at the end of the 4th millennium in the region and showing the shortness of its first use. The second one refers to the closure process of the monument. Formerly considered as a unique event at the dawn of the 2nd millennium cal. BC, the data from Bury have demonstrated several stages in this process and spatial differences in the grave. Finally, the biological study allow to interpreting the discontinuities observed in cultural and social terms.

The same discontinuities and the shortness of the first use have already been observed in several monuments from Western Europe. A comparative analysis questions finally the reality of the collective graves, from their origins until their final use that seem to refer to different phenomena.

In this paper we present detailed information on the archaeological, bioanthropological, and isotopic data obtained from the 1989 excavation remains recovered from the cave of El Rebollosillo (Torrelaguna, Madrid). The site

is a small natural cave of approximately 23 square meters located in the Cretaceous carbonatic rocks of the karstic massifs south of the Spanish Central Range. A minimum number of 21 human individuals were buried here, consisting of 12 adults, 2 juvenile, 5 infants and two perinates. The remains of all individuals were disarticulated and mostly dispersed, although some remains suggest that long bones and crania may have been treated with special care. Only an minority of bone fragments were exposed to fire, while just one -a perinatal tibiae fragment- exhibits cutmarks, which may have served some sort of decorative purpose. Bayesian modeling of 7 <sup>14</sup>C determinations obtained from 7 different individuals (6 adults and 1 juvenile) suggest that the secondary disposal of disarticulated bodies spanned for no longer than 190 years (1  $\sigma$ ), although the majority (5 out of 7) most likely belonged to a single generation dating from 2550 to 2510 cal BC. Preliminary isotopic data suggests that these individuals were from local communities. These findings will be discussed in reference to their regional historical context.

*kishajdu@gmail.com*

Between 2009 and 2011 three Late Bronze/Early Iron Age settlement pits containing great amounts of human remains in different states of decomposition were unearthed at Pusztataskony - Ledence 1 (Eastern Hungary). Beside huge quantities of single bones and clear crania complete skeletons and body parts in approximate anatomical order were found. Associated finds were sporadic and mostly fragmented.

The presentation surveys stratigraphical observations

with a description of the deposits' structure, with a discussion of methods, problems and possibilities of micro- and macro-scale interpretation of the phenomena, completed with similar finds from the surrounding settlement, the results of the anthropological surveys, and the analysis of the soil micromorphological samples. The current results, especially placed in the context of contemporaneous mass deposits of human remains from South-East Europe, raise the possibility of an emerging multi-stage funerary practice in the Carpathian Basin. The application of diverse methods of 'classical' archaeology and other sciences allowed us to reconstruct the particulars of this unusual burial process.

Collective burials found in Late Prehistoric sites in the Iberian Peninsula have increased significantly in numbers in the last decades. Recently developed approaches have applied new methodologies and techniques to recover as much data as possible on the anthropological information these burials provide. This communication proposes a new approach to regional osteological samples: the assessment of the functional use of teeth by individuals exhumed from collective burials and the inferences one might gather from their activities. The use of the mouth for working activities such as a plier, cutting tool, and for breaking or grasping objects, as well as for processing materials such as leather or fibers, is widely acknowledged in the ethnographic record. Studies of individual burials show these activities alter the morphology of teeth and bones of the oral cavity and can be traced in archaeological human remains. In collective burials, inferences from this material are more difficult to make due to the frequent disarticulation of the skeletonized elements. On the other hand, this kind of context provides solid MNIs, sometimes over hundreds, which can be submitted to statistical treatment enabling us to gather data on the probable functional use of the mouth.

Materials and methods employed include a laboratory protocol of data collection that can be submitted to statistical tests to (I) differentiate dietary masticatory function from the functional use of teeth as tools (tested with Kendall's tau to understand the correlations between types of wear and Pearson's chi-squared test to evaluate the significance of different frequencies); (II) identify the teeth and surfaces more commonly used (tested using analysis of variance); (III) differentiate the levels of morphological alteration, the kinds of damage left on dental and bone tissues, and their probable relation to specific activities through distribution statistics.

A comparison of these data to archaeological cases published for individual inhumations allows us to propose that although information at the individual level cannot be specific, it can provide data on the population level on the most common functional uses of teeth for members of a given sample.

*Oosterbeek, Luiz (Instituto Politécnico de Tomar, Instituto Terra e Memória (Mação) e Centro de Geociências da Universidade de Coimbra) loost@ipt.pt*

Geographic Information Systems (GIS) applications in Archaeology represent a dynamic field. They may be used for managing excavation data, Cultural Resource Management and landscape assessment. One can also regard GIS as “a place to think”, environments in which to test hypothesis of a spatial nature.

Late Prehistory collective burials are a context where GIS may prove an invaluable analytical tool. Such contexts often present taphonomical challenges to interpretation, due to the disarticulation and fragmentation processes human skeletal remains usually undergo. In Portugal, many of these burials were excavated throughout the XIXth and XXth centuries. Many older excavations displayed little care for a detailed recording of human remains, with many bones being discarded, their study deemed useless. Nevertheless, recent assessments of Portuguese prehistoric collective burial samples have been able to shed some light on funerary aspects of these societies.

Two burial-caves were considered for GIS assessment, Gruta do Cadaval (CDV) and Gruta dos Ossos (GRO), both belonging to the Canteirões Late Prehistoric burial-caves complex (North Ribatejo – Portugal). Sample choice was determined by several factors: both caves share a similar morphology; they were excavated in the 1980's, with care being taken regarding tridimensional coordination of the remains; the samples have a partially overlapping chronology.

A database combining data resulting from the osteological assessment and the original field records was assembled. The point data files created from this database were used to perform an analysis of spatial dispersion of the remains, attempting to correlate biological parameters determined in the osteological assessment. Kernel

Density Estimation was performed on these data point files, generating heatmaps that represent the spatial dispersion patterns of human remains inside each cave. The analysis was performed with Open Source software (QGIS 2.2).

Results suggest both similarities and discrepancies among CDV and GRO regarding spatial dispersion of human remains. Both caves exhibit a main depositional cluster in the central part of the room closer to the entrance. In both cases there is also a secondary cluster, located in smaller, deeper rooms. Adults and non adults spatial patterns differ – on CDV adult remains are found mostly on the main cluster, non adult remains mostly on the secondary cluster; on GRO, there is a clearer concentration on the main cluster of both adults and non adults, non adults being absent from the secondary cluster.

Regarding specific skeletal regions, on CDV cranial and axial remains concentrate mostly on the main cluster, while appendicular remains are present on both clusters. As for GRO, the spatial patterning is not so clear-cut but, still, there is a differential distribution of the long bones – upper limbs were located mostly on the centre of the main cluster, lower limbs being more peripheral, closer to the cave walls.

GIS can be a powerful tool for the study of collective burials. Furthermore, the use of Open Source software allows for an inexpensive approach. This study demonstrates that, in the vast realm of analytical techniques allowed by GIS, heatmap generation analysis is a viable path in the study of Prehistoric collective burials.

**8. MORA CAVORSO CAVE: A COLLECTIVE UNDERGROUND BURIAL IN NEOLITHIC CENTRAL ITALY**

*Rolfo, Mario Federico (Università degli Studi di Roma Tor Vergata) rolfo@uniroma2.it*

*Achino, Katia Francesca (Universitat Autònoma de Barcelona) katiаfrancesca@libero.it*

*Fusco, Ivana (Università degli Studi di Roma Tor Vergata) ivanafusco@yahoo.it*

*Silvestri, Letizia (Durham University)*

*letizia.silvestri@durham.ac.uk*

**An exceptional underground discovery**

Since the year 2006, the excavations at Mora Cavorso Cave have started to cast new light on the later prehistory of central Italy. Systematic investigations, following a fortuitous speleological discovery, revealed the presence of at least 21 incomplete individuals, dated to the Early Neolithic. This site appears

to be the best preserved and most numerous collective burial of the region. Therefore, archaeological sciences have joined forces to obtain the most complete interpretation of the context.

### Physical and molecular anthropology

The human remains have been examined morphologically to identify gender, age, minimum number of individuals and markers of pathologies and behavioural stress. This osteological approach has been integrated by the analysis of DNA, in order to investigate the aspects of geographical provenience and genetic affinity. The study of the stable isotopes, moreover, allowed to reconstruct the palaeodiet.

### Geology

Geologists have sampled stalactites and karst formations, in order to understand the natural formation processes of the cave, the impact of possible sources of light or air, the growing speed and intensity of the limestone in the burial area and the surroundings.

### Archaeology

Bioarchaeology and geology have added more details to the already data-rich archaeological context. Further ongoing studies involve taphonomy and chrono-spatial distribution of the human remains, along with radiocarbon, ecofact and artefact analyses. One remarkable challenge will be that of correlating the uses of the various chambers of the cave, which seem to have been frequented also for non-funerary reasons. The combination of isotope, zooarchaeological and botanical analyses shows that sheep husbandry was already practiced and the diet was rich in meat and poor in plants. Local provenience of the individuals has been ascertained as well. From the funerary point of view, the inhumated are not selected by age or gender, the grave equipment is poor, whereas the effort put in carrying the dead inside the chambers seems to have been extraordinary.

Although the interpretation of the Neolithic frequentation of Mora Cavorso Cave is still in progress, some aspects of the human occupation of the site can be still highlighted. The demographical studies and analyses of the grave goods, predictably, indicate that social complexity had not yet emerged. From a cultural point of view, the choice of such a symbolically powerful site is notable. Despite the quantitative and qualitative poverty of artefacts, the effort put in carrying the dead can be considered a great energy investment. Rather than just indicate the social relevance of the buried, this might testify to the importance of such a ritual process in strengthening the social relations of the living. The integration and combination of all the aforementioned studies will allow an overarching interpretation, which by taking into account several biasing factors, will show the potential of a multidisciplinary approach and lead to a contextualization of the discovery its wider archaeo-anthropological framework.

## ORAL

### 9. RESTING IN PEACE OR IN PIECES: TOMB I AND DEATH MANAGEMENT IN THE 3RD MILLENNIUM BC AT THE PERDIGÕES ENCLOSURE (REGUENGOS DE MONSARAZ, PORTUGAL)

*Evangelista, Lucy - (CIAS - Departamento Ciências da Vida, Universidade de Coimbra, Portugal)*

*lucyshawevangelista@gmail.com*

*Silva, Ana Maria (CIAS - Departamento Ciências da Vida, Universidade de Coimbra, UNIARQ, CENCIFOR)*

*amgsilva@antrop.uc.pt*

The Perdigões 16 ha ditched enclosure has been continuously investigated since 1997 and widely published. Several funerary structures have been unearthed, showing a variety of mortuary practices (inhumations and cremations found in different architectural solutions like tombs, pits or ditches). Among them is Tomb 1, a tholos type structure discovered in the eastern side of this site. Preliminary data available from the Perdigões Tombs seems to indicate the collective secondary depositions of bones. If this is confirmed by the anthropological study underway, several important questions are raised regarding the process of body manipulation at the time.

This study seeks to, through anthropological analysis of the human remains recovered from the several archaeological phases in Tomb I, contribute to the better understanding of the Late Neolithic/Chalcolithic individuals that used the Perdigões enclosure as a burial site and their death management strategies, in light of a changing mental framework that can be perceived in several spheres of the archaeological evidence.

In this conference the first results of our study will be presented.

Excavation of Tombs I in the Perdigões archaeological complex was undertaken using state-of-the-art methods and care. The great investment in terms of field work that continues in the laboratory may provide valuable clues for a better understanding of the site's complex and varied burial practices. Laboratorial methods include the cleaning and inventory of the great number of skeletal remains recovered, their taphonomic analysis, assessment of their relative representativeness, estimation of NMI, estimation of age at death and determination of sex (when possible) and morphological analysis. The various bones will also be studied to look for indications of pathologies. A funerary analysis of space is essential for a better understanding of the way death was managed during the period in which the Tomb 1 was in use.

The laboratorial work is underway and follows the different archaeological phases defined for this structure. In this way we will try to understand if there are differences in the way the monument was used through time. It seems to have a long and complex history of utilization that continued even after it

began to fall into disrepair. A preliminary analysis of the human remains recovered from Tomb I indicates, in general terms:

- An overall poor bone preservation level and high level of fragmentation.
- The presence of adults (both sexes) and non-adults.
- All skeletal parts seem to be present although with very different levels of preservation.
- Bone and artifact dispersion seem to point to a differentiated utilization of the Tomb along its several phases.

The anthropological study of Tomb I will provide important additional biological information on the people buried at Perdigões. It will also provide results, that compared with the already obtained for the rest of the site and for other similar structures, will help shed light on the cultural and mental framework behind these communities idea of death and choices regarding death management strategies.

## 10. NEW BIOARCHAEOLOGICAL INVESTIGATIONS AT TOMB 3, LA PIJOTILLA (SOLANA DE LOS BARROS, BADAJOZ, SPAIN)

*Díaz-Zorita Bonilla, Marta (Tübingen Universität)  
marta.diaz-zorita-bonilla@uni-tuebingen.de*

This research is based on the bioarchaeological analysis done at Tomb 3 at La Pijotilla applying standard methods in osteology, biochemistry and paleopathological analysis in combination with the funerary context. La Pijotilla represents one of the most extensive Copper Age settlements in the Iberian peninsula including a funerary complex with one of the largest human bone deposits such as Tomb 3. The aim of this work was to reconstruct the mortality, morbidity, dietary and mobility patterns of this skeletal population from the Copper Age (c. 3300-2100 cal BC) and placing into context within the Late European prehistory.

The human bone collection from Tomb 3 at La Pijotilla was given a MNI of 178 individuals based on the analysis of 283,329 human bone and teeth fragments. Results showed an equal distribution of adults by sex and non metric traits suggested close biological relationships between the population and compared to other southwestern Spanish population. The evaluation of the health status identified mainly joint diseases and for dental paleopathology calculus and linear enamel hypoplasia among the most frequent recorded. Analysis of the stable isotope of carbon and nitrogen, when compared to other 3rd millenium BC sites in southern Spain, do not showed any differences between inland and coastal sites. However,

analysis of strontium isotope revealed a significant number of non local humans. This higher degree of mobility was also found in other larger settlements and results showed interaction among these sites.

The analysis of bioarchaeological remains is essential to any archaeological site due to the extensive information they could offer to interpret past populations. In addition, the application of new biochemical techniques brings extra information about subsistence and mobility patterns and will complement our understanding of the past with new biochemical techniques brings extra information about subsistence and mobility patterns and will complement our understanding of the past with new perspectives.

Sáez, Reinaldo (Universidad de Huelva) saez@dgeo.uhu.es*

The use of pigments was a frequent ritual practice in funerary contexts (megalithic tombs, dolmens, caves, hypogea or tholoi) with occupations ascribed to IV and III Millennium BCE. From the data provided by research in the megalithic tomb of Santa Rita (Vila Real de Santa Rita, Portugal), we reflect on contexts, circulation, chronology and use of cinnabar in funerary environments in the Southwest Iberian Peninsula.

## 12. THE COLLECTIVE BURIAL OF SAN JUAN ANTE PORTAM LATINAM (ÁLAVA), IN THE CURRENT DEBATE.

*Etxeberria, Francisco (Universidad País Vasco)  
paco.etxeberria@ehu.es  
Herrasti, Lourdes (Sociedad de Ciencias Aranzadi) antropologia@aranzadi-zientziak.org  
Armendariz, Ángel (Universidad Cantabria) angel.armendariz@unican.es  
Vegas, José Ignacio (Instituto Alavés Arqueología)*

The study of the collective burial of San Juan ante Portam Latinam was published in 2007. Nevertheless, the discussion of the results of the analysis still remains valid.

In this burial, which is dated around 3000 cal BC, there were found more than 330 individuals. The skeletons were arranged in a clogged space, that is why the anatomical connections have persisted, so it could be inferred that the bodies had been buried in a short period of time.

Only 40% of the buried individuals had reached adulthood, so there is a clear predominance of subadult population. The registration of 13 cases of arrowheads of flint embed in bone, with signs of survival in some cases, and a direct cause of death in most, it could show the existence of repeated violent clashes. The atypical nature of the burial site, the presence of such a large group of individuals where all age-groups are represented, as well as the previously mentioned arrows wounds and other traumatic injuries also suggest an episode of catastrophic death, of the violent type. This conflict could be related to a intergroup struggle in the aim of the control of natural resources and the domain of the territory.

space between the alluvial fan which accumulated inside the cave and its northern wall. The individuals are longitudinally aligned, oriented to the entrance of the cave and following the conical shape of the sediment deposits. The forced folded position shown by the lower extremities of the individuals indicates that the corpses must have been deposited in the cave inside a strongly-tied shroud.

These are therefore successive primary burials within a hypogeum (in this case, a natural cavity), conceived as a great pantheon or cemetery. Unlike in most cave deposits, a taphonomic process consisting in the collapse of the ceiling of the cave covered the inhumations and protected their integrity, preserving them in connexion. The individuals were not buried but deposited in a space which had probably been flattened before the final deposition.

It is calculated that this funerary episode lasted for two hundred years. Sedimentation processes continued after it and new corpses were deposited. A new rock fall occurred and human remains were displaced (layer 10b). In this presentation a detailed approach to these events will be presented, as well as a description of the apparel found in relation to the individuals singled.

During the excavations of 2013, a series of burials dated to the Middle Neolithic I or Early Middle Neolithic (5460±40BP and 5540±40BP) were discovered. These constitute a new funerary model of collective burial practices, which is unknown to date in the northeast of the Iberian Peninsula. In previous excavations a very mixed layer of collective burials had appeared, but a small number of skeletal parts were found in connection. Four inhumations have been excavated this last campaign. The bodies were in foetal position, on their right side, in the

### 14. THE ROCK CUT TOMB OF BAÚTAS AND SURROUNDING NECROPOLISES (CARENQUE/BELAS, PORTUGAL)

*Boaventura, Rui (UNIARQ: Archaeology Center of the University of Lisbon; CIAS: Research Center for Anthropology and Health; Municipality of Odivelas; Portanta, Association for Iberian Archaeology) rui.boaventura@campus.ul.pt*  
*Ferreira, Maria Teresa (CENCIFOR Centro de Ciências Forenses; CIAS: Research Center for Anthropology and Health) mtsferreira@yahoo.com*  
*Silva, Ana Maria (Departamento de Ciências da Vida da FCTUC; CIAS: Research Center for Anthropology and Health; CENCIFOR Centro de Ciências Forenses; UNIARQ: Archaeology Center of the University of Lisbon) amgsilva@antrop.uc.pt*

The remains of a rock-cut tomb were detected in the south-east limit of a quarry at Baútas in 1932. The then curator of the National Museum of Archaeology, Manuel Heleno, proceeded with the recovery of the objects and human remains, which were never properly presented. Immediately after, three more rock-cut tombs were discovered just 1 km to the Northeast of Baútas, and three years later another tomb nearby.

Given that a cluster of three dolmens was known since the middle of the 19 century, located about 1,3 km toward WNW,

this region of Belas and Carenque presents an interesting case study for populations of the 4th-3rd millennia BCE. The archaeological and anthropological remains of these rock-cut tombs are being systematically studied, making it possible to present in firsthand the results for the rock cut tomb of Baútas. Despite some recording limitations regarding context, it is possible to ascertain who was deposited in that tomb as well as what socio-economic relationships there might have existed with neighboring groups.

### 15. THE ARTIFICIAL CAVES OF VALENCINA DE LA CONCEPCIÓN DE (SEVILLA)

*López Aldana, Pedro Manuel (Universidad de Sevilla) aldana-astrogodo@gmail.com*

*Pajuelo Pando, Ana (Universidad de Sevilla) anapajuelo@gmail.com*

Collective burials are one of the most common funerary practices during Later Prehistory and show a diversity of structural solutions. Nearly all contemporaneous morphological types are known to exist at the 3rd millennium BC archaeological site Valencina de la Concepción (Sevilla). The site extends over a wide area of some 400 ha and includes a necropolis with tholos tombs featuring different sizes, morphologies, construction methods, demographic attributes, etc. On the other hand, several funerary structures have been identified in recent years on the site's outskirts and even out of the referred tholoi area. In typological terms, these structures fit well into the types known as "artificial caves". They were found in 3 different zones, located at C / Dinamarca, El Algarrobillo and La Huera, the latter in the locality of Castilleja de Guzmán.

From a morphological point of view, there is significant variability concerning not only architectural aspects but grave goods and anthropological elements as well. This is particularly evident in all the C / Dinamarca tombs, ranging from structures where a large number of individuals were buried to structures featuring a very limited number of burials only.

Concerning the treatment of the bodies, the most widespread ritual is the hyperflexion of upper and lower extremities, probably indicating the use of shrouds or bandages. In structures where larger numbers of individuals were buried, human remains were often rearranged in piles to make room for new inhumations. Some individuals seem to share morphological features that might link them to certain family groups; DNA studies were carried out to test this observation.

Grave goods are rather scarce or even absent, as in the case of smaller structures. The distribution of grave goods in relation to the burials doesn't enable linking grave goods to any par-

ticular burial.

This type of funerary structures are definitely a novelty in the Copper Age site Valencina de la Concepción. Their presence and location must be assessed in chronological, social and cultural terms.

ORAL

### 16. BIOARCHAEOLOGICAL APPROACH TO THE LATE NEOLITHIC AND CHALCOLITHIC POPULATION OF CAMEROS MEGALITHIC GROUP (LA RIOJA, SPAIN)

*Fernández-Crespo, Teresa (Universidad del País Vasco) teresa.fernandezzc@ehu.es*

The main aim of this article is to go deeply into the nature of people buried and to broaden the knowledge of the funerary practices performed in the monuments of Cameros (La Rioja, Spain) during the Late Neolithic and Chalcolithic (5 500 - 3 500 BP).

Four anthropological collections are selected for the approach (Peña Guerra II, Collado del Mallo, Fuente Morena and Collado Palomero I), which correspond to the main sites used as graves in that period. The sample comprises 92 individuals. Conventional anthropological methods (NMI, age and sex estimation, morphometry and macroscopic observation) together with a palaeodemographic analysis of the collections and a reassessment of the main archaeological data recovered in the excavation of the sites, are used in the study.

Concerning the anthropological characterization, some aspects must be noted: the identification of various demographic anomalies clearly incompatible with the normal structure of human populations; the morphometrical description of individuals as people with a slender constitution, a balanced proportion of skeletal structure and an average stature; and, finally, the finding of a high incidence of arthrosic, degenerative and, to a lesser extent, oral diseases, in contrast to the scarcity of infectious, neoplastic and traumatic signs.

With regard to the funerary practices, the aforementioned demographic anomalies result on a bias in the age and sex distribution of buried people that could be related to funerary selection. The analysis of bone representation and manipulation shows, despite the frequent alteration and disorganization of burial contexts, the preeminence of primary deposits but, at the same time, a probable introduction of secondary assemblages in certain megalithic graves. The presence of the ochre colorations in some bones is related to the application of different iron oxides, a result of whether depositional or post-depositional practices.

Bioarchaeological analysis of Cameros megalithic human remains reveals a population with the typical morphological

and pathological features of pre-industrial societies. However, the presence of biases in the distribution of deaths could be suggesting the existence of a cultural selection that further research should try to assess. Despite the frequent alteration of the assemblages, the main primary nature of graves can be determined and some specific funerary practices are identified. The paper finally stresses the relevance of current bioarchaeological approaches to obtain irreplaceable data on Prehistoric collective burials.

POSTER

**17. ANTHROPOLOGICAL AND TAPHONOMICAL STUDY OF HUMAN REMAINS FROM THE BURIAL CAVE OF EL ESPINOSO (RIBADEDEVA, ASTURIAS, SPAIN).**

*González Rabanal, Borja (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) borjagrabanal@gmail.com*

*Marín-Arroyo, Ana B. (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) anabelen.marin@unican.es*

*González Morales, Manuel Ramón (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) manuelramon.gonzalez@unican.es*

During the Chalcolithic and Bronze Age in the Cantabrian Region, Spain, human groups buried their dead depositing them in narrow caves coexisting this tradition with the megalithic structures at times. This work is based on the anthropological, archaeological and taphonomical study of the human remains found in 1993 at El Espinoso Cave, located in Ribadedeva (Asturias, Spain). Up to now, it constitutes the only collective burial known from this cultural period in the western Cantabrian Region.

These human bones were deposited on the surface in a small room at the end of the cavity. Bones were found in surface, scattered throughout the room, without any apparent anatomical connection. Remains are very fragmented due to post-depositional processes showing diagenetic modifications such as concretions and water activities. Although during the excavation was not recovered any type of grave goods, the presence of two metal bracelets recovered during a furtive action is known. Also, the presence of faunal remains was documented.

First, an anatomical and taxonomic identification of the human remains was achieved. Later, age of the individuals was determined from the dental eruption and epiphyseal fusion of long bones. Sex and stature was estimated based on the measurements taken from talus, calcaneus and patella bones. This osteometrical study is interesting in sites where long bones are

highly fragmented or absent. Finally, a taphonomic analyses based on the different biostratigraphic and diagenetic modifications that altered the skeletal remains within the deposit was carried out. Thereafter, relevant quantitative and statistical analyses were made.

The human remains represented belong to a minimum of eleven individuals with different ages and both sex. While any peri-mortem fracture was identified, the taphonomical results report a significant post-depositional activity within the cave, both natural and anthropic. Regarding burial treatment is difficult to say something although the presence of carbons remains has been documented in different locations of the burial area. About the animal species represented, cow, red deer, pig, and ovicaprids were identified. Whether if they could have been part of grave goods or not is discussed here. However, faunal bones showed butchering activities.

This study presents novel methodological aspects applied to the only collective burial known from Chalcolithic and Bronze Age in Asturias.

From the first reactions to the most simplistic processualist views, it is clear that what is represented in burial contexts does not linearly reflect traits of the living community. We can have a mediated glimpse of the ecological ties between humans and other species in the very rare cases when faunal and

human remains are found together, but single situations need to be carefully decoded. In the Western Mediterranean Copper Age, such relationships may provide indications on the theorized intensification of animal products exploitation, and its aspects in specific environments and fields of practices.

The bone remains from Santa Caterina di Pittinuri, coming from a 4th-3rd millennium BC undisturbed context on the west coast of Sardinia, provide an ideal case study. Ten humans and 11 animals were sampled for C, N and O isotopes, which reflect to some degree the food consumed over several years before an organism's death. While collagen yield was scarce and uneven, good preservation of both collagen and the mineral signal is suggested by C:N ratios and the physiology-dependent species-specific distribution of apatite O and C. Taphonomy was also investigated through FT-IR spectroscopy, which confirmed different diagenetic pathways for the human and animal remains, possibly also connected to pre-burial treatment. Interpretation of diet was cautiously carried out considering the different species represented, and must be tentative due to the modest numbers involved. The human diet, despite the coastal location, did not include any detectable amount of marine resources. As inferred based on the  $\delta^{15}\text{N}$  interval between humans and ovicaprines, it probably included terrestrial animal proteins, but in a relatively low proportion compared to other prehistoric Mediterranean groups, possibly indicating heavier reliance on agriculture rather than animal meat and secondary products. In line with starchy foods could be the high prevalence of caries observed.

The small spacing between collagen  $\delta^{13}\text{C}$  and apatite  $\delta^{13}\text{C}$ , appearing possibly contradictory, could be the effect of mostly ruminant products, coherently with the scarcity of animal offerings representing daily, 'normal' foods. The diet of pigs overlaps with that of herbivores, supporting their identification as wild boars based on bone morphology; as hunting was likely a key practice in structuring gender identities rather than barely a subsistence activity, this also implies that ritual offerings of defleshed body parts, mostly mandibles, involved special animals and not daily food remains.

The methodological implications – and complications – of assessing human diets based on all animal species represented as if they were a coherent whole are discussed, and at a broader scale the need to complement traditional tools with different analytical techniques is underlined.

The potential wider significance of the data discussed above is that there is no isotopic trace of marine foods, nor a radical difference reflecting increased reliance on milk products, whereas there might be clues of strong reliance on vegetal foodstuffs alongside the symbolic relevance of wild boar hunting.

ORAL

## 19. FUNERARY PRACTICES OF THE CHALCOLITHIC PERIOD: THE COLLECTIVE SECONDARY CREMATIONS AT PERDIGÕES ENCLOSURE

*Valera, António Carlos (NIA Núcleo de Investigação Arqueológica, ERA Arqueologia, S.A.) antoniovalera@era-arqueologia.pt*

*Leandro, Inês (CIAS, University of Coimbra) inesleandro@hotmail.com*

*Pereira, Daniela (CIAS, University of Coimbra, Portugal) niela.pereira@gmail.com*

*Silva, Ana Maria (CIAS, Department of Life Sciences, University of Coimbra, Portugal; UNIAO; CENCIFOR) amgsilva@antrop.uc.pt*

Perdigões is a large set of ditched enclosures located in Reguengos de Monsaraz, South of Portugal, and dates from Late Neolithic/Chalcolithic. In the middle 3rd millennium the central area of Perdigões ditched enclosures was reused for funerary purposes. There, two pits were used for secondary depositions of cremated human remains and associated votive materials also submitted to fire. In pit 16 a conical deposit with these remains showed that they were dumped inside, probably in one single action. In pit 40, still under excavation, thick layers of cremated human remains and archaeological material filled the top of this structure. Then, a semi-circular stone cairn containing a small cist was constructed overlapping part of the pit. This stone structure was later covered by deposits also with cremated human remains and archaeological material in a depositional activity that seems to have been done in open area. Contrary to pit 16, this sequence shows a continuous activity of depositions for some time, starting in the middle of the millennium and developing through the 3rd quarter.

The aim of this work is to document the evidences of collective secondary cremation contexts in the Perdigões Enclosure. The human remains were cleaned and catalogued prior to data collection. For that, the human bone fragments were sorted into skeleton division's categories. Non-adults bones were separated from adult bones.

Information recorded for the human bones included data related to modifications due to thermal changes caused by fire as colour changes, types of fractures, level of distortion, degree of shrinkage and fracture pattern. Paleobiological data, as demographic characteristics – ageing (adult versus non-adults), sexing – and other skeletal data as discrete variants and pathology were recovered.

Pit 16 contained burnt human remains, highly fragmented and predominantly calcined bones. The paleoanthropological study of the sample recovered from pit 16 reveals a minimum number of 9 individuals: 6 adults and 3 non-adults. Evidence

of several pathologies was detected and several alterations due to the exposure of heat were observed. The obtained data confirms that the majority of the bones were submitted to high temperature and, at least some of them, were submitted as fresh bones to the fire. On the other hand, the human remains recovered from Ambiente 1 correspond to a minimum number of 90 individuals: 72 adults and 18 non-adults. The burnt human remains exhumed from cist correspond to a minimum number of 8 individuals: 5 adults and 3 non-adults. The secondary collective cremation burials from Perdigões Enclosure are a unique funerary context in Portuguese Chalcolithic burial practices. These contexts give a new perspective of the importance cremation might have had in the middle 3rd millennium amongst the funerary practices and rituals in South Portugal.

niences within the site including Pit 11, 16, Tomb 1 and Tomb 2 with radiocarbon dates that span the known chronology of the site. The samples produced a high variation in mercury content, ranging from 0.057 to 115.62 ppm; samples from Tomb 2 had the highest levels. The most likely explanation for high mercury levels is from diet with individuals feeding at higher trophic levels being more exposed via biomagnification. However, stable isotope analysis ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ ) of the same 21 bone samples revealed a weak negative relationship with  $\delta^{15}\text{N}$ . Mercury was lowest in individuals with the highest  $\delta^{15}\text{N}$  values indicating no relationship between a high trophic diet and exposure to this contaminant. Instead, these results imply a possible age and/or sex bias in exposure to mercury, possibly through the use of cinnabar as a pigment in funerary rituals, body paintings, pottery or other cultural uses.

Numerous ditched enclosures of late Neolithic and Chalcolithic ages have been documented throughout Europe including the Iberian Peninsula. The large enclosure at Perdigões, south-central Portugal, has been excavated since 1997 and includes at least eight funerary features (pits, ditches and tholoi tombs). This site does not show clear evidence for habitation and most likely was a meeting place for local communities and a stage for social practices. Depositions of human remains (including cremations), animal remains, and a diversity of archaeological materials were deposited in pits, ditches or tombs at the site. Here, 21 samples of human bone were analyzed for total mercury concentration using a Direct Mercury Analyzer (DMA-80). The samples were from a variety of pro-

*Valera, António Carlos (Nia Era Arqueologia, S.A., Portugal) antoniovalera@era-arqueologia.pt*

The recent work of rescue archaeology in Portugal has permitted the detection of an increasing number of pit graves from different time periods, dated from Late Neolithic until Final Bronze Age.

Based on three sites from the Southwest Iberia, the aim of the present work is to show some preliminary results about funerary contexts of Alto de Brinches 3 (Serpa), Ribeira de S. Domingos 1 (Serpa) and Monte do Vale do Ouro 2 (Ferreira do Alentejo), where evidences of burials on this kind of structure were identified.

Fieldwork information was articulated with laboratory results to achieve a better understanding of the funerary practices. These pits were used as multiple burials, ranging the minimum number of individuals between 3 and 5: Pit 691 of Alto de Brinches 3 includes a Minimum Number of Individuals (MNI) of 3; Pit 1 of Ribeira de S. Domingos 1 has a MNI of 5; and, Pits 97 and 102 of Monte do Vale do Ouro 2, have each one a

MNI of 4. In general, all osteological remains were affected by several taphonomic agents leading to a high fragmentation of the skeletons. These were deposited in several positions (supine, lateral and ventral decubitus) and orientations. At pit 97 of Monte do Vale do Ouro, 2 individuals showed evidences of fire action. Individuals of both sexes, adults and non-adults are represented: Alto de Brinches includes 4 adult individuals; pit 97 of Monte do Vale do Ouro, 1 adult and 3 non-adults; pit 102 of Monte do Vale do Ouro, 3 adults and 1 non-adult; at Ribeira de S. Domingos 1, 3 non-adults and 2 adults were represented. Among the more relevant data was the evidence of non-masticatory use of teeth in the sample of Monte do Vale do Ouro.

Valencina de la Concepción (Sevilla, Spain) is one of the most important 3rd millennium BC sites of the Iberian peninsula. The large number of archaeological excavations carried out since the 1860s make it one of the most extensively excavated prehistoric sites of Iberia. A wide range of archaeological features have been identified throughout the site, including several burial structures that have yielded a substantial collection of human remains, most of which remains unstudied. The purpose of this paper is to present a review of the funerary practices and the human anthropological record currently known for Valencina de la Concepción, looking into the variability of burial structures and the results of the bioarchaeological analyses carried out to date.

The resulting discussion, which also make use of recently obtained radiocarbon and stable isotope analyses for some specific sectors of the site, will deal with issues pertaining the demographics as well as spatial and social organisation of the people who occupied this site throughout the Copper Age.

# A25c Standing stones and megalithic monuments in context

**1. STONEHENGE, DROMBEG AND AVEBURY: THE RATIONALITY OF THEIR STONE-CIRCLE DESIGN PLANS WHEN INTERPRETED BY HIROS GAMOS AND VALIDATED BY PHOTOGRAPHIC SUNRISE EVIDENCE FOR THE EIGHT TRADITIONAL AGRICULTURAL FESTIVAL DATES**

*Meaden, G. Terence (Oxford University) terencemeaden01@gmail.com*

Little is known about the intentions of the builders of the stone circles of Neolithic and Bronze Age Britain and Ireland, and the use to which the stones were put. Yet there are sites where constructive clues can be deduced by analysing stone settings relative to specific sunrises or sunsets. Because the stone circle at Drombeg is accurately explained this way—with photographs that powerfully demonstrate it—the solution strongly supports similar explanations for sites like Stonehenge where the action can be watched by any visitor and verified under clear-sky conditions.

The research has taken many years. The key lay in studies conducted at sunrise for particular dates of the year. Drombeg Stone Circle excels in this reconstructive analysis because the crucial stones are still present, and accurate survey authenticates it. The truths are convincingly demonstrated by photography.

At Drombeg particular standing stones play critical roles at sunrise for the eight festival dates of traditional agricultural communities. Crucial is the positioning of a male-type perimeter stone (bearing an anthropomorphic image) such that its phallic shadow at midsummer sunrise envelops a vulvar engraving on the recumbent stone diametrically opposite. Gradually the shadow moves aside allowing sunshine to reach the female symbol. It is the same for sunrises at Beltane, Lughnasadh and mid-year points (equinoxes) when shadows from other perimeter stones couple similarly, before being immediately followed by penetrating sunlight. For the winter half of the year (including Samhain, the solstice and Imbolc), the target stone for shadow reception is a huge lozenge-shaped megalith. At the equinoxes the drama is enacted between an arguably-male pillar stone and the seemingly-female lozenge stone.

Consequently, all eight sunshine-and-shadow events have been photographed at sunrise at Drombeg.

Stonehenge behaves similarly at midsummer sunrise where sunshine initially illuminates the Altar Stone, before the phallic shadow of the Heel Stone intervenes and

penetrates the monument to reach the Altar Stone. The enigma of the short round-topped anomalous Stone 11 at Stonehenge is solved too. The surviving stones of Avebury's southern stone circle act similarly at midsummer, midwinter and Beltane. Avebury's Cove works likewise with respect to midsummer sunrise.

An explanation in terms of the ancient, widely-loved worldview of the Marriage of the Gods between Sky and Earth seems warranted. This mythology was known classically as the hieros gamos (Sacred Marriage)—a concept known for classical historical times and encountered latterly by anthropologists interviewing tribal communities. The sun-and-shadow display is a dramatic, highly visual effect that still occurs and can be witnessed on the intended days by any visitor to Drombeg and Stonehenge. In the Neolithic and Early Bronze Age numerous spectators standing outside these monuments could witness the spectacle. This is the paramount fundamental meaning for the basic design plan of Stonehenge, and explains much about the meanings underlying the intrinsic design plans of many other monuments—including Avebury, Drombeg, Newgrange and Knowth.

This report also includes a reconstructed 365 day-by-day calendar for early Britain resulting from a study involving sunrise directions that accord with the axial orientations of over 60 Wessex long barrows.

ORAL

**2. KNOWTH PASSAGE-GRAVE IN IRELAND ? AN INSTRUMENT OF PRECISION ASTRONOMY?**

*Prendergast, Kate (University of Oxford) kate@brodgar.fsnet.co.uk*

There are three large Neolithic passage-graves at the monumental complex on the banks of the river Boyne in County Meath, Ireland: Newgrange, Knowth and Dowth. It is becoming increasingly clear that astronomical alignments comprise a central function of these monuments, but while astronomy at Newgrange has been extensively researched and interpreted, less is known and understood about the way astronomy functions at Knowth and Dowth. This paper focuses on the evidence for astronomical alignments at Knowth, and on interpretations of this evidence.

While at Newgrange there is one passage - facing south-east – at Knowth here are two passages - one facing east and one facing west. It has been believed for many years that these are equinoctial solar alignments and hence directly complement the winter solstice alignment at Newgrange. This paper will draw on new surveys, as well as interpretations of the evidence at Knowth. A synopsis

of this evidence will be presented and reviewed in the context of the rock art at Knowth - prominent examples of which can also be interpreted as depictions of astronomical cycles. These will be illustrated by photos taken at the site.

This paper will hope to successfully argue that, while the passages do function in relation to the equinoxes, they are not direct equinoctial alignments. Rather, they may have been constructed and used to facilitate the harmonisation of the solar and lunar cycles—much in the same way as does the equinoctial Judeo-Christian festival of Easter.

The paper concludes by suggesting that like Newgrange, Knowth may be an instrument of precision astronomy, which enabled its builders and users to construct highly sophisticated calendars and counting systems, which in turn facilitated calculated planning, and was a fundamental structuring principle for their ritual lives and cosmological beliefs.

### 3. REPORTING THE MAJOR DISCOVERY OF AN EXTRAORDINARY CULT SITE WITH ROCK ART ENGRAVED IN CALCITE, UNIQUE TO SARDINIA

*Gradoli, Maria Giuseppina (Geologist and Archaeologist, PhD researcher, University of Leicester (UK) ggradoli@yahoo.it, Anardu, Giuseppe (Freelance Geologist, PhD) anardu.geol@yahoo.it, Kovacs, Keith (University of Central Florida, School of Visual Arts & Design, Orlando (USA)*

This abstract announces the recent identification in East-Central Sardinia of an extraordinary cult cave displaying specific and unique use of natural surfaces on which complex patterns of rock art, always linked to past or present running water, were engraved. The small cave, now partly filled with sediments and rocks and disturbed by human action, shows intentional use of the physical and contextual properties of the natural resources by means of three different symbolic levels. The site is located on the upper part of a limestone plateau, in a marginal position not easily reached. In the central part of the main room of the cave, the remains of some speleothems arranged in a sort of oval open space (the deep first level) demarcate a flow of white calcite incised with signs and swirling lines of difficult interpretation. Nearby, several pieces of calcite-coated pottery were found scattered among the stones. The cave environment is linked to an external rock shelter by a 1.5 metres high step and a steeply sloping surface. Several now extinct waterfalls are recognisable in this second level that again is charac-

terized by a white calcite pavement where a great number of little cup marks were pecked, together with other incised and artificially modified features.

The third and highest level is an open-air surface with carvings, including cup marks and channels departing from a shallow broad central pool cut into a very thick layer of pure and well-formed calcite crystals. The latter with their special crystalline consistency and colour (white, translucent and, in the upper part, pinky-brownish) must have been 'visually appealing' for the prehistoric people using the site. Moreover, due to the presence of a great quantity of water flowing and passing through the different physical levels in which the site is articulated, and coming from both the walls and inner part of the cave and from the sky as rain on the open-air exterior engraved surface, the site must have been perceived as a powerful place for sacred rites.

Such a complex cult site—the first of the kind reported for Sardinia—and its uniqueness due to the curving action of a complex pattern of cup marks and different signs including female anthropomorphism cut into a thick crystalline surface, deserves much research, careful excavation, and urgent protection by the local authorities.

### 4. THE PEDRA DA ENCAVALADA AND ITS RELATIONSHIP WITH THE MEGALITHIC WORLD (ABRANTES, PORTUGAL)

*Cruz, Ana (Instituto Politécnico de Tomar) anacruz@ipt.pt, Graça, Ana (Instituto Politécnico de Tomar) anagrace@ipt.pt*

In Central Portugal, with a tripartite geomorphological diversity formed by the confluence of three rivers (the Nabão, the Zêzere and the Tagus), the Alto Ribatejo is home to some megalithic funerary monuments but to only one menhir structure.

Within the area affected by the Nabão river (a subsidiary of the Zêzere) are the sites of Alvaiázere and Quinta do Paço. In the river Zêzere area (a subsidiary of the Tagus) are the sites of Alverangel and Pederneira on the right bank and Martinchel site and Medroa menhir on the left bank. It is also on the left bank of the river Zêzere that lays Pedra da Encavalada, which is the subject of this paper. Finally, within the area affected by the Tagus River, is the monumental set of Mação. In none of them Rock Art has been detected.

The Pedra da Encavalada stands out as an atypical megalithic monument. In architectural terms it is a partial set

of monoliths adjoined to a large outcrop standing out in the landscape. His mound consists of burial pits (probably single) with circular plan, filling the entire perimeter of the "megalithic" structure. It is a unique monument of its kind in Alto Ribatejo, and based on the datings obtained by TL, it must have been a landmark in the consolidation of the megalithic architectural process in the region.

The megalithic monuments organised, in part, the cultural landscape of agro-pastoral communities during the Holocene. They are thought to have had a symbolic character that is widely discussed in the academic literature and, according to some authors, megalithic architects have built these monuments for "astronomic" purposes, thus giving them several uses at the same time. The significance of the devotion of agro-pastoral communities to these mega-constructions can be found within the spatial, cultural/collective and cognitive contexts as an epistemological rupture with the sphere of the Early Neolithic.

The relationship that can be established between Pedra da Encavalada and all its surrounding megalithic structures can only be explained by the emergence of a new attitude towards death.

### 5. A CONSTRUCTIVE RELATIONSHIP? FORAGER-FARMER CONTACTS AND MEGALITH CREATION IN KURNOOL DISTRICT, SOUTH INDIA

*Blinkhorn, James (Université de Bordeaux) jblinkhorn@outlook.com*

The creation of megalithic monuments marks a significant change in community relationships with geological landscapes. Although regularly incorporated within meaningful landscapes by hunter-gatherer populations, by engaging with geological resources more conspicuously, farming populations have been able to symbolically enrich their landscapes in new ways. This presentation, focusing on southern India, will discuss the different ways in which foragers and farmers have engaged with geological resources, and how contact between these groups may have led to new means for symbolically enriching a shared landscape. The Erramali range form part of the Cuddapah Supergroup, comprising a suite of limestone and shale deposits, capped by quartzites. Huge quartzite boulders litter the sides of the plateau as they roll gently toward the valley floors below, forming innumerate rockshelters inhabited by forager populations and providing a canvas for rock art production. On

low rises in the valley floor, megalithic burial grounds are found, produced primarily from limestones and yielding late Neolithic and early Iron Age material culture. The presence of human burials and both quartzite and limestone stone structures within and around the huge boulders beneath the plateau presents a unique manifestation of Megalithic trends in southern India. This is interpreted within the context of forager-farmer contacts in prehistory, and such contacts have also extended into the ethnographic present.

ORAL

### 6. INDIAN MEGALITHIC CULTURE SINCE ITS DAWN IN PREHISTORIC TIMES AND ASPECTS OF CONTINUING MEGALITH USES AND BELIEF SYSTEMS

*Das, Subhashis (www.megalithindia.in) subdas.hzb@gmail.com*

The paper considers the fact that much of India's landscape is interspersed with megaliths. India is one of few countries in the world where megalith making, as a tradition by many tribes, has continued uninterrupted till today—dating arguably from the Neolithic/Chalcolithic/Iron ages. In addition to the above, the paper examines the diverse megalithic architectures that are spread across the country, and studies graves and their associated deposits. The paper also delves into the realm of the cupmarks—an enigmatic symbolic art form associated with megaliths.

The presence of innumerable and diverse forms of megaliths ranging in time from the Neolithic/Chalcolithic/Iron Ages to the contemporary period suggests that these monuments should be one good source of India's ancient history, yet they are not acknowledged as such. The populace remains oblivious of the worth of these primitive monuments. As a result megaliths are fast being destroyed by villagers who tow them away for mundane domestic purposes. However a few megalithic-using tribes still raise megaliths to the dead in many parts of our country—thus making these monuments one of the rarest of the heritages that continues to be made unabatedly since antiquity.

Such a circumstance of megalith-making even in the present era is unknown for most parts of the globe, so this means that knowledge of Indian customs and practices may help to explain megalithic uses and practices worldwide including Neolithic and Bronze Age Britain, Ireland, Continental Europe and the Mediterranean.

Cupules (cup marks) and related forms of symbolism and traditions bind megaliths and these symbolical art forms to the archaic fertility cult that surprisingly link an-

cient India with Europe. This study deeply investigates megalithism in India finding that megaliths, contrary to conventional thinking, are not solely funerary monuments or commemorative stones to the dead but serve other purposes as well.

The paper shows that quite a number of megalithic monuments across the Indian landscapes, being of diversified architecture, are non-sepulchral in nature. Some stones further reveal mathematical and astronomical positioning that seems to suggest they were erected for their fertility rites in which astronomy was necessary. Among traditional customs of the tribals the Sarhul being a fertility festival in which the Sky Father is believed to marry the Earth Mother with the result that the fertility of farming lands and livestock is again renewed. In North-East India where megalith erection after death among several tribes still continues uninterrupted, many of these monuments are dedicated to the Mother Earth—and this may have been true of Neolithic Europe too.

These findings, along with grave goods, could also help in understanding more about the megalithic monuments and culture not only of early India but even of Neolithic Europe, and even get to be accepted as the long-overlooked source of India's ancient history. In the process these will obtain the status of venerated relics of India.

## **7. SIMILARITIES OF INDIAN MEGALITHS WITH NEOLITHIC EUROPEAN AND BRITISH MEGALITHS AND MONUMENTS: A CONSIDERATION OF POSSIBLE INFLUENCES IN ANTIQUITY**

*Das, Subhashis (www.megalithindia.in) subdas.hzb@gmail.com*

The paper investigates various lines of evidence for a connection between the lands of Britain and India including especially the Age of the Neolithic. The similarities in architecture of many megalithic settings and monuments between these distant lands are a mystery. Why are so many megalithic monuments in these lands identical or nearly so? Can they be the result of mobile contacts between the peoples of these countries in unknown antiquity or were the ideas spread by broadly the same set of people?

Unexpectedly but crucially one finds scores of Mundari/Kol words present in some European languages, and even in English, that could have been loaned from the different Mundari languages to the European vernacu-

lars or vice versa, and suggestive of the existence of various megalithic Mundari tribes in Europe at some remote past.

Since very ancient times India is a heterogeneous land of numerous cultures and faiths. The overwhelming presence of innumerable prehistoric megaliths across India's sacred landscape confirms the supposition that it was due to the various tribes who were the predominant population of this country among which many were megalith builders. Many Indian megalithic monuments, seemingly of later date than those of Britain, disclose European and British influences.

The paper looks into such megaliths that are identical both in India and Britain. It is all the more astonishing when one discovers similar names prevailing for the same object in Britain, Europe and also among some Mundari tribes in India. One astounding find is the name sarsen or sasan which is used widely for megaliths and large stones in Britain, Europe and even in the Jharkhand state of Eastern India by the Kolarian Mundaric tribes. The presence of identical megalithic structures and designating the same object or thing with the same name in lands so far apart is unlikely to be the outcome of random coincidences but, rather, a consequence of a likely interaction between them. Nevertheless, some archaeologists and scholars tend to shirk at the utterance of such a communication between ancient India and Britain.

Several proto-austroloid Kolarian tribes of India have rich folklores that propose their origin to be in lands outside India. One oral tradition of the significant Kolarian Santali tribe recounts sagas of their traversing many far-off locales for centuries which many tribal gurus presume to be ancient Europe. No wonder the parallels of many ancient megaliths in India could be traced to Britain.

ORAL

## **8. THE AVEBURY HILLS, SOUTHERN ENGLAND: A PREHISTORIC LANDSCAPE WITH POSITIONED MEGALITHS AND SETTINGS SUPPORTED BY NEOLITHIC AND EARLY BRONZE AGE PORTABLE LITHIC FINDS**

*Meaden, G. Terence (Oxford University) terencemeaden01@gmail.com*

Thousands of sarsen stones lie near Avebury across the heights of the Marlborough Downs in Southern England. Many are in shallow combs, the result of geological processes that began in the Eocene. Others, dotted about the higher slopes of Overton Down, were arguably intentionally positioned in the Neolithic Age. Unfortunately hundreds were split and removed by

a commercial stone-breaking industry in the nineteenth and early twentieth centuries. Even today sarsen stones continue to be sold or stolen. As a consequence, the author launched a project 18 years ago to compile a survey and photographic inventory of all noteworthy surviving stones. Major discoveries resulted.

The highest zone of Upper Overton Down—two square kilometres in area—is hugely significant. Most of its numerous megaliths, whether standing or recumbent, were specially selected, carefully positioned and in some cases subtly sculpted or inscribed. A megalith database with photograph albums together with detailed lists and photographs of diagnostic struck flints and carved portable-size sarsens have been prepared.

Far-reaching is the recognition of a pillar stone weighing 7-8 tonnes positioned to suggest calendrical functions—similar to the Obelisk in the South Circle of Late Neolithic Avebury on the plain below. Because of its remote location and lesser sophistication compared with Avebury, this highland obelisk seems to predate the Avebury megalith arrangements.

Another major result is the locating of an array of human and animal carvings. Human representations on placed stones include one with a well-proportioned carved head. Another is a splendid female torso with breasts. Animal likenesses include masterful full-body and head-alone exemplars. Groupings that incorporate aligned megaliths further suggest that in this highland region stones were ordered as open-air temples, sometimes having sunrise and sunset alignments.

Numerous portable-size sarsen stones—slightly worked and weighing up to 48 kg—have been examined. Refinements by tooling and polishing help explain their purpose. Several depict human heads, another is a female bust, and two are isosceles triangular in shape deliberately pierced or hollowed at the apex.

Of many flints found at a megalithic shrine, one resembles the top of a human skull with the brain partly exposed—a stone that a medical or spiritual practitioner might meaningfully use. It had been stored in a rock cavity along with struck flints, tools, and sarsen artefacts. At another site a third triangular sarsen stone has a true cup mark hollowed at the apex. Its reverse side is shaped for human buttocks. This implies it was made to be sat upon, as if it was a sacred seat bearing fertility hopes. The nature of the finds and postulated sarsen shrines and temples indicate that the origins of the Overton Down megalithic complex belong to the fourth millennium BC. Together, the artefacts and stones, with their social and religio-ancestral implications, and Early Neolithic long barrows suggest that this upland region east of Late Neolithic Avebury was occupied for centuries by a zealous agricultural community.

ORAL

## 9. ARCHAEOZOOICONOLOGY: A CORPUS OF ROCK ART ANIMAL SCULPTURES ON MEGALITHS IN THE AVEBURY HILLS OF SOUTHERN ENGLAND

*Meaden, G Terence (Oxford University) The best examples represent the mammals Bear, Sheep, Hare, and a Birthing Calf or Deer. Another is a raptor, probably Buzzard or Eagle. There is a good reproduction of Frog, and another may be Toad. The subtle artwork dates from the Neoli) terence-meaden01@gmail.com*

The paper about Neolithic archaeozooiconology announces the recognition of lifelike animal depictions deliberately carved into megaliths on the hills east and south of prehistoric Avebury in Wessex in Central Southern England.

The relevant localities are small—only a few hectares in area. No carved megaliths of similar character have been sighted elsewhere on the vast expanse of the sarsen-dotted landscape known as the Marlborough Downs with their tens of thousands of hard sarsen sandstones. Within the said localised regions special attention has been paid to photographing and studying pertinent megaliths on sunless days and at different times of day with the sun shining at different angles. In some cases the images are at their best in the light of the rising sun. Many stones in this landscape were carefully positioned. The stones of Avebury and West Kennet Long Barrow were studied too, and as a consequence an outstanding example of a fine animal sculpture is reported from each.

The best examples represent the mammals Bear, Sheep, Hare, and a Birthing Calf or Deer. Another is a raptor, probably Buzzard or Eagle. There is a good reproduction of Frog, and another may be Toad. The subtle artwork dates from the Neolithic and Early Bronze Age.

The Calf or Deer is on the lintel of the Early Neolithic chambered long barrow on a hill above the hamlet of West Kennet, a part of the Avebury complex. This monument is known to date from 3700 BC. Galleried and chambered long barrows, besides being places for depositing ancestral bones, may have been treated as cultic sites bearing hopes for rebirth after death. This can explain the lintel's artwork with its full-body image of a bovine calf or a deer at, it would seem, the moment of birth.

At Late Neolithic Avebury (2900 BC and later) on the great Cove stone the outline of a Hare was carved, rearing upright in typical springtime 'boxing' mode. As sculptural artistry this is an extraordinary and magnificent example of interactive imagery—of a type unknown elsewhere in world prehistory and possibly unique in the history of art. For, as the spectator's angle of view changes while walking through an arc of 90 degrees, the animal's outline transforms from a hare into a perfect left-profile human head facing the midwinter sunset.

The several other animal images discussed in this paper are high on Overton Down, which is above and immediately east of Avebury Down. There are human head images too. The sheep's head is best admired when illuminated by the light of the rising sun, especially at midsummer sunrise to which direction the megalith was set squarely perpendicular some 5000 years ago.

This archaeological survey of thousands of sarsen stones took many years.

It is suggested that iconography was the intention of the art form. On Overton Down the stones were positioned within zones of what appear to be open-air temples where, additionally, numerous portable size, meaningful, carved sarsen stones weighing from 1 to 48 kg have been found.

**10. AN ANALYSIS OF RECENTLY-DISCOVERED CARVINGS AND STONEMASONRY AT WEST KENNET LONG BARROW, AVEBURY, SOUTHERN ENGLAND: WAS THE CELEBRATION OF THE SKILLS AND ARTISTRY OF STONECRAFT AS IMPORTANT IN THE DESIGN AND CONSTRUCTION OF THIS BUILDING AS THE HONOURING OF THE ANCESTORS ENTOMBED WITHIN?**

*Pattison, Di (Independent) di@dipattison-artwork.co.uk*

The focus of this paper is the examination of a major feature of the design of one of Britain's finest early buildings - the newly-published presence of worked stones in the form of surprisingly large quantities of masonry and sculpture. These are considered in relation to the architecture and to finds of stone artefacts, tools and pottery.

Documentary studies, observational fieldwork and photography are used to record and assess the possible meaning of the large number of worked stones discovered by the author at this and other megalithic monuments within the Avebury World Heritage Site. The diversity of stoneworking methods, sculptural motifs and styles is noted together with the variety of tools and levels of handling expertise from the abundant toolmarks on the exposed surfaces. The placement of the worked portions on the stones and within the architecture are plotted on ground-plans and related to the two phases of construction dating to c3800 and c2200BCE. The faithfulness of the reconstruction is first established from archival and published sources.

The findings are related to known locations where stone artefacts, tools and pottery were found. An assessment was made of the number of persons involved in the architectural stonework at each period and how the work activities were organised, using an analysis of toolmarks. The supporting stone shapes and sizes and the dimensions of the carvings were re-

corded noting similarities and differences between the work of the two phases. The iconography of the imagery was analysed and considered in relation to the pottery, and artefacts. The stonework was planned and undertaken before the megaliths were upraised in most cases. The results indicate however that some Phase One stones were modified in Phase Two using new tools and processes and more sophisticated work organisation. The majority of Phase Two worked stones appear to deliberately partner stones and images of Phase One and this spirit appears in some ways to extend to the general architecture and earthworks too. Therefore the second phase of stonework seems in these ways to very deliberately pay homage to that of Phase One. The Phase One works by their diversity appear to celebrate the skills and achievements of stoneworkers/stoneworking for the two purposes of masonry and sculpture in particular, and also for toolmaking and other artefactual/craft purposes. However the excellence and complexity of the Phase Two works suggests a more professionally organised workforce. The quality of the best sculpture from the outset is superb, without comparison in the European megalithic monuments of either the Neolithic or Bronze Ages, including highly innovative three-dimensional large-scale carvings of animal and human subjects, indicating both a unique local style and the influence of people and cultures from far afield. These esoteric eclectic and also highly creative elements suggest strongly that this tiny building was designed from the outset as a most magnificent and singular structure.

ORAL

**11. THE WEST KENNET STONE AVENUE AT AVEBURY, SOUTHERN ENGLAND: AN ANALYSIS OF THE FAITHFULNESS OF ITS RESTORATION AND OF THE ICONOGRAPHY OF A BODY OF RECENTLY-RECOGNISED SCULPTURES OF HUMAN HEADS AND ARTIFICIALLY-SHAPED STONES.**

*Pattison, Di (Independent) di@dipattison-artwork.co.uk*

The paper examines the possible usefulness and meaning to the Neolithic community of the megalithic art and stonemasonry at West Kennet Avenue in Wiltshire, England. From unpublished and recently-published archives an assessment is made of the faithfulness of Alexander Keiller's restoration of the 1930s for the first time. Do surviving stones now stand as in c2200BCE? Was Keiller correct in suspecting stones were deliberately shaped and carved?

Documentary studies, observational fieldwork, annotated site plans and photography are used to establish the faithfulness of the restoration. The presence of toolmarks on every stone surface has been recorded and discussed in recently-published work by this author. New research adds to the detailed understanding of the carvings. Their sizes, orientation, loca-

tion and iconographic detail are recorded including the views 'seen' by the sculpted faces; the play of sunlight and shadow over the three-dimensional artworks; the alertness or otherwise of their gaze; their age; expression; clothing; pose; scale and imaginative elements. Gendered imagery was the subject of an earlier paper by the author. Keiller recorded many observations of marks and debated their artefactual nature with colleagues - these were checked individually. The fertility symbolism of certain stone shapes was understood in his period. How do viewers interact with the stones and their imagery? The impression that this, the longest stone avenue in the UK, was a consistently-paired row of upraised natural stones is corrected. Almost every one has been worked, many very intensively. The majority carry carvings and large-scale images of the human head are the dominant motif. The size, direction of view, placement on the stone and details all appear to be the result of deliberate decision-making. The lozenge-like stones are all carefully worked as are the pillars, but other worked and unworked shapes are also present.

Earlier writers have understood the meandering avenue as a processional walkway with views over a monumental and sacred landscape, suggesting it prompted discussion, story-telling and cultural discourse. The number, scale and detail of the images supports this but suggests the stonework was intended to add greatly to the magnificence of this monument. Perhaps the carved faces helped define and protect the boundaries/features of the sacred landscape, commemorated people and events of the past and fulfilled an educational role while the stonemasonry also served very practical purposes. This monument reflects the culmination of centuries of stonemasonry at the Avebury World Heritage Site, presenting unique artwork of high quality and importance.

ORAL

## 12. STAR-BEINGS AND STONES: ORIGINS AND LEGENDS

*Bender, Herman (Hanwakan Center for Prehistoric Astronomy, Cosmology and Cultural Landscape Studies, Inc.) ash-co@charter.net*

Native American myths, legends and oral traditions are rich with stories of giant beings existing in ancient times. They all talk of giant Thunderers or Thunder-beings, giant snakes and great Thunderbirds. Even the first humans were said to be giants, some half man, half animal. The Tsistsistas (Cheyenne) have a name for the giant beings their ancestors encountered during the early migration to the grasslands of the Great Plains. They called them *haztova hotoxceo* or "two-faced star people". Other tribes such as the Black Feet, Gros Ventres and Lakota have similar stories.

These old stories may have real world counterparts. After de-

veloping a field model based on landscape parameters including prominence, springs, prehistoric trails and habitation sites, areas of prime interest were identified and visited in the spring of the year after the snow had melted and before the trees leafed out for the season. One site was in an effigy mound group overlooking a marsh to the west, another on a low prominence overlooking a marsh to the east.

Both sites had a number of large rocks and boulders deeply embedded in the land surface. After intensive field clearing, mapping of every rock exposed on the surface and aerial photographs, two human-like petroform effigies emerged. One has a serpentine body and wing-like arms now known as the "Star-being", discovered in a prehistoric effigy-mound group in southeastern Wisconsin (USA). Configured in stone, it is approximately 20 meters in length with a red colored, bison-shaped headstone aligned to face the summer solstice sunrise. There is another called the Starman which also has a red-colored, bison-shaped headstone aligned to face the summer solstice sunrise. Like the Star-Being, the Starman petroform is also approximately 20 meters in length.

Each giant effigy appears to be a reflection of certain constellations and stars, the "Star-being" a mirror-image of the (western) constellations of Scorpius and Libra (with Sagittarius); the Starman an almost exact representation of Taurus and the Pleiades. Both giant effigies are estimated to be 3500-6000 years old, embodiments of ancient legends and traditions writ large in stone and connected to "The People" through ceremony and acts of cosmic renewal.

There is another called the Starman which also has a red-colored, bison-shaped headstone aligned to face the summer solstice sunrise. Like the Star-Being, the Starman petroform is also approximately 20 meters in length.

Each giant effigy appears to be a reflection of certain constellations and stars, the "Star-being" a mirror-image of the (western) constellations of Scorpius and Libra (with Sagittarius); the Starman an almost exact representation of Taurus and the Pleiades. Both giant effigies are estimated to be 3500-6000 years old, embodiments of ancient legends and traditions writ large in stone and connected to "The People" through ceremony and acts of cosmic renewal.

**13. MANITOU OR SPIRIT STONES AND THEIR MEANINGS FOR NATIVE INDIANS OF NORTH AMERICA**

*Bender, Herman (Hanwakan Center for Prehistoric Astronomy, Cosmology and Cultural Landscape Studies, Inc.) ash-co@charter.net*

Since ancient times the Native or Indian people of North America have believed in the existence of a supernatural, omnipresent and omniscient 'force' or 'presence'. All encompassing, it is universal in scale. For many of the Native people living here, manifestations of the supernatural could be expressed by one word: Manitou.

Manitou itself was seen to rest in rocks and boulders, sometimes referred to as 'spirit' or 'image' stones. They were once a common feature of the landscape. Hilltops and other significant places considered important were favored locations for the manifestation of Manitou. On the cultural landscape, the stones together with their physical setting were considered sacred. Physically, both the hills and Manitou stones were (and are) generally associated with water, i.e. springs, rapids and water falls, creeks, straits, river bends and drainage divides. Association with springs seems to have been most common. There is also a definite trail (i.e. prehistoric footpath) association, and the places venerated by the presence of Manitou(s) may have functioned as part of a broad 'trail-shrine' network,

identifying 'place' itself in both a spiritual and geographic context.

Using a variety of historic sources and place names, many Manitou stones were located. They appear to be from an ancient tradition. Some Manitous can be dated back many millennia. Historically, early French explorers, Jesuit priests and the later missionaries frequently mentioned them as did Henry Rowe Schoolcraft during his travels in the upper Midwest and Northern Great Lakes States in the early 19th century. Once the target of destruction by many missionaries, a surprisingly high number have survived, discovered where they were originally erected. Recently discovered lithic Bison effigies and other distinctive shapes, including rock outcrop resembling human and animal profile styles, can be considered as part of the phenomena.

This paper, the product of 15 years of continuing research, features some of the approximately 140 images of Manitou stones in many forms found spread across North America

POSTER

**14. DOLMENIC TOMBS AND LANDSCAPE IN CENTRAL-WESTERN SARDINIA (ITALY): A CASE OF STUDY**

*Cabras, Marco (Universidad de Granada) marcocabras@correo.ugr.es, Cicilloni, Riccardo (Università degli studi di Cagliari) r.cicilloni@unica.it*

The Sardinian dolmenic phenomenon attracted the interest of scholars since the beginning of the twentieth century. However, it is during this century that essential features of the phenomenon have been examined and the consequent field studies have led to the knowledge of over two hundred specimens of various types, which make, in number and characteristics, one of the most important megalithic groups in western Europe. It now seems confirmed the rise of the phenomenon during the culture of San Michele of Ozieri (recent Neolithic, 4000 – 3300 B.C.) and this is probable because to this culture precisely are attributed the first examples of megalithism, such as aniconic and proto-anthropomorphic menhirs, some megalithic circles and various monumental tombs. The Sardinian dolmenic graves, however, had the maximum spread during the Chalcolithic, as evidenced most of the finds from the excavations. The phenomenon also shows a close relationship to extra-wide island and especially with the monuments of Catalonia, Pyrenees, non-coastal departments of French-Midi, Corse and Puglia.

Here it is under investigation about 90 dolmenic graves of various types (simple type, "corridor" type, "allée couverte" type, and others of uncertain attribution) located in central-western Sardinia, and particularly in a significant area of about 3500 sq

km coinciding with the historical regions of marghine-planargia, guilcer and montiferru, today belonging to the provinces of oristano, nuoro and sassari. This area is covered by about 40% of the whole sardinian dolmens known in bibliography. Locational trends and relationships with landscape elements have been investigated with the aid of gis methodologies such as viewshed and cost surface analysis that have been used to evaluate the role visual dominance on the surroundings in relation to waterways, natural access routes, and eventually to other types of settlement and burials of the final neolithic and eneolithic.

The analysis shows that the analyzed dolmens enjoy an isolated locational character, more frequently they are found in plateaus, but also at low plateaus and hills. Although different concentrations are found in dolmenic emergencies, these don't seem to have direct relationship between them, but their influence is apparently directed towards the ways of traveling and sensitive elements of the landscape that have capabilities of a territorial demarcation.

The particular location emphasizes the significance of these monuments as territorial markers for segmentary societies. It seems that the dolmen was built according to the territory immediately surrounding it. This fact reinforces the hypothesis of the secondary task, as well as to the burial, to symbolizing a message or a landmark for those who moved towards "other" territory: a sign of belonging. The peculiarity of the dolmens as territorial markers is then reaffirmed by these analysis. The casuistry of articulation in the necropolis also suggests a stratification of a burial area, sometimes in the form of connections and integration between dolmenic and hypogean aspects occurring during the chalcolithic, which demonstrate changes in territorial strategies and perhaps social.

# Monumentality and territory: relationship between enclosures and necropolis in the European Neolithic

**1. SYMBOLIC TERRITORY OR LIVING SPACE? A CASE STUDY IN WEST-CENTRAL FRANCE**

*Ard, Vincent (Université Toulouse 2 - UMR 5608 TRACES) vincent.ard@univ-tlse2.fr*

In many European areas, the Neolithic period corresponds to the development of architectural monumentality which left important marks in the landscape, as well as the land clearing and the cultivation by the first agro-pastoral societies. This monumentality can be observed in the domestic sphere, particularly by the edification of enclosures with various functions and surfaces, and in the funeral and ritual sphere, by the development of many megalithic or pre-megalithic cemeteries. It is noteworthy that the concomitant development of these monumental sites reveals the complexity of cultural, symbolic and socio-economic practices of Neolithic societies. These monumental sites probably reflect socio-cultural dynamic systems in which the notion of territory seems to be a fundamental concept. Obviously, in many areas of Europe, Neolithic people have appropriated their surrounding landscape, exploited or not, by the edification of these monumental sites. In this way, they probably sustain their control over a defined territory. That's why burial, domestic or even defensive monumental sites, must be jointly analyzed in order to understand the organization of these Neolithic spaces, in which enclosures and cemeteries can structure a territorial network.

We conducted a spatial study of the distribution of the neolithic monumental sites in the Nord-Charente (France), which is placed in the continuity of the recent spatial analysis of megaliths of this area conducted by Elias Lopez Romero and Luc Laporte (in press). In this area, many space was used for the installation of many sites (necropolis, enclosures) which, according to recent studies (PCR "The Nord-Charente during Middle and Late Neolithic : causewayed enclosures, megalithic tombs and territories", coord: V. Ard), are dated of the Middle and Late Neolithic periods. Through the application of varied spatial analysis (distribution, dispersion, visibility, etc.), we attempt to know if

- Is-it possible to determinate an organization of the occupied space?
- What characterizes this territorial organization?
- Can we suppose that these monumental sites reveal a new way of appropriating space?
- What are the patterns of territorial organization, in

which enclosures and cemeteries have a fundamental role?

This paper will be an opportunity to present the first results of this study and to discuss the concept of landscape appropriation, combining domestic, symbolic, economic or natural spaces.

ORAL

**2. BURIALS OR ENCLOSURES: A PHENOMENON OF SUBSTITUTION IN THE LATE NÉOLITHIQUE IN THE EASTERN LANGUEDOC (FRANCE)?**

*Jallot, Luc (Paul Valéry- Montpellier 3 University) ljallot@9business.fr*

In south east France a long experience in building techniques gave the little communities of the Fontbousse culture (2600-2200 cal. B. C.) the means to increase the expansion of their architectural realizations. This expertise no longer applied to the tombs, which only rarely require the edification of an ostentatious monument, but to the dwelling place and systems of delimiting, stone enclosures and earthworks. The question then arises of the identification of new funerary sites and their relationship with these works.

As attested by carbon dating and the analysis of archaeological material, the construction of enclosures increased during the second half of the third millennium. In the hinterland some stone enclosures were built in concurrence with numerous open villages. The coastal plains and valleys became covered with extensive settlements showing ditch networks. These works belong to a general construction technique consisting of the aggregation of modules or segments. The delimitation systems surround the inhabited areas and the animal pens. The megalithic monuments of the Ferrières group (3200-2800 cal BC) are reutilised. They are succeeded by small dispersed tombs and underground cavities are also use. In the plains ossuaries and individual graves replace earlier collectives tombs.

This oscillating process is general in the eastern part of Languedoc. The settling of the land is firstly established by small mobile agro-pastoral communities which leave hardly visible traces of their habitation and build monumental megalithic tombs or not, sometimes grouped in necropoles. It can be suggested that the anchorage of these communities and the probable affirmation of lineages are expressed essentially by emblematic funerary monuments. In a second phase, the habitat is grouped.

The enclosures only appear during a third phase, probably in the last third of the third millennium. These realizations, which depend on a segmented conception of architecture, express in their turn the territorial anchorage of the new communities. The tombs are grouped in the living spaces, succeed to them or move away from them by reutilizing earlier funerary sites. At the end of the Bell Beaker period and at the beginning of the early Bronze Age (2250-2150 cal BC) a change in economic activities again provokes a spreading of settlements and the preference for hilltop sites. The diversification of sepulchral practices continues in a general context of diminishing population and concentration of the settlement. This simplified representation can hardly be surpassed in the current state of field data.

The oscillating movement between necropoles and enclosures expresses all the more the growing importance of land and the extension of settlement limits in view of the socialization of the landscape. Formal connections exist between Languedocian stone enclosures and the enclosures of southern Spain and Portugal, within a general context of diffusion of symbolic productions, harnessing food-producing resources and social tension. Moreover, the development of enclosures is generally interpreted in terms of social "complexification". This academic view does not seem to be applicable to the situation described in eastern Languedoc.

ORAL

### 3. CONTINGENT CORPSES? ON THE VARIABILITY IN THE DEPOSITION OF HUMAN REMAINS AT NEOLITHIC AND CHALCOLITHIC IBERIAN ENCLOSURES

*Jimenez-Jaimez, Victor (University of Southampton) V.J.Jimenez-Jaimez@soton.ac.uk, Marquez-Romero, Jose E. (Universidad de Málaga) jemarquez@uma.es*

The multiple ways of seeing the variability in the location, distribution, position and character of human bones at Neolithic and Chalcolithic Iberian enclosures ultimately depend on how we define what 'funerary' means. Often, two contrasting types of funerary practices are perceived in those contexts: a) normalised funerary practices, in which human remains are deposited in conventional or recurrent ways and positions, usually with clearly identifiable grave goods and within distinguishable, somewhat standard funerary containers; b) non-normalised funerary practices, as a result of which human bodies or body parts are deposited within pits and ditches, or between the stones forming the enclosure walls, in a myriad of different states and positions,

seldom repeated.

In order to challenge these views, we will assume that not every human bone recorded in an archaeological survey or excavation necessarily entered the context in which it was found in the context of funerary practices. For us, the heterogeneous presence of human bones in ditched or walled enclosures need not be the materialisation of either non-normalised funerary practices in ditches/pits/walls or standard burials in regular graves. Quite the contrary, this heterogeneity may be an effect of two very different kinds of conventional practice: a) one funerary, in graves and focused on the body of a dead person; b) and one non-funerary, reflected in the fillings of pits and ditches, that involves the ritualised deposition of a much wider range of material elements, and in which human bones are contingent.

ORAL

### 4. THE ROLE OF ENCLOSURES IN TERRITORIAL STRUCTURATION IN THE PARIS BASIN BETWEEN 4500 AND 3800 BC

*Lietar, Claira cliraa@hotmail.fr*

From the fifth millennium BC, widespread and progressive complexification of enclosures is observed in the entire Paris Basin. Analyzed more precisely, this phenomenon shows variability across regions in this area. Through the study of this variability, we can identify different forms of territorial structures. This paper presents a method for analyzing the function of enclosures and synthesis of territorial organization patterns for the Paris Basin during the Middle Neolithic.

Here, we propose a classification of these sites based on multiple criteria, integrating morphology of enclosures structures (dimensions of enclosed areas, complex structures) but also deposition patterns and internal structures. This classification provides a basis for reflection on the function of these sites and lets discuss the complexity of some of them.

Location analysis of the enclosures in different environmental contexts provides further insight into the function of these sites and their organization within the territory. It relies on the modeling of environmental contexts across micro-regional analysis windows, defined from a combination of environmental variables (topography, drainage network, soil quality for agriculture).

Different patterns of territorial organization can be highlighted according to contemporary cultural groups. Some territories, such as the Aisne valley and the Bassée offer similar models of territorial structure with a con-

centration and a wide variety of enclosures. Their hierarchical structure reveals different levels of social organization, local, regional or supra-local. In the Aisne valley, the presence of monumental tombs is another sign of social hierarchy and division of territory between social groups. Same time territories of northern Chassean have, in comparison, less structured areas. The enclosures are fewer and more dispersed. Some territories, in the lower Seine valley, do not show any enclosure.

Observed over the long term, the development of territorial structures corresponding to regionalized processes and can be related to procurement flint systems.

### **5. ENCLOSURES AND NECROPOLISES IN THE TERRITORIAL PATTERNING DURING THE MIDDLE OF THE FIFTH MILLENNIUM B.C. IN THE SEINE-YONNE AREA (FRANCE)**

*Pillot, Lucile (UMR 6298 ARTeHIS - Université de Bourgogne (Dijon, France) lucile.pillot@u-bourgogne.fr*

In France, in the Paris Basin, at the beginning of the fifth millennium BC, during the Middle Neolithic period, we observe a monumentalisation of some sites. These sites, which are enclosures and monumental necropolises (Passy-type necropolises), are attributed of the Cerny Culture, which is considered as a significant period of social, economic or even political and religious changes in complete break compared to the early Neolithic. Indeed, these sites can illustrate the emergence of a new way of the territorial appropriation.

Spatial analysis of the distribution of these monumental sites (Ripley's K function, density analysis, etc.) allow to try out these assumptions of territorial strategies.

By this way, it's noteworthy that enclosures and monumental necropolises are included in the territorial patterning. Indeed, the association of the both types of sites is often systematic. These are generally located nearly than another (the necropolises are located in the 2km radius around enclosures). Moreover, these sites seem to be complementary by their functions (habitat/funeral). Our study highlights that these monumental sites can be integrated inside specific occupation "poles" which aggregate a lot of sites. Monumental necropolises are globally distant of being 6/7km than another. It allows us to suppose large influence areas around each monumental complex which gathered necropolises and enclosures. The others types of sites (habitat, funeral, temporary occupations, etc.) are located inside these largest influence areas.

These both monumental sites seem to have significant role(s) in territorial patterning and organization. This communication it's a way to present these spatial studies.

ORAL

### **6. THE MONUMENTALIZATION OF THE TERRITORY: THE CONSTRUCTION OF PASSY-TYPE NECROPOLISES AS AN APPROPRIATION OF SPACE**

*Pillot, Lucile (UMR 6298 ARTeHIS - Université de Bourgogne (Dijon, France) lucile.pillot@u-bourgogne.fr, Fusani, Nicolas*

The installation of a monumental site often seems to mean a significant territorial appropriation of one community. Examining Passy-type cemeteries (Yonne, France), we question the motivations, mentalités and the socio-cultural context that contribute to this monumentalization? Passy-type cemeteries consist of huge earthen monuments (Paris Basin, mid-5th mill. BC).

Our studies highlight the principle of repetitive organisational patterns that structure the cemeteries. These result from well-codified building project. A same architectural module seems repeated several times over time, explaining the huge aspects of some structures (>300m). We can illustrate this model by the comparison between two sites: the excavated site of Passy and the surveyed site of Vinneuf. A geophysical survey was conducted on the Vinneuf cemetery (Yonne, France. Almost thirty neolithic long ditched monuments (until 320 m) were identified. By shape, layout and size, Vinneuf monuments are very similar to Passy excavated funeral monuments. By looking at the organisation of Vinneuf monuments, we can ask ourselves if the spatial distribution is the result of a deliberate process, as is the case in Passy. Despite of the important length of some monuments, a recurrent building module is identified ( $\pm 30$  m). This process can be a result of one persistent cultural norm up a very long time. By the installation of one more monument or module, the community show her anchorage in the occupied space.

This construction model reveal the appropriation of one part of space by Neolithic communities during a long time. There is a wish to maintain and perpetuate a symbolic signification of this place. Indeed, these cemeteries are persistent monumental places that are reused from the Neolithic to the Protohistory, during Bronze Age

POSTER

**7. TOWARDS A DEFINITION OF THE PREHISTORIC LANDSCAPE IN THE PLATEAU OF SIGARRA: VISIBILITY AND TERRITORIALITY BETWEEN THE MIDDLE NEOLITHIC AND BRONZE AGE**

*Salazar, Natalia natalia.salazar@historia.udl.cat*

As part of the Territory and Landscape Archaeology, spatial analysis related to visibility are showing that the comparison between the preponderance between establishments, monuments and places with a strong religious symbolism has been used by humankind since immemorial time and throughout all periods to delimit territories from political, social and economic terms.

This study presents the practical application of GIS method of Cumulative Viewshed Analysis, in order to infer intervisibility relationships between archaeological sites of the Middle Neolithic, Chalcolithic and Bronze Age. We may find these sites chronologically and typologically connected in a particular historical territory structured around the ancient Iberian settlement and afterwards Roman town of Sigarra (current population of Els Prats de Rei, Barcelona).

Based on the Digital Elevation Model (DEM) of this territory, Cumulative Viewshed Analysis has been applied looking for a possible answer to a specific research approach: try to find the visibility spatial relationships between habitat and megalithic necropolis related, as a tool for elucidate the structure of possible territories and, by comparing the results for chronologies and typologies, establish its diachrony. The analysis has provided generally positive and interesting results allowing new hypotheses for understanding the spatial distribution parameters of necropolis and habitats based on a territorial and landscape conception.

The diachronic perspective of maps that we have developed allows aiming a number of general assessments. We note that the visibility is very important in prehistoric burial sites, as their visual impact is revealed as remarkable. However, the Neolithic visibility patterns show a lack of political and territorial hierarchy; while in the Bronze Age, in direct relation to the social complexity detected by archaeology, visibility patterns reflect a spatial hierarchy. In both periods the choice of the highest locations in the territory studied is a constant, which leads us to conclude that the visibility of these burial monuments was sought and calculated, becoming territorial and landscape landmarks difficult to ignore.

In light of the specific interest of these results we conclude that the archaeological application of Cumulative Viewshed Analysis reveals itself as a useful tool for the in-

vestigation of potential prehistoric territorial structures.

POSTER

**8. ARE SOME DITCHED ENCLOSURES FUNERARY CEREMONIAL CENTRES? QUESTIONING THE CURRENT DATA FROM 3RD MILLENNIUM SOUTH PORTUGAL**

*Valera, António Carlos (NIA-ERA Arqueologia) acvalera25@gmail.com*

Valera, António Carlos (NIA-ERA Arqueologia) acvalera25@gmail.com

In the last 15 years the archaeology of South Portugal Recent Prehistory has been in permanent empirical "revolution", namely in what concerns funerary practices.

The traditional image of the megalithic monuments as the main funerary architectures of Neolithic and Chalcolithic communities no longer stands and pit graves, hypogea and other enclosures have been shown equally important funerary solutions in the region.

In this context of more diversified funerary architectures and spaces, some ditched enclosures have emerged as places that maintain specific special connections with areas of necropolis and revealing themselves as places where funerary practices and body manipulations appear as significant social practices, inclusive to the very meaning of those enclosures. Some examples will be presented and discussed.

This communication pretends to do a revision of the available data in South Portugal regarding the relation between ditched enclosures and funerary practices and underline that the funerary world is part of a cosmogony embedded and expressed by some of those enclosures.

### 1. POPULATION AND SUBSISTENCE: PATTERNS IN EUROPE'S EARLY FARMING POPULATIONS

*Shennan, Stephen (University College London) s.shennan@ucl.ac.uk*

The ERC-funded EUROEVOL project has gathered a large database to create proxy measures of human demography and subsistence patterns for the period 8000-4000 cal BP in western and central Europe north of the Mediterranean, during which farming arrived in this region. The demographic proxies have revealed a widespread regional pattern of boom and bust. In most regions population increased rapidly with the arrival of farming but then declined sharply; in some cases there is more than one boom and bust. The talk will present the main outlines of the demographic, archaeobotanical and archaeofaunal evidence and explore the feedback relationships between population and subsistence that the patterns suggest.

ORAL

### 2. DEMIC VERSUS CULTURAL DIFFUSION IN THE NEOLITHIC TRANSITION IN EUROPE AND SOUTHERN AFRICA

*Fort, Joaquim (Universitat de Girona) joaquim.fort@udg.edu, Jerardino, Antonieta (ICREA/CSIC) amsjerardino@gmail.com, Isern, Neus (UAB) nisern83@gmail.com*

The speed of the Neolithic transition in Europe, as determined from archaeological data, was about 1 km/yr. Such a spread rate has been recently shown to imply that this transition was about 60% demic and 40% cultural (Fort, PNAS 2012). This conclusion was reached by using a recent model that unifies demic diffusion and cultural transmission theory. Here we review that model and case study, and apply the same approach to estimate the percentages of cultural and demic diffusion in the Neolithic transition in southern Africa.

We used databases for the Neolithic transitions in Europe (12,000-6,000 cal yr BP) and southern Africa (2,000-1,000 cal yr BP). We first applied GIS interpolation techniques to map both transitions. We then computed linear regressions to estimate the speed in both cases. We also estimated independently the parameters necessary to apply the model, namely initial growth rate (reproduction rate) of farmers/herders, their generation time and

dispersal kernels, and the intensity of cultural transmission from hunter-gathering into farming and into herding.

The Neolithic transition in Europe had a speed range substantially different from that in Southern Africa. According to the demic-cultural model (Fort, PNAS 2012), this implies that the relevance of demic and cultural diffusion was rather different in both case studies. We suggest that these differences could be due to the fact that the final state of the transition was herding (without farming) in the southern African case, whereas it was farming and stockbreeding in the European case.

A recent demic-cultural model makes it possible to compute the importance of demic versus cultural diffusion in Neolithic transitions. Here we have discussed the only two cases for which we have enough high-quality data to obtain statistically sound results. In the future, the same approach could be applied to Neolithic transition in other continents, as well as to other human spread phenomena in which both demic and cultural diffusion could have played a role.

ORAL

### 3. EARLY NEOLITHIC IN IBERIA. TESTING THE HYPOTHESIS OF AN AFRICAN ENTRANCE

*Isern, Neus (Universitat Autònoma de Barcelona) neus.isern@uab.es, Fort, Joaquim (Universitat de Girona) joaquim.fort@udg.edu, Faustino Carvalho, António (Universidade do Algarve) a.faustino.carvalho@gmail.com, Gibaja, Juan F. (CSIC-IMF) jfgibaja@gmail.com, Ibañez, Juan José (CSIC-IMF) ibanezjj@imf.csic.es*

Here we analyze an Early Neolithic database for Iberia to study the spatial dynamics of the Neolithic transition in the peninsula. Particularly we study how the Neolithic was introduced in order to test the hypothesis of an African entrance nearly simultaneously with the European arrival.

We use an Early Neolithic database with 93 dates in Iberia, selected so that only dates on short-lived species are included in order to obtain a reliable representation of the Neolithic expansion. We analyze this database to test the possibility of an African entrance by applying GIS techniques (creating interpolation maps) as well as by studying space-time trends. We also apply a very simple reaction-diffusion computational model with different scenarios —namely, with and without spread along the African coast— in an attempt to reproduce the patterns from the interpolation maps.

The interpolation maps show the presence of very early

dates surrounded by later dates both at the northeastern and the southwestern coasts, which is consistent with a double-origin expansion of the Neolithic. The analysis of space-time trends for different origins also suggests a Neolithic expansion from the south at the western part of the peninsula. In addition, our numerical simulations provide better predictions when allowing a Neolithic expansion from the Near East, along the African coast and with an entrance from northern Africa.

Our results show that the hypothesis of a dual Neolithic expansion in Iberia, with an African origin besides the European entrance, is a reasonable possibility. This is further supported by the presence of early dates at the African coast consistent with those near the strait in Iberia, as well as the similarity in several archeological elements, which in turn differ from those at northern Iberia. However, due to the scarcity of dates in the African shore, we cannot yet exclude the possibility of a very fast Neolithic expansion along the Mediterranean coast until further data is gathered.

ORAL

#### 4. THE PURSUIT OF CULTURAL DYNAMICS IN THE SPREAD OF NEOLITHIC

*Pardo Gordó, Salvador (Departament de Prehistoria i Arqueologia. Universitat de Valencia) salvador.pardo@uv.es, Bernabeu Auban, Joan (Departament de Prehistoria i Arqueologia. Universitat de Valencia) juan.bernabeu@uv.es*

The archaeological literature focused on the spread of the Neolithic in Europe combines its efforts in understanding the influence of demic diffusion (diffusion of population) versus cultural diffusion (cultural influence) to establishing that a 40% dispersal of the Neolithic could be associated with second process. In this perspective, the only variables that had taken in consideration are space (where = archaeological sites) and time (when = radiocarbon dates).

Several of the hypotheses proposed to explain the dispersion need to use others variables than simple spatio-temporal dynamics; they need in particular involving the dynamics of cultural change associated with the above. Consequently the spread model needs to implement this variable.

In this paper we propose to approach the expansion of cultural traits in the western Mediterranean, using for this purpose the ceramic decorations like cultural variable.

To make this approach we have developed an Agent-Based Models, its traits bottom-up, across-level and capacity to simulate multiple hypotheses can become a

very useful tool for our purpose. In this methodological context, evolutionary archeology has a major role, as it will give our agents computational model of behavior and interaction rules.

ORAL

#### 5. CONNECTIONS AND DISCONNECTIONS IN LITHIC PRODUCTION BETWEEN NORTHERN AND SOUTHERN LEVANT DURING THE PRE-POTTERY TO POTTERY NEOLITHIC TRANSITION: A VIEW FROM BEISAMOUN, CENTRAL LEVANT

*Lozano, Sergio (IPHES) slozano@iphes.cat, Bernabeu Auban, Joan (Universitat de Valencia) jbauban@uv.es, Pardo Gordo, Salvador (Universitat de Valencia) salvador.pardo@uv.es, Orozco Köhler, Teresa (Universitat de Valencia) teresa.orozco@uv.es, Garcia Puchol, Oreto (Universitat de Valencia) oreto.garcia@uv.es*

Interactions among individuals and groups in human societies can be represented as networks, in which the nodes are social agents and the connections between the nodes (edges or links in network terminology) represent their interactions (Wasserman & Faust, 1994). This allows for the application of a wide range of mathematical tools, with which to understand their evolutionary dynamics. During the last decade the analysis of complex networks has raised significant interest, especially since its ubiquity across scientific fields was uncovered (Newman, 2010).

The impact of these theoretical and methodological tools on issues concerning exchange and social interaction is evident and their utility has been perceived by archaeologists (e.g., Knapett, 2010; Mills et al., 2013). However, the application of network analysis' tools to archaeological data requires addressing a number of issues concerning, for instance, objective clarification and the appropriateness of the available data (Brughmans, 2012).

Our goal in this work is to apply network analysis to a particularly challenging scenario, namely Iberian first farming societies. Specifically, we aim at studying the dynamics of cultural evolution and change of the earliest agricultural groups in Iberia.

Concerning network construction, we will use the analysis of ceramics' style, applying methods developed recently (Bernabeu et al, 2011), to obtain proximities or distances as a measure of relationship. Once the network is obtained, we will evaluate the macro effect (in terms of network connectivity) of micro changes such as the

removal of a node (focusing specially on “hubs”, which are responsible of the transmission of information to the entire network).

microtine species (voles) has been detected in the Chalcolithic and Bronze Age levels in all of the studied sites, coinciding with the overture of the landscape.

POSTER

## 6. HUMAN INFLUENCE ON THE SMALL MAMMALS DIVERSITY IN NORTH OF IBERIA FROM EARLY TO MIDDLE HOLOCENE

*Bañuls Cardona, Sandra (Universita di Ferrara) sandra.banulscardona@unife.it, López-García, Juan Manuel - (Universita di Ferrara) lpzjmn@unife.it*

The Holocene period in the Iberian Peninsula is characterized by important changes in the vegetation and rapid climatic fluctuations. We are analysed from early to middle Holocene levels of three sites: El Mirador cave (Atapuerca, Burgos), Colomera cave (Sant Esteve de la Sarga, Lleida) and Valdavara-1 cave (Becerreá, Lugo). The studied samples are part of late Boreal, Atlantic, Sub-Boreal and Subatlantic periods. During these periods the human influence in the environment is more important than in the latest Pleistocene. The human are, since the agriculture appearance, the principal modified agent of the landscape, and therefore also in the richness and diversity of species, and this activity is more important since the Chalcolithic and Bronze Age.

Eight small mammal taxa adapted to conditions created or modified by human activity (synanthropic species) have been identified in our studied sites: *Microtus (Terricola) duodecimcostatus* (the Mediterranean pine vole), *Microtus (Terricola) lusitanicus* (the Lusitanian pine vole), *Myodes glareolus* (the Bank vole), *Microtus arvalis* (the Common vole), *Microtus agrestis* (the Field vole), *Micromys minutus* (the Eurasian harvest mouse), *Eliomys quercinus* (the Garden dormouse) and *Crocidura russula* (the Greater white-toothed shrew).

In general, we observed that the percentage of the synanthropic species is elevated (55.8%) in all of studied sites. However, this percentage in the Chalcolithic and Bronze Age (61.6%) is higher than in the Neolithic levels (46.1%).

The human influence on the small mammal species is produced by rearing of livestock and agricultural activities, and these activities caused the forest deterioration and destroyed the high grasslands. The climatic and the environmental records performed with the small mammals, as well as, other disciplines shows that the forest deterioration is not so evident. From the small mammal point of view, *Apodemus sylvaticus* (the Wood mouse) is the best represented species, but an increased of the

## 7. STRUCTURED-POPULATION MODELS OF THE NEOLITHIC TRANSITION

*Pérez-Losada, Joaquim (Universitat de Girona) joaquim.perez@udg.edu*

Reaction–dispersal front propagation models have been applied to investigate many systems, such as human invasions. A variety of models have been developed in recent years for analyzing the speeds of human invasion fronts. In the called the non-overlapping generation model, all traits in the life history of the individuals are ignored, i.e. only the age-independent parameters are used. Therefore, this model cannot analyze any effect on the front speed of the fact that the fecundity, mortality and dispersal kernel depend on the age of individuals. We present a model that makes it possible to analyze the effect of the age dependences of mortality, fertility and dispersal persistence on the speed of propagating fronts in two spatial dimensions. We apply the model to the Neolithic transition in Europe.

In order to take into account the dependences of fecundity, mortality and dispersal on age, we regard the population as subdivided into several age groups. At each time interval, we compute the new subpopulation number densities at all nodes of a two dimensional grid in a two-step process: dispersal and growth (the latter includes reproduction and deaths). In the dispersal step, a fraction of the population in age group stays at the original node, and the remaining fraction is distributed equally among the nearest neighbors. In the second step, the effects of reproduction and mortality are computed. The two-step dispersal–growth cycle is then repeated many times, until a constant speed for the propagation of the population profiles is reached.

We apply our model to the Neolithic transition in Europe. Simulations of the front speed were plotted as a function of the adult dispersion persistence. The numerical results for the model with several age groups agree well with the analytical results for the same model. We see that the infant mortality has a very important effect on the front speed. The sensitivity of the results has been analyzed, with reference to a baseline case for the parameter values obtained from the ethnographic literature. Infant mortality and total fecundity ratio have the most important effects, speed, whereas the adult mortality rates and

dispersal persistences are less important. We have found that there is a relatively narrow range for the value of the infant mortality consistent with the observed range of the Neolithic front speed.

We have analyzed the effect of age-dependent mortality, fecundity and persistence on the invasion speed for populations that spread across a two-dimensional space. Our simulated and analytical front speeds are consistent with each other and, for realistic parameter ranges, with the observed speed of the Neolithic transition in Europe. Predicted speeds fall within the experimental range for realistic values of the infant mortality, and this conclusion is independent of the adult dispersal persistence. The model can also be used to constrain demographic traits from measured front propagation rates.

POSTER

**8. CARDIAL WARE, SICKLE BLADES AND 14C C. 5600 - 5000 CAL BC: CULTURAL, CHRONOLOGICAL, TERRITORIAL MARKER DURING THE EARLY NEOLITHIC OF THE NW MEDITERRANEAN**

*Oms Arias, F. Xavier (SERP (Universitat de Barcelona) xavier-oms@gmail.com, Gibaja Bao, Juan F. (CSIC-IMF) jfgibaja@imf.csic.es, Mazzucco, Niccolò (CSIC-IMF) niccomazzucco@imf.csic.es, Ibáñez, Juan José (CSIC-IMF) ibanezzj@imf.csic.es*

There are two fundamental variables that we need to control when we speak of the Neolithisation processes: a chronological and a geographical variable. In this work we are going to analyze both aspects, trying to identify some key-elements that can help us to establish a correlation between space and time.

We built a database collecting three different variables from sites of the NE of the Iberian Peninsula. We collected: (a) a total of 35 radiocarbon dates from 16 different archaeological sites; (b) the information about ceramic assemblage of 32 archaeological sites, with special emphasis on the decorative motifs represented in each assemblage; (c) the information about the presence/absence of the sickle blades in each site and their typology. With this three variables we will be able to establish whether exists or not an homogeneous model for the distribution of two fundamental elements of the Neolithisation process (ceramic and agricultural production) over space and time.

The calibration of the radiocarbon dates has permitted to establish a totally of three chronological phases for a period comprised between 5600-5000 cal BC. During this interval we can appreciate moments of major and minor occupation in the area of study. At the same time,

the decoration motifs observed in pottery assemblages and the specific type of sickle blades represented in each area, allow to establish geographical and cultural boundaries.

During the first phase (5600-5450 cal BC) we only have two dated sites. The information we have is quite scarce. Both of them are located in the littoral and pre-littoral area of the Catalan southern coast. Even if ceramic data is not abundant, sickles appear composed of little inserts (mainly blade/bladelets but also flakes) hafted in series, forming a serrated edges.

During a second phase (5500-5350 cal BC), human occupation is increasing in the area, expanding toward the Llobregat valley and the surrounding plains. Ceramic record suggest the existence of slight territorial differences on small-scale, even if decorative motifs are generally simple. Sickles suffer a change, being composed of larger blades hafted parallel or diagonal to the haft, isolated or in pair.

During a third phase (5300-5000 cal BC) human occupation is fundamentally consolidating in the littoral and pre-littoral area, extending also to the north, south and west of Catalonia. A major decorative differentiation between near territories is now detected.

The analysis of the chronological, ceramic and sickles data had allow to identify new insight into the Neolithisation of the NW of Mediterranean. Our results suggest a very rapid process of diffusion, however not homogeneous or linear.

**9. ALTERNATIVE HISTORIES OF AGRICULTURAL ORIGINS: TESTING MODELS FOR THE SPREAD OF FOOD PRODUCING ECONOMIES IN THE IBERIAN PENINSULA**

*Bergin, Sean (Arizona State University) Sean.Bergin@asu.edu, Barton, C. Michael (Arizona State University) Michael.Barton@asu.edu, Pardo Gordó, Salvador (Universitat de València) salvador.pardo@uv.es, Bernabeu Auban, Joan (Universitat de València) joan.bernabeu@uv.es*

The combination of a growing database of high-precision radiocarbon dates and experimental computational modeling protocols permit systematic testing of alternative scenarios for the spread of farming across the Iberian Peninsula. We create a set of different algorithms for the dispersal of agropastoral economies, ranging from simple diffusion to ones based in Human Behavior Ecology and statistically compare their ability to replicate the spatial/temporal distribution of the earliest, securely

dated Neolithic sites in Iberia. The results of these digital experiments offer insights into the social and ecological processes that drove the spread of agriculture, as well as suggestions as to the most likely points of origins for the arrival of these novel socio-economic systems in the Iberian Peninsula.

**1. ACTING DEATH AND BURIAL IN VARIABLES. A NORTH-SOUTH COMPARATIVE THANATOGRAPHY OF THE LEVANT DURING THE MIDDLE BRONZE AGE.**

*Andreou, Panayiotis (IANES, Eberhard Karls Universität Tübingen, Germany) Panayiotis.Andreou@gmx.de*

The first impression of comparative mortuary behaviour between North and South during the Middle Bronze Age in the Levant is much affected by the blinding display of affluence in its northern regions (such as Ebla, Qatna or Byblos) contrasted by an ostensible uniformity in the South, which recent scholarship has referred to as a "funeral kit". Admittedly when set against the seemingly undifferentiated burials of the South, the "glamour" of northern "elite" mortuary behaviour does a lot to obscure an otherwise pluralistic means of cultural expression and highlights discontinuity in the way of a self-fulfilling prophecy.

This paper discusses continuity and discontinuity in mortuary behaviour and activity, on the terms of it being a funerary process, by addressing a wide spectrum of individual variables derived from the archaeological mortuary remains of the first half of the second Millennium Levant. It is less concerned with deducing either social structure, or ideology, or patterns of eschatological beliefs per se, since burials are merely one of many constituent parts of these systems and their holistic understanding depends on a synthesis of all of the aforementioned. At its core lies a sincere effort to normalize mortuary data in a way that facilitates interregional comparability. As a second step it endeavours to disentangle and conceptualize individual elements of the burials themselves and map potential ritual activities, as these can be inferred from interrelationships of objects, tomb architecture and/or the deceased.

Past agents of burials, both active or inactive, have shared "values" and have "valued" materials expended during funerary ceremonies. By breaking down ritual action in overlying layers of information over space and time, it is envisaged to augment the potential of mortuary data in revealing tentative conceptual boundaries or patterns of their interregional interdependence, resulting in a more conspicuous detection of continuity and discontinuity in mortuary behaviour in MBA Levant.

**2. NILE VALLEY-LEVANT INTERACTIONS DURING THE UPPER, EPI-PALEOLITHIC AND NEOLITHIC**

*Bar-Yosef, Ofer (Harvard University) ofer.baryosef@gmail.com*

The connections between Egypt and the Levant are a constant subject for inquiry but more often the archaeological highlights focus on the 4th millennium BC and later times. Earlier relationships are more poorly known. It is assumed that modern humans migrated from this general area of Northeast Africa into western Asia some 47/45 Ka cal BP, but sound evidence for presence of Upper Paleolithic blade making foragers in both regions dates to ca. 35/30 Ka cal BP.

Sound documentation for migrating foragers in the same south to north direction is the makers of the microlithic industries of the Mushabian (including the Ramonian) who played an important role in the emergence of the early Natufian culture.

The establishment of semi-sedentary and sedentary hamlets across the Levant and the onset of intentional cultivation that marked the Neolithic Revolution in the northern area of the Fertile Crescent, changed the history of the Eastern Mediterranean basin.

The spread of Neolithic farmers and their products (plants and herded animals), along the Levant and Mesopotamia, carrying elements of the new cosmology, had an impact of the cultural history of the Nile Valley. Selected cases from this intricate series of contacts and interactions will be presented.

ORAL

**3. CULTURAL INTERACTIONS DURING THE EARLY UPPER PALAEOOLITHIC PERIOD IN THE LEVANT AND BEYOND: THE CONTRIBUTION OF MANOT CAVE**

*Barzilai, Omry (Israel Antiquities Authority) omryster@gmail.com, Hershkovitz, Israel (Tel Aviv University), Marder, Ofer (Ben-Gurion University in the Negev)*

The Early Upper Palaeolithic of the Levant consists of two cultural entities, "Early Ahmarian" and "Levantine Aurignacian", which are assumed to have coexisted at ca. 36/34,000 -28/27,000 Cal BP. The Early Ahmarian, distributed throughout the Levant, is conceived as local tradition whereas the Aurignacian, restricted to few cave sites in the Mediterranean woodland region, is considered an interference of European population/s.

A recent excavation project at Manot cave in the western Galilee, Israel exposed at least five archaeological layers corresponding with the Early Upper Palaeolithic stage.

Four excavation seasons resulted with rich archaeological finds attributed to the Early Ahmarian and Aurignacian traditions that are currently dated to 40,000-31,000 cal. BP.

This paper presents the chrono-cultural sequence at Manot cave with an emphasis on the two traditions. These are further compared to other parallels from the Levant region and beyond, which reflect (or not) the cultural interactions during the Early Upper Palaeolithic.

#### **4. NORTH-SOUTH CONNECTIONS DURING THE PRE-POTTERY NEOLITHIC: A POINT OF VIEW FROM THE DEAD**

*Bocquentin, Fanny (CNRS) fanny.bocquentin@cnrs.fr, Ortiz, Anabel (Universitat Autònoma de Barcelona) inhija@hotmail.com*

The processes of Neolithisation developed in the area of the Near East between 12,000 and 7,000 cal. BC were related to important economic, social and cultural changes in the people lifestyle. One of these notable changes is observed in the funerary practices, not just in the pattern of location of the graves but in the treatment of the bodies. The Pre-Pottery Neolithic (PPN) burials which have been found in great quantity over decades of archaeological works carried out in the north and south areas give, for the first time of the Levantine history, the opportunity to compare the funerary treatment developed in this period throughout the area. The way of handling corpses is an important part of group identities which must be thorough considered. If the PPN burials are known to be quite diverse over time and place, we expect to give an overview of burial customs in the Levant and debate in details some uncommon funerary gestures as secondary burials, seated primary burials or cremation, in order to discuss the connections and disconnections between north and south highlighted by the dead community.

#### **5. CONNECTIONS AND DISCONNECTIONS IN LITHIC PRODUCTION BETWEEN NORTHERN AND SOUTHERN LEVANT DURING THE PRE-POTTERY TO POTTERY NEOLITHIC TRANSITION: A VIEW FROM BEISAMOUN, CENTRAL LEVANT**

*Borrell, Ferran (Centre de Recherche Française à Jérusalem)*

*silmarils1000@hotmail.com*

*Khalaily, Hamoudi (Israel Antiquities Authority) hamudi@israntique.org.il*

During the Pre-Pottery (PPN) to Pottery Neolithic (PN) transition (ca. 7,000 cal. BC in the northern Levant, slightly later in the southern Levant) broad changes in cultural and economic patterns occurred in the Levant. These ran parallel to significant changes in lithic technology such as the transition from blade to flake production. The causes and consequences of the major socio-economic changes are still debated (agricultural intensification, abandonment of hunting, decline of different degrees of specialized artisans, etc.) and have become one of the most urgent issues facing present Neolithic research in the Levant. The full characterization and reconstruction of human behavior related to chipped stone tool production at Beisamoun in the Hula Basin, central Levant, provides an excellent opportunity to understand the mechanisms through which the PPN to PN transition occurred in the central Levant. Moreover, the central Levant is the key to identifying connections and disconnections between northern and southern Levant during this unstable period, and increasing the general understanding of the Neolithisation process in the Levant.

ORAL

#### **6. EXPLORING CONNECTIONS AND DISCONNECTIONS BETWEEN NORTHERN AND SOUTHERN LEVANT IN THE EARLY BRONZE AGE THROUGH THE ANALYSIS OF FUNERARY DATA**

*Bouso, Monica (UdL/GRAMPO) monicabouso@gmail.com*

The aim of this presentation is to understand and define the diverse burial customs of northern and southern Levant cultures during the 3rd millennium BC, as well as to assess the level of communication and interaction among them.

Funerary data offer an essential means of learning about the lives of past peoples. This type of archaeological inquiry contributes to a broader understanding of social organization and political and ritual structure by studying aspects such as the type and location of funerary structures, the type of disposition of the anthropological remains, and the disposition, assemblage and origin of the grave goods. It will be the analysis of the interrelation among all of these aspects that should allow us to define the burial customs practiced in these regions and to explore their possible connections and disconnections. Additionally, the different chronological sequences used

in these regions and their place within a single chronology will be discussed.

ORAL

## 7. THE IMPACT OF THE NEOLITHISATION PROCESS ON THE FUNERARY PRACTICES AND HEALTH STATUS OF THE LEVANT POPULATIONS: FROM NORTH TO SOUTH

*Chamel, Bérénice (CNRS Archéorient) berenicechamel@gmail.com*

*Le Mort, Françoise (CNRS Archéorient) francoise.le-mort@mom.fr*

Numerous archaeological excavations were conducted in the Levant that have produced large quantities of human skeletal remains recovered from Pre-Pottery Neolithic sites. In the last few decades, research in biological anthropology gradually intensified in the region and recently developed approaches have led to new results. Analysis of the documentation provided evidence of the increased diversity of funerary practices and of the prevalence of both infectious diseases and stress indicators related to new lifeways, from the hunter-gatherers to the first farmers. Thanks to the new set of available data, it is now possible to analyse the impact of the Neolithisation process on the funerary practices as well as on the health status of the populations, in the Northern Levant as in the Southern Levant and to perform comparisons between the two regions.

ORAL

## 8. NORTHERN CULTURAL INFLUENCES IN SOUTHERN LEVANT BURIAL TRADITIONS AND IMAGERY IN THE CHALCOLITHIC PERIOD

*Dina, Shalem (Kinneret Institute for Galilean Archaeology) shalemdina@gmail.com*

One of the widely known burial traditions in protohistoric periods is the secondary burial in ossuaries and jars from the Late Chalcolithic period (4500-3700 cal. BCE), known only from sites in Israel.

In 1995 an excavation conducted in a Late Chalcolithic burial cave at Peqin, Upper Galilee, Israel, revealed an unusually large number of finds which shed new light on the anthropomorphic imagery of the period. The ossuaries and jars bear anthropomorphic features, which include a large prominent nose and a pair of large eyes,

sometimes other human features such as hair, mouths, hands, female breasts and beards, as well as zoomorphic, geometric and floral symbols. Although the phenomenon of this burial tradition of richly decorated ossuaries and jars seems to be unique to this period and to a very limited area in the Near East it is here suggested that its origin may partially be in the symbolism of the Neolithic period.

An example of such tradition is the special treatment of the head of chosen individuals in secondary burials.

Moreover, a careful examination of the motifs on the ossuaries suggests that many of them origin in the northern Levant. If so, these symbols partially survived and were culturally transmitted and transformed into Late Chalcolithic social contexts.

ORAL

## 9. THE CHRONOLOGY AND DISPERSAL OF THE PRE-POTTERY NEOLITHIC B CULTURAL COMPLEX

*Edwards, Phillip (La Trobe University (Melbourne) p.edwards@latrobe.edu.au*

The Pre-Pottery Neolithic B (PPNB) period saw the establishment of village farming in South-west Asia and it is one of the earliest cultural complexes for which we can follow complex patterns of interaction across the Mediterranean Levant. This paper reviews the current status of a prior model of PPNB chronology published in 2004 by the author and colleagues.

The study reviews stratigraphy, radiocarbon dates and associated material culture sets from Pre-Pottery Neolithic A (PPNA) and Pre-Pottery Neolithic B (PPNB) sites from the northern and southern Levant and Cyprus.

This review argues that, over the past decade, excavations of new Early Neolithic sites across the Levant and on Cyprus have lent additional support to the model that the Early PPNB (EPPNB) emerged in the northern Levant around 9,600 BP/ ~ 9,200 cal BC and the PPNB entity or many of its derived traits appeared significantly later in the southern Levant later around 9,200 BP/ ~ 8,300 cal BC.

ORAL

## 10. CONTACTS BETWEEN THE SOUTHERN AND NORTHERN LEVANT IN THE FIRST HALF OF THE 5TH MILLENNIUM BC: A VIEW FROM JORDAN

*Gabrieli, Eva evagabrieli@hotmail.com*

In the first half of the 5th millennium BC, the territories

which roughly correspond to present-day Jordan, unlike the vast majority of the Near East, do not seem to be significantly involved in long-distance trade networks. However, even if evidence relating to exchanged items is rather meagre, the similarities apparent in the material culture point to the existence of an 'interaction sphere' which implies some sort of connexion with the Northern Levant.

Contacts between the Chalcolithic Levantine populations, although their meaning and modes are still scarcely understood, took place both within and between communities, but almost certainly did not usually exceed short or middle-range distances, apparently perpetuating older, well-established practices. Such long-standing interactions, apart from the more easily recognisable stylistic or formal similarities displayed by the artefacts, can account for the emergence and adoption of important innovations, like the tournette or, later, metallurgy, and the sharing of social/ritual customs, like the segregation of the dead. In fact, the comparison of the sequences provided by selected archaeological sites from all over the Levant, despite differences occurring at a local level, allows us to recognise some broad parallel lines of development or commonalities, highlighting the greatest importance of these contacts in entangling and structuring Levantine communities over the time, even in the case of areas which seems to be scarcely connected like the Transjordanian territories.

## 11. SHARING SPHERES IN 6TH MILLENNIUM BC CAL. HALAF COMMUNITIES AND BEYOND

*Gómez Bach, Anna (Universidad Autónoma de Barcelona) annagomezbach@gmail.com*

*Cruells Banzo, Walter (Universidad Autónoma de Barcelona) cruellsw@gmail.com*

*Molist Montaña, Miquel (Universidad Autónoma de Barcelona) miquel.molist@uab.cat*

Sixth millennium BC cal. is a large period where several sustainability strategies and technological processes took place by farmers and herders groups. The recent field works in northern Mesopotamia, mainly in Syria, but also in Levant, Jordan and Israel, provide an important database suitable for a reflexion about the social and economic strategies attributed to the Halaf and other "cultural groups identified (Wadi Rabah, Gassulian, etc.). Archaeological remains and material objects shows a more complex interaction between communities and regions and only their attribution in well stratigraphic

contexts becomes essential for a review perspective both in Levant and upper Mesopotamia. Analyzing sequences, materials, networks and circulation of manufactured items and raw materials this work wants to put in order the results obtained. Also, absolute C14 data available will enrich to establish a more consolidated chronological framework for these 6th millennium BC cal groups.

Through the regional sequences this paper tries to identify the presence or absence of connections between regions that, in fact, are not very distant from each other.

ORAL

## 12. POSIBLE CONTACTS OF HALAF AND UBAID WITH THE SOUTH LEVANT

*Gil Fuensanta, Jesus (Seminario de Estudios Orientales ) jesus.gil@uam.es*

Much has been debated on the possible influences or connections of northern Syria and eastern Anatolia in the southern Levant during the 5th and 4th millennia BC. The presence of possible materials in connection with the Halaf and Ubaid cultures in parts of the southern Levant (i.e. Israel) offers a new starting point for this debate. So far, although the 5th millennium (Halaf and Ubaid cultures) offers relations between the two regions with a relative diffuse character, the connections seem clearer during the 4th millennium BC.

ORAL

## 13. THE PPN IN SOUTH LEVANT AND THE RELATIONS WITH OTHER REGIONS. A CLIMATOLOGICAL QUESTION?

*Gil Fuensanta, Jesus (UAM (Spain) jesus.gil@uam.es, Boynikolu, Ediz (Trakya Üniversitesi (Turkey) boynik@gmail.com*

After the research, the Pre-Pottery Neolithic (PPN) period of the South Levant have been compared to the cultural development in neighbouring regions during the same period, ca. X to VIII Millennia BC.

The PPN sites taken into account for this comparative study include, among others, North Mesopotamian places such as Abu Hureyra, Mureybet, Jerf el Ahmar, Sheikh Hassan, Tell Halula, or Tell el Abr, plus other Turkish sites such as Gobekli Tepe, Nevali Cori, Teleilat, or Cayonu. The Southern Levantine PPN sites include places from different regions, such as Ain Ghazal, Beisamoun,

Gesher, Hayonim Terrace, Jericho, Nahal Oren or Yiftahel, among others.

The comparison of PPN lithic sequences and cultural contexts of Southern Levant to the Northern Mesopotamian bulk offers certain similarities but some local variations. As example, the blade technology was very sparsely through all the areas into study. The lithic industry shows conservatism for a long period (naviform and bipolar cores, burins) but also homogenous changes in most of the affected regions when certain innovations happened from time to time. The fact of a dispersal of those industries could be not a reflection of climatological change but the possibility of long exchanges and mobility through this extensive period.

This PPN long sequences lived deep changes in the ecosystems and lifestyles through the whole extension of the period. The transformation of hunter-gatherer societies into agrarian societies could have been not simultaneous in all the regions. In several of the researched areas, the hunting or foraging remained a basic diet for most of the societies during the PPNA and most of the PPNB in the Middle and Upper Euphrates region. Agriculture took a long time to be adopted as the main source for the diet. The extinction of some wild species in regional areas could have been an important trigger that forced a change of strategy.

For certain climatological and ecosystem changes happened in the transition of the PPNA to the PPNB and the end of the same PPNB of the Near Eastern regions with the result of the abandonment of sites and ex-novo habitation of places, if no changes into the ritual and lifestyles of the sites.

The climatological conditions of certain areas could be explained in cases as a trigger, and not perhaps as the main cause, for the cultural developments of the PPN.

#### **14. TESTING THE EASTERN TRAJECTORY: IS THERE ANY GENEALOGIC RELATIONSHIP BETWEEN THE AHMARIEN AND EUROPEAN EARLY AURIGNACIAN?**

*Hauck, Thomas (Institute for Prehistory, University of Cologne) Thomas.Hauck@uni-koeln.de*

Searching for the origin of the European Upper Palaeolithic (UP) remains a major scientific challenge. Questions concern the place and time of UP innovations as well as their subsequent diffusion trajectory. Moreover, it is commonly believed that the colonisation of Europe by Anatomically Modern Humans is closely related to the marked change in the archaeological landscape be-

tween 45.000 and 35.000 years ago. Some models are based upon the assumption the spread of the UP cultural package followed a rather uniform and linear trajectory from the place of its origin, the Middle East, over SE Europe to the Atlantic. In this respect, the Early Aurignacian of Europe is seen as a derivative of the Ahmarian. Alternative models propose a multi-local origin of UP technology.

Notwithstanding which scenario is favoured, the Early UP landscape of Europe was more complex than previously thought. In this paper, we critically examine the proposed genealogic relationship between the Ahmarian and the Early Aurignacian of Europe. It will be shown that both cultural units witness a high degree of variability sincerely affecting the validity of cross-continental linkages.

It is only by identifying contextual areas within both cultural units that meaningful comparisons can be made.

ORAL

#### **15. CONNECTING NORTH AND SOUTH LEVANT THROUGH COMPLEX NETWORKS OF OBSIDIAN EXCHANGE DURING THE PPN: A MATHEMATICAL SIMULATION**

*Ibáñez Estévez, Juan José (IMF-CSIC) ibanezzj@imf.csic.es*  
*Ortega, David (IMF-CSIC) ortega@imf.csic.es*  
*Campos, Daniel (Dpt Física-UAB) Daniel.Campos@uab.cat*  
*Méndez, Vicenç (Dpt Física-UAB)*  
*Khalidi, Lamya (Archéorient-CNRS) lamya.khalidi@mom.fr*  
*Teira, Luis (III PC-UC) luis.teira@unican.es*

Most models used to explain the mechanisms of obsidian exchange during the Neolithic in the Near East continue to be based on the down-the-line model proposed by C. Renfrew in the 1960s. However, Renfrew's model, which results in a very regular and clustered network of exchange, does not permit the circulation of obsidian to distant regions of the Near East as it is observed in the archaeological record.

In order to better replicate the archaeological data and to better understand the parameters that may have been involved in the modalities of obsidian exchange, we explore multi-agent modeling which can treat the topic of obsidian exchange as a complex system composed of interacting agents (Neolithic communities).

We propose a small-world exchange network, in which some Neolithic communities were able to move long distances to attain new exchange partners, as an alternative to the down-the line model. Multi-agent simulation allows us to test the small-world hypothesis and to ex-

plore the characteristics of obsidian exchange networks during the PPN. Later, the results of the mathematical modelling are compared with the archaeological data of obsidian presence in the Levant

The existence of a small-world type network of exchange and interaction during the PPNA explains the co-evolution of the North and South Levant at the dawn of the Neolithic. Even more complex and efficient networks of interaction during the PPNB gave rise to a kind of cultural similarity along the Levant, which has been defined as a PPNB interaction sphere or a PPNB civilization.

### 16. SOME ICONOGRAPHIC MOTIFS FROM THE 6TH-5TH MILLENNIA BC IN MESOPOTAMIA AND THE LEVANT: CLUES FOR CULTURAL CONNECTIONS

*Milevski, Ianir (Israel Antiquities Authority) [ianirmilevski@gmail.com](mailto:ianirmilevski@gmail.com)*

*Getzov, Nimrod (Israel Antiquities Authority)*

*Galili, Ehud (Israel Antiquities Authority)*

*Horwitz, Liora K. (The Hebrew University of Jerusalem)*

Several artefacts bearing iconographic motifs have been recovered in recent salvage excavations and surveys in southern Levantine sites, dating to the 6th – 5th millennia BC. The artefacts were manufactured on a variety of raw materials (bone objects and stone palettes) and depict anthropomorphic motifs - often a female figure, occasionally accompanied by horned animals and trees (usually identified as palms). In the southern Levantine sites (Hagosherim, Ein Zippori and the submerged site of Neve Yam) these motifs are associated with the Wadi Rabah culture, identified with the Late Neolithic/Early Chalcolithic periods.

These artefacts have attracted attention since they resemble objects from the northern Levant and Mesopotamia. For example, some of these motifs appear in stelae from Ashur and Mari and depict an association between anthropomorphic symbols and horned animals and occasionally with trees.

Other 6th and 5th millennia BC iconographic items, found in both the northern and southern Levant, show a schematic representation of rams heads, probably representing personal amulets. These objects are associated in the north with the Halafian culture (Domuztepe), and in the south (Kabri, Hagosherim and perhaps Gilat) with the same Late Neolithic/Early Chalcolithic entities as the anthropomorphic motifs noted above.

These finds reinforce the suggestion, put forward decades ago by Jacob Kaplan, on the relations between the

southern Wadi Rabah culture and the northern Halafian. The following paper will describe and analyse the motifs and distribution of these iconographic bearing artefacts in the two Levantine regions

ORAL

### 17. THE PROTOURBAN MODEL OF URUK: A COMPLEX PROCESS OF TERRITORIAL EXPANSION DURING THE 4TH MILLENNIUM BCE

*Montero Fenollós, Juan Luis (Universidad de A Coruña) [fenollos@udc.es](mailto:fenollos@udc.es)*

*Sanjurjo Sánchez, Jorge (Universidad de A Coruña) [fenollos@udc.es](mailto:fenollos@udc.es)*

Archaeological activity in the Near East allowed to verify that the Middle and Late Uruk period (Late Chalcolithic 4-5) represented a geographic expansion process from southern Mesopotamia to northern (Syria and eastern Turkey) and esaterns territories (western Iran) during the middle of 4th millennium BC.

The study of the material culture defined as "southern Mesopotamia-style Uruk" in the Syrian Euphrates valley (from north to south) has helped to define that there were different types of protourban settlements in Syria within a hierarchical process characterized by mass production.

This is the case of the bevelled rim bowls, a diagnostic Uruk-type pottery of unknown function, the location of which archaeologists have intended to draw the connections and disconnections of the Uruk geography. Our working hypothesis is that these bowls are material evidence of a new and common food culture of leavened bread.

ORAL

### 18. THE "NATUFIAN" IN NORTHERN LEVANT: THE LATE EPIPALAEOLITHIC OF DEDERIYEH CAVE, AFFRIN VALLEY, NORTHWEST SYRIA

*Nishiaki, Yoshihiro (The University of Tokyo) [nishiaki@um.u-tokyo.ac.jp](mailto:nishiaki@um.u-tokyo.ac.jp)*

*Kanjo, Yosef (Aleppo Museum) [kanjou00@yahoo.com](mailto:kanjou00@yahoo.com)*

*Takeru Akazawa (Kochi University of Technology) [akazawa.takenu@kochi-tech.ac.jp](mailto:akazawa.takenu@kochi-tech.ac.jp)*

The geographic distribution of the Natufian remains unclear. Its northern extension is particularly ambiguous. Archaeological assemblages showing some cultural sim-

ilarity with the Natufian did exist in the northern Levant during the Late Epipalaeolithic; however, some authors believe that they represent a local cultural tradition, while others interpret them to be a consequence of the Natufian's expansion from the south. One difficulty in investigating this issue is that well-documented Late Epipalaeolithic sites of the northern Levant are confined to the inland steppe—notably, Tell Abu Hureyra and Mureybet on the Upper Euphrates. These sites are rather isolated from the Natufian homeland in the southern Levant and sites bridging the two regions are absent. In addition, the environmental setting of the Euphrates steppe is significantly different from the Mediterranean woodland dominating the Natufian homeland. This sharp contrast might have resulted in functional variability of sites and would thus blur cultural affiliation of the northern group. In this respect, the discovery of Late Epipalaeolithic assemblages at Dederiyeh Cave in the woodland region near the Syrian-Turkish border is remarkable for providing us with a different dimension. The case at Dederiyeh is comparable to the Natufian homeland in terms of ecological setting, but is geographically closer to the Euphrates steppe. Comparing the cultural remains from Dederiyeh, the southern Levantine Natufian, and the Upper Euphrates entity should help clarify the issue.

ORAL

### 19. BETWEEN THE DESERT AND THE SEA - THE LEVANTINE CORRIDOR DURING EARLY PREHISTORY

*Sharon, Gonen (Tel Hai College) gonen@telhai.ac.il*

The Mediterranean environment of the narrow strip of land between the Mediterranean Sea to the west and the Arabian Desert to the east has enabled its use as the king's highway leading in and out of Africa since the dawn of human evolution. World famous archaeological sites, ranging in age from 1.5 million years to present, excavated along the Levantine corridor offer a unique opportunity to explore the fundamental questions of Early Human migration and evolution. The rich lithic assemblages excavated are the primary tool enabling us to reconstruct the history of human migration, behavior, technology and cultural development. The primary assemblages represent migration waves Out-of-Africa. As many as five distinguishable phases can be identified within the Lower Palaeolithic cultural sequence in the Levantine Corridor. The Middle Palaeolithic is an additional, stand-alone cultural phase in which the emergence of Anatomically Modern Humans occurred. Studying the uniquely preserved sites of the Levantine Corridor al-

lows us to suggest a continuous sequence of migration waves (or local cultural developments?) in a resolution that cannot be achieved in other regions of the world. This paper aims to present the different identifiable migration "waves" visible from the Levantine Corridor lithic assemblages, estimate their chronology, origin and geographical distribution and discuss their significance for our understanding of Early Human migration and behavior during the Middle and Late Pleistocene at the gateway to Europe.

ORAL

### 20. THE RELATIONS BETWEEN THE NORTHERN AND SOUTHERN LEVANT DURING THE SECOND HALF OF THE 7TH MILLENNIUM CAL BC: ÉVIDENCES FROM POTTERY

*Vieugué, Julien (Centre de Recherche Français de Jérusalem) archeojulien@hotmail.com*  
*Garfinkel, Yosef (Hebrew University of Jerusalem) garfinkel@mscc.huji.ac.il*

The second half of the 7th millennium cal BC corresponds to the end of the Neolithisation process in the Near-East which is connected with the widespread adoption of ceramic vessels throughout the region. The completion of the Neolithic "revolution" goes hand in hand with a process of splitting up of cultural entities. This paper addresses the relations between the northern and southern Levant during the Pottery Neolithic period, relying on the typo-functional aspects of fired clay containers. Recent research on the use of the earliest ceramic vessels from the southern Levant has demonstrated the diversity of the culinary functions of pottery, ranging from the storage to the consumption of foodstuffs. Storage vessels and cooking pots are the most frequent functional categories within the ceramic assemblages. This is apparently not the case in the northern Levant where the pottery from the same period seems to have been mainly used for the food presentation and consumption. Such differences in the pottery range emphasize the existence of regional variations in the culinary habits of Neolithic communities during the second half of the 7th millennium cal BC.

**1. ROCKS, SOILS, MOUNDS AND MEGALITHS: AN APPROACH TO NEOLITHIC LANDSCAPES AND THE ENVIRONMENT OF NORTH-EASTERN GALICIA**

*Rodríguez Casal, Antón Abel (Universidad de Santiago de Compostela) antonabel.rodriguez@usc.es*

*García-Rodeja Gayoso, Eduardo (Universidad de Santiago de Compostela) eduardo.garcia-rodeja@usc.es*

Considering the megalithic culture as an atlantic and coastal phenomenon has been a cliché in Galician archaeological literature. This concept was supported by the fact that most megalithic necropolises were located in the northwestern areas of Galicia. With odd exceptions, the province of Lugo had always been marginalized in research programmes. In 1993 we proposed an ambitious research project, which saw the start of archaeological prospection from precisely the most unexplored area, the province of Lugo. The intention was to try to provide answers to a few questions that had been raised. On the occasion of the International Meeting held in Santiago de Compostela in 1996, we had already presented a synthetic work about the megalithic culture of Lugo. Nowadays, we have a number of 1.051 megalithic monuments and a number of pedological and petrographical analytics in which this work is based. In order to establish the relationship between geological and pedological characteristics of the megalithic surroundings sites, the geological materials and the soils of 29 mounds of Lugo have been sampled, described and analyzed. In the different levels that were studied (131 samples), both the characterization of their physicochemical properties and the particle size analysis were performed. In order to determine the rock type and its mineralogical composition, were carried out the petrographic analysis of 36 thin rock sections using an optical microscope. For some samples, a brief description of their weathering degree was also included.

The mounds generally presented the existence of soil materials with properties comparable to those of the most representative soils of the surrounding area. In general, the organic matter contents on the surface horizons of the mounds are lower than those on the surface horizons of the surrounding soils. The contribution of the vegetation developed on the monuments over time could explain the trend to a higher organic matter content in many of the studied surface layers. The results of the particle size analysis are consistent with what would be expected from the soils developed from the local geological materials. Through

petrographic analysis we have determined the rock type used in the construction of the megaliths and their relationship with the local geology.

Our contribution to the study on the interrelations between environment and megalithic monuments, with the newness of systematically using, for the very first time in Galicia, pedological and petrographical data, challenges previous theories, which were based more on speculation than on scientific scrutiny. In this sense, we have clearly seen that the nature of soil seems to be less important than the litology when it comes to the choice of the megalithic monuments location.

---

ORAL

**2. NEOLITHIC SETTLEMENT AND FUNERAL SPACE IN GALICIAN MEGALITHIC PHENOMENON: A SYNTHETIC STUDY BASED ON TWO DECADES OF RESEARCH**

*Carrero Pazos, Miguel (Universidad de Santiago de Compostela) miguel.carrero@usc.es*

*Rodríguez Casal, Antón Abel (Universidad de Santiago de Compostela) antonabel.rodriguez@usc.es*

Since the 1990s, the research group "Arqueoloxía e ecoloxía do fenómeno megalítico galego" at the University of Santiago de Compostela, has been developing intensive fieldwork prospection that has generated a large database, containing about 4.000 monuments. Therefore, we now are in a position to establish the basis of a methodology for studying the Galician megalithic complex based on different statistical analysis, using computer tools like the geographical information system (with LiDAR extension), all from a holistic perspective.

The main purpose, hence, will be to provide us with a whole range of formal tools that will help us to explore the new realities of the megalithic phenomenon. In this sense, on the database, that nowadays has more of four thousand monuments, we are to test mathematical and statistical analysis. The guideline established by our research group will be followed when the first assessments of the work developed in the megalithic phenomenon of Lugo province (1997) were studied, then also, later in the Galician-Portuguese Miño region (Eguileta, 1994; Sousa, 2012; Carrero, 2012), as well as the more intensive work developed in other country areas. Accordingly, we are to try to characterize and contextualize both dolmenic monuments and burial mounds, all according to their relation with the

environment. We will also go deeper into the patterns of location and settlement in order to indicate similarities and differences in the main groups of monuments, by implementing the predictive model. Furthermore, we are to study the volumes of these monuments.

Nowadays, it can be highlighted that one of the main study tools for the megalithic complex are the geographical information systems, to such an extent that they have constituted as a separate, specialized line of research. This technology is now widely used for the wide array of possibilities it gives, not only analytical but also those dealing with time saving.

In addition, through the use of LiDAR, which is now publicly available to all the regions of Galicia (although the data are not rated and they appear in ellipsoidal heights), we can implement our archaeological prospection, something in fact is already being done by checking the database. The rugged Galician terrain, characterized by intense vegetation, often makes intensive exploration impossible. The development of this applied technology seems to fill the gap in the survey prospection, although at the moment it is at an early stage.

To sum up, we can establish the basis, together with using the traditional methodology based on archaeological prospection, as a general outline of the possibilities that the mathematical-statistical analysis and new technologies (GIS and LiDAR) could provide in the research of the Galician megalithic phenomenon.

---

ORAL

### 3. STRATIFIED MEMORIES: PAINTED ORTHOSTATES AND MEGALITHIC ARCHITECTURES

*Carrera, Fernando (Escola Superior Conservación Galicia)*  
[fcarrera@uvigo.es](mailto:fcarrera@uvigo.es)

*Fábregas, Ramón (Universidade de Santiago de Compostela)*  
[ramon.fabregas@usc.es](mailto:ramon.fabregas@usc.es)

The systematic analysis of the preserved paints on the stones making up the megaliths can bring insights about the Neolithic cultural complex surrounding this kind of funerary architectures. From that standpoint, we have centered our efforts in NW Iberia approaching, among other issues, the question of the diverse painting techniques and the eventual superimpositions reported. Other issues we have dealt with are the images associated to certain painting techniques, the radiometric dates –either from the paints or from the

monuments themselves- or the architectonic designs and their transformation.

As a result, we shall be putting forward some proposals regarding the relationship between certain chamber designs and specific painting techniques in a well-defined lapse of time. Such an interpretive exercise might be particularly useful for the research of the earlier stages of the regional megalithic phenomenon.

---

ORAL

### 4. MEGALITHIC ARCHAEOASTRONOMY IN GALICIA: AN ENLARGEMENT OF THE ARCHAEOASTRONOMICAL DATABASE OF ORIENTATIONS OF GALICIAN MEGALITHS IN QUANTITY AND QUALITY

*Vilas Estevez, Benito (University of Wales Trinity Saint David)*  
[vieito4@hotmail.com](mailto:vieito4@hotmail.com)

Galician Megalithic culture is characterized by a large number of monuments throughout the country, albeit of different types. Following the classification of Anton Rodríguez Casal there are: paramegalithic chambers, simple dolmens, passage graves and megalithic cists. Chronology of the megalithic period in Galicia could be situated between 4500-2000 cal BC. All these different megalithic monuments display clear orientations in the way they are structured. Comprehensive surveys of similar monuments elsewhere have suggested that they are oriented toward particular areas of the horizon, drawing attention to natural markers in the landscape (Christopher Tilley) or to places where astronomical events, such as sunrise, moonrise and the rising of the stars, could be witnessed and even predicted (Michael Hoskin, Clive Ruggles). With respect to the megalithic orientations in Galicia only two previous studies have been undertaken: one in 1993 which measured two dolmens, and another in 1997 where 36 dolmens in different regions of Galicia were measured and both considered only solar alignments. This project aims to amplify the database in quantity and quality, considering not only potential solar alignments but also lunar, stellar and topographic alignments.

To study the orientation of the monuments, it is required to measure the azimuth and the horizon altitude. In this project all measurements were made using a compass (which values were corrected for the True North by using the NGDC geomagnetic calculator), a clinometer (when this will not be possible due to vegetation, the software HeyWhatsThat will be used to obtain horizon altitudes) and a handheld GPS unit.

To define the line of orientation, that is the line one wants to measure the azimuth of, Hoskin used the middle point of the backstone and the middle point of the corridor. This determines something he called the axis of symmetry. But given the present state of dolmens in Galicia, and that not all megalithic structures have a corridor this method was adapted.

In addition a new method to complement this study will also be used: the window of visibility, developed by Fabio Silva, that it is based on the idea that our notions of a defined axis and a precise alignment were not a primary concern of the dolmen builders. So as not to exclude other possible alignments that fall on this window of visibility, but not on the axis of symmetry, the total arc of horizon visible from within the chamber is measured. The results show that the monuments are oriented towards particular areas of the horizon where astronomical events, such as sunrise, moonrise and the rising of the stars, could be witnessed and even predicted.

This project has helped to amplify the database of orientations of Galician Megaliths, in quantity and quality, by direct fieldwork measurement and it has proved that the monuments were not randomly oriented but on the contrary to specific astronomical events. This project also reveals the importance of this kind of studies to help developing our knowledge about past civilizations.

#### ORAL

### **5. ARCHAEOLOGY AND MEGALITHIC HERITAGE OF COSTA DA MORTE: THE OUTCOMES OF AN INTERDISCIPLINARY RESEARCH.**

*Rodríguez Casal, Antón Abel (Universidad de Santiago de Compostela) antonabel.rodriguez@usc.es*

*Romaní Fariña, Emiliana (Universidad de Santiago de Compostela) emiliana.romani@usc.es*

Costa da Morte, in the Galician Land's End is one of the areas with the highest megalithic density in the northwest of the Iberian Peninsula, and also has some of the more emblematic monuments (such as Dombate, Parxubeira, Pedra da Arca, Arca da Piosa, Casa dos Mouros, Casota de Freán, Pedra Cuberta...). These were some of the reasons why the Galician Megalithic Park, was placed here, within the Galician Archaeological Heritage Network, created by the Galician autonomic government.

Our research group, consisting of archaeologists, geologists, edaphologists, geographers and art historians of the University of Santiago de Compostela, has carried out intensive field work over the fourteen municipalities of Costa da Morte in the last few years, providing a wide monument field record, the creation of distribution maps, database, topographical surveys and the detailed analysis of burial mounds. All of this has been completed with laboratory work: database creation, geographic information systems, statistics and mathematical analysis.

The work contains a very specific line of research that our group has been developing since 1995. The first main objective that we proposed were to obtain a rigorous and updated mound distribution map, which allowed us to fill in the gaps in archaeological literature and to investigate the megalithic culture from an objective base and contextual evidence. After this initial stage, we started a second, focused on field work using an extensive and probabilistic prospecting, combined with intensive prospection in some areas. The result of the campaigns was the cataloging of 304 megalithic sites. Likewise, we have carried out the survey with total station of the main megalithic sites, a diagnosis of the monument's conservation, including some proposals for restoration and heritage management.

From the field work database we are able to define the environment factors that are conditioning and/or determining the choice of setting the megalithic tombs. In connection with this, we also have analyzed the possibility that the transit and visibility would influence the location of the mounds. In conclusion, we are able to say that the results we obtained provide us with a better understanding of the ecotypes used by the communities who built the megalithic monuments, as well as an in-depth approach to the regional differences that exist among them. Our research provides substantial support for the creation of a Galician megalithic park in the Costa da Morte, which will include the entire catalogued heritage. Nearly twenty large megalithic structures are to be reevaluated, linked to cultural tourism. Archaeology, conservation and musealization are therefore, the main axes of the ongoing project on the megalithic culture in the Costa da Morte.

ORAL

## 6. A VIEW FROM THE CENTER: MEGALITHS OF THE DEZA REGION

*Vilaseco Vázquez, Xosé Ignacio (Grupo de Estudos para a Prehistoria do NW Ibérico. Departamento de Historia I. Universidade de Santiago de Compostela) ignacio.vilaseco@usc.es*

*Fábregas Valcarce, Ramón (Grupo de Estudos para a Prehistoria do NW Ibérico. Departamento de Historia I. Universidade de Santiago de Compostela) ramon.fabregas@usc.es*

The Deza district, with 1.027 km<sup>2</sup> of surface, lies in a fairly central position within the Galician lands. It has a varied landscape, being formed by a series of parallel valleys running down from the mountain ranges to the South and East while the river Ulla constitutes a clear boundary towards the North.

Before the surveys done by our research group in 2002-2004 no systematic work had been carried out in that area. Still, it was reknown as a megalith-rich region with a significant number of painted or carved chambers. The aim of our research was making an appraisal of the preservation of the numerous mounds, noting the alterations affecting them and evaluating the risks for their survival. Though no intensive survey was undertaken, we came in the end with information on 475 barrows, 125 previously unknown. Later on, other researchers raised that figure to 570, or a density of 0,55 mounds/km<sup>2</sup>.

Such a large sample allows us to make some statements about the siting of the mounds, their formal variability, chamber tipology or the artistic decoration found in several cases. As to the first aspect and unlike the usual pattern elsewhere in Galicia, the largest concentrations are not found on the flattened tops of the mountain ranges. Moreover, the find of rock-art on stone outcrops nearby puts some qualification on the alleged relationship between both phenomena. Otherwise, recent digs are giving interesting glimpses on the building process and use of the megaliths.

A final word on the issue of the survival of the mounds: 19% of those previously known had been destroyed at the time of our survey, mostly during the last 20 years; the main part show serious problems of preservation and barely a 14% were in good condition.

ORAL

## 7. THE MEGALITHIC PHENOMENON IN THE GALICIAN-PORTUGUESE MIÑO REGION: NEW RESEARCH PROPOSALS FROM A COMPREHENSIVE STUDY MODEL

*Sousa, Goreti (CIESG/Escola Superior Gallaecia) goretisouza@esg.pt*

*Carrero Pazos, Miguel (Universidade de Santiago de Compostela) miguel.carrero@usc.es*

*Eguileta Franco, José María (Departamento de Arqueoloxía. Concello de Ourense) arqueoloxia.jeguileta@ourense.es*

The Miño River, main defining element of the current political border between northern Portugal and Galicia, is here taken from an integrative perspective, as a communication element between landscapes and communities in what is here identified as the Galician-Portuguese region of Miño. This region shows a clear geographical unity. The Galaico-Duriense massif extends to Portugal the natural elevations of Galicia and the alignment of the large river valleys straightens that unity. Archaeologically, a ??cultural identity in the North western region of Iberia has been suggested by authors such as López Cuevillas. However, several factors associated with different traditions and methodologies of archaeological work hampered, until recently, the development of comprehensive studies of this reality. The field work carried out in this area, since 2011, resulted in a database with more than 400 monuments, providing a solid base on which to perform statistical analysis, trying to achieve global interpretations.

An integrated methodology, applied to one of the most interesting Megalithic areas of the Northwest, provides excellent conditions for undertaking a comprehensive project, based on the work started on the beginning of the XX century that was also the subject of the PhD thesis of Eguileta Franco (1994). Despite its small size this area presents more than two hundred dolmen, of monumental architecture. The relationship between Megalithic culture and topography is evident, with two concentrations, one on the Salas valley and other in the Serra do Leboreiro mountain.

Finally some conservation work (eg: displacement of Casiña da Moura) and pedagogic activities (creation of a megalithic circuit on the Salas Valley) have already been carried out.

The proposed research methodology will follow, both, the propositions of previous work in Galicia and northern Portugal (Eguileta Franco, 1994, 2003; Rodríguez Casal,

et al., 1997; Sousa, 2012; Carrero Pazos, 2012) and the models carried out in other peninsular areas.

Different variables will be mathematically processed to study the regularities regarding types, resources, settlement patterns, etc... GIS technology will be applied to study patterns such as mobility and visibility/intervisibility between monuments and territory.

Thus enabling the study of functional significance of megalithic monuments, beyond the strictly funerary aspect. The results allow the establishment of general trends and eventually regional variants, also revealing the criteria behind the construction of each type of mound in a specific place or in association with a particular natural element.

Presented from a holistic perspective, this work will undoubtedly provide, in a comprehensive way, relevant theoretical and operational data for the study of the megalithic phenomenon in the North western region of Iberia. This research model can, then, be applied to other megalithic regions.

## 1. NEW INSIGHTS FROM CYPRUS ON THE BEGINNING OF ANIMAL DOMESTICATION AND ON THE NEOLITHISATION IN THE NEAR EAST

*Vigne, Jean-Denis (CNRS-MNHN) vigne@mnhn.fr*

The recent discoveries in the Cypriot sites of Aetokremnos, Klimonas and Shillourokambos shed new light on the beginning of animal domestication in the Near East, between 10,500 and 7000 cal BC.

The results presented here are based on archaeological and archaeozoological analyses, and on radiocarbon dating.

The osteological analyses and radiocarbon dating of large mammal remains at Aetokremnos and Klimonas evidenced the overseas introduction of this species to the island during the Epipaleolithic, and the control of wild animals long before the earliest evidence of anatomic modification due to domestication.

The introduction of cats as early as 9000 cal BC confirms that the domestication of this species was tightly connected to the birth of agriculture and rodent commensalism.

The later introduction of early domestic goat and cattle evidence an intensification of exchanges of domesticates and early husbandry practices within a vast Near Eastern area of incipient neolithisation (including Cyprus).

The later introduction of sheep (8000 cal BC) emphasizes the diversity of the processes in the different mainland areas and the diversity of the areas of origin of the different domesticates.

The detailed analyses of the evolution of the relationships between humans and the different species of large mammal during the occupation of the village of Shillourokambos (8300-7000 cal BC) provide a very rich image of the opportunistic techniques and strategies which have been used by the PPN people during this time when hunting and control of wild animals was still important besides early husbandry practices.

ORAL

## 2. AN INTEGRATED APPROACH TO THE STUDY OF PIG DOMESTICATION PROCESSES IN THE NEAR EAST

*Alcàntara Fors, Roger (Universitat Autònoma de Barcelona) roger.alcantara.fors@gmail.com*

*Cucchi, Thomas (Muséum National d'Histoire Naturelle. UMR 7209, Paris) cucchi@mnhn.fr*

*Tornero Dacasa, Carlos (Muséum National d'Histoire Naturelle. UMR 7209, Paris) ctornero@mnhn.fr*

*Evin, Allowen (Muséum National d'Histoire Naturelle. UMR 7209, Paris) evin@mnhn.fr*

*Saña Seguí, Maria (Universitat Autònoma de Barcelona) maria.sana@uab.cat*

Recent studies demonstrate that early pig domestication is a complex and very variable phenomenon. Tell Halula, a PPNB site located in the Middle Euphrates Valley in the Arab Republic of Syria, presents an exceptional archaeological sequence representative of the historical changes that occurred between 7.800-5.800 cal BC, a crucial time interval during which significant transformations related to husbandry practices are documented. This presentation focuses on the results obtained from exhaustive analyses on *Sus* remains samples recovered from Tell Halula with the aim to elucidate the dynamics of pig domestication and exploitation strategies, in relation to adjacent regions.

A detailed analysis of the totality of pig bone remains was carried out according to the different occupation phases documented at tell Halula. The evaluation of the management and exploitation dynamics was established through the analysis of the variability in representation percentages, demographic patterns of the flocks, anatomical variability, physical characteristics of the animals and spatial analyses of the faunal remains according to settlement space use. Differentiation between wild and domestic specimens is established through morphological criteria, biometric analyses and geometric morphometric data, correlated with pig consumption and distribution patterns. The integrated analyses of all these parameters allows us to evidence dynamics and changes in husbandry strategies at tell Halula and elucidate how pig domestication process was performed. In order to establish the spatial and temporal dynamics of pig husbandry adoption in a wider geography of the Near East, we compare this data with the published results, and finally discussing the continuities and discontinuities in pig domestication processes and the role of pig husbandry in Neolithic economy.

The obtained results support a high degree of variability in pig exploitation during the early phases of pig husbandry adoption. Animal domestication and the adoption of domesticated animals were probably not mutually exclusive options during initial stages. This variability is not represented through physical characteristics of the animals only.

From a methodological point of view, an integrative approach is required to differentiate between wild and domestic populations. Archaeological and historical parameters as production and consumption patterns are key variables for this purpose. On the other hand, further progress on methods such as geometric morphometrics and aDNA analysis should give us a better comprehension of the biological steps guiding boar to its domestic forms.

POSTER

### 3. A FORAGER-HERDER TRADE OFF, FROM BROAD SPECTRUM HUNTING TO SHEEP MANAGEMENT AT ASIKLI HÖYÜK, TURKEY

*Stiner Stiner, Mary C. (University of Arizona) mstiner@email.arizona.edu*

*Buitenhuis, Hijlke (Archeosupport)*

*Duru, Güne (Istanbul University)*

*Mentzer, Susan M. (Eberhard Karls University of Tübingen)*

*Munro, Natalie D. (University of Connecticut-Storrs)*

*Peters, Joris (Ludwig-Maximilians-Universität München)*

*Pöllath, Nadja (Ludwig-Maximilians-Universität München)*

*Quade, Jay (University of Arizona)*

*Tsartsidou, Georgia (Ephoreia of Palaeoanthropology-Speleology Southern Greece)*

*Özbaşaran, Mihriban (Istanbul University)*

Asikli Höyük is the earliest known pre-ceramic Neolithic mound site in Central Anatolia. The oldest Levels 4 and 5 span 8200 to ca. 9000 cal BC, associate with round-house architecture and arguably represent the birth of the Pre-Pottery Neolithic in the region.

Results from upper Level 4, reported here, indicate a broad meat diet that consisted of diverse wild ungulate and small animal species. The meat diet shifted gradually over just a few centuries to an exceptional emphasis on caprines (mainly sheep). Age-sex distributions of the caprines in upper Level 4 indicate selective manipulation by humans by or before 8200 cal BC. Primary dung accumulations between the structures demonstrate

that ruminants were held captive inside the settlement at this time.

The zooarchaeological and geoarchaeological evidence together demonstrate an emergent process of caprine management that was highly experimental in nature and oriented to quick returns. Stabling was one of the early mechanisms of caprine population isolation, a precondition to domestication.

ORAL

### 4. CHANGE AND CONTINUITY IN BEHAVIORAL PATTERNS OF HUNTER-GATHERERS AND PASTORALS AT QUMRAN CAVE 24

*Schechter, Heeli C. (Tel Aviv University) heelinka@gmail.com*  
*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*

The cave site of Qumran 24 is a good example for the study of the transition from hunting-gathering to herding. The cave is located on the north-western shore of the Dead Sea, in an extremely arid environment. The area does, however, offer seasonal resources, especially in the late winter and spring, for both hunter-gatherers and pastoral herders. The cave was used as a seasonal camp, intermittently, from the PPNA to the Chalcolithic period. Major socio-economic transformations take place during this long period of time in the region and Qumran Cave 24 provides an opportunity to monitor and follow these changes from a peripheral context.

Analysis of faunal remains and bone tools, as well as lithic assemblages, including flint and stone tools. Comparison of assemblages from the different layers of the cave.

Comparisons of faunal remains and lithic finds from the different layers indicate both elements of continuity and change. A major change is the appearance of domesticates in the late Neolithic and the use of the cave as a pen for domesticated herds during the Chalcolithic period. Another apparent change along the layers can be seen in the typology of flint tools. However, many behaviors remain constant and continuity is apparent in many aspects: Hunting continues and hunted animals remain an important component of the diet of the cave's users even when domesticates are prevailing, as opposed to the situation in richer farming areas; Very little energy is put into finding quality raw material (flint) for routine use in the cave, while the few exquisite items

are brought prepared to the cave from the “parent” settlements; Domestic activities such as grinding, weaving, and hide processing are performed at the cave in all periods, presumably reflecting the presence of women; and more.

It is concluded that Qumran Cave 24 Shows continuity in many aspects and at the same time reflects the profound changes which took place in the richer Mediterranean zones, especially the domestication of animals and specifically the adoption of pastoralism.

ORAL

## 5. THE BIOLOGICAL AND CULTURAL DISTINCTION BETWEEN PLANT DOMESTICATION AND CROP EVOLUTION

*Shahal, Abbo (Hebrew University, Jerusalem) shahal.abbo@mail.huji.ac.il*

*Avi, Gopher (Tel Aviv University) agopher@post.tau.ac.il*

The Domestication Syndrome (DS) is a collective term denoting morphological and -physiological differences between domesticated crop plants and their wild progenitors. Crop-plants are dynamic entities hence one cannot assume that all parameters distinguishing between wild progenitors and cultigens are associated with domestication. Using agronomic, genetic and archaeobotanical considerations, we refine the Domestication Syndrome concept by distinguishing crucial domestication traits from traits that are likely to have evolved post domestication (i.e., under domestication). We propose that only traits showing a clear dichotomy between the wild and domesticated forms (e.g., strong dormancy imposed by hard seed coat in wild grain legumes vs free germination mediated by water permeable seed coat of domesticated legumes) played an important part in the pristine domestication episode, whereas, traits showing a phenotypic continuum between wild and domesticated genepools (like seed size that show an overlap in values documented in both wild and domesticated cereals and legumes, respectively) mostly reflect post domestication diversification. The genetic and agronomic distinction between crucial Domestication Syndrome traits and post-domestication diversification traits provides valuable arguments for discussing the time frame of plant domestication and might be relevant for modern breeding programs.

ORAL

## 6. AGRONOMIC CONDITIONS AND CROP EVOLUTION IN ANCIENT NEAR EAST AGRICULTURE

*Araus Ortega, José Luis (Universitat de Barcelona) jaraus@ub.edu*

*Ferrio Dñiaz, Juan Pedro (Universitat de Lleida) pitter.ferrio@pvcf.udl.cat*

*Voltas Velasco, Jordi (Universitat de Lleida) jvoltas@pvcf.udl.cat*

*Aguilera Delgado, Mónica (Universitat de Lleida) monica.aguilera@udl.cat*

*Buxó Capdevila, Ramon (Museu d'Arqueologia de Catalunya, Seu de Girona) ramonbuxo@gmail.com*

The appearance of agriculture in the Fertile Crescent propelled the development of Western civilization. The study of how growing conditions, farming practices and crop domestication evolved from the beginning of agriculture is crucial for revealing the complexity and dynamics of ancient societies and to understand the current Mediterranean landscapes. The initial steps toward plant domestication in the Fertile Crescent can be pushed back to the 12<sup>th</sup> millennium cal BP, with different cereals being the main staples. Plant domestication in this region was a slow process with crop cultivation appearing at least 1,000 years before the earliest morphological changes supporting domestication (e.g. changes in seed shedding, increase in kernel size). However, evolution of agricultural systems after domestication, including water availability, soil fertility and potential yields achieved, as well as the pace of “post-domestication” progress in kernel size, remains mostly unknown.

The evolution of agronomic conditions in the Fertile Crescent was investigated by reconstructing cereal kernel weight and using stable carbon and nitrogen isotope imprints of kernels and charcoal from a set of 11 archaeological sites from Upper Mesopotamia, with chronologies spanning from the onset of agriculture to the turn of the era.

Water availability for crops, inferred from  $\Delta^{13}\text{C}$ , was two- to fourfold higher in the past than at present, with a maximum between 10,000 and 8,000 cal BP.  $\delta^{15}\text{N}$  decreased over time, which suggests cultivation occurring under gradually less fertile soil conditions. Domesticated cereals showed a progressive increase in kernel weight over several millennia following domestication.

Our results provide a first comprehensive view of agricultural evolution in the Near East inferred directly from archaeobotanical remains.

ORAL

## 7. OVERLOOKED CROPS: EARLY HISTORY OF BARLEY VARIETIES IN WESTERN ASIA

*Charles, Michael (School of Archaeology, University of Oxford) michael.charles@arch.ox.ac.uk*

Domesticated barley is one of the major crop components of late PPNB deposits of the West mound at Çatalhöyük, Turkey, [7400 to 7100 cal BC] as it is in many sites of the period. Unusually the barley is of the naked form and even more unusually two-row marking this crop's first significant appearance in the archaeobotanical list. A thousand years later on the Chalcolithic East mound at Çatalhöyük the barley crop was exclusively made up of hulled forms. This paper considers the early history of barley, in all its forms, in Western Asia based on improved identification criteria, morphometric analysis and a comprehensive database of plant remains from early farming sites. Particular reference is given to the shifting fortunes of naked barley in the region and its implications for the study of crop plant use.

ORAL

## 8. THE CEREAL DOMESTICATION PROCESS VIEWED THROUGH THE QUANTIFIED ANALYSIS OF HARVESTING GLOSS.

*Ibáñez Estévez, Juan José (IMF-CSIC) ibanezjj@imf.csic.es*  
*Anderson, Patricia (CEPAM-CNRS) peachypie616@hotmail.com*  
*González Urquijo, Jesús Emilio (IIIPC-UC) jesuse.gonzalez@unican.es*  
*Gibaja Bao, Juan Francisco (IMF-CSIC) jfgibaja@imf.csic.es*

There are still many open questions about when, where and how cereal domestication took place in the Near East.

As one way to advance in this topic, we propose focusing on the use-wear analysis of sickle elements. Wild cereals must be harvested before the complete maturation of the plant, while domestic cereals are harvested ripe. Most probably, wild cultivated cereals were harvested in an intermediate state of maturity. This variability

in the degree in humidity when harvesting provokes differences in the characteristics of the use-wear polish. We have measured harvesting polish from 19 experimental tools used for cutting wild cereals in natural stands (in Syria and Israel), cultivated wild cereals (in Jalès, France) and domestic cereals (in France and Spain) through confocal microscopy. Later, the discriminant function which distinguishes the three types of use-wear polishes was used to classify 75 archaeological sickle elements from the Early Natufian of Hayonim Terrace, the Late Natufian of Mureybet and Abu Hureyra, the Khiamian, Mureybetian (PPNA) and Early PPNB levels from Mureybet, the Middle PPNB from Abu Hureyra and the Middle and Late PPNB from Tell Halula.

Results suggest the early cultivation of wild cereals in the Middle Euphrates (in the Khiamian and maybe even in the Natufian) and the first appearance of harvesting of fully ripe (domestic cereals) in the Early PPNB.

ORAL

## 9. PLANT USE AT THE EARLY NEOLITHIC SITE OF SHEIKH-E ABAD IN THE EASTERN FERTILE CRESCENT CA. 10 000 - 7600 BC

*Whitlam, Jade (University of Reading) jade.whitlam@gmail.com*  
*Bogaard, Amy (University of Oxford)*  
*Charles, Michael (University of Oxford)*  
*Matthews, Roger (University of Reading)*  
*Matthews, Wendy (University of Reading)*

During the 1960s research on the origins of agriculture was focused at the eastern end of the Fertile Crescent, with areas of Iran and Iraq assuming prominence in models of plant and animal domestication. Subsequent geo-political events caused a shift in focus to the west and resulting excavations, coupled with the development of modern archaeobotanical techniques, have generated our current model of pre-domestication cultivation, which sees this region as the centre for the origins of agriculture. In recent years renewed research and excavations in the eastern Fertile Crescent, including by the Central Zagros Archaeological Project (CZAP - www.czap.org), have provided us with the opportunity to reassess the role this region played in the domestication of plants and animals.

The archaeological mound of Sheikh-e Abad is located in the Central Zagros of western Iran. It was excavated by CZAP in 2008 and deposits at the base of the mound

returned a date of 9800 cal BC. This makes it one of the earliest Neolithic sites known in the area; only Chogha Golan has produced similar dates (Riehl *et al.*, 2012). Occupation at the site covers a period of ca. 2200 years, which spans the agricultural transition. The location and chronology of Sheikh-e Abad make it significant for addressing biases in the current archaeobotanical record.

Charred macrobotanical remains were recovered during a single season of excavation at the site, from multiple contexts including open-area/midden deposits, areas of *in situ* burning/hearths and the fill and floors within rooms. This yielded a limited but significant dataset allowing us to assess long-term plant use, including tracking the emergence of domesticates.

Notable across the assemblage is the frequent occurrence of a suite of large-seeded grasses (including *Piptatherum*, identified here for the first time in the eastern Fertile Crescent) in conjunction with both wild and domestic-type barley in later levels. We suggest these formed part of the inhabitants diet and more tentatively that this provides evidence for the auditioning of wild species (*sensu* Smith, 2011) prior to the emergence of a narrower range of domesticated crops as part of a farming package. It is also striking that the small-seeded grasses, which are relatively rare in earlier levels, come to dominate later levels along with other taxa that potentially originate from the burning of animal dung. This may represent a change in plant use and deposition practices associated with an increasing intensity in animal management that is implied across the site at this time. Future work at the site is planned that will allow zooarchaeological aspects to be investigated further. Integration of macrobotanical analyses with micro-stratigraphy and micro-morphology is also currently being undertaken within the CZAP project as a means of understanding plant use and preservation in archaeological deposits.

The archaeobotanical assemblage from Sheikh-e Abad provides a new and much needed dataset for the eastern Fertile Crescent. Crucially our findings support recent evidence from Chogha Golan (Riehl *et al.*, 2012) for the independent cultivation and domestication of plants in the eastern Fertile Crescent.

ORAL

## 10. THE VICIA FABEA IN SOUTHERN LEVANT: NEW DISCOVERIES FROM PRE-POTTERY NEOLITHIC SITES IN THE LOWER GALILEE (ISRAEL)

*Caracuta, Valentina* (Weizmann-Max Planck Centre for Integrative Archaeology and Anthropology, D-Reams Radiocarbon Laboratory) [valentina.caracuta@weizmann.ac.il](mailto:valentina.caracuta@weizmann.ac.il)

*Boaretto, Elisabetta* (Weizmann-Max Planck Centre for Integrative Archaeology and Anthropology, D-Reams Radiocarbon Laboratory) [elisabetta.boaretto@weizmann.ac.il](mailto:elisabetta.boaretto@weizmann.ac.il)

*Barzilai, Omry* (Israel Antiquities Authority) [omry.barzilai@weizmann.ac.il](mailto:omry.barzilai@weizmann.ac.il)

*Vardi, Jacov* (Israel Antiquities Authority) [kobi.vardi@gmail.com](mailto:kobi.vardi@gmail.com)

The faba bean (*Vicia faba* ssp.) is an important legume in the Mediterranean regions, where it is either consumed as food in its major form (*Vicia faba* var. *major*), or used as fodder for livestock in its minor (*V. faba* var. *minor*) form. Despite the value of this protein-rich species in the human and animal diet, little is known about it and the pristine centre of its domestication, although Taxonomical and genetic analyses point out at the Near East as the 'core' area of origin.

So far, the largest evidences of cultivated small faba beans (*V. faba*) come from the Middle Pre-Pottery Neolithic B site of Yiftah'el, in Southern Levant, and radiocarbon dated them to the end of the 8<sup>th</sup>-beginning of the 7<sup>th</sup> millennium cal. BC.

New discoveries of *V. faba* in Southern Levant PPNB site Nahal Zippori 3, re-open the debate about the pristine centre of domestication. New radiocarbon dating of the Nahal Zippori legumes assists in refining the chronology of such a process.

## 1. PUSAKA: HUMAN ECOLOGY IN PREHISTORIC SOUTHEAST ASIA

*Sémah, François - (UMR 7194 CNRS - Département de Préhistoire du Muséum national d'Histoire naturelle (MNHN), 1 rue René Panhard, 75013 Paris, France) semahf@mnhn.fr*  
*Forestier, Hubert - (UMR7194 MNHN-CNRS-UPVD, France) hubforestier@gmail.com*

Southeast Asian Prehistory is part of the most topical questions related to palaeo-history of the human lineage. At the heart of a fantastic natural laboratory to study biodiversity and global changes during past and present times, the continental and island Southeast Asian prehistoric sites document, along a time range of more than one and a half million years, the evolution and the biological and cultural adaptation of several hominids, from *Homo erectus* (the Javan 'Pithecanthropus') up to Anatomically Modern Humans.

The scientific methods that are operated for the multi- and interdisciplinary study of these populations remain similar, since the very first islanders of the history of humankind, via endemic species that still remain mysterious (the Flores Island fossils) up to the Austronesian navigators who reached the banks of the Pacific islands several thousand years ago.

The Pusaka project is grounded on long term international collaborations, each of them aiming at answering the needs of the host countries in terms of: research, education, training, conservation, heritage development in the field and in laboratories or museums. The ambition is to develop a dynamic study of the relations between humans and ecosystems throughout the Pleistocene and during the major part of the Holocene, encouraging the disciplinary bridges between Prehistory and Evolution and Environmental sciences.

The Pusaka network will be meshed by major prehistoric sites and by academic institutions (research centres, universities, museums) as well. In the framework of collaborative projects between Asian countries (including all countries represented in the project) and Europe, these institutions trained numerous young scientists, mainly from ASEAN countries. Such results were acquired notably thanks to the investment Asian institutions, of the European Commission, of the French Ministry of Foreign Affairs, and of research and dissemination institutions (CNRS, IRD, Muséum National d'Histoire Naturelle). Field researches, mobility towards Europe and Asia were the major instruments implemented for such a purpose.

The Pusaka International project is intended to invest in a new generation of Asian researchers and teachers within the framework of emergent scientific and university.

It will answer the need to set up a network based on fundamental research, clearly established in Southeast Asia, whose first mission will be to support and contribute to the sustainability of high quality scientific exchanges at the regional scale.

-A number of young Southeast Asian colleagues have reached the doctoral and post-doctoral level.

-With the collaboration of deeply involved European countries, these scientists might set up a community of interest that will generate human and scientific competence flows, sharing of know-how that will significantly strengthen the quality and the sustainability of the exchanges.

-Beyond Europe-Asia exchanges, this structure will develop in priority, in Southeast Asia, the synergy between the best available scientific and academic instruments in concerned countries (sites, heritage funds that include numerous new collections, analytical laboratories, teaching programs, museums).

-The modern interdisciplinary –and, to a certain extent, inter-sector- approach will also address the development perspective of the Asian partner countries.

ORAL

## 2. THE LATE NEOLITHIC SETTLEMENT SITE OF SAMRONG SEN, CENTRAL CAMBODIA

*Vanna, Ly - (APSARA Authority Preah Norodom Sihanouk-Angkor Museum) vanna1357@gmail.com*

Neolithic research in Cambodia remains meagerly done. The earliest Neolithic settlement site to be archaeologically recognized so far in Cambodia is the cave site of Laang Spean, recently dated back to the 5th millennium BC, from where several evidences of animal domestication, agriculture and polished stone tools using culture are identified. Other known cave sites such as Kbal Romeas (circa 3500BC) and Phnom Laang (circa 2300BC) are also classified to belong to the middle Neolithic settlement sites which are located along the southern coastal area of the country. Samrong Sen (2205BC) and other shell midden sites are the only late Neolithic settlement open air sites to be known in the central floodplain of Cambodia. My paper will discuss exclusively on the cultural complexity of the shell midden site of Samrong Sen by first focusing on the long history of human occupation in the site through analysis of archaeological materials and site stratigraphy excavated between 1999 and 2001.

**3. OBSIDIAN ARTEFACTS FROM PAWON CAVE WEST  
JAVA, INDONESIA**

*Ferdianto, Anton - (UMR 7194 CNRS - Département de Préhistoire du Muséum national d'Histoire naturelle, 1 rue René Panhard, 75013 Paris, France) anton.ferdianto@edu.mnhn.fr*

*Simanjuntak, Truman - (enter for Prehistoric and Austronesian Studies (CPAS) Indonesia) simanjuntaktruman@gmail.com*

In Indonesia stone tools are one of the technical object that prehistoric man made for more than million years ago by Homo erectus. Those produce by Modern Human present a high variability of reduction sequences, tool types and rock type materials selection as we can observe in the West part of Java Island where obsidian have been used by prehistoric groups (von Koeningswald, 1934; van Heekeren, 1972). Bandung basin and Pawon Cave site are an interesting study case to understand the human adaptation to the environment i.e the geological determinisms and the cultural choices. From years of research in Pawon Cave by Balai Arkeologi Bandung had been discovered many bones, and lithic remains, including also more than five human burial remains. The high quantity of obsidian artifact (more than 1000 pieces) founded in stratigraphical context, reveals that these sources have been exploited in the Kendan Mounts (Nagrek) around 60 km far from the cave.

The localization of the obsidian sources gives information of the occupation area. Moreover through technological and typological study of the obsidian lithic assemblage from Pawon Cave, are a good example for examining variability of lithic assemblage and also aiming to bring light of the factors determining stone tools production at Pawon Cave during the Pre-Neolithic and Neolithic period. For the same period some comparison should be do with others sites in Java and in across the Archipelago.

Island Southeast Asia has been the subject of important archaeological discoveries regarding human population history. However, the eastern part of Borneo (Kalimantan, Indonesia) remains poorly documented despite its strategic location facing the Wallace line on the edge of Sundaland. This region has probably played a more important role than is currently recognised since it was a gateway from Sunda to Sahul during the late Pleistocene period, and had a central location in the Holocene network of cultural, linguistic and population diffusion.

Since 2011, thanks to the French Ministry of Foreign Affairs and Research Center for Archaeology (Indonesia), we have developed a collaborative and interdisciplinary French-Indonesian archaeological research project in the karstic rainforest region of East Kalimantan (Mangkalihat Peninsula, Indonesia).

We aim to determine the chronology of human occupation and its technological development in this part of Kalimantan, and interpret it within the regional context of South East Asia. Our diachronic project combines archaeological surveys and excavations, ethno-linguistic investigations and anthropobiological analyses. In this paper we present a synthesis of the results from the three last years of research from three rock shelter excavations and studies of surrounding indigenous populations.

Our results provide new data that will lead to the reappraisal of the role of this region from the late Pleistocene-Holocene prehistory South-East Asia and the associated cultural and population diffusion processes.

Laang Spean is one of the most important prehistoric cave sites in Cambodia with discoveries attempted to Hoabinhian and Neolithic period: Late Palaeolithic hunter-gatherers to Neolithic transition. Laang Spean cave is situated at the upper part of a limestone hill (Phnom) in the North-West of the country not far from the Sangker River in the plain of Battambang.

The site was discovered and previously excavated by French archaeologists R & C. Mourer during the 1960s and recently re-excavated by the Franco-Cambodian Prehistoric Mission (MNHN - Ministry of Culture and Fine Arts, Phnom Penh).

The result obtained during the last five years permit to discuss the position of the Hoabinhian technocomplex in his cultural, stratigraphical, chronological, environmental and spatial context.

The archaeostratigraphy of Laang Spean indicated that around 3300 BP Neolithic burials (including stone adze, pierced canine of Suid used as finery, ochre pencil, turtle, shell etc.) have disturbed a former hunter-gatherer occupation/Hoabinhian level (cobble tool) spanning from 11ka to 5 ka and that an older human occupation (chert flake and core) ranging from 71 to 26 ka.

he Laang Spean archaeological sequence with new OSL and 14C dating results represent one of the best documented stratigraphy in cave (# 5 meters) in Southeast Asia Mainland and intends to open a discussion on: the evolution of the prehistoric cultures and the use of cave for different activities through the time.

*Manipon, Dante Ricardo (Archaeological Studies Program University of the Philippines Diliman) danmanipon@hotmail.com*

*Titton, Stefania (Muséum national d'histoire naturelle) stefania.titton1@gmail.com*

Archaeological exploration in northern Mindanao has led to the discovery of a stone assemblage bearing the Oldowan lithic tradition. The assemblage is predominantly composed of large lithic artefacts made of locally available volcanic cobble-sized blank materials. They were reduced employing hard hammer percussion, executed by either a combination of both a free-handed or anvil technique depending on the size or weight of the blanks. The consistency in the dimensions of the flaking negatives was extracted on the exterior platforms with an exceeding angle of 90° at the lateral and distal sides. This implies the intention of trimming the blanks in preparation for the cutting edges that form them as large cutting tools. The flaking was carried out in a unidirectional orientation which somewhat converges on the center of the blank. This action was repeatedly applied on a one-sided face. Trimming on the peripheral zone of the cobbles produced various morphologies of cutting edges (straight, pointed and semi-round) that can classify them as unifacial choppers and picks. Furthermore, end-scar terminations of the flaking negatives on the

cobbles display inefficient cutting edges for the flakes. Hinge and step fractures combined with sirt and overhangs suggest the reduction was not designed for the acquisition of the flake blanks. Rather, the emphasis of these tools' design was intended for heavy duty tasks.

*Hidayat - (Sangiran conservation office, Java, Indonesia) hidayat\_bpsmps@yahoo.com*

*Widianto, Harry - (Conservation of Cultural Properties and Museums, Jakarta, Indonesia) h-widianto@indo.net.id*

Matar is situated on the banks of Solo river, across from Ngandong where the youngest Homo erectus in Indonesia was found. The site has long been neglected by its hidden location and the greatness of Ngandong. Researches that have just carried out since the last three years at this site have unearthed new interesting data. The site is in fact very large located in a more than 5 km long of the Solo river terraces. Measured from the sea level, the terraces can be distinguished into at least three elevations: Terrace 1 (62-66 m), Terrace 2 (49-56 m), and Terrace 3 (< 40 m), with variations of thickness from <2 metres up to >6 metres. The excavations at different locations of the terrace have unearthed 7187 finds. Faunal fossils are the most dominant, which represent open woodland and aquatic environments with exceptions on several species that indicate the existence of forest environment. Lithic assemblage was found, consisting of pebble tools, bolas, polyhedral, retouched flakes and

cores, made out of varied types of stone. Human remains are yet to be found and is considered as the challenge for future researches. All of the findings mentioned show similarity to those found in Ngandong. Therefore Matar is a promising site for a better understanding on the last Homo erectus, as well as their environment and culture.

Numerous archaeological data, including use-traces and residues present on stone tools, suggest that plants played a major role in the economy of Southeast Asian prehistoric hunters-gatherers. An advanced use of plants and the production of specialised implements made of wood or bamboo has been suggested by some archaeologists[i] to explain the apparently simple lithic technology and paucity of formal stone tools in Southeast Asian prehistory.

Unfortunately, the absence of vegetal artefacts in the archaeological record and at present the lack of a detailed and widespread reference collection of diagnostic use traces from regional lithic assemblages limit the possibilities to detect and characterize plant use and prevent the suggested models to be put to the test.

Therefore, the objective of our research was to apply a multi-disciplinary approach for building up such a reference collection of use traces considering the specific vegetation of Southeast Asia and its large variety of plant material.

First, ethnoarchaeological fieldwork was conducted among Palawan indigenous communities to study what plants are used nowadays, the ways they are used and their potential for a possible use during prehistoric times.

Then, selected activities, involving 15 plant taxa that include three different genus of bamboo were reproduced experimentally in controlled conditions with stone tools made of local red jasper.

These stone tools were carefully analysed for wear traces under low and high power microscopes. The use-wear resulting from each activity and each plant was described and recorded in detail.

The results show some qualitative differences of use-wear between groups of plant taxa and revealed the existence of specific patterns related to specific activities such as fibre preparation for basketry.

The established reference collection opens new perspectives for functional analyses of stone tools and the understanding of human behaviour and human-environment relationship in prehistoric Southeast Asia.

ORAL

## 10. MAPPING PREHISTORIC LANDSCAPES IN HIGHLAND NORTHWEST THAILAND

*Shoocongdej, Rasmi - (Department of Archaeology, Faculty of Archaeology, Silpakorn University, Bangkok 10200, Thailand) rasmi@su.ac.th*

This paper explores the relationships between prehistoric societies and environments in seasonal tropics both synchronically and diachronically. Particular emphasis will place on how prehistoric populations mapping their landscapes through the examination of the variability in settlements associated with economic and ritual activities in the mountainous landscapes of northwest Thailand. Given the complexity and variability of tropical environments in landscape, latitude and altitude, rainfall patterns and vegetation, one important aspect of the research is to explore the change of cultural landscape in order to study prehistoric societies and their beliefs through integrated approaches from multi-disciplines. The analyses of site types, locations and functions, temporal and spatial distribution of sites, and ethnoarchaeological observations permit us to interpret landscape as a cultural map of prehistoric societies.

This paper will focus on the social landscape and resource exploitation of late Pleistocene to early Holocene inhabitants (Iron age), ca. 32,000 – 7,500 B.P). The data derive from my research and previous surveys and excavations in highland Pang Mapha, Pai, and Khun Yuam, northwestern Thailand. Recent archaeological data have witnessed little changes in the physical landscape; especially, cave occupations during the late Pleistocene to early Holocene periods whereas the shifting patterns from habitations to cemeteries were greater in the late Holocene period. The result of analysis increases our understanding of human-environment relations through the study of cultural landscape changes over time and space across the highland Northwest region.

ORAL

## 11. SOUTHEAST ASIA PREHISTORIC DISPERSALS AND ADAPTATION: EVIDENCE FROM LENGGONG VALLEY, MALAYSIA

*Saidin, Mokhtar - (Center For Global Archaeological Research Universiti Sains Malaysia) mmokh@usm.my*

Lenggong Valley with an altitude at present of around 100 m above sea level, is part of a large valley in Upper Perak which roughly follows the northeast-southeast axis of Peninsular Malaysia. It is bordered to the east by the Main Titiwangsa Range,

less than 300m in height, made up of porphyritic granitic rock. On the other site, the valley is limited by the Bintang Range, which is less than 250m in height, also of porphyritic granitic rock. The Lenggong Valley contains slate, phyllite and metamorphic limestone from the Kroh Formation of an age of Odo-visi-Devon. There are eight limestone hills in this valley with 72 caves. Archaeological evidence of the Lenggong Valley, which comprises both open-air and cave sites, provides a series of chronologically-ordered and spatially-associated culture sequences from the Palaeolithic through the Neolithic to the Metal period. These sites have been chronometrically dated from 1.83 million to 1,000 years ago. Lenggong Valley contains a large number of undisturbed in situ Palaeolithic sites making it, in this respect, unique outside of Africa and of extraordinary importance for the study of the culture of Palaeolithic man. All of the sites are located above 72 m above sea level. This suggests that the suitable area for the Pleistocene population in Lenggong Valley was at least at this altitude, and above. Palaeoenvironmental reconstruction at these sites suggest that the area under 72 m above sea level is not suitable for habitation in the Pleistocene because it is still under the waters of the paleolake. Archaeogeological surveys in this valley have mapped more than 30 sites with Quaternary river gravel deposit, the thickness ranged between 30 – 150 cm and at the terraces 72 – 183 m above sea levels, along the paleolake-shore. Therefore, Lenggong Valley was provided with a wealth of materials (river gravel) for a stone tool industry. All of these sites revealed evidence that they were used as workshop to produce Palaeolithic stone tools. And all located along lakeshore, thereby supporting the theory that early man adapted to the lakeshore environment. In addition to the open-air sites, the Lenggong Valley contains numerous cave and rock shelter sites which were occupied by the inhabitants of the valley during late Palaeolithic. The cave sites give further evidence of the prolonged and permanent presence of humans in the Lenggong Valley from the Palaeolithic through the Neolithic into the Metal Period. These cave sites give an extraordinary and unique insight into the culture of the prehistoric societies in the Lenggong Valley. These archaeological discoveries, all located within single valley whose geology and environment have remained stable over the past 2 million years, provide important milestones in dating the presence of prehistoric people in South-east Asia and impact on theories concerning the expansion of hominids throughout Australasia and the evolution of their stone tool cultures. This makes archaeological evidence of the Lenggong Valley a unique cultural landscape of outstanding universal value for the study and understanding of world prehistory.

## 12. STUDY OF THE "SA HUYNH-KALANAY" CERAMICS FROM THE KRA ISTHMUS

*Favereau, Aude - (Muséum National d'Histoire Naturelle )  
aufavereau@gmail.com*

*Bellina, Bérénice - (Centre National de la Recherche Scientifique )  
berenice.bellinapryce@gmail.com*

By the middle of the first millennium BC, pottery with shared morpho-stylistical features - the so-called Sa Huynh-Kalanay type of pottery - are found associated with valuable artefacts in metal, glass and stone scattered along the South China Sea, from the Thai-Malay peninsula to the West to the Philippines to the East.

The technological analysis of these ceramics aims at characterising this cultural sphere and how individuals, goods, technologies and ideas have been circulating within the sphere. A particular focus is made on corpus unearthed from settlement and cave sites in the Kra Isthmus excavated by the Thai-French archaeological mission, a region which was highly involved in the early days of the maritime silk roads.

There, the diversity of these ceramics, some locally made others imported, reflect a complexity that echoes the deep social, political and economic evolution this region was then facing. We investigate these trajectories by analysing the different groups of ceramic producers and consumers, the organization of ceramic distribution within the peninsula and its insertion in the South China Sea networks.

Tabon Cave in Palawan, the Philippines is one of the most important sites for the understanding of regional prehistory in Southeast Asia. First excavated by Dr Robert Fox of the National Museum of the Philippines in the 1960s and later reinvestigated through a partnership between the National Museum of the Philippines and the Muséum national d'Histoire naturelle in Paris, France in the 2000s, the cave has delivered the earliest confirmed Homo sapiens remains in the Philippines dating back to as far as around 47,000 years ago. Upper Palaeolithic occupation layers characterised by chert flake assemblages, as well as later jar burials placed in the Philippine Early Metal Age, make Tabon Cave important for understanding the lifeways of early modern man in the region. The lack of complete stratigraphical information, however, has hampered the construction of a sound geochronological framework for the cave. In an attempt to address this, stratigraphic studies were undertaken in recent years, and the presence of organic deposits consisting of guano in various stages of alteration was brought to the fore. Mineralogical characterisation of these deposits reveals phosphate mineral assemblages that could have implications for the preservation of archaeological remains and thus touch on issues of prehistoric cultural heritage, while geochemical analysis suggests that the deposits could be used for geochronological and palaeoenvironmental reconstruction. Efforts to apply uranium-series dating to the deposits have so far not borne positive fruit due to the open-system nature of the cave with respect to uranium mobility, but investigation of  $^{13}\text{C}$  and  $^{15}\text{N}$  isotopes suggests the possibility of inferring information on vegetation and ecology. Ongoing research on Tabon Cave combines and expands these various approaches in order to gain a deeper understanding of the archaeological preservation, geochronology, and palaeoenvironment of the site.

#### 14. 40AR/39AR DATING OF THE ARCHAEOLOGICAL LAYERS IN MATA MENGE, INDONESIA

Lindelof, Poul Erik - (Niels Bohr Institute and Saxo Institute, University of Copenhagen) lindelof@it.dk --<http://www.nbi.ku.dk/english/about/>

Bohr, Niels (Institute Blegdamsvej 17, 2100 Copenhagen) <http://www.nbi.ku.dk/english/about/>

Southeast Asia plays an important role in understanding the human evolution (Dennell 2009). On Java, Indonesia, 1.6 million years old Homo erectus skeletons and artefacts show a very early immigration. The recent findings by Brumm et al. (2010) show that settlements on Flores are as early as 1 million years BP. This is in spite of two sea crossings of no less than 30 km. The discovery of Homo floresiensis on Flores has accelerated the interest.

In 2011 a major excavation at Mata Menge was ongoing, and I took volcanic material for dating of layers just above the archaeological artefact layer [Lindelof 2013]. The findings of fossils of Stegodons (elephants) and of stone artefacts indicated former life at a seabrink. In the laboratory at Roskilde University, Denmark, sanadine (potassium feldspar) crystals were collected out of the volcanic ash. Irradiation in a nuclear reactor converted a known part of the remaining  $^{40}\text{K}$  into  $^{39}\text{Ar}$ . This was then the precondition for Ar mass spectroscopy, and the ratio of  $^{40}\text{Ar}$  to  $^{39}\text{Ar}$  was determined by stepwise heating of the sanadine crystals. This, in turn, yielded an accurate age of the sanadine crystals from the volcanic eruption.

The volcanic layer on top of the archaeological layer at Mata Menge was dated by the  $^{40}\text{Ar}/^{39}\text{Ar}$  method to  $1.02 \pm 0.02$  million years BP. This was surprisingly close to the  $^{40}\text{Ar}/^{39}\text{Ar}$  dating at Wolo Sege and indicated a population of presumably Homo erectus at that time. There are always possibilities of rework due to streaming water, which may confuse chronology. But the very large fossils of Stegodons found and the two independent datings as well as studies of the volcanic layers makes this unlikely.

A volcanic layer at Mata Menge immediately above a layer with archaeological artefacts and animal fossils has been dated by the  $^{40}\text{Ar}/^{39}\text{Ar}$  technique. The result is  $1.02 \pm 0.02$  million years BP. The results are much more accurate than the previous fission track methods. Together with the previous  $^{40}\text{Ar}/^{39}\text{Ar}$  dating at Wolo Sege only 1 km away from Mata Menge in the Soa Basin, the results confirm human settlements on Flores to at least 1 million years BP.

Acknowledgements: Discussions with Gert van den Bergh,

Michael Storey, Stephanie Flude, and Ulla Lund Hansen are acknowledged. The Fiedler Foundation supported the field work on Flores, Indonesia.

age estimates resulting from the implementation of several dating methods, though being sometimes less precise, have a higher reliability.

Java Island geodynamic context may be a priori considered as a favourable one in order to build a detailed chronological framework of early human settlements, from the oldest Homo erectus fossils recovered in Lower Pleistocene layers up to the dispersals that followed the severe environmental change subsequent to the Holocene sea level rise. Such a long history of human presence in the Southeast Asian archipelagos includes numerous milestones that are critical for the study of human lineage (e.g. the dating of early Palaeolithic archaeological assemblages or the replacement of Homo erectus by Homo sapiens).

This paper provides examples of various methods that are currently implemented on volcanic effluents, sedimentary elements, speleothems and fossil animal remains, including radiometric and palaeodosimetric grounded techniques as well as magnetostratigraphy. Analyses may also be performed directly on human remains. Though isolated results are sometimes widely disseminated in the scientific literature in order to support chronological hypotheses addressing the above mentioned scientific issues.

However, a number of results must be considered with caution, in order to identify bias that might be for example linked to uncertainties related to several analytical parameters, to the geochemical evolution of the sedimentary matrix, or to the natural reworking of dated minerals (e.g. natural sweeping of volcanic chimneys, erosion and re-deposition of volcanic tuffs).

Such bias, mostly related to this contextual complexity, might well explain apparent contradictions between absolute dating results and other, chronologically significant records (e.g. the biostratigraphical one). Experience shows that converging

The Sangiran Dome (Central Java, Indonesia) is one of the most important sites regarding Homo erectus evolution, including dispersals and adaptation to isolated conditions during the Late Lower and Early Middle Pleistocene. Though, characterized archaeological assemblages are still rare poorly studied in the dome.

The SSE quarter of the dome, between Dayu and Pucung villages, includes the sites that yielded the oldest artefacts found in Sangiran, the quite complete Sangiran 17 Homo erectus skull, and several important archaeological and paleontological layers.

Cartographic and structural records allow to locate the main sites along a synthetic stratigraphical log, and also to discriminate several structural zones (where the dip varies) linked to the formation of the dome. Our work, that includes the excavation of the Pucung PCTS site, provides a stratigraphical and structural instrument which is hopefully able to help future paleontological and archaeological surveys, allowing to infer the probable location of rich horizons in the topography and to identify possibilities regarding conservation aspects and values.

The Sangiran Dome features Quaternary sediments that have yielded important fossil discoveries such as remains of *Homo erectus* and other vertebrates. Moreover, the Dome preserves an abundant molluscan fauna, stratified in a continuous succession that demonstrates the shift from a marine to a freshwater environment (upper Kalibeng and Lower Pucangan Formations). While research on the Early Pleistocene palaeoenvironment at the Dome has been underway, the approaches used so far have not included isotope geochemical studies of mollusc shells. Isotope geochemistry, notably the analysis of carbon, oxygen and strontium isotopes, is a powerful tool for palaeoclimatic and palaeoenvironmental reconstruction. In this study, we perform stable isotope analysis on growth increments and bulk carbonate of molluscan shells from 16 stratigraphic levels in the lower part of the Sangiran Dome series and combine this with sedimentological analyses to understand the scenario of climatic and environmental changes in the Early Pleistocene of Sangiran. It is hoped that the study will contribute to filling in the gaps in current knowledge on the environmental context of the Sangiran Dome, just prior to the arrival of earliest hominins on Java.

While there is consensus that Africa is the primary place of origin for anatomically modern humans, the timing and geographical dispersal pattern out of the continent continues to be intensely debated. Out-of-Africa hypotheses include either a single dispersal out of the continent or multiple dispersals that entail an initial migration into Southeast Asia via a "southern route." In the latter scenario, Australo-Melanesian and "Negrito" populations of Southeast Asia have been hypothesized to represent descendants of the first modern humans in Asia. Using Mantel tests, we examined competing out-of-Africa models by determining the association of their geographical distance predictions with biological distances between modern human populations from Africa and Asia. Our biological data consisted of genomic single nucleotide polymorphisms of N=714 individuals and anatomical 3D landmark data of N=233 crania. Sampled individuals were grouped into ten populations demarcated by geographic and ethno-linguistic provenance. We controlled for ancient demographic effects by calculating effective population sizes and divergence times using the genomic data, as well as estimates from archaeological, paleontological, and climatological data.

The best supported model was a multiple dispersals scenario in which Australo-Melanesian populations are relatively isolated descendants of an early southern route dispersal, whereas other Asian populations are descended from members of a subsequent migration event. The genetic divergence estimate between South Africans and Melanesians at ~116 ka is in intriguingly close correspondence with archaeological and pa-

leontological evidence of modern human occupation in the Arabian Peninsula and the Levant. Interestingly, the Aeta/Agta "Negritos" of the Philippines were determined to be highly admixed descendants of both dispersal events.

Our biogeographical approach supports a multiple dispersals out-of-Africa model and a southern route into Asia. Our results have important implications for detailing the mode and tempo of modern human occupation in Southeast Asia. They point to the importance of continued field work in this region and highlight the value of integrative, multidisciplinary approaches.

### 19. OUT OF AFRICA AND INTO ASIA: POPULATION GENETIC AND CRANIOMETRIC PERSPECTIVES ON PLEISTOCENE MODERN HUMAN MIGRATIONS

*Reyes-Centeno, Hugo - (Palaeoanthropology, Senckenberg Center for Human Evolution and Palaeoenvironment, Eberhard Karls Universität Tübingen) hugo.reyes-centeno@senckenberg.de*

Recent multidisciplinary work has supported a model stipulating that Asia was populated by two separate modern human dispersal events from Africa (Reyes-Centeno et al., 2014; Reyes-Centeno et al., In Review), with an initial migration via a "southern route" into Southeast Asia and a subsequent migration into northern Eurasia. This scenario originated in large part from the "Negrito" hypothesis, which considers short-statured and dark skin-colored populations of Southeast Asia to be descendants of the first modern humans in Asia and from a common ancestor. In this talk, I review how population genetic and craniometric data of Pleistocene-Holocene modern humans were used as two independent lines of biological evidence for testing competing dispersal models. Likewise, the "Negrito" hypothesis is revisited by looking at how the Aeta/Agta of the Philippines have been determined to be a highly admixed population descended from both dispersal events (Reyes-Centeno et al., 2013, 2014). These findings are placed in the context of other lines of evidence, assessing to what degree a multiple dispersals and southern route model is consistent with the extant archaeological, paleontological, and climatological records.

Acknowledgements: This work was supported by the Senckenberg Gesellschaft für Naturforschung.

### 20. MIDDLE MENINGEAL VASCULAR SYSTEM IN INSULAR ASIAN HOMO ERECTUS AND CONTEMPORANEOUS EUROPEAN FOSSILS HOMININS

*Grimaud-Hervé, Dominique - (UMR 7194, Dpt Préhistoire, MNHN, Paris, France) dgherve@mnhn.fr*

Among hominins, modern humans have the most complex meningeal patterning, with many vascular ramifications and anastomoses constituting a dense network. Differences in development and orientation of vascular impressions are observed during human evolution. Here, I compared the endocranial vasculature of contemporaneous human fossils remains from insular Asia (Java) and western Europe.

Comparison were made between the endocasts of fossil humans from insular Asian (Sangiran, Trinil, Sambungmacan and Ngandong, Java) and contemporaneous European sites (Arago, Swanscombe, Reilingen, Biache-Saint-Vaast 1) and some classical Homo neanderthalensis (e.s. La Chapelle aux Saints, La Ferrassie, La Quina...). This endocranial material is described morphologically with specific attention to their dural venous sinuses and middle meningeal impressions. Comparison between these two geographical samples is done chronologically.

The morphology of sinus impressions are similar for most specimens, with the exception of the development of the sphenoparietal sinus, which is more developed in later European specimens. The pattern of middle meningeal vascular impressions of all insular Asian and European endocasts shows identical development, even through time.

The question is how does one interpret the similar pattern of middle meningeal system evolution in such large and distant geographical region?

Ricaut, François-Xavier - (Laboratoire d'Anthropologie Moléculaire et Imagerie de Synthèse UMR5288, Université Paul Sabatier Toulouse-III, Toulouse, France) [francois-xavier.ricaut@univ-tlse3.fr](mailto:francois-xavier.ricaut@univ-tlse3.fr)

The spread of Austronesian-speakers is the widest expansion in human history, occurring eastward across the Pacific Ocean and westward across the Indian Ocean to Madagascar. The settlement of Madagascar by Austronesian-speakers more than 1000 years ago may be considered as one of the last major Austronesian expansions.

The genetic, cultural and linguistic characteristics of the Malagasy suggest that people from both Africa and Island Southeast Asia (ISEA) were involved in the colonization of the island. However, populations from the Indonesian archipelago played a major role as (1) linguistic evidence suggests that the Malayo-Polynesian language spoken by the Malagasy is related to the Barito language of southern Borneo (Maanyan speakers), and (2) genetic evidence suggests that the Southeast Asian genetic ancestry of the Malagasy may have originated from populations in the Java-Kalimantan-Sulawesi area. Despite these results, major issues remain unresolved regarding the contribution of Indonesian populations to the settlement of Madagascar.

In this paper we aim to determine if the linguistic affinity between Maanyan speakers (Barito River) and Malagasy (Madagascar) is correlated with a genetic affinity, and, if there is a sex bias origin of the Malagasy (Malagasy men and women have different origins in Indonesian archipelago).

The study uses Indonesian samples, well-defined from their historical/linguistic contexts, as the best proxy of descendants of those populations involved in the settlement of Madagascar. DNA was collected from 145 Ma'anyan individuals from 14 villages (Tamiang Layang region, Central Borneo), analysed using uniparental markers (mitochondrial DNA and Y chromosome) and compared to more than 102 Indonesian populations from 24 islands and 4 Malagasy populations.

Phylogeography analysis of maternal and paternal DNA lineages suggest multi-regional ancestral origins of the Malagasy in Indonesia (several Indonesian sources), and a Maanyan contribution restricted mainly to male lineages.

Our data support a more complex scenario of Austronesian-speakers settlement in Madagascar than is currently recognised.

Grimaud-Hervé, Dominique - (UMR 7194, Dpt Préhistoire, MNHN, Paris, France) [dgherve@mnhn.fr](mailto:dgherve@mnhn.fr)

Dizon, Eusebio Z. (National Museum of the Philippines and Archaeological Studies Program, University of the Philippines, Quezon City, Philippines) [drbongdizon@yahoo.com](mailto:drbongdizon@yahoo.com)

Since the late XIXth century, the Southeast Asian archipelagos have played a central role in the study of the extinct species *Homo erectus*. To the contrary, the study of *H. sapiens* in the same region received much less attention. Since the 1990' however, several field researches and analytical approaches developed in Indonesia and the Philippines brought to light important fossil finds and significant new results. Those discoveries and data are particularly relevant to a better understanding of the origin and evolutionary history of *H. sapiens* and its contemporaries in the region, including the diminutive insular endemic species *H. floresiensis*. In the same time, numerous results obtained from population genetics and ancient DNA focused a particular attention on several aspects of human evolution in the easternmost part of the Old World. While Africa is still widely recognized as the major place of origin of the species *H. sapiens*, the hypothesis of several episodes of interbreeding between local populations of archaic hominins and newly arriving modern humans is becoming more and more pregnant. In some scenarios, Island Southeast Asia East of the Wallace Line is even seen as the most probable place for past events of hybridization with "Denisovans".

Using 3D geometric morphometrics, we examine the size and shape characteristics of the predecessors of *Homo sapiens* in East and Southeast Asia, as well as those of the Callao third metatarsal (MT3). Cranial shape analyses include large samples of Australasian fossil hominins, with a particular focus on the late Middle Pleistocene hominins from China (Dali, Jinniushan) and Indonesia ("Solo series"). The analyses show that late Middle Pleistocene Chinese hominins share cranial shape affinities with *H. sapiens*, while their Indonesian con-

temporaries present *H. erectus* –like cranial shapes, with the addition of derived features of their frontal bone. The second series of analyses aims at characterizing the size and shape affinities of the Callao MT3 that was directly dated to ca. 66 ka and thus represents the oldest human remain known from the Philippines so far. We present here the results of a Procrustes analysis that includes a large comparative sample of 138 third metatarsals of adult *H. sapiens* and other Asian mammals for which the morphology and size of the MT3 is relatively close to human. The shape of the Callao MT3 is clearly closer to that of *H. sapiens* than to any other group included in the analysis. It lies however at the margin of the variation of *H. sapiens*, with a small size and a series of particular anatomical traits.

Both series of results are discussed with particular reference to recent hypotheses on the origin and evolutionary history of *H. sapiens* that accommodate in their scenarios one or several episodes of hybridization with archaic hominins, as well as the influence of isolation and insular endemism on human groups in Southeast Asia.

ORAL

### 23. THE LATEST DISCOVERIES OF HOMO ERECTUS IN JAVA ISLAND

*Widianto, Harry - (Directorate of Cultural Heritage Preservation and Museums, Directorate General of Culture, Ministry of Education and Culture, Republic of Indonesia) h-widianto@indo.net.id*

*Grimaud-Hervé, Dominique - (UMR 7194, Dpt Préhistoire, MNHN, Paris, France) dgherve@mnhn.fr*

Hominid, *Homo erectus*, and Java Island are three inseparable words on the human evolution context in the world. The discovery from the ancient deposits of Kendeng Hills – cut off by the Bengawan Solo river- in Trinil, East Java, in 1891, had enlightened the knowledge about the early man. From such deposits, Eugene Dubois discovered – for the first time- a species of an early man called *Pithecanthropus erectus*.

Based on this, paleoanthropology science was born in this eastern region of Southeast Asia, that later becomes one of the reputed centers of human evolution in the world, with further discoveries from: Sangiran (Solo depression), Kedungbrubus and Mojokerto (Kendeng Hills range), Ngandong and Ngawi (Bengawan Solo alluvial deposit), Patiyam (Muria volcanic deposit), and Samedo (North Serayuvolcanic range). The morphological comparisons, traditional linear measurements for 2D metric analysis and landmarks for 3D geometric morphometric analysis studied on the assemblage of *Homo erectus* specimens in Java had unveiled three stages of human evolution: archaic *Homo erectus* (1.5 – 0.9 my), typical *Homo erectus* (0.8 – 0.3 my), and progressive *Homo erectus* (0.2 – 0.1 my).

As a matter of fact, the discovery machine never stops working on this area. For the last 10 years, various kinds of human fossils have been exposed. These findings add not only the quantity of existing information, but also the new information. A 700.000 years old skull cap from Samedo, Tegal, western part of Central Java, for example, gave a new look on the migration mechanism of the early man in Java Island during the Pleistocene. The site was located in the tip of north western part of Central Java, far from other hominid sites where normally located in the eastern part of Central Java and East Java. These discoveries of *Homo erectus* will be presented along with the spectacular discovery of *Homo floresiensis* in East Nusa Tenggara.

*Sémah, François - (Département de Préhistoire, UMR7194-CNRS, Muséum National d'Histoire Naturelle, Paris, France) semahf@mnhn.fr*

Among the seven biozones presently used for Java Island Quaternary, the most recent one, the so-called Wajak, composed of modern species, has recently been aged to before the Last Glacial Maximum (28.5 ka; Strom et al., 2013). The consequence is the absence of any description of the faunal diversity of Java after the dry OIS2 and the related impact of

the possible resulting impoverished fauna on Australo-Melanesian prehistoric groups behavior.

The Southern Mountains that border the Indian Ocean coast in East Java (Indonesia) include karstic massifs such as the Gunung Sewu near Punung, in which numerous caves recorded human occupation of the area since the late Middle Pleistocene. Most of them include rich archaeological records dating back to the early Holocene.

The Song Terus cave, excavated since the 1990s, provides a rich sequence dated around 9 000 BP, so-referred to as Keplek layers, including the remains of occupation floors and human burials as well. It documents a strong relationship between the pre-Neolithic groups and the monkey communities (mostly *Trachypithecus auratus*), that is illustrated in the analysis of subsistence, technical and symbolic behaviors.

Although those prehistoric groups show some specialization, the fauna appears to be very diverse, including very large mammals such as *Rhinoceros sondaicus* or *Elephas maximus*. The whole range of the extant climatic mammalian fauna of Java are represented in the Keplek assemblage of Song Terus, including *Bibos sondaicus*, *Bubalus*, *Axis kuhli* and *Cervus timorensis*, *Sus vittatus*, *Panthera tigris*, *Cuon javanicus*, *Paradoxurus*, *Martes* and *Herpestes*. Grounding on the recently published Wajak fauna dating, it appears that no major extinction seems to have occurred during the LGM, while several species disappeared (or would have if not protected) more recently. Notable, cultural differences appear between the Holocene layers and the older ones, among them are forest games targets, symbolic behaviors and the utilization of the osseous industry which appears to be much more intense.

Further characterization of this naturally equilibrated fauna is also critical to understand the disturbances resulting from the later introduction of domestic species by Austronesian people.

## ORAL

### 25. THE CULTURAL ANTIQUITY OF RAINFORESTS: A 6000 YEAR ENVIRONMENTAL AND ARCHAEOLOGICAL RECORD FROM THE INTERIOR HIGHLANDS OF SARAWAK, MALAYSIAN BORNEO

*Jones, Samantha - (IPHES) sjones@iphes.cat*

Tropical rainforests contain a wealth of resources for health, construction, food and commodities. Survival and development is about knowing how to manage the resources around you. It seems only natural that modern-humans (*Homo-Sapiens*) have always been altering and manipulating tropical forests, to gain maximum benefit from these economically useful plants. This is far from previous beliefs, that tropical forests remained pristine environments, relatively untouched by humans; the

cultural antiquity of early tropical forest manipulation by hunter gatherers and the transition to farming however, is still poorly understood. This is partly due to rapid decomposition and poorer preservation of organic material in tropical environments. It is also due to the rich biodiversity of plant specimens in tropical forests, making accessibility to search for archaeological sites difficult. In 2005, the International Timber Trade Organisation (ITTO) mapped c. 50 archaeological sites around the Kelabit Highlands of Sarawak, Malaysian Borneo. This led to the establishment of an interdisciplinary project in 2007, directed by Professor Graeme Barker from the McDonald Institute at Cambridge University and sponsored by the Arts and Humanities Research Council (AHRC). The project was entitled 'The Cultured Rainforest project' and combined anthropology, archaeology and palaeoecology to investigate the long term and the present day interactions between people and the rainforest in the interior highlands of Borneo, with an aim to better understand past and present agricultural and hunter-gatherer lifestyles and landscapes.

Archaeological sites were selected predominantly from the southern Kelabit Highlands within the vicinity of Pa'Dalih and Long Kelit. Sites selected included abandoned settlement sites, occupation sites, ditches and cemeteries. Palaeological sites were selected from both the northern and southern Kelabit Highlands. Multi-proxy analysis was undertaken on cores extracted from Bario, Pa'Dalih and Pa'Buda. Analysis included pollen, phytoliths, lithology, magnetic susceptibility and loss on ignition, and produced a 50,000 year environmental record from two of the cores.

The archaeological excavations and palaeoecological analysis combined produced a c. 6000 year record of potential human clearance episodes and a c. 3800 year record of potential settlement; although secure evidence of human occupation and cultivation is not present until c. 2800 cal BP. This includes archaeological contexts which stretch back almost 2000 years and evidence for palm cultivation c.2800 cal BP. Experimental forms of rice cultivation may also have been taking place 1800 cal BP: although evidence is limited and does not become pronounced in the record until more recently.

### 26. DETERMINING HUMAN SUBSISTENCE STRATEGIES IN INSULAR ENVIRONMENTS: ZOOARCHAEOLOGICAL INSIGHTS FROM WALLACEA ISLANDS

*Samper Carro, Sofia Cristina - (Department of Archaeology & Natural History, ANU College of Asia & the Pacific, Australian National University) sofia.samper@anu.edu.au*

*O'Connor, Susan - (Archaeology & Natural History, ANU College of Asia & the Pacific, Australian National University) sue.oconnor@anu.edu.au*

*Louys, Julien - (Department of Archaeology & Natural History, ANU College of Asia & the Pacific, Australian National University) julien.louys@anu.edu.au*

The islands of Wallacea (which include Alor, Pantar, Lembata, Kisar, Leti, Wetar and Timor) are remarkable on a world scale as they register first hominin occupation by 60,000 cal BP, with firm evidence of permanent habitation by modern humans by 45,000 cal BP. Despite lower sea level during the late Pleistocene, these islands have never been connected to Sunda (including the Malay Peninsula, Borneo, Sumatra and Java) or Sahul (including Australia and New Guinea). Thus, crossing to any of the Wallacean islands resulting in sustainable populations would have required the use of watercraft.

Jerimalai rock shelter, East Timor, has yielded remains of pelagic fishes, as well as the earliest fishhook manufacture demonstrating that early modern humans in this region were well equipped to undertake complex exploitation of the marine environment. Despite the impoverished land-based fauna identified in Wallacea, stegodons, rodents, marsupials, birds and bats were or are still present on many island and would potentially also be exploited by early modern humans. Nevertheless, a holistic understanding of human subsistence strategies on these islands during the Pleistocene remains elusive. This research focuses on the taphonomic analysis of zooarchaeological assemblages from late Quaternary sites in Wallacea. The analysis of skeletal part representation, mortality and fragmentation patterns, and anthropogenic bone modifications (i.e. cut marks, burning, deliberate fracturing to produce bone tools or to access marrow etc.) in archaeological deposits and their comparison with naturally-occurring deposits will provide insights of the subsistence patterns of past human populations in these isolated islands.

The results of this study contribute to identifying whether hu-

man subsistence strategies in Wallacea were predominately arboreal-based, coastal-strand/marine-based or hybrid systems.

The climatic fluctuations and the resulting changes in configurations of tropical rainforest in Island Southeast during the Pleistocene-Holocene transition is supposed to have greatly impacted human societies during the period. One way to evaluate human adaptation is to look at faunal remains accumulated in archaeological sites, since they can provide direct evidence for subsistence and hunting strategies and to a general extent human-environment interaction. In this paper, we look at the faunal assemblages recovered from Late Pleistocene to Mid-Holocene layers of Song Terus and Braholo Cave sites in Eastern Java. The faunal turnover observed in these sites have provided concrete evidence for a broad-scale paleoenvironmental reconstruction of the region (see Sémah et al. & Ingicco et al., this session).

First, we present preliminary data from the analyses of cervid postcranial functional anatomy and ecomorphology and their utility as evidence in providing a detailed picture of the environment where past human populations foraged and hunted. Cervid ecomorphology could provide a suitable addition in the suite of paleoenvironmental proxies that currently exist for the area. Cervid species were present in the site all throughout the archaeological sequence, and akin to human groups, they developed behavioral adaptations in response to the dramatic shift in the environment during the onset of the Holocene. Specifically we look at the outlines of the proximal articular surface of the metapodials which are directly related to the substrate/ground hardness (i.e. wet, dry ground) and by extension to the vegetation cover (i.e. close, open environment).

In depth analysis of cervid functional anatomy could also provide insights on the range of environment types utilized by human groups through time.

We then consider these paleoenvironmental reconstructions as a background for detailed zooarchaeological and taphonomical analyses of faunal assemblages from the Song Terus and Braholo Cave. We looked at taphonomic indicators such as carnivore modifications, bone surface damage and skeletal element representation to fine tune the understanding of processes that resulted to the formation of the sites. We also focused at bone element fragmentation and butchery marks, including anatomical placement and microscopic analyses of cutmarks. Detailed analyses of these anthropic modifications, in contrast to those resulting from carnivores or other predators, allowed us to elucidate on carcass processing sequence and ultimately to describe, depending on the animal taxa, the different stages of scavenging, hunting or commensalism. We discuss the findings in the framework of whether changes in human behavior and relationship with animals during this key period resulted from climatic adaptations or cultural development.

*Sémah, François - (Département de Préhistoire, UMR7194-CNRS, Muséum National d'Histoire Naturelle, Paris, France) semahf@mnhn.fr*

Earliest Palaeolithic implements discovered in Java Island are older than 1 Ma, and largely postdate the oldest Homo erectus fossils discovered on the island. The archaeological record subsequently covers the appearance of Acheulean-like tools in early Middle Pleistocene deposits, a diversity of flake tools assemblages found in late Middle/ early Upper Pleistocene sites, and the conspicuous development of cave occupations

during the end of the Pleistocene and the early Holocene.

Along this time frame, the environment of Java was notably impacted by the severe environmental climatic changes which took place during the set up of Mid-Pleistocene characteristic conditions (duration and contrast of major climatic glacial cycles compared to Lower Pleistocene ones). It was impacted as well during conspicuous transitions which took place at the beginning of the Upper Pleistocene and, subsequently, at the boundary between OIS 2 and 1. Though, palaeoenvironmental reconstructions must also consider more local factors such as the repetitive effects of the tectonic and volcanic activities, which had severe consequences on local climate but also on the palaeogeography of the area, notably resulting into major erosional phases, vegetation disturbance, or even isolation of faunistic and floristic groups.

This paper grounds on examples of multidisciplinary studies carried out in Central and Eastern Java, mostly in the Sangiran Dome area (axial depression of the island) for the earliest considered periods and in the Punung karstic massif, along the coast of the Indian Ocean, for the younger ones. The environmental context of the ancient human settlements is considered under numerous aspects, among others: palaeogeography and dispersals (e.g. contacts with the continental mainland through land bridges), nature of the vegetal cover in relation with the extension of human groups' territories (tropical rainforest vs. more open forest or even grasslands during glacial stages), occupation ability of caves, nature and availability of lithic raw material. The associated vertebrate faunas, considered both as an environmental proxy and as a subsistence resource, were influenced in their composition by the contrast between periods of contact with the mainland (increased biodiversity) and periods of isolation favouring endemism, and by local environmental constraints as well.

*Rink, William Jack* - (School of Geography and Earth Sciences, McMaster University, 1280 Main St. W., Hamilton, Ontario, L8S 4L5, Canada) [rinkwj@mcmaster.ca](mailto:rinkwj@mcmaster.ca)  
*Auetrakulvit, Prasit* - (Department of Archaeology, Silpakorn university, Na Phra road, 10 220 Bangkok, Thailand) [sent.hw.aj.prasit@gmail.com](mailto:sent.hw.aj.prasit@gmail.com)

Proboscideans had very different ecologies, times of extinction and 'last stand' in different regions of the world and, Human-Proboscidean interaction may have a span of time covering almost two million years while paleoenvironmental conditions have played a noticeable role in the evolution of both taxa. Focussing on Southeast Asia, since the complex Ailuropoda-Pongo-Stegodon is considered to be a faunal association with chronological significance, further palaeoecological, palaeobiogeographical or biochronological studies are using this assemblage as a benchmark but do not provide sufficient information regarding site formation and duration to be consistent enough to do so. A critical review of the robustness of the geological, taphonomical and chronological data associated to this faunal assemblage suggests a deep reappraisal of this "biochronological assemblage". Focussing attention on the occurrence of Stegodon and Elephas, such a reappraisal is showing that both taxa may co-occur or replace each other, depending of the time resolution used.

### 30. THE ROLE OF SUBSISTENCE, ADAPTATIONS AND ENVIRONMENTS IN THE FORMATION OF COMPLEX HUMAN SOCIETIES.

*Paz, Victor* - (Archaeological Studies Program, University of the Philippines Diliman) [victorpaz67@gmail.com](mailto:victorpaz67@gmail.com)

We try to make sense of patterns we see from our field data in very conventional ways. This paper will address two major ways we set as defaults when we formulate research questions, or when we try to make sense of discerned patterns from our excavations. The first way is to see patterns, in terms of transformations through time, as driven by a change in either environment/subsistence, or both. The second way is to limit the description we may call societal complexity within the confines of developed cereal agriculture, together with a suite of domesticated animals. I will argue based on my own observations working in Island Southeast Asia that these may not be the case in the deep human past. This paper will raise questions, and suggest alternative ways of looking at the patterns without prescribing alternative models. It will draw from my own personal research experience, and on my reading of the literature from work done in the region of Southeast Asia.

*Puaud, Simon* - (UMR7194 CNRS- MNHN-UPVD, France) [simon.puaud@mnhn.fr](mailto:simon.puaud@mnhn.fr)  
*Forestier, Hubert* - (UMR7194 MNHN-CNRS-UPVD, France) [hubforestier@gmail.com](mailto:hubforestier@gmail.com)  
*Mourer, Roland* - (3 rue Julien, 69 003 Lyon, France) [roland.mourer@online.fr](mailto:roland.mourer@online.fr)

The Laang Spean cave (western Cambodia) has been firstly investigated during the 70's by R. and C. Mourer. One of their most salient result lay in the discovery of a complete footed and ornate vessel. This vessel was associated date which led them to identify Laang Spean as a Neolithic settlement. Since 2009, a French-Cambodian Prehistoric project aims to go further into the archaeological potential of this site. After several decades of archaeological stagnation, data from Cambodia are now of crucial importance in order to supplement to the regional models of Neolithisation in South-East Asia, which have benefit from the numerous excavations performed in neighboring countries, notably in Thailand.

In 2011, Laang Spean appeared as a new landmark toward a better understanding of the late Prehistory in Indochina with the discovery of a burial dated back (radiocarbon dating of bone) to 3310±29 BP. The burial contains several items, including five complete pottery vessels and numerous sherds (stone adze, pierced canine of Suid used as finery, ochre pencil, etc.) Beside this material, pottery remains have also been found in the levels above the grave.

In this paper, we aim to present the results of the first analysis of this assemblage. We will present the main features of this material and discuss its potential relative chronology. Insights concerning the comparison with other sites will finally be given.

ORAL

### 32. INTO THE ORIENTAL ZONE AND OUT OF INDIA: ASYNCHRONOUS DISPERSAL ACROSS SOUTHERN ASIA?

*Blinkhorn, James* - (Université de Bordeaux) [jblinkhorn@outlook.com](mailto:jblinkhorn@outlook.com)

A major biogeographic boundary occurs in southern Asia, between the Saharo Arabian deserts that stretch into the Thar Desert of India and the Oriental zone spanning monsoonal India and South-East Asia. Crossing this interface may have required hominins to significantly readapt to new environmental and climatic regimes. A number of physical barriers also exist in southern Asia that may have impacted human dispersals. At both the east and west sides of the Indian subcontinent major rivers (Indus/ Ganges-Brahmaputra) and mountains (e.g. Iranian Plateau & Siwaliks/Patkai Range) may have complicated eastward population expansions into and out of South Asia. In addition, and unlike either South-West or South-East Asia, *Homo sapiens* fossils appear in the South Asian record ca. 30ka, significantly after their appearance in Australia. As a result, addressing patterns of hominin adaptation and dispersal is reliant upon comparative analyses of lithic assemblages. I will present a synthesis of the most recent Palaeolithic evidence from the Thar Desert following recent fieldwork at Katoati, Buddha Pushkar and Jogpura, which will be situated within the broader context of the South and South-East Asian record. An asynchronous model for dispersals into and out of South Asia is presented, indicating that eastward dispersals into South Asia are unlikely to occur at the same time as dispersals from India into South-East Asia.

ORAL

**33. THE WORLD'S OLDEST HOMINIDS AND THEIR ARTEFACTS FROM THE SIWALIK HILLS OF SOUTH ASIA**

*Singh, M.P. - (Department of Biochemistry Post Graduate Institute of Medical Education and Research Chandigarh -160012 India.) mpsinghchd2000@yahoo.com*

The palaeoprimatological significance of the Siwalik Hills has yielded what is perhaps the world's most ancient early hominids and their artefacts. In December 1992, I discovered hominids teeth, mandibles, post-cranials and a skull cap in association with stone and ivory tools in the Tatrot Formation of the Upper Siwalik. The discovery was made from the Tatrot Formation exposed at Khetpurali and Masol village near Chandigarh, North India. The teeth are arranged in a parabolic dental arch and the enamel ultrastructure reveals pattern -3 prisms. The P3 is malariform and single rooted. The mandibles are devoid of simian-shelf. The femurs are platymeric and have medullary stenosis like that of *Homo erectus*. The patella has an oval-shaped articular facet crossed by a vertical ridge. The ilium is low, broad with posteriorly displaced sacral articular surface. The first metatarsal head presents a convex articular surface, the plantar portion

of which extends farther proximally than the dorsal like those of sapients. The groove on the cuboid bone suggests that the peroneus longus tendon had moved across the sole of the foot. On the navicular groove for the tibialis posterior is discernible. The skull cap is devoid of nuchal crest. The associated artefacts are chopper-type. Magnetostratigraphic dating of the Tatrot Formation ranges from 2.47 mya at the top to 5.44 mya at the base. The hominid-yielding bed is dated at 3.40 mya, i.e., Middle Pliocene. Palaeoecology of the Tatrot Formation was open grasslands having grassland community like *Hipparion*, *Leptobos*, *Stegodon* and *Sivatherium*, etc. The Upper Siwalik Plio-Pleistocene is marked by the first appearance of C4 grasslands. Oxygen isotopes also exhibit a shift from the forest to grasslands favoured by the monsoonal climate in the Plio-Pleistocene of the Siwalik Hills. The discovery will cast a new light on the human origins and invoke the Siwalik Hills of South Asia as the Garden of Eden.

The Upper Siwaliks exposed near Chandigarh (Fig. 1) are potentially important for the fossil remains of *Homo erectus* and stone tools. In November 1980, I made the first discovery from the Indian subcontinent fossils of *Homo erectus* and stone tools dated at 2 myr from the Pinjor Formation exposed at Nadah village (Singh in Kennedy, 1982a), (Singh, 1982b), (Singh, 1986a), (Singh, 1986b), (Singh et al, 1988), (Singh, 1989), (Singh, 1990), (Singh, 1991). In December 1992, and to-date exploration, I discovered fossils of *Homo erectus* i.e., femurs, patella, ilium, first metatarsal, cuboid, navicular, mandibles and a skull cap, etc., dated at 3.40 myr from the Tatrot Formation exposed at Khetpurali and Masol village (Singh, 1996), (Singh, 1998), (Singh, 1999), (Singh, 2003a), (Singh, 2003b). During the last 33 years of exploration, I discovered about 80 percent fossils of *Homo erectus* from the palaeoprimatological significance of the Siwalik Hills near Chandigarh. Due to limited time only selective specimens are announced. Rest would be announced later on. All the three formations Pinjor, Tatrot and Bunder Conglomerate are exposed in the present area (Nanda and Halstead, 1975), (Gaur and Chopra, 1984).

Since 2003, a French-Indonesian archaeological research project, coordinated by the National Research Center for Archaeology (Indonesia) and the University of Toulouse (France), has been developed in the karstic region of East Kalimantan (Mangkalihat Peninsula, Indonesia) to investigate human occupation processes during prehistory. Within the context of debates about the population history of Island South-East Asia (ISEA), the Kalimantan region remains poorly documented and understood. When authors mention this region it is usually with regard to its strategic location facing the Wallace line on the edge of Sundaland, as a gateway from Sunda to Sahul during the late Pleistocene period, or as part of models of the diffusion of the Neolithic cultural complex from Taiwan and the Philippines and the Malay Peninsula.

Such discussions lead us to expect that archaeological investigation of Kalimantan will provide new data that may lead to the reappraisal of the role of this region during Holocene prehistory and the associated cultural and population diffusion processes.

Archaeological research in the Liang Abu rock shelter (East Kalimantan) led to the discovery and analysis of a pottery assemblage including red-slipped, cord-marked and incised pottery sherds, radiocarbon dated to 1672±21 BP and 1524±22 BP.

In order to discuss our findings we undertake a reappraisal of the pottery material and associated radiocarbon dates from archaeological sites on Borneo Island, which provide us with an appropriate framework for a comparative analysis. This allows us to include the inland region of Kalimantan in the technological network of Neolithic Island South East Asia.

### **34. THAM LOD ROCKSHELTER (PANG MAPHA DISTRICT, NORTH-WESTERN THAILAND): EVOLUTION OF THE LITHIC ASSEMBLAGE DURING THE LATE PLEISTOCENE**

*Chitkament, Thanon - (University Rovira i Virgili, Tarragona) sabuyc@yahoo.com*  
*Gaillard, Claire - (Muséum national d'Histoire naturelle, UMR 7194, Paris) gaillacl@mnhn.fr*  
*Shoocongdej, Rasmi - (Silpakorn University, Bangkok) rasmi@gmail.com*

Tham Lod Rockshelter is located in northern Thailand in

a karstic context. It is facing north and widely opening to a forested landscape, approximately 200 meters from the Nam Lang River. This site was excavated under the direction of R. S. (2002-2006) and provided a rich archaeological sequence developed on 10 layers from 35 ka to about 3000 years B.P.

An abundant lithic material was recovered along with fauna, human burials and, in the upper layers, pottery. It can be considered as "Hoabinhian" since it includes typical sumatraliths and short-axes.

Analysis of lithic material from Area 2 shows that most of it comprises fragments of rocks brought to the site and artificially or thermally broken. The flakes seem to result mainly from the shaping of the large tools; cores proper are very few. In the lower layers the shaped / retouched tools are equally distributed between sumatraliths (including partial sumatraliths, not shaped all around), choppers and small tools (mainly scrapers) while in the upper layers the choppers decrease in number to the benefit of small tools and the sumatraliths reduce in size. This site allows to describe the technical changes in the late Pleistocene, across the LGM. It is especially interesting as besides the lithic assemblages, a rich faunal material helps in assessing the environmental variations and the subsistence strategies.

### **34. TECHNOLOGICAL AND MORPHO-FUNCTIONAL RECONSIDERATION OF THE EARLY HOLOCENE LITHIC ASSEMBLAGES OF SONG TERUS (EAST JAVA, INDONESIA)**

*Borel, Antony - (MNHN) borel@mnhn.fr*  
*Forestier, Hubert - (MNHN) hubforestier@gmail.com*  
*Gaillard, Claire - (CNRS) gaillacl@mnhn.fr*  
*Simanjuntak, Truman - (Pusat Arkeologi Nasional) simanjuntaktruman@gmail.com*  
*Sémah, François - (MNHN) semahf@mnhn.fr*

Even if severe environmental and climatic changes occurred at the Pleistocene-Holocene boundary in Southeast Asia, discoveries show a relative continuity through time and space concerning lithic industries. If some lithic artifacts are well identified like for instance the Hoabinhian cobble cutting tools (chopper, chopping tool, split and uniface - sumatralithe) often associated to forest environment on the continental area or the Maros point of the Toalian industries of Sulawesi, it is difficult to set up a tool typology with well-defined geochronological references. Indeed, artifacts from East Java consist mainly in informal flakes and are delicate to characterize. Nevertheless, the significance of this large lithic archaeological record needs to be elucidated to understand human behaviors of the early Holocene.

With an innovative approach focusing on production (lithic technology), form (geometric morphometrics), functions (use-wear analysis) and their relations, we propose a reconsideration of the early Holocene lithic artifacts from Song Terus cave (Java, Indonesia). The upper layers of this site yielded an anatomically modern human burial dated to 9000 years BP, an abundant bone industry, numerous shell tools and a large collection of stone artifacts

These artifacts are mainly cortical flakes (between 50 and 70%) made of chert. The reduction sequence is simple, based on an alternative knapping of two orthogonal surfaces. A high proportion of pieces were used without being retouched and only rare artifacts show traces of resharpening. Use-wear analysis showed the importance of the activity related to vegetal processing. It is also demonstrated that retouches and use traces are not randomly located on artifacts. They are often adjacent to the smallest angle of the artifact. A tendency to use non cortical straight segments, often cutting edges ( $<75^\circ$ ) and preferentially adjacent to an angle of 65 to 96° is also noticed. Very often, the artifacts are used only on one area (angle or segment). Moreover, a specific form of artifact is not related to a particular function and vice versa.

The results show that human interest was not oriented towards artifacts of specific forms but towards the presence of active areas with a specific morphology and associated to prehensile zones permitting a better use. The debitage method involved is both simple and efficient for a quantitative production of flakes. The discussion of this assemblage regarding to these results and the other remains of the sites lead us to suggest that this material was a transitory and efficient mean to build up a toolbox with raw materials (plant and bone) better adapted and adaptable to the needs of the users in a forest environment. The technical behaviour suggested and described by this research is not anecdotal and its consistency is reinforced by the results of several ethnological studies made in the region.

The discovery of Cueva Blanca rock shelter in 2006 and the archaeological excavations and investigations that have been developed subsequently have a noticeable relevance because there is the only stratigraphical reference of human occupation for the Late Mesolithic in a broad area of the northernmost part of Betic mountains. This region houses outstanding levantine rock art sites such as Minateda but traditionally lacks of evidences of Mesolithic / Early Neolithic settlements that can link to those. Cueva Blanca has come to provide the first piece of a puzzle that in the next years is going to increase.

This work collects the results coming from the multidisciplinary investigations conducted on Cueva Blanca and the archaeological material registered there. We must remark those concerning paleoenvironment, absolute dating, lithic industry and fauna.

The recent data confirms the attribution of Cueva Blanca to the Late Mesolithic. The last excavation campaign (2013) has allowed us to increase the lithic assemblage and to ratify its consideration within the first facies of *Cocina*. The archaeobotanical analyses indicate a

Mediterranean open coniferous forest and steppe conditions around the site. Radiocarbon dates point to a contemporaneity of the human occupation with the 8.2 cal yr BP event. On the other hand, fauna analyses state the predominant consumption of lagomorphs and the scarce presence of medium-small size herbivores.

The closest geographical region where we can find well known Mesolithic sites is the area of Villena (Alicante). Examining the data we defend a similar functionality between Cueva Blanca and the archaeological site of Cueva Pequeña de la Huesa Tacaña.

Cueva Blanca was occupied during temporary and seasonal periods in the Late Mesolithic according to the different data that we have handled so far. Despite it, we believe this site has an undeniable importance to deepen in the knowledge of the settlement patterns during this period in the hinterland of southeastern Iberia. In the future new sites belonging to the transition Meso-Neolithic will be made known in this area and therefore we could contrast the possibility of a settlement by the same last hunters-gatherers groups throughout the northern Betic valleys and mountains from Villena (Alicante) to Hellín (Albacete).

ORAL

**2. WHO IS AFRAID OF CARDIAL POTTERY? GROUP IDENTITY AND POTTERY STYLES IN SOUTHWEST EUROPE AND WESTERN MAGHREB NEOLITHISATION PROCESS**

*Diniz, Mariana (Centro de Arqueologia - Faculdade de Letras da Universidade de Lisboa) m.diniz@fl.ul.pt*

Pottery styles have been a core element in defining Neolithic cultural circles during the neolithisation process of the (North shore) Mediterranean basin (eg. Guilaine 2003) and for its westwards limits Cardial ceramics diffusion was a synonym of the first agro-pastoralist spread out in the region. In recent years, the *Impresa* style has been documented in Southern France and in Eastern Iberia suggesting a pre-Cardial movement on the area but at least in Iberian Peninsula it seems more an exploratory movement than a real departure towards a neolithisation process. In this picture where groups and/or cultural movements are traced upon ceramic styles, Southern Mediterranean shoreline has an alternating role mainly due to political factors then to archaeological ones (Diniz 2007) but it is becoming clear (again) that western Mediterranean neolithisation process can only be understood if we link continents and

look for data coming from both margins. Pottery and in particular pottery styles - as a major expression of group choices, identities and communication strategies - is selected to detect similarities and/or disparities between Western Mediterranean groups and areas and to identify local responses to a global event as was the neolithisation process.

A review of published data for Western Mediterranean/Atlantic border line Early Neolithic sites from both shores will be made with a special focus on pottery styles, stratigraphic data, absolute dates and the nature of archaeological materials chosen as absolute dates samples in order to detect divergences and similitude's in both Mediterranean margins archaeological records. Particular attention will be paid to pottery decorations attending to decoration techniques and

Two major pottery groups can be identified in Western Mediterranean/Atlantic both shorelines: Cardial and Channeled pottery - and chronology is not the only explanation for that difference - in fact in both margins of Western Mediterranean basin Cardial groups seem to have less/or to lose penetration capacity in areas where previous hunter-gatherer groups are solid established and in those areas Channeled pottery appear as the most frequent decorative system. Testing this hypothesis on future data is also intendment as part of an ongoing project on Western Iberia neolithisation in order to understand how people, from different cultural and backgrounds, communicate their social identity and cultural distinctiveness trough material culture.

ORAL

### 3. UZZO CAVE (TRAPANI-SICILY, ITALY) AND THE ISSUE OF THE CHAÎNES OPÉRATOIRES AND THE LITHIC TRADITIONS OF THE LATE MESOLITHIC AND THE EARLY NEOLITHIC IN SOUTHERN ITALY

*Collina, Carmine (Museo Civico Biagio Greco (Mondragone, Caserta-Italia) carminecollina\_1972@libero.it*

The main target of this paper is to put forward a technological and typological analysis of the lithic assemblages of Late Mesolithic and Early Neolithic concerned in the process of neolithisation in Southern Italy. The main aims of this research are to highlight the methods and the techniques of débitage and to identify the *chaînes opératoires* set up by the last hunter-gatherers and the early groups of farmers in the South of Italy and in Sicily.

The lithic series examined belong to the different horizons concerned in the process of Neolithisation of Southern Italy in the several areas of the envisaged region. Particularly, Uzzo Cave, located in Western Sicily, is one of the most important sites for the understanding of the Mesolithic-Neolithic transition process not only in Southern Italy, but also in the Western Mediterranean Basin. A long sequence of archaeological levels attests the human presence during the final phases of the Upper Palaeolithic, the Mesolithic and the Neolithic periods.

The rooting concepts are centred on the principles of the lithic technology outlined by J. Tixier, H. Roche, and M.-L. Inizan, D. Binder, C. Perlès, N. Pigeot et J. Pelegrin. The technological data derived from the analysis of the lithic series are set in a landscape perspective of management and control of raw materials. The purpose is to identify a management model of both technical behaviours and technological strategies. These last are intended as the combination of all the activities carried out since the acquisition of raw material until the abandon of the lithic objects considering the effect produced by the same activities in terms of landscape behaviours, raw materials availability and acquisition modalities.

Starting from the analysis of Uzzo cave, in a view to reconstruct the economy of débitage and the economy of raw materials and the possible formation of technical traditions, the results of this work concerns the following points:

- a) the economic and petrographical analysis of the raw materials;
- b) the analysis of the technological aspects and of the technical facts;
- c) the typometrical analysis of the different products of the *chaînes opératoires*;
- d) the typological analysis through the creation of an inventory allowing to integrate the study of the technological criteria with that of specific characters of the lithic tools.

Is it possible to recognize a techno-economic variability in the débitage systems of the Early Neolithic of Southern Italy? Is it possible to give a cultural value to the variability of technical facts? What is the rate of continuity and discontinuity among the lithic traditions of the last hunter-gatherers and the first farming societies? These questions allowed to shed lights on the whole of technical and cultural transformations between the VII and VI mill. B.C. in the South of Italy, a region that played a key role in the process of diffusion of Neolithic towards the West Mediterranean.

ORAL

**4. EMOTIONAL ASPECTS OF NEOLITHISATION: THE  
IRON GATES REGION (SERBIA, ROMANIA)**

*Lopicic, Milica (University of Belgrade, Faculty of Philosophy) milica.lopicic@fbg.ac.rs*

The Neolithic transition in the Balkan Peninsula was influenced in varying intensity and way by a demographic expansion from the Near East, during which the existing Mesolithic communities actively engaged with newcomers and neighbouring areas. Research in psychology has demonstrated that emotional factors are of great importance for human behaviour, influencing both the realization of successful contact with other people and their attitude towards material objects (later from the stand-point of a consumer). However, this remains poorly explored when archaeological record is concerned. Human remains and goods of foreign origin in local Mesolithic contexts of the Iron Gates region (Balkans, SE Europe) demonstrate that neolithisation was a process of encounters and a diverse exchange between hunter-gatherers and farmers. An approach to the phenomenon through the concept of globalization implies that emotions played a significant part in creating the conditions which readied local communities to incorporate Neolithic items as both necessities as well as desirable goods. In order to meet these criteria, changes in emotional sphere of hunter-gatherers are hypothesized to exhibit two trends: 1) showing positive emotions towards foreign people and goods, and 2) an increase in negative emotions related to own culture and the way of life.

The assessment of the expression and promotion of emotions on a group level through the perspective of a long development encompasses finds from the Mesolithic (Early, Late and Final) sites, dated to 13000-6000 cal BC. Stress is placed on symbolic, artisan and non-utilitarian items, which could have served as media in the creation of the public mood and collective action as demonstrated in the study of the core area of the neolithisation. The systematization of previous analyses of burials, ornaments, decorated objects, sculptures as well as exotic materials, including Neolithic products, in terms of their typology, spread, frequency and contexts, reveals the changes in emotional domain. They are comparable to already acknowledged shifts in ideological and social systems.

**1. FROM THE HYPOTHESIS OF A CULTURAL ISOLATION TO THAT OF THE A CULTURAL CROSSROADS: NEW PERSPECTIVES ABOUT THE RECENT PALEOLITHIC IN SOUTH-EASTERN FRANCE FROM TECHNO-ECONOMIC STUDY OF THE SITE OF LA BOUVÉRIE (VAR).**

*Vadillo, Margarita (Universitat de València) margarita.vadillo@uv.es*

*Naudinot, Nicolas (Université Nice Sophia-Antipolis, CEPAM UMR 7264) nicolas.naudinot@cepam.cnrs.fr*

*Tomasso, Antonin (Université Nice Sophia-Antipolis, Università di Pisa, CEPAM UMR 7264) antonin.tomasso@cepam.cnrs.fr*

Throughout the recent Upper Paleolithic, South-eastern France has constituted a at the border of two major cultural areas of Europe: on the west the succession goes through the Solutrean, Badegoulian, Magdalenian, Azilian and post-azilian techno-complex; on the east is the Epigravettian. This particular situation makes South-eastern France a particularly relevant space to study cultural transfers and interculturalities. Neglected by researches for a long time, the first research dedicated to this area was carried out in the 60's by M.Escalon de Fonton, who established a chrono-cultural evolution model based on the definition of regional and micro-regional chrono-cultural entities (Montadien, Salpétrien, Arénien, Bouverien, Valorguien,...) on the basis of a typological analysis of the retouched artifacts.

While the archaeological reality of these entities is increasingly criticized, there have been few attempts to discuss in detail the particular features, real or supposed, of the concerned industries. Recently, new investigations are based on a more systemic approach of lithic assemblages has been carried out by French and Italian researchers. They combine review of old collections and excavations of new sites.

This communication illustrates this dynamic of study by reviewing the assemblages of the cave of la Bouverie (Var). This key site, excavated during the 60's and 70's provided several archaeological layers attributed to Gravettian, Arenian and Bouverian by Onoratini in his PhD.

The review of this lithic assemblages was associated to a critical analysis of the integrity of the collection

and the stratigraphy of the site. The techno-economic analysis of the lithic material has focused on the entire lithic technical system, and not only on the retouched artifacts. It aims the study of raw materials provisioning strategies and production objectives and methods.

According to our results, three coherent sets have been defined in the section of the sequence. They were established by comparison with other regional assemblages and can be linked with the different stages of the Epigravettian. No tangible evidence arguing for particular chrono-cultural entities in this part of Europe has been highlighted by our study.

Otherwise, important changes, both in raw material provisioning strategies and production objectives and methods can be identified when considering the entire archaeological sequence. These elements of change are keys to develop a new chrono-cultural model for the Epigravettian of South-eastern France and more broadly of Italic's and Balkan's peninsulas.

This desire of reconstruction of the recent Upper Paleolithic of South-eastern France, should associate with this effort of seriation of the Epigravettian that allow us gradually to integrate the North-west Mediterranean area in the context of the European Upper Paleolithic.

ORAL

**2. TECHNICAL DYNAMICS AND TECHNOLOGICAL ORGANIZATION AT THE END OF THE UPPER PALEOLITHIC OF THE NE IBERIA.**

*Morales Hidalgo, Juan Ignacio (IPHES - URV) jignacio.morales@gmail.com*

*Román Monroig, Dídac (UB) Didac.Roman@uv.es*

*Cebrià Escuer, Artur (UB) arturcebria@gmail.com*

*Vergès Bosch, Josep Maria (IPHES-URV) jmverges@iphes.cat*

*Fullola Pericot, Josep Maria (UB) fullola@ub.edu*

The end of the Upper Paleolithic in NE Iberia seems to be a complex cultural and adaptive scenario on which different technological traditions appears to have been present for long chronological spans. The Magdalenian decline results in both geometric and non-geometric assemblages that, based on <sup>14</sup>C dates, persist until the beginnings of the Boreal. This results in the apparent

coexistence of three techno-complexes during the earlier moments of the Holocene: Epi-Magdalenian, Sauveterrian/Geometric, and the Notches&Denticulates Mesolithic. Classical typological discretization uses the presence of certain tool-classes in order to specify the "cultural" origin of the different assemblages, but, traditionally, little or nothing is said about the whole technological organization of the prehistoric groups. Differences in site function, occupational intensity and mobility dynamics can result in very different assemblages produced by a single "cultural" group, or in similar accumulations generated by different ones.

In this work we try to test which is the influence of some of these factors in the final composition of the assemblages. The integrity of the typological classifications will be also evaluated, trying to observe if intra-tool-class differences between sites and periods are culturally-based or, on the contrary, are forced by different technological organizations.

In order to reach our objectives we analyze or re-analyze some of the most significant Late Upper Paleolithic sequences of the NE Iberia. Assemblages from *El Filador*, *Hort de la Boquera*, *La Cativera*, *Balma de la Vall*, *Cova de la Guineu*, and *Balma del Gai* has been studied under a single methodology. We focus our approach in issues like compared morphometrics, tool reduction, retouch intensity, recycling, and raw material constraints in order to isolate convergent and divergent technical dynamics. The results presented at the conference will be the first step of a longer research process that wants to go in depth in the technological, cultural and environmentally conditioned behaviors of the last hunters and gatherers who lived in the northeastern part of the Iberian Mediterranean facade during the Pleistocene - Holocene transition.

ORAL

### 3. BONE TOOLS AND PERSONAL ORNAMENTS FROM BADEGOULIAN-INITIAL MAGDALENIAN LEVEL OF EL GATO 2 CAVE (ÉPILA, ZARAGOZA)

Duarte Matías, Elsa (Universidad de Oviedo) elduarma@gmail.com

Álvarez-Fernández, Esteban (Universidad de Salamanca) epanik@usal.es

Blasco Sancho, María Fernanda (Ayuntamiento de Zaragoza)

Rodanés Vicente, José María (Universidad de Zaragoza) jro-danes@unizar.es

El Gato 2 cave (Épila, Zaragoza) was excavated in four archaeological fieldworks between 2004 and 2011 and a succession of prehistoric occupations from Upper Paleolithic to Bronze Age has been documented.

In Level II of Test II it has been identified an archaeological level attributed to Badegoulian-Initial Magdalenian. It contains five radiocarbon dates ranged between 18850±100 BP and 17700±70 BP.

Faunal and technotypological studies of lithic and osseous assemblages show important elements for the cultural characterization of this level. And so it has been possible to recognise for the first time this cultural complex in the Ebro basin, a territory placed within Mediterranean, Cantabrian and Pyrenean areas.

Regarding the osseous assemblage, the finished objects predominate over preforms or waste products. Employed blanks are antler, bone, tooth and shell. Even though the high antler quantity of pieces, cervids constitute minority species, since rabbit is the most represented animal (97%).

The hard animal toolkit is typologically formed by 10 pointed pieces (9 antler points and one natural base punch), 8 perforated pieces (7 shell and one antler suspended objects of adornment) and 2 composite pieces (needle and perforated antler point). It must be added a tine's cervid fragment and a doubtful extraction matrix. Bone points show circular and oval sections and only three of them conserve their base (2 simple beveled bases and one pointed base), highlighting within them a Placard point. On the other hand, the antler pendant contains an engraved complex motive formed by short oblique strokes which are organised in parallel bands. It remembers Magdalenian engraved short stroke series, but also pectiniform motives documented as well in other chronoculturally analogous peninsular sites. Nevertheless, these ones usually present less complex pectiniforms. Shell ornaments are made of freshwater gastropods such as 2 *Melanopsis* sp and one *Teododoxus fluviatilis*, and marine gastropods like 2 *Trivia* sp and 2 *Homalopoma sanguineum*. All of them show polished orifices as result of a fairly long use.

Cervid shortage, lack of waste products and use marks in tools and pendants show that these pieces have been brought to the site already made. They could have also been manipulated in other parts of the site currently not preserved. Despite the domestic nature of the assemblage, the most characteristic piece is the Placard point. This antler point linked with the absence of

square sections from Lower Magdalenian and Solutrean plate retouch are arguments in favor of Badegoulian-Initial Magdalenian. Furthermore, shell's origins evoke connections with Mediterranean area.

---

ORAL

#### 4. AZILIAN DYNAMICS OF THE SOUTH-PYRENEES: ARE THEY RELEVANT TO ANALYZE "CLASSIC" AZILIAN?

*Martínez-Moreno, Jorge (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria -UAB) jorge.martinez@uab.cat*  
*Martzluff, Michel (Departement d'Histoire de l'Art et d'Archeologie Univ. Perpignan Via Domitia,) martzluf@univ-perp.fr*

*Mora Torcal, Rafael (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria -UAB) rafael.mora@uab.cat*  
*Roy, Miquel (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria -UAB) miquel.roy@uab.cat*

Azilian is a cultural phase originally described in the north face of Pyrenees and well documented in Cantabria. This tradition was developed during Younger Dryas, in contrast to Late Magdalenian which begins to be scarce in Late Glacial. In this chronometric interval, around 2000 years, although important changes can be detected, Late Glacial techno-typological trends are difficult to characterize.

Recently, we have suggested the presence of Azilian techno-complex in the south of the Pyrenees. We would be analyzing if Ebro Basin dynamics was involved in the configuration of this techno-typological tradition.

Techno-typological trends in knapping methods and lithic projectiles from Balma Margineda and Balma Guilanyà are compared with other sites from the Northeast of Iberia. This contextual approach allows us to define the "azilination" recognized in these south Pyrenees sites.

Current data suggests that initial apparition can correspond to the Bolling chronozone. The small assemblages cannot make an accurate diagnosis, but it permits to differentiate from Late Magdalenian. Otherwise, presence of thick backed points, straight truncated pieces, backed bladelet and the absence of geometrics have been mentioned in some sites from the Lower Ebro Basin and in the Levant coast.

During Allerod, hunting tools allow us to suggest possible influences/contacts from the Atlantic area (Cantabria and North Pyrenees). At least, we interpret the apparition of "azilian" harpoons, trihedral points, darts and backed knives. These tools coexist in the South Pyrenees with fusiform points and incipient pygmy microliths.

Along Younger Dryas, first geometric such as truncated points and microburin -similar to the Magdalenian tradition- has been recovered at Balma Margineda. These artifacts are present in the Lower Ebro Basin and it continues in the PreBoreal. In some cases these assemblages has been assigned to the Sauveterrian sphere.

Changes in weaponry tools detected along the Bolling/PreBoreal in the south of the Pyrenees are pertinent to define techno-typological trends. If these changes were produced previously, it can help us to understand the configuration of the classic Azilian. This proposition is not easy to verify in absence of detailed morphological studies on backed points and microliths, artefacts associated to very homogeneous lithic assemblages and scarce bone tools.

---

ORAL

#### 5. WHY THE MESOLITHIC OF NORTHEAST OF IBERIA IS DIFFERENT IN THE EARLY HOLOCENE?

*Martzluff, Michel (Departement d'Histoire de l'Art et d'Archeologie. Univ. Perpignan Via Domitia) martzluf@univ-perp.fr*

*Mora Torcal, Rafael (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UAB) rafael.mora@uab.cat*

*Martínez Moreno, Jorge (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UAB) jorge.martinez@uab.cat*

*Roda Gilabert, Xavier (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UAB) javier.roda@uab.cat*

A new phase in the Postglacial lithic assemblages was defined in the Vitoria workshop. This techno-complex named *Mesolítico de muescas y denticulados* -MSD- (notch and denticulate Mesolithic) is located around the Ebro Basin and temporarily ascribed to the Preboreal (PB) and Boreal (B) chronozones.

These assemblages share a number of common trends such as the management of local resources, application of expedient knapping methods to obtain flakes, low diversity of retouched tools, important number

of notches and pieces with clactonian retouch and identification of knapped or unknapped cobbles like used artifacts.

This diagnosis deserves to be analyzed in the context of the techno-typological trends detected in both sides of the Pyrenees.

Analysis of Balma Margineda, Balma Guilanyà and Font del Ros assemblages combined with contextual data obtained from other sites of the Ebro Basin, highlight spatio-temporal breaks in the PB and B techno-complexes. Throughout these two thousand years it is not easy to identify internal changes, due to the importance achieved by the *fond-commun* tools in these assemblages.

Main characteristics that define the MSD can be recognized in other contemporary assemblages of Western Europe. Alternatively, we sustain that radical difference is the virtual absence of geometric and backed pieces. This attribute allows a better identification of this phase in the south Pyrenees. This absence of weaponry tools is challenging and it can be correlated with the disappearance of bladelet knapping methods.

This trend can not correspond with dynamics observed in adjacent areas such as the North Pyrenees in the PB and B, and it seems exclusive of the MSD, or as we prefer to refer: Ageometric Mesolithic (or Mesolithic without armatures).

This Ageometric Mesolithic differs from the previous Sauveterrian and post-Boreal techno-complexes. Post-Boreal techno-complexes are recognized for the reappearance of laminar knapping methods carried out by indirect percussion with a punch, technical trait associated with the elaboration of trapezes and others armatures.

The Ageometric Mesolithic detected in the South Pyrenees differs from the techno-typological trajectory developed in the same period in the North Pyrenees. This is the different trend that characterized the Boreal assemblages at the Southern Pyrenees and the Ebro Basin. Guilanyà, Margineda and Font del Ros derive key arguments to typify the evolution of this postglacial techno-complex.

ORAL

## 6. EARLY AND MIDDLE HOLOCENE OPEN-AIR OCCUPATIONS IN THE UPPER VINALOPÓ VALLEY (SE SPAIN): CHRONOLOGICAL FRAMEWORK, SUBSISTENCE AND LAND USE PATTERNS

*Fernández-López de Pablo, Javier (Institut Català de Paleoecologia Humana i Evolució Social (IPHES) jfernandez@iphes.cat*

*Gómez Puche, Magdalena mgomez.puc@gmail.com*

*Ferrer García, Carles (Museu de Prehistòria de València i Servei d'Investigació Prehistòrica de la Diputació Provincial de València) carlos.ferrer@dival.es*

Over the past 8 years, the Upper Vinalopó Valley -located in the contact fringe between the central Mediterranean region of Spain and the Southern Meseta- has provided a fresh archaeological record of open-air sites dated between the Younger Dryas and the 8.2 kyr cal BP event. Arenal de la Virgen and Casa Corona sites have produced new data on human paleoecology, subsistence patterns, habitation features and funerary behaviour during the Early and Late Mesolithic periods.

In this contribution we present a synthesis of ongoing multi-disciplinary research at both sites. We will focus on the chronological framework of the open-air occupations to further discuss patterns of habitat selection and land use at local and regional scales.

POSTER

POSTER

## 7. LATE MESOLITHIC / EARLY NEOLITHIC OCCUPATIONS IN THE "CAMPOS DE HELLÍN" REGION (ALBACETE, SE SPAIN): VEGETATION, CLIMATE AND HUMAN INTERACTIONS.

*Uzquiano Ollero, Paloma (UNED) p\_uzquiano@hotmail.com*

*Casas Gallego, Manuel (Alicontrol SA) dp@alicontrol.com*

*Mingo Álvarez, Alberto (UNED) amingo@geo.uned.es*

*Barba Rey, Jesús (UNED) barba@yahoo.es*

*Yravedra Sainz de los Terreros, José (UCM) joyravedra@hotmail.com*

The new archaeological research carried out in the Campos de Hellín region focused on the Mesolithic to Neolithic transition, specially on the interactions between the human settlement patterns and the Holocene climatic instability, has revealed Late Mesolithic and

Early Neolithic occupations in a geographical area traditionally considered as empty of human settlement for these periods. We present the archeobotanical results conducted mainly on the Mesolithic site of Cueva Blanca rock shelter as well as some preliminary archeobotanical data obtained in the close Early Neolithic site of Pico Tienda III.

Archaeobotanical analyses (pollen and charcoal) have provided relevant information about vegetal landscape and woodland exploitation performed by late Mesolithic groups. Radiocarbon dates obtained  $7610 \pm 40$  BP (8450-8370 cal BP) and  $6730 \pm 40$  BP (7660-7560 cal BP) at Cueva Blanca indicate the contemporaneity of this human occupation with the 8.2 cal yr BP cooling event and subsequent arid conditions.

A Mediterranean open coniferous forest with *Pinus* and *Juniperus* was inferred around Cueva Blanca where *Pinus halepensis* and *Rhamnus lycioides* were the main sources of woodfire managed by late Mesolithic inhabitants. Steppic conditions were also noticed by the abundance of *Ephedra* and Asteraceae. Other environmental factors are suggested to explain the fluctuations of the main woody taxa, especially those of *Pinus* in accordance with the palynological and anthracological information available for the western Mediterranean area.

The early Neolithic occupation of Pico Tienda III seems to have been developed under similar paleoecological conditions according to archeobotanical analysis implemented by now.

In conclusion, the Mesolithic / Neolithic transition in the "Campos de Hellín" has been developed under steppic conditions inherited from the 8.2 cooling climatic event.

### 8. GENERAL RECONSTRUCTION OF PALAEOGEOGRAPHY, PALAEOTEMPERATURE AND PALAEOENVIRONMENT IN THE SOUTHERN COAST OF IBERIA BETWEEN THE LAST GLACIAL MAXIMUM AND THE 8.2 EVENT

Jordá Pardo, Jesús F. (UNED, Madrid) [jjorda@geo.uned.es](mailto:jjorda@geo.uned.es)  
Maestro González, Adolfo (IGME) [a.maestro@igme.es](mailto:a.maestro@igme.es)  
Aura Tortosa, J. Emili (Universidad de Valencia) [emilio.aura@uv.es](mailto:emilio.aura@uv.es)  
Carrión Marco, Yolanda (Universidad de Valencia) [yolanda.carrion@uv.es](mailto:yolanda.carrion@uv.es)

*Badal García, Ernestina (Universidad de Valencia) [ernestina.badal@uv.es](mailto:ernestina.badal@uv.es)*

The aim of this paper is to present a general reconstruction of the palaeogeography of the coastline of southern Iberia and the sea surface palaeotemperatures both the Alboran Sea and the Gulf of Cadiz, from the beginning of the Last Glacial Maximum (Upper Pleistocene) to the event 8.2 (Lower Holocene), as well as a reconstruction of the vegetal landscapes of southern Iberia. From this reconstruction we can have an idea of the configuration of the coast that was inhabited by the prehistoric peoples of southern Iberia in the moments of the transformation Mode 4-Mode 5.

For this we used different sources of information from which we can mention:

- Bathymetric and topographic data from the GEBCO database (IOC, IHO y BODC, 2003).
- High-resolution sea-level variations curve of the last 250,000 years adjusted to the SPECMAP timeline and isometrically calibrated (Thompson & Goldstein, 2006)
- High-resolution curves of the variations of sea surface temperature (SST) obtained from the study of alkenones of the MD95-2043 (Alboran Sea) and M39-008 cores (Gulf of Cádiz) (Cacho et al., 2001).
- Anthracological sequences of southern and eastern Iberia.

The analysis of the cited proxies allows recognizing a progressive rise of sea level that began in the second half of the LGM and having small oscillations over time. In the case of SST is remarkable an important rise of its values at the start of the Tardiglacial (GI1) followed by an abrupt decline during the Younger Dryas (GS1). An abrupt increase in the temperature is observed at the beginning of the Holocene followed by a period of stability that continues to the small temperature decrease at 8.2 event.

During the LGM the southern coastline of Iberia has an increased amplitude that varies depending on the area. On the Mediterranean coast this increase exceeds 5 km due to the narrowness of the continental shelf, while the Atlantic coast suffers a largest increase because the continental shelf has a greater extent. From the Tardiglacial the coastal strip begins to decline with the advance of the marine transgression up to the current situation. On the other hand, variations of sea temperatures condition the arrival of cold Atlantic faunas in the Alborán Sea at times of low thermal. Regarding the continental vegetation, the dynamics observed from the Tardiglacial indicates a progressive reduction of pioneer species (junipers basically) and

the establishment of mesophile or thermo-mediterranean formations in each of the areas. In relation with the 8.2 event, local sequences do not reflect significant changes in the presence of vegetal species.

### 9. EXPLOITATION OF MARINE RESOURCES AT THE UPPER PALAEOLITHIC AND MESOLITHIC OF NERJA CAVE (MÁLAGA, SPAIN)

*Salazar García, Domingo Carlos (University of Cape Town / Max-Planck Institute for Evolutionary Anthropology) domingo\_carlos@eva.mpg.de*

*Jordá Pardo, Jesús Francisco (Universidad Nacional de Educación a Distancia)*

*Álvarez Fernández Esteban (Universidad de Salamanca)*

*Avezuela Aristu, Bárbara (Universidad Nacional de Educación a Distancia)*

*Pérez Ripoll, Manuel (Universitat de València)*

*Vicente Morales, Juan (Universitat de València)*

*Richards, Michael P. (University of British Columbia / Max-Planck Institute for Evolutionary Anthropology / University of Durham)*

Palaeolithic and Mesolithic archaeological sites from southern Iberia (along the coast of the Alborán Sea) have ample zooarchaeological and archaeological evidence for the use of marine foods by humans. In addition there are artistic representations of marine fauna representations in Palaeolithic art from this region. However, until now, there has been no direct evidence for the importance of marine foods in human diets. We here present carbon and nitrogen isotopic results carried out on human and animal remains from Upper Palaeolithic and Mesolithic remains from the site of Cueva de Nerja (Málaga, Spain). Our results clearly show that marine foods were not only intensively exploited, but also intensively consumed, by humans dating to the Upper Palaeolithic and Mesolithic periods from this site. This contrasts to the Neolithic period at the site, as the isotope evidence instead shows that the diets became then mainly terrestrial.

### 10. ON FISHING AND BOATS IN ALBORAN SEA, SOUTHERN IBERIA (14 - 8 KY BP)

*Aura Tortosa, J Emili (Universitat de València) jeaura@uv.es*  
*Pérez Herrero, Clara I. (D'Arqueo) claraperez@darqueo.com*

*Marlasca Marin, Ricard - ricard.marlasca@hotmail.com*

*Rodrigo García, María J.*

*Jardón Pérez, Paula (Universitat de València) Paula.Jardon@uv.es*

Southern Iberia is a peripheral region of Europe, overturned in North Africa and well connected to the Atlantic coast. In the early twentieth century were identified representations of marine fauna (fishes and a probable seal) in the Palaeolithic parietal art (La Pileta and Ardales). Also were excavated shell-middens cave sites near Malaga city. Nowadays, here are located some of the oldest evidence on the use of marine fish in the European Palaeolithic, dated between OIS 5/4 and 1 is preserved.

Coastal sites prior to the last interstadial are preserved here thanks to morphology of the continental profile. Its sudden drop, resulting in deep waters close to the coast, has allowed the preservation of many caves and shelters. However, open air sites on the low beaches were flooded from the Late Glacial Maximum.

The first part of this presentation summarizes data on marine fishes from Southern Iberia region. These data have allowed to raise an analysis of fish species diversity and diachronic changes. The second part deals with an evidence of fishing methods which require fishing gear use. We study the use-wear traces of toolkits found in archaeological contexts that containing marine fishes (macrolithic tools made on pebbles and bone gorges from Nerja).

Our knowledge of marine fish remains and Palaeolithic fish catching methods is biased by data from old excavations.

The available data from Southern Iberia show that Neanderthals and firsts modern humans exploited marine fish. This situation did not change until after the LGM, although some increase in the exploitation of marine resources is appreciated.

At the end of the Upper Palaeolithic marine economies orientation existed in Southern Iberia and is possible to identify fishing equipments. Also may be appropriate to hypothesize about the use of macrolithic tools (skin-boats making?) at sites located on the Iberian coasts of Alborán Sea.

## 1. ARCHAEOLOGICAL THEORY EXPLORATION BY CHINESE SCHOLARS

*Xiyuun Yu (Department of Archaeology, School of History, Wuhan University) yuxiyun@aliyun.com*

Chinese archaeology began in 1920s. Johan Gunnar Andersson used Diffusion Theory as an explanation for the Painted Pottery Culture? Yangshao Culture? when it was first found in China. Then? in 1940s, Cultural Evolution Theory was accepted by some scholars. In this period, although Chinese archaeology was mainly influenced by Western archaeology, it also had some characteristic in Stratigraphy and Typology. In 1950s, Chinese archaeology was deeply influenced by Soviet Union archaeology, Marxism was used to explain the archaeological remains. In the middle of 1970s, Su Bingqi opposed to treat Marxism and Chinese traditional history as dogma, he proposed the genealogy (regional systems and local culture series) theory in order to systematically construct the Temporal and Spatial Frame of archaeological culture, set up different culture regions and their cultural sequence, and begin to investigate the origin and development of culture. After that, Zhang Zhongpei proposed the cultural lineages theory to reveal cultural internal structure and the process and reasons of cultural change in mid-1980's. In 2011, I proposed Agency theory which stress that the agency of ideology? art? religion and cultural identity is the internal dynamic of cultural change. Chinese archaeologists insisted on inducting experience in the base of research practice, then sublimating into new theory. They have their own particular cultural theory and research norms while refuse to copy the existing theory of western archaeology? simply fill the chinese archaeological data into the box of western archaeological theory?.

## 2. LA COUCHE CII2 "DU SITE DE LONGGUPO" CHINE : UN NIVEAU D'OCCUPATION ANTHROPIQUE D'ANTANT DU PLÉISTOCÈNE ANCIEN.

*Boëda, Eric (Université Paris Ouest) boeda.eric@gmail.com*  
*Griggo, Christophe (Université de Grenoble)*  
*Christophe.Griggo@ujf-grenoble.fr*  
*Hou Yamei (IVPP) houyamei@ivpp.ac.cn*

*Wanbo-B. Huang (Chongqing Three Gorges Institute of Paleoanthropology)*

Le site de Longgupo est localisé au sud de la traversée des Trois Gorges du Yangtsé, à l'est de la province du Chongqing. Il présente une importante séquence stratigraphique du Plio-Pléistocène, datée entre 1,8 et 2,5 millions d'années. La couche CII2?, fouillée sur environ 7 m<sup>2</sup>, renferme une importante accumulation osseuse, associée à une industrie lithique taillée dans le calcaire triasique local. L'analyse pluridisciplinaire a montré que cette accumulation osseuse est bien le fait d'hominidés qui ont fréquentés la grotte de façon répétitive, en apportant sur le site les parties alimentaires les plus riches d'animaux, tels que *Bos (Bibos) sp.*, *Cervus sp.* et *Metacervulus sp.*, qu'ils avaient chassés et/ou charognés de façon active. Par ailleurs, la morphologie et la disposition des cassures, ainsi que la présence de traces sur certains ossements, indiquent un travail de boucherie secondaire important dans le site, ce que prouvent les données techniques des artefacts lithiques.

The site of Longgupo is located south of the crossing of the Three Gorges of the Yangtze River, in the eastern part of the Chongqing province. It presents an important stratigraphic sequence of Plio-Pleistocene, dated between 1.8 and 2.5 million years ago. The layer CII2a, excavated about 7 m<sup>2</sup>, contains significant bone accumulation, associated with lithic artefact knapped in the local Triassic limestone. The multidisciplinary analysis showed that this bone accumulation is the fact of hominids who visited the cave repeatedly by bringing in the site the richest body parts of animals such as *Bos (Bibos) sp.*, *Cervus sp.* and *Metacervulus sp.*, that they had hunted and/or scavenged actively. In addition, the morphology and arrangement of fractures and the presence of traces on some bones indicate a significant secondary butchery work in the site, what demonstrate the technical data of lithic artifacts.

Scientific members from the Institut Català de Paleoec-

ologia humana i Evolució Social (IPHES, Spain) and the Institute of Vertebrate Paleontology and Paleoanthropology (IVPP, Chinese Academy of Sciences, China) have a long record of scientific relationship regarding different aspects of the research focused mainly on Palaeolithic lithic technology. This collaboration has been developed in form of various research visits in both directions, the incorporation of Professor Eudald Carbonell as visiting Professor of the IVPP since 2009, and the organization of an International meeting held in Shanghai in 2010. At 2010 funding was obtained from the Catalan Government in order to establish and to consolidate a scientific exchange among researchers from both institutions. These exchanges have the objective of encouraging the collaboration between researchers and institutions for the study of archaeological materials, training of young researchers in the frame of their doctoral thesis and the development of postdoctoral carriers. The scientific scope of the research was based on 3 objectives: the study of lithic technology Palaeolithic assemblages, the start up of an experimental project on bamboo and the study of archaeobotanical remains from Palaeolithic deposits. Firstly, the Sierra de Atapuerca sequence includes assemblages from the late Early Pleistocene to the late Middle Pleistocene; they are clearly framed in the general Western Europe context. As a consequence of the analyses of the evolutionary trends of the technological factors in the Atapuerca sequence, and discussed until which point these trends can be extrapolated to the other European sites, our aim was to collect data to improve our vision of the technical evolution in a really broad scale, in order to be able to compare the technological evolutionary trends identified at both ends of Eurasia along the Early and Middle Pleistocene.

Secondly, our project aimed to develop an experimental project regarding the use of bamboo as a raw material for manufacturing tools. This research has provided new insights in relation to the manufacture and use of bamboo.

Thirdly, this project was focused in starting up the study of charcoal remains from Palaeolithic sites in collaboration with the Institute of Archaeology (ICASS). Anthracology is an archaeobotanical discipline devoted to charcoal analyses which is well recognized in Europe. This discipline has provided data on palaeoenvironment and plant resource uses among early hunter-gatherers. In China, this discipline is at present in its starting point regarding Palaeolithic data that will provide elements for comparison to the results from Palaeolithic sites from Europe.

Our perspectives for the future will be focused in the application of European methodologies (usewear analyses, anthracology, and experimental archaeology) for the study of Asian Palaeolithic assemblages that would improve our knowledge on Palaeolithic human groups regarding different aspects.

#### 4. PANXIAN DADONG, LITHIC IMPLEMENTS OF A MIDDLE PLEISTOCENE SITE IN SOUTHWEST CHINA

Otte, Marcel (*Université de Liège*) [Marcel.Otte@ulg.ac.be](mailto:Marcel.Otte@ulg.ac.be)  
Weiwen Huang (*Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences*)  
[huangweiwen@ivpp.ac.cn](mailto:huangweiwen@ivpp.ac.cn)  
Yue Hu (*Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences*) [hy.ivpp@gmail.com](mailto:hy.ivpp@gmail.com)  
Ya-Mei Hou (*Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences*)  
[hoyamei@ivpp.ac.cn](mailto:hoyamei@ivpp.ac.cn)

Around three hundreds thousands years, the Panxian Cave has been filled and fully occupied until 100.000 years. The main humans implements were consisting of prepared cores and flakes on the Levalloisian kind of preparation. This is one of the oldest known in both in both Africa and Asia.

The core preparation has been fully shaped by convergent flaking techniques with a high degree of shaping both on platforms and usage of convergent techniques. The fully shaping of both surface and butts prepares a high degree of refinement that should fully look like the middle Paleolithic technique both in Europe and Africa. Different methods of shaping show a high refinement technology that only comes elsewhere much later. Several other sites show this high refinement technologies already obtained in China much earlier than in different parts of the world.

ORAL

#### 5. HALLAM MOVIVUS AND THE LINE THAT NEVER WAS

Dennell, Robin (*University of Sheffield*) [r.dennell@sheffield.ac.uk](mailto:r.dennell@sheffield.ac.uk)

The "Movius Line" is one of the most fundamental concepts in studies of the Asian Palaeolithic. Despite its importance in contrasting the Acheulean, biface-using in-

habitants of west and south Asia with the core and flake using inhabitants of East and SE Asia, there has been almost no discussion of the validity of the field data that Movius collected in Myanmar in 1938 and which underpinned his 1948 synthesis, or of the Pleistocene chronological framework of Helmut de Terra that was used by Movius. Here, I show that the geological sequence of de Terra is almost certainly invalid; that Movius was unable to demonstrate that any of his "Anyathian" artefacts could be correlated with de Terra's alleged Pleistocene terraces; or that the lithic assemblages that he considered from Southeast Asia were Early or Middle Pleistocene in age. Overall, the "Movius Line" was a house built on sand, and is best forgotten.

ORAL

#### 6. THE PALEOLITHIC IN CENTRAL CHINA: CHRONOLOGY, TECHNOLOGY AND COGNITION

Youping Wang (*School of Archaeology and Meseology, Peking University*) [ypwang@pku.edu.cn](mailto:ypwang@pku.edu.cn)

Through the analysis of Dingcun light duty tools and the cores of Dingcun, the basic characteristics of Dingcun industry are shown more comprehensively.

This paper will focus on the chronology, technology, cognition and related issues in Middle to Upper Paleolithic in Central China. Since 2000, several Paleolithic sites near Zhengzhou, the capital city of Henan Province, Central China such as Zhijidong Cave at Xingyang, Zhaozhuang at Xinzheng, Xishi at Dengfeng and Lijiagou at Xinmi were excavated. Much more new information related chronology, technology and cognition were collected from those sites. The preliminary research result on new discoveries indicates that the pebble tool industry occupied the leading position when early human came to the Zhijidong cave. However, the flake tool industry apparently succeed and developed from the pebble tool tradition since about 40000BP both in the cave and open air sites, and then were blade industry at Xishi site about 25000BP. The microlithic assemblages were found from Lijiagou, an early Holocene site around 10500 to 9000 BP. The process from pebble tool to flake, blade and microlithic tools is not only the change of lithic technology in the Late Pleistocene Central China, but also related with the developments of modern human cognition and so on.

ORAL

## 7. THE TECHNO-ECONOMIC BEHAVIOR OF DINGCUN LITHIC INDUSTRY

*Shi-Xia Yang (IVPP, Chinese Academy of Sciences)*

*yangshixia122@gmail.com*

*Ya-Mei Hou (IVPP, Chinese Academy of Sciences)*

*houyamei@ivpp.ac.cn*

*Wei-Wen Huang (IVPP, Chinese Academy of Sciences)*

*huangweiw@ivpp.ac.cn*

Dingcun, excavated in 1954 and 1955, was the first properly-excavated paleolithic site after the foundation of P. R. China in 1949. It is a famous Paleolithic site in North China that lies in the rift zone of the Fenhe Graben, which is located in the eastern Chinese Loess Plateau in Shanxi Province. Although Pei (1958) stated that Dingcun was Late Pleistocene in age, according to the cultural layer is below the first paleosol (S1) which is dated to 73~128 ka (Ding et al., 1991, 1994; Wu and Liu; 2002), and the U-series dating results is 160 ~210 ka (Chen et al., 1984), so in recent work, the Dingcun assemblage dates to the Late Middle Pleistocene (Yang et al., 2014).

This re-studies, which includes the whole assemblage, will focus on using the technological and typological analytic methods to define the techno-economic behaviors of Dingcun lithic industry. Aiming to have a whole perspective of the lithic industry, we also applied the geological mapping and the geochemical test to establish the source of the hornfels used in the Dingcun industry. Study of the chaîne opératoire shows that in the Dingcun industry the two product processes (or production line) are paralleled, and the residents had a clear knowledge of both. Since the by-products of heavy duty tool production were saved to work as the supplement blanks of the light duty tools production. Through the analysis of Dingcun light duty tools and the cores of Dingcun, the basic characteristics of Dingcun industry are shown more comprehensively. Compared to the other sites in north China and other sites in Africa or Europe, the transitional traits of Dingcun can be identified. At present, it is hard to state conclusively that the Dingcun industry is a Lower to Middle transition site, although progress on producing light duty tools should be acknowledged and the new traits that are in keeping with an MP should be highlighted. The Paleolithic transition in China did not appear abruptly in the Late Middle Pleistocene, instead the progress was made step by step.

ORAL

## 8. MODERN HUMAN BEHAVIOR EMERGENCE IN LONGQUAN CAVE, LUOYANG, CHINA

*Shuisheng Du (School of History, Beijing Normal University)*

*ssdu@bnu.edu.cn*

The Longquan cave site in Luanchuan county, Luoyang of China is about 26-36kya. In 2011, the joint archeological team have excavated 512 stone artifacts and a large number debitage fragments and chippings which was knapping by simple core-flake technology, hearth and a polished bone awl. These findings suggest that residents of Longquan cave were able to division their living areas by different functions with different landscape conditions. A constructed hearth and barbecue stone to to bank energy is also an important finding. Which means modern human behavior emergence in China, and there are a different adaptation model exist in China.

## 9. USE-WEAR EVIDENCE AND FUNCTIONAL INFORMATION ON LITHIC TOOLS AT WULANMULUN SITE, INNER MONGOLIA, CHINA

*Hong Chen (Department of Cultural Heritage and Museology, Zhejiang University) hollychen@zju.edu.cn*

*Ya-Mei Hou (Key Laboratory of Vertebrate Evolution and Human Origin of Chinese Academy of Sciences, Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences) houyamei@ivpp.ac.cn*

*Zemeng Yang (Ordos Antiquity & Archaeology Institution)*

*Ziming Zhen (Ordos Antiquity & Archaeology Institution)*

*Huiru Lian (Department of Cultural Heritage and Museology, Zhejiang University) lhr336@126.com*

*Yang Liu (Ordos Antiquity & Archaeology Institution)*

The Wulanmulun site was discovered on the left bank of the Wulanmulun River in Ordos, Inner Mongolia, North China. It is considered as another new important discovery of paleolithic culture in Ordos region beyond the sites of Salawusu and Shuidonggou. Up to the end of 2012, about 4200 stone artifacts and 3400 fossils mammal and abundant evidence of hominid use of fire were excavated from Locality 1. In order to explore tool function and human behavior at Wulanmulun during the Middle to Late Pleistocene, we have selected 283 specimens excavated from Locality 1 in 2010 for use-wear analysis. Many stone artifacts display used wear, and several show wear from hafting. The working motion was dominated by de-

fleshing and slicing, and the main contact material were animal substances.

Since the amount of stone artifacts is huge, and the commonest raw material is quartzite, we employ the low power technique with an Olympus SZX16 stereo microscope at magnifications ranging from 8.75 to 143.75 diameters. All wear patterns were photographed using a Nikon EOS 600D digital camera, and measured by Olysim Basic software.

The concept of Functional Unit (FU) is used to count the number of use-wear indications, including traces of prehensile use and hafting. The analytic results suggest that 134 specimens retain use-wear, accounting for 47.4% in the observed samples. As 17 specimens were found with more than one segment of FU, a total of 154 FUs are therefore found at different locations.

Six types of working motions are identified, including defleshing (slicing), cutting (sawing), piercing, drilling, scraping and engraving. The contact materials were mainly identified as animal substances, including flesh, fresh hide, dried hide, and fresh bone with a slight difference in hardness. From a cross-tabulation of working motion and contact material, many use-wears exhibit the possibility of contacting both flesh and bone at the same time.

Hafting wear refers to micro-fracture and abrasion traces caused by either the pressures of handling or binding as a way of making a composite tool. Compared to our experimental data, at least three specimens are identified as bearing both used wear and hafting wear, indicating that some tools might have been used as composite tools at Wulanmulun site.

The preliminary results reveal direct evidence of tool function and human behavior, indicating that most stone artifacts were used as tools, and some might have been used as composite tools.

It is suggested that animal-processing, including skinning and defleshing, is a main working task at Locality 1. Palaeozoological and palaeoecological research also provides us with evidence that animal substances were utilized in this site since fossil animal remains, burnt stones and combustion features were discovered in situ. Some bones also showed cut marks at anatomical parts. The results suggest that some lithic artifacts from Locality 1 might have been made and used as composite tools, which maybe currently the earliest ones identified in China. This study sheds light on the emergence and

subsequent success of composite tools during Middle Paleolithic in North China.

ORAL

## 10. THE SOCIETY OF PRE-YANGSHAO PERIOD IN CHINA(7000BC?5000BC)

*Jinying Cai (School of History and Museology, Anyang Normal University) caijinying12@hotmail.com*

Pre-Yangshao period belongs to the early Neolithic age in China. Its radiocarbon dates range is 7000BC-5000BC. During this period, there were many cultures in China. The Peiligang culture, the Cishan culture, the Laoguantai culture and the Houli culture were distributed in the Yellow River Valley. The Pengtoushan culture and the Kuahuqiao culture were distributed in the Yangtse River Valley. The Xinglongwa culture was located in the northern region of China. Among those cultures, the Peiligang culture appeared to be the strongest. And the society began to be complicate at this time.

There were many sites and cemeteries excavated in every culture. In this paper, the author mainly uses these materials which had already published. Like Peiligang Neolithic site in Xinzheng, Henan (1978). Excavation of Peiligang site in 1978(1979). Wuyang Jiahu(1999). Excavation report of Peiligang cultural relics in Tanghu site, Xinzheng City, Henan in 2007(2010). Excavation of Cishan Neolithic site in Hebei(1977). Cishan site in Wu'an, Hebei(1981). Beifudi—prehistoric site in Yi River valley(2007). The first and second excavation report of Houli site in Linzi, Shandong(1992). The third and fourth excavation report of Houli site in Linzi, Shandong(1994). Excavation report of Xiamengcun site in Bin County, Shaanxi(1960). Lijiacun Neolithic site in Xixiang, Shaanxi(1961). Pengtoushan and Bashidang(2006). Excavation report of Xinglongwa Site in Aohanqi, Neimenggu(1985). Excavation report of Baiyinchanghan Neolithic site in Linxi County, Neimenggu(1993). The research methods are mainly stratigraphy analysis, typology analysis and pedigree analysis. By using the stratigraphy analysis and typology analysis, we can understand the spatial and temporal distribution of each culture. And by using the pedigree analysis, we can analyze the relationships among those cultures.

The analysis shows that the Peiligang culture is the strongest among those cultures in Pre-yangshao period. Combination of the stratigraphy and typology analysis, the Peiligang culture was divided into three phases. By using the pedigree analysis, the Peiligang culture

originated from the Jiahu culture. Because of the early Cishan culture, the Jiahu culture transferred into the Peiligang culture. The Peiligang culture was influenced by the Houli culture in phase?. It affected the Houli culture, the Cishan culture, the Xinglongwa culture, the Pengtoushan culture and the Laoguantai culture with varying degrees in Phase?. It had less control in phase ?.

During Pre-Yangshao period, the Peiligang culture played a very important role. It was the strongest among those cultures and It had a great impact on surrounding contemporary cultures with different degrees, especially on phase?. The Peiligang culture were mainly distributed in the central plains region. It played an important role in the foundation of the Chinese Civilization development. Judging from the development of the Peiligang culture, we can say that the society began to be complicate at Pre-Yangshao period. Pre-Yangshao period, especially the Peiligang culture was a key step in the process of social complexity.

POSTER

### 11. ISOTOPIC EVIDENCE OF ANIMAL DOMESTICATION IN CHINA

*Yaowu Hu (University of Chinese Academy of Sciences)  
ywhu@ucas.ac.cn*

The animal domestication is a great focus in the archaeological and anthropological field. However, Due to the uncertainty of discerning the domesticated animals from the wild during the early stage of animal domesticated, it is quite difficult to reveal the occurrence of the animal domestication and the mechanism on animal domestication.

In this poster, we tried to analyze the stable isotope ratios in the human and animal bones to find out the dietary difference among animal species and the influence of human feeding behaviour on animal foods.

Based on the above methodology, we succeeded in the identification of the domestic pigs from pig bones around 8500 years ago and the commensal and mutual relationship between cats and humans around 5300 BP, which shed fresh light to the evidence of animal domestication in China.

Longgupo cave, located in Chongqing Municipality, was discovered in 1984. A number of mammalian fossils and stone artifacts were unearthed from the site, fourteen Gigantopithecus teeth and two hominid fossils (one frag-

mental mandible with two teeth and an upper incisor) distinguished the site as one of the earliest evidences of hominid settlement in China. Previous paleomagnetic and electron spin resonance (ESR) dating studies place the site as early as 1.9 Ma (Huang et al., 1995). However, this result is questioned because of the complexity of deposition history. During the Sino-Franco joint excavation between 2003 and 2006, the stratigraphy of Longgupo was reinvestigated in detail (Boëda et al., 2011; Rasse et al., 2011), and mammalian fossil teeth were collected systematically from different layers for dating study. In this paper, we present our dating work on these fossils by combined ESR and uranium series analysis, and the new results suggest that the chronology of hominid settlement in Longgupo site as old as 2.5 Ma.

Seventeen fossil teeth were analyzed in this study, including seven teeth from layer C II 2 to C III 8 of south wall, and ten from layer C III' 2 to C III' 6 of north wall of Longgupo site. All the samples are mammalian teeth and well preserved with enamel and dentine tissues. In this dating work, we applied combined ESR and U-series methods with US-ESR model (p-value model) to calculate the fossil age, this combined method could reconstruct the internal dose of fossil teeth with measured U-Th data, instead of artificial assumption (EU and LU models) of uranium uptake history for dose rate determination which used in previous study. The paleodose of enamel samples were determined by ESR method with double saturation exponential fitting function. The external dose rate were determined by in situ dose rate measured in 2012 with NaI portable gamma spectrometer and laboratory analysis of surrounding sediments by high-purity Ge gamma spectrometer in low temperature.

Uranium-series analysis shows that  $^{230}\text{Th}/^{234}\text{U}$  activity ratios of all the samples are not beyond equilibrium, which indicate no obvious uranium leaching occurred and US-ESR model could be applied for fossil age calculation. The p-values of the dental tissues in all the samples are beyond zero, which represent a recent uranium uptake history, except one from layer C III 3 of south wall, which also gives a much younger age than others. For the north wall, ten teeth from unit C III' show consistent ages in general, about 2.3 Ma in average; for the south wall, the sample ages distribution are not in accordance with the stratigraphic order, three teeth are much younger than the other four, probably because of the relative higher uranium concentration and U/Th ratio in the dental tissues, and significant higher in situ gamma dose rate, respectively. Nevertheless, the three teeth from C III give the age of  $\sim 2.5$  Ma in average. This result is older than our preliminary results (Han et al., 2012) since in situ dose rate measurement was not available for some layers in the previous study. This updated results based on

detailed in situ dose measurement in 2012 agrees with the paleontological evidences of Longgupo, which the co-occurrence of *Sinomastodon*, *Nestoritherium*, *Equus yunnanensis*, *Ailuropoda microta* and the rodent *Miomys peii* suggest a time range of late Pliocene to early Pleistocene (Huang et al., 1995), and could also explain the new paleomagnetic analysis which all the samples show negative magnetic polarity except the upmost ones collected from layer C II-2. The result in this study places Longgupo site between the end of Gauss chron and onset of Olduvai subchron.

This study date the fossil teeth systematically from different layers of south and north wall of Longgupo site according to the new stratigraphic division and updated in situ gamma dose rate measurement by Sino-Franco team. The age results of both wall unambiguously reach to  $\sim 2.5$  Ma, which place Longgupo site at the very beginning of Early Pleistocene. Although the creators of "Longgupo culture" is still a mystery (Wei et al., in press), comparing with other convincing evidences of early hominid settlement in China, such as Majuangou III Paleolithic site in Nihewan Basin ( $\sim 1.7$  Ma, Zhu et al., 2003) and Xihoudu Paleolithic site in Shaanxi Province ( $\sim 1.4$  Ma, Kong et al., 2013), Longgupo site is undoubtedly the oldest hominid sites in China and East Asia so far.

**1. A CRITICAL ANALYSIS OF THE EVIDENCE FOR TECHNICAL SPECIALISATION IN THE UPPER PALEOLITHIC**

*de Beaune, Sophie (Université Jean Moulin Lyon 3 - UMR Ar-ScAn Nanterre) sophie.de-beaune@mae.cnrs.fr*

In this paper, I propose a critical analysis of the evidence for technical activity specialization in the Upper Paleolithic according to age and sex. Some hypotheses are based on suppositions generated by ethnographic comparisons, while others rely on direct or indirect indices including task diversification, activity zone locations, the identification of different skill levels, the diversity of grave goods, and even evidence from the body, such as hand prints. Three types of explanations have been proposed for this subject:

- 1, simple suppositions based on ethnographic comparisons, particularly concerning the sexual division of tasks, through reference to what is most often observed among living or recent populations;
- 2, explanations based on indirect archaeological evidence;
- 3, explanations based on direct evidence, which, as we will see, is rare and difficult to interpret.

Based on the analyzed information, as well as simple common sense, I propose that there was a reasoned distribution of activities within groups, accompanied by an emerging social hierarchy.

I will conclude by insisting that we must be cautious in our interpretations since what we seek to understand is the identity of our Paleolithic actors, while this identity forcibly evolved throughout the millennia of prehistory and was subject to the ebbs and flows that shaped the history of Paleolithic societies.

ORAL

**2. COGNITIVE AND NEUROPSYCHOLOGICAL PRE-REQUISITES OF TASK DISTRIBUTION IN PREHISTORIC SOCIETIES COOLIDGE, FREDERICK (UNIVERSITY OF COLORADO, COLORADO SPRINGS) FCOOLIDG@UCCS.EDU**

*Wynn, Thomas (University of Colorado, Colorado Springs) twynn@uccs.edu*

Kuhn and Stiner (2006) proposed that sex and age divisions of labor are unique to *Homo sapiens*. We agree but have further argued (e.g., Coolidge & Wynn, 2001; Wynn & Coolidge, 2008) that this division of labor, whether hunting, gathering, or technical, is characteristic of a particular *pattern of thinking* based on species-specific neurological characteristics that evolved within the last 200,000 years. These neurological characteristics appear to be linked to an expansion of the superior parietal lobe in *Homo sapiens* (Bruner, 2004; Bruner, 2010; Bruner, Rangel de Lazaro, Cuetara, Martin-Loeches, Colom, & Jacobs, 2014). One social phenomenon that appeared late in human evolution, and which was arguably related to division of labor and other forms of social specialization, was the planning and execution of long-distance trade with acquaintances and strangers (Ambrose 2008). The present paper explores this neglected aspect of *Homo sapiens* thinking, and proposes that two cognitive developments were critical: enhanced executive functions (or enhanced working memory [Baddeley 2002; Coolidge & Wynn, 2005; Wynn & Coolidge, 2010]), and Theory of Mind, the ability to read the intentions, attitudes, and feelings of others.

ORAL

**3. ASTURIAN PICKS AND MAINTENANCE ACTIVITIES IN LA RIERA CAVE (ASTURIAS, SPAIN)**

*de Juana Ortín, Cristina (Universidad de Alcalá (Madrid, España) cristina.juana@uah.es*

Based on the study of the Asturian Picks of La Riera, we propose the following: firstly, to relate them to maintenance activities (M.A.) and secondly, to use them as a basis to justify the distribution hypothesis of these tasks by gender or age.

The pieces in question, are characteristically found in low numbers on archaeological sites. Furthermore, some of the Asturian Picks in La Riera cave have other residues. Like in other industries, as quartzite, in them, it's possible to differentiate "variety of their traces of use" (Beaune 1994:64).

The Asturian Picks in La Riera cave were in domestic environments and if we associate this picks with maintenance activities, the result it is convincing. We want

to study the specific site of the Asturian Picks in different jobs.

Our intention is to reflect on the involvement of individuals, by gender and age, within the M.A. associated with these production cycles in The Finiglacial period.

To do so, we selected "the Asturian Picks" of La Riera deposited at the Museum of Natural Science of Madrid.

Our methodology consisted of the following steps: 1. Standardize information about the pieces in order to compare them. 2. Use parallels in experimental archeology that allow us to define the M.A. in which they could have been used, and specify their possible uses. 3. Search for studies in ethnoarchaeology linking our production cycles with the division of labour, without losing sight of the fact that we are referring to hunter-gatherer people. They are multifunctional objects, which allows us to relate them to a greater or lesser extent to women and different ages, as ethnographic comparisons suggest. The operational chains that we have identified would have been closely related to maintenance activities (M.A.) given that "the cycles of the various materials are never completely separate from each other. By way of analogy, not only can you transfer certain phases of the production of one material to another, a cycle can also reuse discards from another production otherwise the success of one activity may mean the failure of others." (Mannoni and Giannichedda 2004:79).

That said, the domestic arena is presented as a social nucleus of hunter-gatherers, where individuals of all ages and both sexes converge, and where the Asturian Picks become "invisible" witnesses to everyday life.

#### **4. THE EVOLUTION OF INSTITUTIONALISED DIVISION OF LABOUR? LITHIC TECHNOLOGY IN STONE AGE SCANDINAVIA**

*Apel, Jan (Lund University) jan.apel@ark.lu.se*

The ability to accumulate culture over time separates humans from other species. A unique form of knowledge-transfer allows individuals to stand on the shoulders of earlier generations and increase the rate of cultural development and change. It has been suggested that important requisites for cumulative culture are evolved brains that allow for shared cultural representations, and an innate human pedagogical ability. Humans have a

natural tendency to be able to create enriched learning environments in which complex technological information and know-how is transmitted to future generation. Among mobile hunter-gatherers such information seem to be reproduced within basic sex and age groups and is more or less freely available for group members. However, in more sedentary societies, an increased dynamic density seems to lead to lineage-based technological specialisation and to the breakdown of segmentary social structures. Such a scenario is discussed in this paper with an example from Late Neolithic southern Scandinavia.

#### **5. DISTRIBUTION OF TASKS WITHIN A NEOLITHIC COMMUNITY: METHODOLOGY, RESULTS, CHALLENGES AND LIMITATIONS**

*Duboscq, Stéphanie (Universitat Autònoma de Barcelona) duboscqstephanie@gmail.com*

*Gibaja, Juan (CSIC) jfgibaja@gmail.com*

*Piqué, Raquel (Universitat Autònoma de Barcelona) raquel.pique@uab.cat*

The goal of this paper is analyzing the sexual division of labor in the Neolithic (VI-III millennium BC) in the NE of the Iberian Peninsula (now Catalonia and Andorra). The main objective of this research is to try to improve our knowledge of the social organization of Neolithic populations, especially the relations between men and women. In history and still today the woman has often been a "victim" of the sexual division of labor, becoming this the cause of the inequality among men and women. The question is when this situation starts and, particularly, if it happened in the Neolithic of NE of Iberian Peninsula. The starting point of this research is the analysis of graves of the Neolithic sites in Catalonia. One of the ways to document the division of labor in this period is to observe the burials, the deceased associated equipment (which can tell us about the activities or social status of the person when living) and bone diseases, when the state of conservation of the skeleton allows it.

But the information obtained from funerary contexts must be handled with care, because of its subjectivity, and here appear the first difficulties. The definition of a specific theoretical framework is essential; some basic notions must be carefully reflected (funeral ritual, work and activities, sex and gender, equality and inequality). Other problems may occur and make our task more difficult: the state of conservation of the site and its remains;

the antiquity of the excavation; possible looting and other taphonomic dislocations; dating problems, etc.

Through the analysis of these funerary contexts, we will see that certain types of objects are more often associated with men, other with women and other with children. This preliminary analysis already enables us to speak about some differences between men and women concerning the activities they are linked with.

It seems that each sex is linked to well-differentiated types of tasks. Women may have been more involved into activities to maintain the community and which can be made without leaving the settlement (like the work of the skin, the couture, etc.). From what we find in the graves, men would be more linked to activities like fleshing, hunting and working hard materials like wood.

The preliminary data resulting from early research on the subject of the sexual division of labor during the Neolithic Catalan show that at certain times, especially during the middle Neolithic, there are differences in the grave goods of the buried people. The differences in what is represented in the burials can provide elements for reflection on the social value of objects/tools, activities and consequently of the individuals who performed them.

## 6. WOMEN'S WORK? FINDINGS FROM THE NEOLITHIC CHERT MINES IN THE "KRUMLOVSKÝ LES", MORAVIA

*Oliva, Martin (Moravian Museum) moliva@mzm.cz*  
*Jarosova, Ivana (Moravian Museum) ivanajar@gmail.com*  
*Nyvltova, Miriam (Archaeological Institute, Brno) miriam@iabrno.cz*  
*Serý, Omar (Masaryk University) osery@elisabeth.cz*  
*Tvrdy, Zdenek (Moravian Museum) ztvrdy@mzm.cz*

In the "Krumlovský les" (Krumlov Forest) in South Moravia the outcrops of the Jurassic chert are located, redeposited in the Miocene sands. Although their quality was only mediocre, they were mined from the Mesolithic to the Hallstatt Age. had caused intensive settlement in this area already since the Middle Palaeolithic. It's obvious that latest since the Early Bronze Age, when the mining culminated, the importance of this old extraction landscape no longer consisted in its lithic resources, but in its past.

Nearly all Late Lengyel dated situations were discovered in trench VI-9-1 into the rather steep slope below a 1 m high chert-breccia boulder, undoubtedly placed here arteficially. The circular cross section of the 100-120 cm wide shaft Nr. 4 continued straight down to the depth of 6 m, where a complete human skeleton (H1) was found. A second skeleton (H2) with a new-born (H2b) was found 60 cm deeper.

Female H1 died at the age of 30-35, individual H2a was aged 35-40. Both females were gracile but with distinct muscle topography. Their statures were estimated at 148.8 and 146.1 cm, respectively; both females were the shortest of all examined individuals from the Moravian LgK period. Both women have delivered. Enamel hypoplasia and Harris lines show evidence of stress experienced by both individuals during growth and development. The health condition of woman H2a was poorer than that of female H1. She suffered from iron deficiency and her left ulna had been broken and healed with pseudoarthrosis. Both skeletons show evidence of hard physical activity (distinct muscle topography, Schmorl nodes, osteophytes).

According to the carbon, nitrogen and strontium isotopic analysis, the women were well alimented during the last year of their lives. They have eaten animal proteins, as well as plant food including berries rich in minerals and vitamins. The results of the DNA analysis (O. Šerý) proved that the skeletal remains of females H1 and H2a are related, and may represent a mother and a daughter, or two sisters.

The unusual physical characteristics of the females buried in the shaft 4 raise suspicion that for the exhausting work in mining shafts (also) weak individuals of small stature were misused, who had starved in their youth. From the ergonomic angle, the small stature in the miners would be advantageous, since they would more easily fit into the narrow shafts. In the Krumlovský les, however, the shafts are wider than e.g. in Abensberg-Arnshofen, where it is assumed that mining was done by youngsters. Another reason may be based in the sphere of religious ideas – in the Dark Continent women allegedly work in the mines because they are more easily accepted by the Earth, since it is of female gender like them. The third explanation results from simple human ruthlessness: the hardest work is not carried out by the strongest, but by those who can be coerced into it most easily. Therefore, the paper demonstrates that the linkage of some facts with the topic of division of labour can be only apparent.

ORAL

## 7. GENDER ACTIVITIES AND SOCIAL ROLES IN SOUTHERN CENTRAL ASIA DURING THE BRONZE AGE

*Luneau, Elise (DAI-Eurasien Abteilung) elise.luneau@dainst.de*

The Oxus civilization – a proto-urban and sedentary culture spread across southern central Asia during the second half of the 3<sup>rd</sup> and the first half of the 2<sup>nd</sup> millennium BCE – counts among those societies with strong social differentiation, which is particularly visible in the burial practices. Graves of deceased females are viewed as richer than graves of males, because they are better furnished in the quantity and/or quality of items, especially in precious materials. Older studies perceived the wealth of the female burials dichotomously: either as the symbol of female power over society (matriarchy), or, oppositely, the reflection of male wealth (husband, father, etc.). Also, according to previous research activities of men and women differ considerably, women tending to be limited to the domestic sector.

However, the precise study of the distribution of funerary gifts in five necropolises attributed to the Oxus civilization has revealed more about preferential dispersal of items according to sexual identity, and enables questions about gender activities and social status.

The inaccuracy of older perceptions of activities based on gender can be posited. The analysis provides a more balanced division of tasks between both than previously asserted.

Different functions of artefacts seem to fit with different high status correlated with specific social roles of men and women in this society.

ORAL

## 8. POTTERY TO IRON: GENDERED TRANSITIONS OF VALUE WITH THE COMING OF IRON IN THE LAKE CHAD BASIN, CENTRAL AFRICA

*MacEachern, Scott (Bowdoin College) smaceach@bowdoin.edu*

During the mid-first millennium BC, agricultural communities in the southern Lake Chad Basin of Nigeria, Cameroon and Chad progressively adopted iron tech-

nologies. The technological and economic implications of that adoption have been widely discussed, but rather less attention has been paid to their social consequences. Historically, as in many areas of Africa, iron smelting was a spectacular and highly gendered activity, often involving images of male potency and the fecundity of a furnace gendered as female. Ceramic production, on the other hand, is undertaken by women and has far less cultural prestige. The characteristics of pre-iron-working ceramic traditions suggest that pottery had earlier occupied a more prestigious role, probably associated with the serving of food and drink in more mobile communities. This paper will discuss probable changes in the values assigned to gendered artefact production before and after the introduction of iron in this region, as well as the implication for archaeological interpretations of an archaeological heritage dominated over the last two millennia by the material remains of tasks undertaken by women.

ORAL

## 9. SEXUAL DIVISION OF LABOR AND SOCIAL VALUE IN SUB-PRESENT HUNTER-FISHER-GATHERER SOCIETIES: AN OBJECTIVE WAY TO MEASURE INEQUALITY IN PREHISTORY

*García Piquer, Albert (Universitat Autònoma de Barcelona) alberto.garcia.piquer@uab.cat*

Ethnography describes most Hunter-Fisher-Gatherer (H-F-G) as egalitarian societies in which sexual division of labor is an unavoidable consequence of the biological features of both sexes or a technical strategy based on the complementarity of male and female features that produces the most successful adaptation. Due to the archaeological invisibility of social relationships through methodological issues available nowadays in prehistoric archaeology, it is commonly assumed that Prehistoric H-F-G societies were egalitarian in the same way and for the same reasons as the former. However, a non-biased, complete and objective analysis of the ethnographic information shows that actually there are two main basic universal features in the organization of H-F-G social relationships: sexual division of tasks (labor) and social inequality between males and females. Despite their universal appearance, the large variability in the morphology and in the intensity of the different cases demonstrates that these relationships are not caused directly by the biology of men and women. They are clearly a social option.

Inequality is materialized in the different effort invested by men and women in the labors related to subsistence and reproduction. This difference is measurable through the consequences of labor and can be retraced considering the work effort invested in the products. It can be objectively evaluated for every product through the calculation of the labor (time\*effort) invested with the available technology.

We have tried to demonstrate this approach with Tierra del Fuego H-F-G societies. We have proposed a system for evaluating, in an objective way, the real value (the effort invested by men and women) via an Ethnographic example as well as its application to an ethnoarchaeological context. We have considered (1) the main environmental features and conditions, (2) the ethnographic information contrasted with experimental and archaeological data and (3) we have replicated almost all working procedures, to gain a more objective and quantitative perspective.

Considering all this information we can succeed in calculating archaeologically the value produced by every social segment in Tierra del Fuego H-F-G societies. Even without considering the effort invested in reproduction, the differences in the working effort between men and women are well documented both in the ethnographic and the potential archaeological record.

The greater contribution of women to the daily subsistence (more labor – more provision of objective value) does not correspond with their social role. Men are considered more socially important, they take decisions and they set up the rules. To explain this situation we suggest a direct link between: (1) division of labor based on sex, (2) devaluation of women (by the devaluation of their contribution) and (3) control of the sexuality of women (fundamentally) in order to regulate the reproduction of the group. Finding archaeological indicators of the sexual division would be a first step to find out when and why started this social organization. Experimental Ethnoarchaeology provides a powerful tool to conduct research on this field.

## 10. MASCULINITY AND FEMININITY VERSUS GENDER SPECIFICITY IN CORPORAL ART

*Bouvry, Florence (ARSCAN UMR 7041), Maison de l'Archéologie et de l'Ethnologie, Nanterre (92) [florence.bouvry@gmail.com](mailto:florence.bouvry@gmail.com)*

In traditional functioning contemporary societies, one's body image has a major part in the way men and women are acknowledged within a community.

Scarification, body painting, as well as ornaments contribute to establishing a « territory » directly on one's skin as an identity mark referring to a specific society or community. Marks and subdivision signs are never a goal but take their purpose in initiations and collective ceremonies. They represent a step forward taken in personal development, the step to manhood and towards a new social status, an acceptance in a specific group, etc.

Depending on the society, male and female gender each have their specific place in taking part in corporal art's production or personal structuring. This task distribution takes place throughout the initiation path and is passed on by the word of the elders as well as traditional ways and customs. Members of a same community exhibit very specific corporal marks, referring to either masculinity or femininity.

Troughout this communication, I intend to analyse how gender specificities take part in the task distribution and more specifically, how those will be assigned either to men or women according to their place in body's identity structuring. This will be based on ethnographic data and observations concerning African and Amazonian societies or communities.

ORAL

## 11. TASK NETWORKS IN CAVE RITUAL CONTEXTS AND ASSOCIATED FEASTING

*Villeneuve, Suzanne (Simon Fraser University) [suzanne\\_villeneuve@sfu.ca](mailto:suzanne_villeneuve@sfu.ca)*

Ritual activity in tribal or village-level (transegalitarian) societies has been implicated in the creation of socioeconomic inequalities and political power. However, the motivations for creating various forms of ritual and the means by which they promote inequalities are poorly understood for transegalitarian societies. There is as yet little ethnographic or archaeological information on how such activities can be identified at transegalitarian levels. Understanding task division and task networks through ethnographic and ethnoarchaeological investigation of various rituals can provide critical insights into the social groups involved, their organization and

motivations with implications for archaeological material and landscape patterning.

When narrowing the focus to restricted ritual spaces such as caves and remote ritual structures, secret societies and cults emerge as a potential key group behind the early use of and elaboration of these spaces in transegalitarian societies. Cults are important aspects of many societies, from relatively egalitarian hunter-gatherers to far more complex state level societies and they potentially play unusually important roles in early cultural developments. Yet, under what conditions secret societies emerge, the extent of their power and influence, their impact on the surrounding community, the specific strategies they employ, the benefits or advantages their members obtain, as well as many other aspects are not well understood in part due to the paucity of ethnographic examples and since very few studies have been conducted to address these issues specifically. Of particular importance for archaeologists who wish to be able to identify such organizations in the past and their influence on early cultural developments, there has been virtually no systematic.

Through an ethnographic and ethnoarchaeological lens examining task division and task networks involved in secret society organizations in a broader cultural context surrounding cave rituals, a number of insights are gained to aid in modeling potential associated archaeological expectations. This paper will focus on key components of an ethnographic ritual pattern associated with caves, including community, small group and individual or private ritual and feasting.

By understanding task division and task networks involved in these scales of connected ritual activity, a broader picture of the social and cultural context surrounding caves emerges. This has archaeological implications for understanding the potential social groups and individuals associated with certain landscape locations, activity areas, materials and special paraphernalia, the elaboration of or investment in spaces including specially prepared walls or floors, special food remains and many other aspects of the material record associated. These implications are also explored in an archaeological case study dealing with remote ritual structures in transegalitarian societies on the Canadian Plateau.

We should expect to see indications of these ritual organizations early in the archaeological record in many contexts where visible socioeconomic inequalities later emerge. Better understanding of these ritual spaces and their broader social and cultural context can provide critical insight into the pathways or trajectories to the

emergence of inequality and centralized power, and the timing of the emergence of inequality in some cases.

ORAL

## 12. LA RÉPARTITION DES ACTIVITÉS ET LA RÉPARTITION DES TÂCHES SELON LES SEXES : L'EXEMPLE DE LA MOUTURE

*Procopiou, Haris (Université de Paris 1 (Panthéon-Sorbonne), CNRS UMR 7041 (ArScAn) haris.procopiou@univ-paris1.fr.*

La mouture a été, depuis le 19<sup>ème</sup> siècle, associée à la femme et à la maisonnée, la meule l'attribut féminin par excellence. Mais le registre ethnographique révèle que la mouture peut, dans certains contextes non-domestiques, être pratiquée par les hommes. Considérer la transformation des grains durant la protohistoire, comme une tâche exclusivement féminine, serait-il une vision anachronique, intimement liée à nos représentations collectives? Pour reconstituer la répartition des tâches entre hommes et femmes, *il faut identifier les tâches sur la base d'analyses technographiques précises, et non à partir des catégories générales ou artificielles dont on se contente trop souvent.* Quel type de mouture, quels outils, quels gestes, quelles postures corporelles, dans quel cadre et dans quelle finalité? Le registre ethnographique montre que la mouture des céréales, lorsqu'elle se fait dans le cadre de l'économie domestique, est une tâche exclusivement féminine.

Les premières attestations archéologiques remontent au mésolithique. Les lésions ostéologiques, identifiées sur des squelettes féminins à Abu Hureyra ont été associées à une activité de mouture prolongée. Les chants qui accompagnent la mouture, montrent que cette action est considérée comme rude, laborieuse, associée à la condition féminine. Des servantes de Pénélope aux chants des meules en Inde les femmes expriment la douleur de leur condition. Les femmes moulent accompagnées le plus souvent de leur fille, les petites filles jouent sur la meule tandis que l'imitation de la mouture, avec des outils miniatures, fabriqués par les enfants, est un jeu courant en Afrique du Nord. La mouture assurée par une main d'œuvre masculine est, par contre, toujours liée à des contextes spécifiques. En l'absence d'une main d'œuvre féminine, la mouture est assurée par des hommes en voyage ou en guerre. Obliger un homme à assurer une activité féminine est aussi une punition sévère, le pire des déshonneurs. Cette pratique, remonte au moins à la période paléobabylonienne (2<sup>ème</sup> millénaire) comme l'attestent plusieurs textes cunéiformes et l'iconographie. La mouture peut

aussi être assurée par une main d'œuvre masculine, mais dans ce cas, comme en Égypte pharaonique et au Proche-Orient sumérien, il s'agit d'une main d'œuvre servile au sein de minoteries dépendant d'une autorité. L'apparition du moulin d'Olynthe à la fin du VI<sup>ème</sup> siècle av. J.C a conduit à la mise en place d'ateliers mobilisant des esclaves, pratique généralisée à la période romaine.

### 13. AN ETHNOARCHAEOLOGICAL PERSPECTIVE ON GENDER DISTRIBUTION OF HARVESTING AND PLANT WORKING ACTIVITIES IN NORTHERN AND CENTRAL TUNISIA: A PRELIMINARY CASE STUDY

*Anderson, Patricia Chabot (CEPAM, CNRS, Nice, France) patriciacanderson@hotmail.fr*

We observed and recorded subsistence agricultural practices, crafts using plants, and tool making in North-western Tunisia between 2005 and 2010, essentially from a technical standpoint. Some of these findings were compared to earlier observations from Syria, and gender division of activities in these regions contrasts with those published earlier for many other regions, particularly European.

Although both women and men knew how to carry out most activities, where agriculture was concerned, plowing, sowing, harvesting and threshing were essentially masculine activities, as well as shepherding, although women sometimes participated in certain of these activities. However, selection of sowing grain, collection of spices and other food plants and food preparation activities, and tending to animals at home were essentially carried out by women. On the other hand, wild plants were collected for fodder and for basketry by men, and basketry to make various objects corresponding to specific nomadic and sedentary activities, was an exclusively masculine domain, with making of these objects carried out alongside other daily activities by certain expert community members or family members, for the family or community. Transmission of skills in all cases occurred through imitation, with children accompanying relatives into the field or working alongside them at home.

Today, in the Northwest much know-how is being lost as young people leave home or prefer other, lucrative activities. Another form of change is occurring with professionalization of some of these activities in central Tunisia, and in particular basketry, although seldom done by men in families and villages today, is being increasingly carried out

by artisans, particularly women, and innovation in forms and decorations of objects is occurring in response to the tourist trade. Although traditional patterns are being broken, the arrival of artisans contributes to preservation of many traditional objects and associated know-how.

Le jeu est une activité multidimensionnelle : joyeuse et ludique elle joue à son tour un rôle majeur dans l'apprentissage social des tâches. Nous considérons l'activité du jeu dans un sens large en incluant aussi le processus de fabrication des jouets par les enfants. La fabrication d'un jouet n'est pas une activité standardisée et formalisée, mais fait partie intégrante du jeu ; dans certains cas, la fabrication du jouet est le jeu.

La différenciation sexuelle est primordiale dans le développement et la socialisation de l'enfant. Des études de cas issus des enquêtes de terrain (Tunisie, Maroc) nous permettent d'aborder les modalités de la transmission de la répartition sexuelle des tâches à travers le jeu. On verra à quel point les enfants reproduisent les normes sociales mais aussi comment le jeu refaçonne et intervient à ces normes.

En parallèle, les enfants en créant leurs propres jouets apprennent les qualités de la matière et les propriétés des matériaux. La fabrication des jouets exige une compétence technique et un savoir-faire parfois assez complexe. À travers le jeu, les enfants apprennent à fabriquer leurs jouets, mais aussi apprennent à *fabriquer*. Ils entrent dans l'univers technique de la société ; en jouant, ils nous dévoilent leur propre perception du monde des adultes qu'ils imitent.

Enfin, l'importance de la création de jouets pour la transmission du savoir par les enfants plus âgés aux enfants plus jeunes est un aspect peu exploré, qu'on essaiera d'éclairer. En effet, si les adultes jouent un rôle dans la transmission du savoir et du savoir-faire, le rôle des enfants plus âgés est primordial dans cette transmission.

## 1. PLEISTOCENE BIOSTRATIGRAPHY OF WESTERN EUROPE BASED ON THE GUADIX-BAZA RODENT SUCCESSION

Agustí, Jordi (IPHES) [jordi.agusti@icrea.cat](mailto:jordi.agusti@icrea.cat)  
Lozano-Fernández, Ivan (IPHES) [ilozano@iphes.cat](mailto:ilozano@iphes.cat)  
Piñero, Pedro (IPHES) [ppinero@iphes.cat](mailto:ppinero@iphes.cat)  
Furió, Marc (ICP) [marc.furio@icp.cat](mailto:marc.furio@icp.cat)

The Guadix-Baza Basin (Granada, SE Spain) is composed of a sequence of fluvial and lacustrine sediments that ranges from the latest Miocene to the late middle Pleistocene and which have yielded dozens of large and small vertebrate fossiliferous levels.

Apparently, there are not equivalent levels of the same age than The Georgian site of Dmanisi in the Guadix-Baza Basin. The closest site would be Barranco Conejos, provided its basal upper Matuyama position, as in the case of Dmanisi. Even so, there is no any evidence of human presence at this time in this part of Western Europe. This is also the case in the forthcoming level of Venta Micena, despite the more than 15.000 bones that have been recovered from this rich paleontological site.

However, the situation changes abruptly at the level of Barranco León D (sites of Barranco León D and Fuente Nueva 3), where thousands of Mode 1 lithic artefacts have been recovered in the last years. The delay of close to 400 kyrs between the Southern Caucasus and the Iberian Peninsula can be explained on the basis of the hard environmental conditions that predominated in the latter region during the first part of the early Pleistocene.

## 2. SMALL MAMMALS ASSOCIATIONS DISTRIBUTION AND EVOLUTION FROM ITALIAN PENINSULA DURING THE LATE PLEISTOCENE

Berto, Claudio (Univeristà degli Studi di Ferrara, Dipartimento di Studi Umanistici, sezione di Scienze Preistoriche e Antropologiche, C.so Ercole I d'Este, 32, 44121 Ferrara (Italy) [claudio.berto@unife.it](mailto:claudio.berto@unife.it)  
Valle, Chiara Dalla (Univeristà degli Studi di Ferrara, Dipartimento di Studi Umanistici, sezione di Scienze Preistoriche e Antropologiche, C.so Ercole I d'Este, 32, 44121 Ferrara (Italy) [dallavallechiara86@gmail.com](mailto:dallavallechiara86@gmail.com)

Luzi, Elisa (Univeristà degli Studi di Ferrara, Dipartimento di Studi Umanistici, sezione di Scienze Preistoriche e Antropologiche, C.so Ercole I d'Este, 32, 44121 Ferrara (Italy) [elisa.luzi@student.unife.it](mailto:elisa.luzi@student.unife.it)

Sala, Benedetto (Univeristà degli Studi di Ferrara, Dipartimento di Studi Umanistici, sezione di Scienze Preistoriche e Antropologiche, C.so Ercole I d'Este, 32, 44121 Ferrara (Italy) [slb@unife.it](mailto:slb@unife.it)

The Italian Peninsula is characterized by several types of environments. Its peculiar position and geomorphology favour the presence of diversified climates which have influenced the small mammals assemblages during the past.

The study of materials coming from Late Pleistocene sites - such as Caverna degli Orsi (San Dorligo della Valle, Dolina, Trieste), Ciota Ciara (Borgosesia, Vercelli), Riparo Mochi (Ventimiglia, Imperia), Grotta Paglicci (Rignano Garganico, Foggia) and Riparo Tagliente (Stallavena di Grezzana, Verona) - and the review of up to 40 Italian sites previously published allow to make general remarks on environmental changes occurring in this period and on biochronology.

The analysis of small mammals shows that Italian Peninsula can be divided into "geographic zones" presenting distinctive landscapes and biodiversity grades. Specifically, in Northern Adriatic zone, Valpadana and piedmont bend, species coming from Eastern Europe, such as *Microtus oeconomus* and *Sicista betulina*, are signaled; Southern Adriatic zone is characterized by marked aridity and low biodiversity degree while Southern Tyrrhenian zone displays richer assemblages normally associated with wooden environments.

Finally, all the results have been processed in order to suggest a biochronological model as detailed as possible, in which the most important Late Pleistocene sequences of Italian Peninsula have been positioned and linked to the NGRIP isotopic curve.

ORAL

## 3. GEOGRAPHICAL AND CHRONOLOGICAL PATTERN OF THE HERPETOFAUNAL PLEISTOCENE EXTINCTIONS IN THE IBERIAN PENINSULA: A BIOCHRONOLOGICAL TOOL?

Blain, Hugues-Alexandre (IPHES, Institut Català de Paleoecologia Humana i Evolució Social, c/ Escorxador s/n, 43003 Tarragona, Spain; Àrea de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain.) [hablain@iphes.cat](mailto:hablain@iphes.cat)

Amphibian and Squamate faunas from Western Europe are known to become progressively impoverished during the Pliocene and the beginning of the Pleistocene, probably associated with the intensification of glaciation pulses in the northern hemisphere.

At the end of the Ruscinian stage (ca. 3.2 Ma) the tropical families Varanidae, Aniliidae s.l. and Elapidae disappeared. At the end of the early Villanyian (the current boundary between Pliocene and Pleistocene, at ca. 2.6 Ma) some Gekkonidae, the scincid *Trachylepis* (formerly *Mabuya*), scolecophidian snakes, Erycinae and oriental vipers disappeared from Western Europe, whereas during the same period other thermophilous groups (Agamidae, Blanidae, some Anguinae and some Colubridae) underwent a southward withdrawal. At the same time, some species (*Hierophis viridiflavus*, *Zanemis* aff. *longissimus*, *Coronella* cf. *austriaca* and *Vipera "berus"*) coming from Central Europe arrived in France, as registered at the Montoussé 5 locality. The last "exotic squamates" supposed to have disappeared from Western Europe were the Agamidae and the anguid *Dopasia* (at the end of the Early Pleistocene; ca. 1.1 Ma). As far as amphibians are concerned only a green toad (*Bufo viridis* sensu lato) disappeared from Western Europe also at the end of the Early Pleistocene (ca. 1.1 Ma).

The geographical and temporal pattern of these progressive southward withdrawals and extinction is analyzed in order to establish a framework that can be used as complement of the biochronological zonation of the early Pleistocene in Western Europe.

ORAL

#### 4. BIOSTRATIGRAPHY OF THE PALAEOANTHROPOLOGICAL ATAPUERCA CAVE SITES (PLEISTOCENE, SPAIN)

Cuenca-Bescos, Gloria (Universtiy of Zaragoza) cuencag@unizar.es

Blain, Hugues-Alexandre (IPHES) hablain@iphes.cat

Lopez-García, Juan Manuel (Università degli Studi di Ferrara) lpzjmn@unife.it

Lozano-Fernández, Ivan (IPHES) lpzjmn@unife.it

Rofes, Juan (UPV) juan.rofes@ehu.es

The palaeoanthropological sites of Atapuerca contain the most extraordinary accumulation of evidences of nearly continuous human occupation in Europe, ranging from the Early to the Late Pleistocene. This is evidenced upon the study of the paleontological and archaeo-

logical content in the key six Atapuerca stratigraphic sequences. The biostratigraphy has been the timeframe for understanding the human evolution and culture of the first inhabitants of Western Europe during the Early to the Middle Pleistocene.

On the other hand, the Biostratigraphy of the Pleistocene in Europe has made substantial progress during recent decades, though there are but few stratigraphic sequences that are in the same geographic area such as the Atapuerca Hill. Also, few are close to being complete or are calibrated with chronological data, and therefore most Biostratigraphic proposals are based on isolated sites representing short time-intervals.

The biostratigraphy based on the stratigraphic distribution of the fossil vertebrates found in the cave-infilling sequences of Gran Dolina, Zarpazos, Galería, Sima del Elefante, Sima de los Huesos, and Portalón in the Atapuerca Hill are thus of the utmost importance because they provide a local biostratigraphy and for the first time allow the knowledge of the evolution of species such as *Mimomys*, *Arvicola*, *Iberomys*, *Allocricetus*, among others; as well as the succession of faunal events (First and Last Appearance Data, FAD, LAD) pertaining to important fossil markers, to be calibrated with magnetostratigraphy and radiometric data. In this way they will provide valuable linking points with the numerical ages of the Quaternary continental Biochronology in Europe.

In this way they will provide valuable linking points with the numerical ages of the Quaternary continental Biochronology in Europe.

Cuenca-Bescos, Gloria (Aragosaurus-IUCA-EIA, Dpt. Ciencias Tierra, Universidad de Zaragoza) cuencag@unizar.es

The Spanish Quaternary small vertebrate faunal record is usually divided into five main biozones: *Allophaiomys pliocaenicus*, *Allophaiomys lavocati*, *Allophaiomys chalinei* (*A. chalinei* has recently reassigned to the new genus *Victoriamys*), *Iberomys brecciensis* and *Iberomys cabreræ*. Among them, the *V. chalinei* biozone is usually considered as the last biozone of the Early Pleistocene, and covers an approximated time range from the Jaramillo suchron to the early Middle Pleistocene. This biozone includes several sites in Spain, like Huescar-1, El Chaparral, Cal Guardiola D5, Vallparadís EVT7 and Gran Dolina TD3-8a.

The chronology of some of these localities has been recently updated by a series of works based on magnetostratigraphy and/or numerical dating such as extended-range luminescence (supergrain OSL, TT-OSL, post-IR IRSL) or Electron Spin Resonance (ESR) methods. A synthesis of these results will be presented, which may lead to some new biochronological interpretations, in particular regarding the chronological boundaries of this biozone. In addition, the chronology of other sites of supposedly Jaramillo age that would potentially fit within the time range of this biozone, such as Le Vallonet (France) and Untermassfeld (Germany), will be also discussed.

### 6. THE FOSSIL BAT ASSEMBLAGE OF SIMA DEL ELEFANTE LOWER RED UNIT (ATAPUERCA, SPAIN): FIRST RESULTS AND CONTRIBUTION TO THE PALAEOENVIRONMENTAL APPROACH OF THE SITE.

Galán García, Julia (Universidad de Zaragoza) galanj@unizar.es

Cuenca Bescós, Gloria (Universidad de Zaragoza) cuencag@unizar.es

López García, Juan Manuel (Università degli Studi di Ferrara) lpzjmn@unife.it

The Sierra de Atapuerca (Burgos, Spain) is well known as some of the oldest European hominine remains have been found there. It is a set of quaternary localities containing a very complete stratigraphic and paleontological record. The deposits are cave filling sediments from a complex karst system which has been precisely studied and dated. Here we describe the fossil bat assemblage from the fossiliferous levels of Sima del Elefante Lower Red Unit (TELRU, TE7-TE14). They belong to the *Allophaiomys lavocati* biozone, with an age estimated ca. 1.5-1.1 Ma. Since bat assemblages are not necessarily

originated by the same processes as other small mammal assemblages, they provide a valuable independent source of palaeoenvironmental information.

The studied material consists of disarticulated cranial and postcranial bat remains collected by water-screening the rock matrix with a tower of superimposed sieves. The sediments were excavated at the Sima del Elefante TELRU from 1996 to 2007. Each level has been studied as an independent assemblage so we can compare the evolution of the fossil bat assemblages from the bottom to the top of the TELRU stratigraphic sequence.

The taphonomic study indicates that the accumulation were due to natural death in the cave of the individuals of a bat colony, according to the high representation of different anatomical parts, low fragmentation, lack of digestion evidences and age-sorting. The identified bat taxa from TELRU are: *Myotis* gr. *myotis/blythii*, *Miniopterus schreibersii*, *Rhinolophus ferrumequinum*, *Rhinolophus* gr. *euryale/mehelyi*, *Pipistrellus* sp. and Chiroptera indet. *Myotis* gr. *myotis/blythii* is the dominant taxon, followed by *Miniopterus schreibersii*; the remaining taxa have a scarce, very low presence. Here we have typically Mediterranean species of which *M. schreibersii* and *R. gr. euryale/mehelyi* are markedly thermophilic. Our preliminary landscape approach with bats shows little variation through TELRU and indicates that woodland and open-woodland areas alternated with open lands and to a lesser extent with rocky surfaces.

Other proxies previously analyzed on TELRU (herpetofauna and small mammals) indicate that it was deposited during a warm and humid period as our bat assemblage also does. Regarding the landscape approach, open lands appear somehow underrepresented in our results with bats in comparison with those previous studies based on other small vertebrate groups, though. We were not able to compare data from basal levels (TE7-TE8) as no published reports are available yet concerning detailed studies of their small vertebrate assemblage. Further results are expected.

ORAL

**7. THE SMALL VERTEBRATES FROM THE STRATIGRAPHIC SEQUENCE OF LEZETXIKI II CAVE (GIPUZKOA, IBERIAN PENINSULA): PALAEOENVIRONMENTAL RECONSTRUCTION.**

García-Ibaibarriaga, Naroa (EHU-UPV) [naroa.garcia@ehu.es](mailto:naroa.garcia@ehu.es)  
Rofes, Juan (MNHN) [juan.rofes@ehu.es](mailto:juan.rofes@ehu.es)  
Salvador Bailon (MNHN) [salvador.bailon@mnhn.fr](mailto:salvador.bailon@mnhn.fr)  
Arrizabalaga, Álvaro (EHU-UPV) [alvaro.arrizabalaga@ehu.es](mailto:alvaro.arrizabalaga@ehu.es)  
Iriarte-Chiapusso, María-José (EHU-UPV) [mariajose.iriarte@ehu.es](mailto:mariajose.iriarte@ehu.es)  
Villaluenga, Aritza (Monrepos) [villaluenga@rgzm.de](mailto:villaluenga@rgzm.de)  
Murelaga, Xabier (EHU-UPV) [xabier.murelaga@ehu.es](mailto:xabier.murelaga@ehu.es)

The cave of Lezetxiki II, located in the upper valley of the Deba River and near the eastern end of the Bay of Biscay, is an archaeological site physically connected to the classical site of Lezetxiki.

Both cavities are well known due to the important archaeological and paleontological discoveries that have been made there. In the deposit of Lezetxiki three human fossil remains were recorded, while evidences of human activities have been detected in both caves. The infilling of Lezetxiki II has provided the first record of *Sicista betulina* from the Iberian Peninsula, which also happens to be the south-westernmost representative of the genus in the Eurasian continent, and also the first records of *Cricetulus (Allocricetus) bursae* and *Macaca sylvannus* in the Cantabrian Region.

The study of microvertebrate remains has been proved as a rich source of information on the paleoenvironmental and paleoclimatic reconstruction. During 2011 excavation campaign, a test trench was conducted near the entrance of the cave, on which a total of 52 samples of sediment were taken along all the stratigraphic units.

Preliminary studies suggests the presence of at least eleven different small mammals taxa, nine belonging to the Order Rodentia (*Arvicola sapidus*, *Microtus (Microtus) agrestis*, *Microtus (Microtus) arvalis*, *Microtus (Alexandromys) oeconomicus*, *Microtus (Terricola) sp.*, *Pliomys lenki*, *Cricetulus (Allocricetus) bursae*, *Apodemus sylvaticus-flavicolis* and *Sicista betulina*) and two to the Order Eulipotyphla (*Sorex araneus-coronatus* and *Talpa sp.*)

We present for the first time, a palaeoenvironmental and palaeoclimatic reconstruction on the basis of the small vertebrate assemblages from Lezetxiki II Cave, showing the diverse habitat and climatic changes that occurred from the end of the Middle Pleistocene to the early Holocene.

Baquedano, Enrique (Museo Arqueológico Regional de la Comunidad de Madrid) [enrique.baquedano@madrid.org](mailto:enrique.baquedano@madrid.org)

Pérez-González, Alfredo (Centro Nacional e Investigación sobre Evolución Humana) [alfredo.perez@cenieh.es](mailto:alfredo.perez@cenieh.es)

The Pleistocene record of small mammals adapted to cold climates in the Iberian Peninsula concentrates mainly in two groups of sites found on either side of the Pyrenees. The species involved are *Microtus oeconomicus*, *Microtus gregalis*, *Chionomys nivalis*, *Spermophilus sp.*, *Marmota marmota* and *Sicista betulina*. More recently, assemblages from sites found in the centre of the Iberian Peninsula have yielded some of these taxa. The aim of this presentation is to describe a cold-climate small mammal assemblage recorded in the Cueva de la Buena Pinta site.

The Cueva de la Buena Pinta is a site located in the Sierra de Guadarrama, in the Central System. It consists of a small cave at 1100 m altitude in the Lozoya Valley, surrounded by mountains over 2000m high. Digging campaigns in the cave have taken place every summer since 2003. Absolute datings performed on levels 2 to 5 in this site place these levels within the Late Pleistocene, at the limit of C14 use or slightly further. Sieve-washing and picking of the small fossils contained in the sediments excavated during these years has yielded several thousands of small mammal teeth and other remains, providing a representative sample of the small vertebrate fauna preserved in these levels.

The Late Pleistocene levels of the Cueva de la Buena Pinta contain an assemblage of small mammals where *Microtus arvalis* dominates. Smaller numbers of other

cold-climate taxa have been identified, such as *Microtus oeconomicus*, *Chionomys nivalis*, *Marmota marmota*, *Ochotona pusilla* and, possibly, *Microtus gregalis*. This faunal composition resembles the Late Pleistocene assemblages found in the Cantabrian region, but differs from them in the presence of *Ochotona*, presently the single record of this taxon in the Iberian Peninsula.

Thus, the small mammal record of the Cueva de la Buena Pinta site provides evidence that cold-climate adapted species reached the centre of the Iberian Peninsula during the mid-Late Pleistocene, distinctly earlier than the LGM. Furthermore, most of them are, to the moment, the southernmost records these taxa attained in the Iberian Peninsula, and even some of them, in Europe.

**Acknowledgements.** This research has been conducted within project S2010/BMD-2330 funded by the I+D activities programme for research groups of the Consejería de Educación of the Community of Madrid.

## 9. EXTINCTION OF SELECTED MICROMAMMAL TAXA DURING THE MIDDLE PLEISTOCENE OF EUROPE

Maul, Lutz Christian (Senckenberg Research Institute) lmaul@senckenberg.de

Heinrich, Wolf-Dieter (Museum für Naturkunde Berlin) wolf-dieter.heinrich@mfn-berlin.de

Horacek, Ivan (Charles University Prague) ivan.horacek@natur.cuni.cz

Masini, Federico (University of Palermo) federico.masini@unipa.it

Parfitt, Simon A. (University College London, Natural History Museum London) s.parfitt@nhm.ac.uk

The Middle Pleistocene (c. 780-130ka) is a period that is characterised by significant climatic oscillations, which can be correlated with faunal changes. The small mammal biostratigraphic subdivision of this time period relies primarily on the extinction of several key taxa, such as *Talpa minor*, *Drepanosorex*, *Macroneomys*, *Beremendia*, *Hypolagus*, *Petauria*, *Trogotherium* and *Pliomys*. This paper examines changes in the spatio-temporal distribution of these micromammals during the Middle Pleistocene and discusses the possible extinction mode for each taxon. Prior to becoming extinct, several of the taxa exhibited a marked contraction of their geographical ranges, whereas in others retardation effects have to

be taken in account, and thus some taxa survived much longer in some areas than in others. The survival of populations in restricted geographical areas has important biostratigraphical implications. The second portion of the paper compares the Middle Pleistocene extinctions with the faunal situation within the late Quaternary.

ORAL

## 10. EVOLUTION OF SMALL MAMMAL COMMUNITIES DURING THE LATEGLACIAL IN THE SOUTH-WESTERN FRANCE

Royer, Aurélien (Laboratoire d'Anthropologie des Populations du Passé, UMR CNRS 5199) aurelien\_royer@hotmail.com

The Lateglacial is a slow gradual warming associated with cold short events that occurred between 18.0 and 11.7 ky cal. BP. Pollen analyses from deep-sea and lacustrine cores have well documented the evolution of floral communities in West Europe and have suggested that climatic fluctuations have influenced the evolution of terrestrial ecosystems. However, the exact impact of these climatic changes on small faunal communities in Southwestern France is still poorly documented.

Peyrazet Cave is an archaeological site located in Lot (France) excavated since 2008, that has delivered a Lateglacial sequence dated between 15.5 and 11.1 ky cal. BP. Thousands of small faunal remains resulting from a natural accumulation were recovered. Investigation of this material reveals the presence of at least 4 insectivores and 9 rodents and more surprisingly the northern birch mouse (*Sicista betulina*) that had been never documented in this region before.

The occurrence of this migrant taxa coming from the east is most likely related to climatic fluctuations of Lateglacial and complexify traditional scenarios developed to explain the evolution of small faunal communities between Last Glacial Maximum and Holocene.

ORAL

## 11. EAST-WEST BAT DIVERSITY DIFFERENCES IN THE LATE PLIOCENE AND PLEISTOCENE OF EUROPE: FACT OR ARTIFACT?

Sevilla, Paloma (Dpto. Paleontología Fac. Geología. Universidad Complutense de Madrid) psevilla@ucm.es

Horacek, Ivan (Dpt. Zoology. Charles University. Prague) horacek@natur.cuni.cz

Latitudinal and longitudinal differences are observed in current bat species richness in Europe that may be easily explained on the basis of ecological factors. The most evident gradient is latitudinal, with a distinct decrease in the number of species towards northern regions, clearly showing the influence of food availability and stationality in the pattern of distribution of European bats. Within the same latitude, an East-West pattern of species richness is observed, the eastern region of Europe being slightly richer than western Europe. This pattern is probably the consequence of both ecological and historical factors. Apparently, this east-west gradient of bat species richness was stronger in Europe during the late Pliocene and early Pleistocene, gradually decreasing during the Pleistocene and Holocene until the present situation. According to the available literature, eastern European countries such as Poland, the Czech Republic or Hungary had a particularly high species richness in the late Pliocene and Early Pleistocene that comprised both recent and extant bat species. At the same time, during this same period western European countries such as Spain or France have a record of a considerably lower number of species. But, to what extent these differences in gradient values are real, or are a consequence of factors that are biasing our appreciation of bat species richness through the Quaternary of Europe?

Here we analyse this issue by checking the available data of fossil bats from late Pliocene and Pleistocene sites in Europe. European countries have been grouped to compare number of species recorded in east, central and western Europe during the Late Pliocene, Lower, Middle and Late Pleistocene and compared with recent values. Data such as number of localities per region and age vs. number of species have been analysed in an attempt to establish whether these differences are real or artificial. Results are discussed from different points of view.

### 12. BIOCHRONOLOGY OF NORTH AFRICAN MICRO-MAMMALS

*Stoetzel, Emmanuelle (Muséum national d'Histoire naturelle, Département Systématique et Evolution - CNRS UMR 7205 ISYEB, Paris, France) stoetzel@mnhn.fr*

Throughout the late Cenozoic, climatic changes have strongly influenced the evolution of landscapes and faunas, especially terrestrial small vertebrates such as rodents and shrews. Compared to other regions, notably western Europe, few studies have been specifically dedi-

cated to fossil small vertebrates in North Africa. However, several Neogene and Quaternary archaeological and paleontological sites from North Africa have yielded small vertebrate remains, allowing us to attempt a correlation between the evolution of small faunas and the global and more local environmental changes. The present paper aims to give a global synthesis on the biochronology and paleoecology of the North African small mammals, punctuated by specific examples. The North African faunas are of several origins, and display both African and Eurasian affinities, together with endemic taxa. The climatic changes and the opening or interruption of migration routes (through the Sahara, via the Straits of Gibraltar and Sicily or via the eastern Mediterranean), have highly influenced the arrival of new species or the isolation of local taxa leading to their extinction or adaptation, with different adaptive and time responses to environmental changes depending on the considered taxa.

### 1. CLIMATIC AND ENVIRONMENTAL CONDITIONS FROM THE NEOLITHIC TO THE BRONZE AGE (7000-3000 BP) IN THE IBERIAN PENINSULA.

*Bañuls Cardona, Sandra (Università di Ferrara) sandra.banulscardona@unife.it*

*López-García, Juan Manuel (Università di Ferrara) lpzjmn@unife.it*

*Cuenca-Bescós, Gloria (Universidad de Zaragoza) cuencag@unizar.es*

On the basis of the small-mammal assemblages, we have analyzed the palaeoenvironmental and palaeoclimatic approach to the Holocene in the Iberian Peninsula.

This period has been characterized by a multi proxy, but in this paper, we have used the small mammal studies of the five sites within the geography of the Iberian Peninsula: Valdavara-1 (Becerreá, Lugo), El Mirón cave (Ramales de la Victoria, Cantabria), Colomera cave (Lleida), Mirador cave (Sierra de Atapuerca, Burgos) and Cendres cave (Teulada-Moraira, Alicante).

In the studied sites we have emphasised a major number of species associated with Mediterranean requirements (*Terricola duodecimcostatus*, *Iberomys cabreræ*, *Crocidura russula*) in the greater part of the sites. In only one studied site, el Mirón cave, there are more taxa with Mid-European requirements (*Chionomys nivalis* y *Microtus oeconomus*).

These assemblages allow us to observe that the climate was more humid than today in the different sites under study, and an environment dominated by woodland and woodland margin in all the studied levels. We have found more taxa with this kind of the environment requirements as *Apodemus sylvaticus*. Moreover, we have seen that *Terricola duodecimcostatus* or *Terricola lusitanicus* are abundant in these assemblages. These species don't live in the eroded or cultivated soil. In this case, these results have indicated the lowest human impact in the studied areas.

Finally all our data have been compared with other environmental and climatic proxies, and we have seen that, the human activities have not had any important influence in the palaeoenvironmental conditions that occurred from 7000 to 3000 BP, in the Iberian Peninsula.

## 2. THE HOMINIDS ENVIRONMENT OF SIMA DEL ELEFANTE (SIERRA DE ATAPUERCA, SPAIN) THROUGH THE TAPHONOMY OF SMALL MAMMALS

Bennàsar, Maria Lluç (Area de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain. [bennasar.maria1@gmail.com](mailto:bennasar.maria1@gmail.com))

Cáceres, Isabel (IPHES, Institut Català de Paleoeologia Humana i Evolució Social, Carrer Marcel·lí Domingo, s/n (Edif), Area de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain.) [icaceres@iphes.cat](mailto:icaceres@iphes.cat)

Cuenca-Bescós, Gloria (Aragosaurus-IUCA, Ciencias de la Tierra, Facultad de Ciencias, Universidad de Zaragoza, 50009 Zaragoza, Spain.) [cuenca@unizar.es](mailto:cuenca@unizar.es)

Paleoecological studies of a specific area permit to know the habitat where within are carried out human activities and their changes. In the Iberian Peninsula, there are a few Pleistocene sites with human presence, although one of the most significant is the Sima del Elefante, in the Sierra de Atapuerca (Burgos, Spain) (Carbonell et al. 2008; Cuenca-Bescós et al. 2013; *inter alia*).

In this paper we present paleoecological conditions of the lower sequence of the Sima del Elefante (TE9-TE14, also known as Lower Red Unit or TELRU), which has a chronology to 1.3 Ma (Carbonell et al. 2008; Cuenca-Bescós et al. 2013), from taphonomic study of small mammals remains. The main objectives are to identify and to describe the paleoecological features of the Sierra de Atapuerca and its evolution. In addition, to describe

the microenvironment features of the cavity, contributing to the definition of karts taphosystem of the Sierra de Atapuerca and delimiting the habitability of the levels studied by human groups.

The results indicate, by one hand the existence of a large semi-open forests biome consisting of watershed and open areas nearby the Sierra de Atapuerca. By the other hand, in lower levels of Sima del Elefante, the environment was characterized for high humidity, it would make difficult the use of cave by hominids groups for developing long-time occupations.

## 3. PALEOECOLOGICAL AND MICROENVIRONMENTAL ASPECTS OF TD5 AND TD6 LEVELS FROM GRAN DOLINA SITE (EARLY PLEISTOCENE, SIERRA DE ATAPUERCA, BURGOS, SPAIN)

Bennàsar, Maria Lluç (Area de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain. [bennasar.maria1@gmail.com](mailto:bennasar.maria1@gmail.com))

Cáceres, I. (IPHES, Institut Català de Paleoeologia Humana i Evolució Social, Area de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain.) [icaceres@iphes.cat](mailto:icaceres@iphes.cat)

Cuenca-Bescós, Gloria (Aragosaurus-IUCA, Ciencias de la Tierra, Facultad de Ciencias, Universidad de Zaragoza, 50009 Zaragoza, Spain.) [cuenca@unizar.es](mailto:cuenca@unizar.es)

Gran Dolina site contain, in addition to a rich and extensive archaeological and paleontological assemblage, the human fossils of *H. antecessor* in TD6 level that contributed to the paradigm shift in the appearance of the genus *Homo* in Europe. This fossil assemblage provides a unique opportunity to know the paleoecological features where is carried out the first human activities and their changes in Europe.

The main objectives of this study are identify and describe the paleoecological features of the Sierra de Atapuerca around 900 ka. when *H. antecessor* lived (Bermúdez de Castro *et al.*, 2008), from data extracted to TD5 and TD6 Early Pleistocene levels. In addition, contribute to the knowledge about the microenvironment of the cavity where human groups developed their activities, contributing to the definition of taphosystem of the Sierra de Atapuerca.

The environment of fossilization is different in the two levels studied. While fossilized remains of TD5 was car-

ried out in a cave environment (high humidity and low light), TD6 (especially sublevel TD6-2) has been associated with a decrease in humidity, which means better habitability conditions.

According to results extracted, the Sierra de Atapuerca was framed within semi-open forests with open and watershed areas. This scenario is similar to the results obtained for small mammal taphonomy of lower levels of Sima del Elefante site (Sierra de Atapuerca) (Bennàsar, 2010).

#### 4. PALEOECOLOGICAL IMPLICATIONS FOR THE LATE PLEISTOCENE-HOLOCENE ENVIRONMENTAL AND CLIMATIC CHANGES IN NORTHEASTERN IBERIA USING RODENTS AS A STATISTICAL TOOL

*Fernández-García, Mónica (Universitat Rovira i Virgili) monica.fernandez.garcia.90@gmail.com*

*López-García, Juan Manuel (Sezione di Scienze Preistoriche e Antropologiche, Dipartimento di Studi Umanistici, Università degli Studi di Ferrara) lpzjmn@unife.it*

Rodents are one of the most significant groups of mammals in the European Quaternary and had become one of the most useful tools to reconstruct the ecology and the environment of the past. This work take into account a compilation of fossil rodent assemblages from Northeastern Iberia in the Late Pleistocene (ca. 128-11 ka BP) and the beginning of the Holocene (< 11 ka BP). A statistic analysis of the occurrence of the species along the prefix chronology, allows to reach a better knowledge about the species involved during these periods and about its paleoecology implications.

Both as a descriptive statistic methods like through more complex statistical methods – Principal Components Analysis has been applied –, appears clearly evident that there are three dominant species during the studied chronology : *Microtus arvalis*, *Microtus agrestis* and *Apodemus sylvaticus*. *M.arvalis* and *M.agrestis* are species related to mid-European requirements and had been especially dominant in the end of the Late Pleistocene (ca. 30-11 ka BP); while *A. sylvaticus*, a generalist species but mainly related with wooded areas and temperate environments, dominated during the beginning of the Late Pleistocene (ca. 128-30 ka BP) and regained importance with the arrival of the Holocene. So, from a statistic point of view, the beginning of the Late Pleistocene and the Holocene show similarities among them

and differed clearly from the end of the Late Pleistocene. This phenomenon shows the singularity of the environment related with the end of the Pleistocene in the Northeast of the Iberian Peninsula.

*Valenciano, Javier (Consejería De Agricultura, Castilla-La Mancha, Cuenca,) jvalenciano@jccm.es*

Stable isotope analysis has proven to be a powerful analytical tool for understanding paleoecology in both modern and ancient ecosystems. Many studies concentrate on determining ecology in (paleo) ecosystems that contain both C3 and C4 plants due to the large differences in <sup>13</sup>C/<sup>12</sup>C incorporated into plant tissues as the results of their utilizing different photosynthetic pathways, and the subsequent incorporation of these values up the food chain. Studies concentrating on ecosystems that are dominated by C3 plants are rarer. However, C3-dominated ecosystems are typical today as well as in the past. In fact, ecosystems with a measurable abundance of C4 plants only become apparent after about 7 million years ago worldwide. Because of the climate changes related to glacial-interglacial cycles and the presence of humans in many, but not all, localities, the C3 dominated Pleistocene ecosystems in Europe, are ideal for studying mammalian evolution, including humans, and the evolutionary implications of the effects of climate change. Although there have been many isotopic studies on Pleistocene European sites, there has been a limited isotopic framework for understanding this data within Europe during this time period.

Here we present isotopic data from mammals collected in Parque de El Hosquillo (Cuenca, Spain) with the aim

of providing a framework for understanding the isotopic values of more ancient mammals in Europe. Samples of scat, hair, bone apatite, bone collagen and tooth enamel were collected from over 100 individuals and were sampled for  $\delta^{13}\text{C}$ ,  $\delta^{15}\text{N}$ , and  $\delta^{18}\text{O}$  values, depending on the type of tissue sampled. Species sampled within the park include: *Cervus elaphus*, *Dama dama*, *Ovis musimon*, and *Sus scrofa*. For each species, isotopic discrimination factors were determined for each sampled tissue type (i.e., scat, hair, collagen, bone apatite, and tooth enamel). Once calculated, these species specific discrimination factors were then utilized to better understand the isotopic values obtained from mammals within more ancient Pleistocene-aged sites.

The data obtained from the modern samples within Parque del Hosquillo permit a more accurate understanding of more ancient samples from the Pleistocene of Europe. The carbon isotope values from Hosquillo from all sampled tissue types reflect a C3-dominated ecosystem. The carbon isotopic pattern remains consistent among sampled species among the different tissue types. Significant differences are observed in  $\delta^{13}\text{C}$  values between *Cervus* and *Ovis* in all sampled tissue types. Additionally, carbon isotope discrimination factors ( $13\text{C}$ ) are similar for all taxa, and are comparable to previously published values for different tissue types. In contrast to the carbon isotope values, the nitrogen isotope values do not follow a pattern among taxa between scat and hair, different taxa show higher and lower nitrogen isotope values. Thus, the nitrogen isotope discrimination factors ( $13\text{N}$ ) vary among taxa.

These results provide a framework for studying and understanding the ecology of mammals in more ancient ecosystems, particularly those that contain the same taxa, such as the C3 dominated ecosystems of the Pleistocene.

POSTER

## 6. LATE PLEISTOCENE BIOTIC REGIONS IN SOUTHWESTERN EUROPE: INFERRED FROM THE SMALL MAMMALS ASSEMBLAGES

López-García, Juan Manuel (Università degli Studi di Ferrara) [lpzjmn@unife.it](mailto:lpzjmn@unife.it)

The small mammals (insectivores, bats and rodents) assemblages from the late Pleistocene of the Iberian Peninsula are characterized by the presence of taxa with nowadays representation, that allow us to observe the

biogeographically changes produced. In this work we present more than 70 late Pleistocene sites from Iberia with micromammal studies.

Five zones have been identified in relation with the excavations scientific tradition and have been grouped by the affinity in small mammal associations. Thereby three groups have been identified: Group 1 (G1) that correspond to the northern-northeastern Iberia and is characterized by the presence of *Microtus oeconomus* and *Chionomys nivalis*; Group 2 (G2) that correspond to eastern and southern Iberia and is characterized by the presence of *Allocricetus bursae*; Group 3 (G3) that corresponds to the center of Iberia where converge several kind of habitats and climates and the three species mentioned above (*M. oeconomus*, *C. nivalis* and *A. bursae*) were present. The G1 and G2 corresponds to the currently biotic regions (R1 and R2) based on mammal assemblages.

An important factor which determine these biotic regions in the late Pleistocene is the orography of the Iberian Peninsula. G1 includes the sites located in the Cantabrian range, the Pyrenees and the Ebro basin; G2 includes the sites located in the Betic range; G3 is a mixed group that includes the sites located in the Central System and the transit areas of Tajo, Duero and Ebro basins.

## 7. EVOLUTIONARY TRENDS AS A CHRONOLOGICAL TOOL: THE CASE OF MIMOMYS SAVINI (VOLE) IN THE IBERIAN PENINSULA DURING THE EARLY PLEISTOCENE.

Lozano-Fernández, Iván (IPHES) [Ivanlozanof@gmail.com](mailto:Ivanlozanof@gmail.com)  
Blain, Hugues-Alexandre (IPHES) [hablain@iphes.cat](mailto:hablain@iphes.cat)  
López-García, Juan Manuel (UNIFE) [lpzjmn@unife.it](mailto:lpzjmn@unife.it)  
Cuenca-Bescós, Gloria (Universidad de Zaragoza) [cuenca@unizar.es](mailto:cuenca@unizar.es)  
Agusti, Jordi (IPHES) [jordi.agusti@icrea.cat](mailto:jordi.agusti@icrea.cat)

An evolutionary trend is essentially a directional change within a single lineage or parallel changes in several lineages. To be considered an evolutionary trend, this directional change has to be maintained over time and may affect one or more taxa within the lineages in which it occurs. Evolutionary trends have been observed in almost all animals groups. If we can determine the rate of change, these evolutionary trends can be a valid tool for biochronological estimations. In the Quaternary, the vertebrate taxonomical group that gives the best results as biochronological tool is Rodentia. This is due to their

higher taxa of reproduction and their rapid expansion. Of course rodents are not free of evolutionary trends, and with their higher taxa of reproduction we can study and accurately determine their evolutionary rates (the speed of these evolutionary trends).

The case of *Mimomys savini* (vole) is especially important for two questions. For one side, it has a marked evolutionary trend in size increase and lost ancient characters. And for another side, its chronological range covers the first human

occupations of Western Europe (Early Pleistocene). The study of populations of *M. savini* from different sites within the Iberian Peninsula allows to estimate their relative chronology. In this work we present a chronological synthesis in base of *M. savini* population of five of the ancient sites with human presence in Europe: Barranco León D, Fuente Nueva 3, La Boella, Vallparadis and levels TD4-TD6 from Gran Dolina.

POSTER

**8. BIOCHRONOLOGY OF THE PLEISTOCENE AND PALAEOENVIRONMENTAL CONDITIONS IN THE NORTH CENTRAL EUROPE (POLAND) INFERRED FROM SMALL MAMMAL ASSEMBLAGES.**

*Nadachowski, Adam (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska 17, 31-016 Krakow, Poland) nadachowski@isez.pan.krakow.pl*  
*Socha, Pawel (Department of Palaeozoology, Institute of Environmental Biology, Wrocław University, Sienkiewicza 21, 50-335 Wrocław, Poland) sochap@biol.uni.wroc.pl*

The effects of large-scale climate fluctuations in Pleistocene on dispersal of land mammal species are better visible in the North European Plain than in the Mediterranean area. The lack of important geographical barriers favored periodic east-west migrations of mammal species and in consequence turnover of the whole communities along with changing climate and environment. This phenomenon is relatively well documented by abundant records of small mammal communities in the area north of the Carpathians and Sudetes Mountains. Altogether ca. 20 key sites were analyzed. The Early Pleistocene assemblages (e.g. Kadzielnia, Kamyk, Kielniki, Zabia, Zalesiaki) were compared with Middle Pleistocene (e.g. Kozi Grzbiet, Bisnik, Deszczowa) and early Late Pleistocene (MIS 5 - MIS 3) (e.g. Bisnik, Raj, Oblazowa, Stajnia, Komarowa) small mammal communities. The reconstruction of climate conditions in the environs of the studied sites was

based on models of bioclimatic analyses applied to the small mammal assemblages. Most of the important climatic and environmental changes in north Central Europe resulted in the appearance of "waves" of newcomers from the east. Successive faunas consisted either of the new species assemblage or species composition was the same but representatives of particular phyletic lineages differed morphologically from both previous and later forms. This regularity is well documented e.g. by Arvicolinae rodents for instance in *Allophaiomys* – *Microtus* and *Mimomys* – *Arvicola* lineages. Morphological, and thus measurable, differences create a basis of biochronological and biostratigraphic correlations.

POSTER

**9. BIOSTRATIGRAPHY OF LATE MIDDLE AND EARLY LATE PLEISTOCENE OF CENTRAL AND WESTERN EUROPE BASED ON SMALL MAMMAL SPECIES.**

*Nadachowski, Adam (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska 17, 31-016 Krakow, Poland) nadachowski@isez.pan.krakow.pl*  
*Socha, Pawel (Department of Palaeozoology, Institute of Environmental Biology, Wrocław University, Sienkiewicza 21, 50-335 Wrocław, Poland) sochap@biol.uni.wroc.pl*  
*Lemanik, Anna (Department of Palaeozoology, Institute of Environmental Biology, Wrocław University, Sienkiewicza 21, 50-335 Wrocław, Poland) anna.lemanik@wp.pl*  
*Klimowicz, Malgorzata (Department of Palaeozoology, Institute of Environmental Biology, Wrocław University, Sienkiewicza 21, 50-335 Wrocław, Poland) ogrady@klimowicz.com.pl*

Some species of rodents (for instance *Arvicola*, *Microtus oeconomus* and *Dicrostonyx*) have distinctly changed their dental morphological features between MIS 6 and MIS 3. This phenomenon creates a basis for biostratigraphic subdivisions in Central and Western Europe. Morphological differences are observed in enamel tooth thickness changes of the water vole (*Arvicola amphibius*) expressed by the enamel SDQ quotient. The mean values of SDQ in Central Europe changed in the species from ~ 110 to ~ 70 during last ca. 150 ka. In spite of the criticism of the usefulness of this method, our results suggested that this index can roughly be used as biostratigraphic tool at the regional scale. In the root vole (*Microtus oeconomus*) the morphological change can be expressed by difference in the frequency of so-called "male" morphotypes characteristic for Saalian and early Weichselian populations for instance in France, England and Poland. Recent studies indicate that higher fre-

quency of “malei” morphotypes (~ 30-60%) occur in *M. oeconomus* from penultimate glaciation (Saalian). During Eemian (MIS 5e) and early Weichselian (MIS 5d-a) this morphological type is found in ~ 10-30 % of the *M. oeconomus* analyzed specimens. In collared lemmings (*Dicrostonyx*) morphological changes concern mainly upper molars and are expressed by gradual increase of more complicated morphological patterns from MIS 6 to MIS 3. The mentioned parameters were analyzed in over a dozen of sites for biostratigraphic purposes.

#### POSTER

### 10. BIOSTRATIGRAPHY OF THE PLEISTOCENE OF UKRAINE ON THE BASIS OF ARVICOLIDAE.

*Rekovets, Leonid (University of Environmental and Life Sciences of Wrocław, Wrocław, Poland) leonid.rekovets@up.wroc.pl*

*Krokhmal, Alexey (Institute of Geology Academy of Sciences of the Ukraine, Kiev, Ukraine) krokhmal1959@ukr.net*

*Nadachowski, Adam (Department of Palaeozoology, Institute of Environmental Biology, Wrocław University, Sienkiewicza 21, 50-335 Wrocław, Poland) nadachowski@isez.pan.krakow.pl*

Pleistocene biostratigraphy of the Ukraine on the basis of small mammals was established at the end of 20<sup>th</sup> century. The main biostratigraphic criteria used at that time were based on changes of faunal composition in time and percentage differences of tooth morphotypes in Arvicolidae. These criteria were at present supplemented by several indices e.g. SDQ, A/L, B/W and C/W, and sometimes SDQH, HH and M/L as well as details of enamel structure. The obtained numerical indices allowed to establish evolutionary changes for particular taxa of Arvicolidae in the Pleistocene. Directions and trends of morphological changes in time of particular phyletic lineages (*Miomys-Arvicola*, *Allophaiomys-Microtus* with division to subgenera, *Pliomys-Clethrionomys*, *Prolagurus-Lagurus*, *Dicrostonyx*, and partly *Chionomys* and *Lemmus*) were analyzed. On the basis of old and new criteria and also taking into account cyclic climatic changes the chronological succession of almost 200 Pleistocene sites of Ukraine was described. Moreover, boundaries of different stratigraphic ranks were established, e.g. boundaries between faunistic complexes and correlation of particular assemblages. The correlation of continental and marine sediments of Pleistocene were also possible because some marine sediments in the Ukraine contain remains of Arvicolidae.

*Castaños, Jone (Universidad del País Vasco UPV-EHU) jcastanosdlf@yahoo.es*

Antoliñako Koba (Gautegiz-Arteaga, Bizkaia, Spain) is a prehistoric deposit located in a karstic cavity 285 m above sea level, in the eastern margin of the estuary of the Oka river (Urdaibai biosphere reserve). In the stratigraphic sequence, excavated between 1995 and 2008, eight Upper Pleistocene levels (MIS 2-3) have been described covering nearly 25.000 years cal. This long deposit comprises six chrono-cultural units: Aurignacian, Gravettian, upper Solutrean, lower and upper Magdalenian, and Aazilian.

The sample of small vertebrates is constituted by some 31.400 remains, of which 2.470 elements were identified either to the family, genus and/or species levels and divided into 20 taxa: 13 species of mammals, 4 of reptiles and 3 of amphibians. Small vertebrates are used for palaeoenvironmental reconstructions since they are very sensitive to climatic conditions and their distributions over time, measured in terms of relative abundance, serve as reliable proxies of habitat and climatic change.

The results are contrasted to those obtained from the large mammal and geochemical records. Many radiocarbon dates obtained for Antoliñako's sequence also allow us to compare our proposal to other palaeoenvironmental reconstructions (both marine and continental) from

north Iberia on the regional scale; and the oxygen isotopic curve of an ice core from Greenland on the global scale.

The small vertebrate associations together with the radiocarbon dates from Antoliñako Koba define climatic and habitat changes along the sequence, from roughly the beginning of the Würm III glaciation to the Holocene. Alternating cooling and warming events are recorded which coincide with the climatic changes of the Upper Pleistocene.

*Seveque, Noémie (Université Lille 3 CNRS UMR 8164 Halma-lpel & Université Lille 1 CNRS UMR 8217 Géosystèmes, Villeneuve d'Ascq, France) noemie.seveque@etu.univ-lille3.fr*

*Auguste, Patrick (Université Lille 1 CNRS UMR 8217 Géosystèmes, Villeneuve d'Ascq, France) patrick.auguste@univ-lille1.fr*

Quaternary small vertebrate assemblages from southern France, and more generally meridional and mediterranean regions, are today well known and well studied. In comparison, septentrional areas of Europe remain poorly considered, as they have yielded relatively few sites with microfaunal remains. However, important sites of human occupation were discovered in these areas, with important issues related to the occupation of these sites by Neanderthals and previous humans, as well as faunal dynamics under climatic pressure. In the present work, we consider new unpublished results from two Late Pleistocene sites of northern France: Le Rozel (Normandy) and Mutzig (Alsace). Both are rock shelter subject of recent archaeological excavations, but in very different contexts: Le Rozel is located in a coastal area of north-western France, while Mutzig is located at the foot of the Vosges mountains in northeastern France. Similarities and differences in faunal composition are discussed, in relation to the geographic and climatic contexts, and with biochronological and archaeological implications.

**1. NEW DATA FROM RESEARCHES ON THE NEOLITHIC DITCHES OF THE TAVOLIÈRE AREA (APULIA, SOUTH ITALY).**

*Tunzi, Annamaria (Soprintendenza Puglia) annamaria.tunzi@beniculturali.it*

*Quero, Tania (University of Trieste) taniaquero82@gmail.com*

Thanks to a long tradition of studies on the Neolithic settlements of the Tavoliere area (Apulia, South Italy), starting with Bradford and Tiné, it was possible to discover at least one thousand sites ascribable to different chronological periods. These sites are characterized by monumental ditches (up to 4m deep and over 5m wide), that is hypogeal structures excavated in the bedrock by means calcareous picks or big pebbles. There are some small stairs carved in the rock and stone walls in the inner space. These constructions required a significant work organisation and involved several communities.

Often, it's possible to note an integration of large external enclosure ditches and internal C-compounds, which divided the internal spaces of the settlements.

The sites are located at a distance of at least 2km from each other and occupy a wide area that appears to be functionally organized. Possibly, there was a kind of hierarchization among these sites.

In this discussion, we would present some data from the most recent researches in the Tavoliere region. In 2013, the first complete excavation of an enclosure ditch was carried out at the Amendola Airport (Foggia). The ditch, elliptically shaped, lies on the top of a low hill (55m of altitude) on the Amendola Plan, covering an area of 8311m<sup>2</sup>, near the Candelaro river and not far from the coast.

Neither internal nor external structures were found, during the excavation works. The site is dated to the first centuries of the VI millennium BC (LTL13341A: 6937 ± 50 BP; LTL13340A: 6856 ± 45 BP).

After, we explored a village in the high Tavoliere region near Troia district, partially visible from the aerial photographs, only by little trenches. This village endowed with four enclosure ditches, along an axis of 722m, and other five internal structures at least, two of which could be C-compounds. All ditches lie on a 250m high hill and are

open to a nearby stream. The site is close to other ones that have been recently discovered in the same area and it is dated to the same period, that is to the second half of the VI millennium BC (LTL14034A: 6622 ± 45 BP; LTL14028A: 6012 ± 45 BP).

The function of these structures is still uncertain: probably, they were meant for draining marshy areas, isolating cattle, fields and huts or for demarcating and enclosing a community's land.

They could have also a symbolic and ritual value, attending to enhance the membership and avoid conflicts.

But, the peculiar pits, found on the bottom of the single-ditch from the Amendola Airport, have suggested an use as quarries for the clay that lies in the lower geological levels (Pleistocene "Amendola sands").

Instead, the Troia village could reveals a structural organization similar to the close villages and the different settlement system in the hills and in the coastal plain.

We cannot solve the problem about these structures, but we believe that new data added to the older studies may help to provide further ideas for the researches on the Neolithic villages of the Tavoliere region.

ORAL

**2. ACTIVITY AREAS IN TWO CEREMONIAL CENTRES OF THE SOUTHERN BRAZILIAN HIGHLANDS: RELATIONS BETWEEN ARCHITECTURE AND FUNCTION**

*De Souza, Jonas Gregorio (University of Exeter) jonas.gregorio@yahoo.com.br*

I present the analysis of the features and artefact assemblages of two funerary mound and enclosure sites of the Taquara/Itarare Tradition of the Southern Brazilian Highlands: sites RS-PE-31 and Posto Fiscal. Both sites are similar in that they exhibit rectangular annexes in their architecture, in addition to the most common circular enclosures. They are also differentiated by having a large amount of lithics and pottery, whereas other ceremonial sites are usually clear of debris.

The lithic and pottery materials were analysed in terms of technology and function, and distribution maps were created in order to identify activity areas. These were then compared to other funerary and domestic sites in the same area, so as to ascertain the function of sites

RS-PE-31 and Posto Fiscal. It was found that, unlike other burial grounds which were short lived and kept clean, the two sites in question had a complex sequence of activities and construction events. The artefact assemblage of sites RS-PE-31 and Posto Fiscal is very similar to domestic contexts of the Taquara/Itarare Tradition, and may be related to feasting events during and after the burial rites. Dates for site Posto Fiscal suggest that these events are related to the architectural elaboration of the site, with the addition of a rectangular enclosure, in a late period.

It can be suggested that the architectural complexity and activity areas evidenced in the sites RS-PE-31 and Posto Fiscal point to a greater elaboration in mortuary ritual associated with greater architectural complexity in later periods, immediately before the European conquest. Those distinctions for the burial of a few individuals may be related to the emergence of chiefdoms, as was reported for the groups that inhabited the area in the colonial period.

### 3. BUILDING POWER: EARTHEN MONUMENTS AND THE CONSTRUCTION OF ELITE IDENTITIES IN PRE-COLUMBIAN NORTH AMERICA

*Baltus, Melissa (University of Illinois at Urbana-Champaign) mbaltus2@illinois.edu*

According to documents recorded at the time of European contact, earthen platform mounds in the southeast United States were the domain of indigenous political and religious leaders. Direct historical projection of this connection has often led previous archaeological research to focus on these constructions as places of elite status and associations. Rather than assuming *a priori* that these were elite spaces, current research into the earthen mounds of the late pre-Columbian period (A.D. 1000-1400) of the American Midcontinent suggests these mounds were monuments of *empowerment*. Incorporating indigenous ontologies into the study of mound construction suggests that the gathering together of naturally powerful elements (earth, water, fire) along with narrations of deep history (i.e. creation stories and ancestor-deity traditions) is itself an empowering act through which elite statuses were (re)constructed and maintained. Current research into earthen mounds of the Midcontinent is refocusing on how these monuments were experienced.

### 4. ON THE THRESHOLD OF EGYPTIAN MUDBRICK ARCHITECTURE.

*Rosinska-Balik, Karolina (Institute of Archaeology, Jagiellonian University in Krakow, Poland) k.rosinska.balik@gmail.com*

The aim of this paper is to characterize the development of the Nile Delta architecture at the era of Egyptian unification. The attempt will be made on the basis on interpretation of archaeological material. Excavation result indicate that, in the period decisive for the ulterior Lower and Upper Kingdoms, Egyptian architecture was profoundly transformed. The transformation was not only viewable in the form of constructed architectural layouts. The execution manner of spacious structures was evolving as well, and building material changed and was adapted to new needs. At this point, new issue, worth further studies, appears. The issue concern mud bricks' application. The main question is the origin of the material. The answer is specially important, when facing the fact that the opinion on Naqadan descent of mud bricks should be strongly verified. Another question is the manufacturing economy. The preparation process of this type of common material must have been simplified and fasted, but the question how simplified and how fasted remains. How much workload it required? How many ingredients were needed and in what quantity? How much time the preparation process, from bath bricks to ready-to-use, required? And the final question we will trying to answer, what area was necessary to produce and prepare sufficient amount of bricks?

### 5. FIRST TEST FOR LUMINESCENCE DATING OF ANCIENT ADOBE BUILDINGS FROM MESOPOTAMIA

*Sanjurjo Sánchez, Jorge (Universidad de A Coruña) jsanjurjo@udc.es*

*Montero Fenollós, Juan Luis (Universidad de A Coruña) fenollos@udc*

Raw earth has been even used continuously from Prehistory to get sun-dried adobe bricks (or mud bricks). Mud bricks are unfired bricks made of a mixture of mud, sand, and water mixed with a binding material such as rice husks or straw, dried under the sun. Since not all the soils are adequate for raw earth building the evaluation and characterization of the soils and the sediments for con-

structive purposes has become of important to define the application contexts of unfired Earth. As occurs with most sediments mud bricks contain abundant silicate and minerals. Among them, quartz and feldspars are ubiquitous. They are specially interesting as they are typically used for luminescence dating. Luminescence allows dating the last daylight exposure of minerals before burial in a sedimentary body. However, this technique has not been testes on mud bricks or earthen structures of buildings. As other materials present in mud bricks are scarce or not preserved after a lapse of some centuries or thousands or years, it could be very interesting to apply luminescence dating on this kind of building materials. This also would allow dating the construction period of important urban structures in several parts of the World. This is still more interesting in the case of Mesopotamia as most buildings were constructed with mud. A wide knowledge on the use of adobe and earth raw materials for the construction of buildings existed in Mesopotamia, where adobe was used for the construction of houses, temples and defensive walls of ancient cities. In this work we have performed the first luminescence tests on adobe bricks from two archaeological sites of Ancient Mesopotamia and compared results with chronological pictures of the studied sites. Results show that adobe bricks are reliable targets for luminescence dating.

## 6. MIXED ARCHITECTURAL COMPLEXITY IN NORTHERN CENTRAL MEXICO.

*Fernández Martínez, Gerardo (Universidad Autónoma de Zacatecas) gerardo2001@hotmail.com*

Recent investigations in the southeast region of the state of Zacatecas, in the central portion of Mexico, have shown that the prehispanic populations which developed in this territory used a mixed system for the construction of their buildings. These architectural works are very complex and were built using, as fundamental constructive materials, rocks and adobe (earth bricks).

Nowadays the research of all this architectural features confront diverse problems as a result of the agency of natural deterioration processes and diverse human destructive activities.

Despite the conservation problems that this archaeological and architectural heritage faces all the time, the investigations at the Buenavista archaeological site allowed to infer, due to the location and characteristics

observed in some architectural compounds, that this constructive system has been used to built the most important ceremonial spaces of the site.

ORAL

## 7. THE MONUMENTAL EARTHEN ARCHITECTURE OF LA JOYA, ON THE HUMID TROPICAL GULF COAST OF MEXICO: POLITICAL AND TECHNOLOGICAL SIGNIFICANCE.

*Jo Elvire Daneels, Annick (IIA-UNAM MEXICO) annickdaneels@hotmail.com*

Recent investigations at one of the thousands of pre-Columbian mounded sites along the southern Gulf coast of Mexico revealed that earth was used as sole building material to create monumental architecture identical to contemporaneous Late Preclassic to Classic period civilizations like Teotihuacan, Monte Albán and the Maya region. These supposedly "simple mounds" resulted to be pyramids, palaces, monumental tombs and shrines, as well as ball-courts, that were part of an urban layout, with a building sequence spanning more than 1 millennium (200 BC-AD 1000). These findings are novel in two aspects: first, they oblige to reevaluate what was up to now considered a secondary and peripheral cultural development during the Mesoamerican Classic period, second, they prove the existence of a particular technology that made raw earth viable as primary building material in extremely adverse wet tropical climatic conditions.

Settlement pattern studies in the 1990's indicate the existence of small state level entities along the Central Gulf coast in the Classic period, supported in some cases by intensive agriculture and hydraulic management. Extensive excavations since 2004 at the site of La Joya, one of such state capitals, allowed to understand the building sequence of the urban layout, that transforms from a feasting center associated to an early palace compound in the Late Preclassic, to a formal ritual administrative closed plaza in the Early Classic, with a 4 staircase pyramid, a shrine and an acropolis-like administrative palace, all lavishly consecrated with offerings including human sacrifice. By 300 AD, contemporary with Teotihuacan contacts, a major modification enlarges the plaza sector to support a second palace compound, probably meant for the religious leader, requiring a major labor input of moving and terracing several million cubic meters of fill. The borrow-pits from which the fill is obtained, become an inverted U shaped water reservoir encircling and effectively differentiating the central monumental com-

pound from the residential and domestic areas outside. The compound has three more building stages spanning AD 300-1000, that significantly enlarge the component buildings but not their layout, suggesting a strong stability during the rest of the Classic period.

The excavations also show a gradual improvement of the building techniques to allow better contention of internal pressures of fills, although some strategies appear to have their origins in the Preclassic Olmec culture: clay facings and use of asphalt as construction sealant. Advanced chemical analysis of construction samples (through FTIR, NMR, and MS) show the presence of hydrocarbons and triglycerides, interpreted as dissolved asphalt. Petroleum seeps occur along the Gulf coast, so the material was available, but this would be the first archaeological case worldwide of the use of dissolved asphalt as an earth construction consolidant.

Thus, the La Joya case demonstrates the development of monumental urban architecture coupled with innovative building technology, sustaining the emergence of a state level capital that will gradually increase its differentiation until it ideologically and literally dominates the surrounding settlement, a trajectory that closely parallels the contemporary "high cultures" of Mesoamerica.

### 8. TRADITIONAL ARCHITECTURE AT FIGUIG OASIS, MOROCCO.

*Ultramar Ramírez, Florencia Tatiana Azul (Escuela Nacional de Antropología e Historia) azulramirez108@gmail.com*

The Figuig Oasis is located at Eastern Morocco. The settlement, whose size is about 600 to 700 hectare, has around 15000 inhabitants and is located at a distance of about 400 km. from the Mediterranean coast of the meridian that crosses the city of Oujda, two kilometers closer from the Algerian border.

In this region, the climate is classified as a Saharan climate, with an average of low temperature in January of 38 ° C and in July, a maximum average of 41.3 ° C. In this conditions, earthen architecture result the best strategy to create an artificial environment to human survival.

However, the human inventiveness is not the same everywhere, what mean, that traditional architecture is not only circumscribed by regional weather, but to the cultural particularities of its builders.

Following the parameters of UNESCO, "traditional architecture" is defined here as a cultural heritage that has a concrete (or tangible) and intangible (or subjective) dimension.

Therefore, the traditional architecture is a cultural heritage, whose social, political and/or religious significance, can only be decrypted and well understood when analysis includes intangible and tangible dimension of it. Thus, the analysis presented here, includes not only the technical dimension of Figuig earthen architecture, but the particular social, cultural and historical dimension of its builders, the amazigh/berber ethnic group who inhabit this oasis.

Concerning historical dimension, it is important to mention that architecture is one of the best witness of cultural and socio-political change, and in this sense, the Figuig oasis architecture provide us of many examples of how different changes take place in different periods of Moroccan history.

As part of the recent (2014) PhD research of one of us (Feiken) at the University of Groningen (NL), the well-known PC-RASTER erosion simulation software developed at the University of Utrecht (NL) has been adapted to include interactions between human and natural processes, and a pilot project has been run to demonstrate its functionality and the issues that still need to be resolved in future work. The study area for the pilot is the hydrological basin of the Maddalena stream, part of the Raganello River basin in northern Calabria (Italy), and the simulation has been run in 60 timesteps for the period 4000 BC - present. This paper will outline the model underlying the simulation and highlight some results and problems. It will be argued that, despite the current limited realism of such simulations, there are good prospects for improvement.

### 2. GEOARCHAEOLOGY FROM SEMI-ARID MASUDPUR: GLIMPSES OF BRONZE AGE LIFE AND RECONSTRUCTION OF MID-HOLOCENE ENVIRONMENTAL CONDITIONS IN NW INDIA.

*Neogi, Sayantani (University of Cambridge) neogi.sayantani09@gmail.com*

As a part of the *Land, Water and Settlement* project, geoarchaeological investigations carried out in and around two Indus sites of Masudpur I (Sampolia Khera) and Masudpur VII (Bhimwada Jodha) near the village of Masudpur in Haryana, India have revealed interesting information about the activities and behaviour of the inhabitants of these settlements.

In particular, within the sampled sequences from the trenches, several activity areas have been identified, such as open spaces used for crop-processing or general floor build-ups interrupted by occasional disturbed layers, all filled with settlement-derived debris and with

evident periods of abandonments. Off-site soil samples have revealed bedded sand deposits beneath Masudpur I whereas Masudpur VII was built on a dune system indicating a symbiotic relationship with the prevalent environmental system.

This paper will highlight the nature of human activities, prevalent environmental conditions and site-formation processes of these sites as depicted through the techniques of thin-section analysis and geochemical studies.

### 3. CORRELATING ENVIRONMENTAL EVENTS WITH HUMAN TRENDS: A LATE BRONZE AGE SITE AND FLUVIAL CONTEXT IN THE MIDDLE EUPHRATES VALLEY (NORTHEAST SYRIA).

*Sanjurjo Sánchez, Jorge (Universidad de A Coruña) jsanjurjo@udc.es*

*Montero Fenollós, Juan Luis (Universidad de A Coruña) fenollos@udc*

Early civilisations were born on Mesopotamian floodplains approximately 6 ka BP. Thus, Holocene alluvial sediments provide archaeological remains and coetaneous records of environmental changes. We have studied a Bronze Age archaeological site in the Middle Euphrates Valley located beside an ancient river channel. The site was definitively abandoned in the Late Bronze Age II. In such river stretch, a single meandering channel existed, but it was moved and the palaeochannel filled with flash flood sediments from a *wadi*, due to either natural or human-induced environmental changes. We have studied the palaeochannel infill and used optically stimulated luminescence (OSL) for dating the alluvial sediments. OSL allows direct dating of alluvial sediments towards inorganic materials. However, the technique has been little tested in this area, while both radiocarbon and pottery style dating have been preferred. When OSL, radiocarbon and stylistic dates were compared there have been significant disagreements, but OSL is the only technique that allows dating sediments if organic materials and pottery remains are absent. The obtained ages allowed making a correlation between the palaeochannel infill process and significant environmental events recorded in other nearby palaeoenvironmental sequences. The results show that meandering is a highly probable cause of the lack of reoccupation of the site.

#### 4. LANDSCAPE AND HUMAN BEHAVIOR IN HOLOCENE: AN ISOTOPIC STUDY.

*Campos, Luana (Doutoranda em "Quaternário, Materiais e Culturas". Universidade de Trás-os-Montes e Alto Douro/Portugal. Bolseira CAPES/Brasil) lcampos.ms@gmail.com*  
*Pessenda, Luiz (Laboratório 14C CENA/USP/Brasil.) pessenda@cena.usp.br*

*Rodrigues, Ana Isabel (Instituto Português do Mar e da Atmosfera, DivGM/Portugal) ana.rodrigues@ipma.pt*  
*Teixeira, Rui (Universidade de Trás-os-Montes e Alto Douro, UTAD, Quinta de Prados, 5000-801 Vila Real, Portugal e Centro de Geociências) rteixeir@utad.pt*

The relationship between the changes in landscape and human behavior during the Holocene has been the subject of several studies over the years.

In this work, we present the results of carbon isotopes ( $\delta^{13}\text{C}$ ) analyses of soil samples from two drills carried out in colluvium deposits from Parque Nacional da Serra da Capivara, Piauí, Northeastern Brazil, near the archaeological sites "Toca do Sítio do Ema do Brás I (Ema I)" and "Toca do Baixão do Perna I (Perna I)". The results of these analyses suggest two distinct paleoenvironmental scenarios for those sites.

On one hand, the values of  $\delta^{13}\text{C}$  of organic matter from soil samples collected in the drill located near Ema I (300 cm depth) show an isotopic enrichment of 1.5 ‰ (from -24.8 to -26.3) from medium Holocene (ca. 6220 cal. years BP) to the present day. This variation in  $\delta^{13}\text{C}$  may be associated with the decomposition of soil organic matter and/or a possible influence of C4 plants (grasses) in the past.

On the other hand, the drill on the slopes of the valley where is located Perna I site (250 cm depth), that distant about 6 km from Ema I, show  $\delta^{13}\text{C}$  values that range from -21.6 ‰, indicative of a mixture of C3 and C4 (grass) plants, at the base, to -25.9 ‰ (predominance of C3 plants, trees) on the top. This variation of 4.3 ‰ may be related to the expansion of C3 plants in this location, from a period of at least 6250 cal. years BP, where there is an influence of C4 (grass) plants with values of ~ -21 ‰. These facts may be related to a climate change from a less wet/dry period, in the middle Holocene to a more humid period in the present.

The analytical results and studies, carried out in archaeological remains found in the two sites, allow us to infer a

relationship between environmental changes and the behavior of prehistoric groups that inhabited the region. In fact, the dates obtained on the site "Toca do Sítio do Ema do Brás I", show an occupation of the region until about 8000 years BP, followed by a hiatus and subsequent reoccupation around 4700 years BP. This differentiated strategy in the occupation of this territory, supported by the material culture found there, would have been conditioned, in part, by the paleoenvironmental changes previously reported for this location. On the other hand, in the drill carried out at about 2600 m from the archaeological site "Toca do Baixão do Perna I (Perna I)" there were not found any traces of human occupation. This may be explained by the geomorphological characteristics of the site, which provided a greater exposure to climate variations.

ORAL

#### 5. HOLOCENE CLIMATE CHANGE AND PREHISTORIC HUMAN SETTLEMENTS IN CHILE'S ATACAMA DESERT.

*A Rivera, Mario (Universidad de Magallanes) marivera41@gmail.com*

*Dodd, Justin (Northern Illinois University) jdodd@niu.edu*

*Olson, Elizabeth (Northern Illinois University) ejolson@niu.edu*

The Atacama Desert is among the driest regions on Earth, and accessibility to water is critical to the settlement of humans. Regional scale climate variations such as the strength of the South American Seasonal Monsoon (SAMS) and El Niño (ENSO) intensity drive precipitation variations in the adjacent Andean highlands, and, therefore, recharge of aquifer systems. Numerous paleoclimate proxies from the region identify changes in ENSO variability in the mid- to late Holocene (~6 ka to present). Drought resistant trees such as *Prosopis tama-rugo* indicate fluctuations in regional moisture availability over the past 10ka.

Oxygen isotope data from fragments of *Prosopis tama-rugo* wood record sub-seasonal variations in moisture availability/water source at La Tirana Refresco (modern), Ramaditas (2615 Cal BP), and Llamara (9130 and 7910/7870 Cal BP). These data provide critical information about how water availability and land-use in Pampa del Tamarugal affected the development of fundamental aspects of Prehispanic economy, political organization, and power relations.

Based on a dendrochronological sequence from Ramaditas, a formative archeological village site in the Pampa

del Tamarugal, Oxygen isotope data was recorded and compared with that obtained from La Tirana Refresco and Llamara. This site contains *Prosopis tamarugo* stumps and logs with a much greater range of  $\delta^{18}\text{O}$  values from 22.8 to 39.4‰ and greater seasonal variability (avg. 3.3‰,  $2\sigma=2.4\%$ ). The greater range in interannual and seasonal  $\delta^{18}\text{O}$  values at Ramaditas most likely reflects a period with highly variable fluxes of runoff/recharge water and increased evaporation. An extensive network of irrigation canals, artisan wells, and over 10 has of agricultural fields at Ramaditas indicate that water was readily available from 2.5 – 2.0 ka when the site was occupied. *Prosopis tamarugo* was the main fuel source for activities such as copper smelting and building construction yet at present, vegetation is completely absent from the Ramaditas site.

Significant changes in water availability and anthropogenic alteration of the landscape may have been a critical factor in the eventual abandonment of the archaeological site. These episodic changes in water availability during the mid-Holocene on the Pampa del Tamarugal can be linked to broader scale shifts in Pacific and Atlantic moisture sources.

The northern Atacama Desert is therefore an ideal location to investigate the variations in the intensity of ENSO/SAMS precipitation throughout the Holocene.

ORAL

## 6. CLIMATIC CHANGE AND SOCIAL CHANGE IN ARCHAEOLOGY. METHODOLOGICAL ASPECTS OF A STUDY CASE IN PATAGONIA.

*Goñi, Rafael (INAPL/UBA) rafaellagustingoni@gmail.com*

This presentation discuss the variable conditions of climate and environment explain important aspects of social organizational systems of the past, in particular hunter-gatherers. It is understood that the climatic and environmental changes occurred during the Holocene in Southern Patagonia, played a very important role to understand what factors varied in the organization of human populations that allow a more truthful explanation of the variability observed in the archaeological record.

Methodologically, it is postulated that the climate is not the determinant of social/cultural change but the behavior or strategy to lead and produce the change. The effect is on human decisions to establish new social strate-

gies and not on the events itself. These are breakpoints to establish new the new human strategies. Because some of the most deep climatic events can occur in very short periods (Mayewski et al. 2004; Taylor 1999), they could be into the direct perception of actors in a single generation; not necessarily all great changes must have been undetectable for hunters in the past. Therefore, our perspectives is focused on social change more than in "cultural" change, the last understood as the material record. A model of human colonization during the Late Holocene has been proposed for the region under analysis (Southern Patagonia). It proposes that in the last 2500 years BP residential mobility underwent a drastic reduction as a result of the environmental desiccation processes suffered by the region during that period (Goñi 2010). The main odea that has guided research has been that, in Southern Patagonia, colonization and pattern of human occupation is highly dependent on the climatic and environmental variables. These variables present important changes during the Holocene: changes in the direction (6000 years BP) and intensity (ca. 1800 years BP) of the westerly winds or southern westerlies (Gilli et al 2001). Then , the height of a progressive desiccation was reached during the so-called Medieval Climatic Anomaly - MCA - (AD 1021 to 1228) (Stine 1994, & 2000). The new ecological characteristics involve the enlargement of steppes and a decline in the water level of lake basins in the region. The distribution of water as a critical resource in Patagonia must have varied drastically in regional terms. Thus, the broader and open sand-dune landscapes in the lowlands, with predominantly shrub vegetation and seasonal pastures in higher areas, present a geographic landscape that sets the scenery in wich the colonizing dynamics of the hunters of the Late Holocene unfolded.

*Guichón, Francisco (CONICET-INAPL) guichonf@hotmail.com*  
*Pasqualini, Sebastián (INAPL-UBA) sebastian\_pasqualini@hotmail.com*

*Agnolín, Agustín (INAPL-UBA) agusagnolin@yahoo.com.ar*  
*Guichón, Rocío (INAPL-UNOCEN) rocioguichon@hotmail.com*

Relative to previous moments, the Late Holocene in Patagonia appears as a less humid environmental period. Nonetheless, this phenomenon registers local variations linked to the characteristics of specific environments, particularly their positions in the altitudinal, latitudinal and longitudinal gradients. These conditions would have necessarily had an impact in the strategies developed by the hunter gatherers groups that occupied this space.

The aim of this presentation is to evaluate the changes in the archaeological record of Central and Southern Argentinian Patagonia, specifically the macro-region limited by the Chubut river in the north (44° S) and the Santa Cruz river to the south (51° S).

Different lines of archaeological evidence will be considered: technology, archaeofauna, stable isotopes, bioarchaeology, rock art and archaeobotany. In our study area -Central-Western Santa Cruz province-, the analysis of these lines of inquiry have led to the identification of recurrent patterns and changes in the archaeological record. These are related both to spatial (plateaus, high and low altitude basins, steppe and woodlands) and temporal aspects (Middle, Initial Late and Final Late Holocene).

In general terms, the Late Holocene is characterized by changes in the composition of different aspects of the archaeological record, namely, the incorporation of new technologies (pottery and structures), new artifact and motifs designs, new animal species in the archaeofaunal assemblages, changes in the human burial types and their sex-age composition, among others. Also, variations in the distribution and density of this record are observed, specially linked to the ecological characteristics and the altitude of the different sectors. On the basis of this information, the hunter-gatherers mobility and land use models proposed for the study area have been corroborated. These models pose a reduction of residential mobility, a concentration of settlements in low sectors and a logistical and seasonal use of high lands.

This presentation seeks to expand this discussion and to compare the observed trends in a broader space scale. To achieve this, the data sets generated by our research team will be considered alongside information published by other teams working in the defined macro-region.

The main contribution of this presentation is to generate a deeper understanding of hunter-gatherers population dynamics in Central-Southern Patagonia during the Late Holocene, under fluctuating environmental conditions

*Sancho, Carlos (Universidad de Zaragoza) csancho@unizar.es*

*Ortega, Luis Angel (Universidad del País Vasco) luis.ortega@ehu.es*

The Bardenas Reales is an amazing region, located southeast of Navarra. The sub-desert character of the landscape and the lack of population centers (given the uniqueness of their ownership regime) are the most determining factors in its evolution during historic times. The combination of a continental Mediterranean climate (low and erratic rainfall, cold winters, hot summers and a major dry season), the irregularity of its waterways, wind, its geomorphological features (alternating layers of different hardness and resistance against erosion) and human action, have generated a unique landscape, which marks from north to south three different units: the alluvial terrace of El Plano, the erosive depression of White Bardena, and the Bardena Tabular or El Plano. The farming activities have relegated the natural vegetation and wildlife to areas hardly adequate to such activities, also influencing the composition of their communities. The pine forests of Aleppo pine and holm oak tree areas are the most characteristics, although their degradation enhances the development of the shrub layer. The degradation and salinization substrate parts of the Bardenas Reales, as the White Bardena, inhibit the growth of tree species, the territory being occupied by tamarisks-espar-

to fields and species with halophilic and/or steppe type. The study based on morphosedimentary analysis, the autoecology of the gastropods assemblage and isotopic analysis of their shells, show us a palaeoenvironmental pattern comprised of an early wetter/colder phase (4763±87 to 2848±55 yr cal BP) followed by a warmer/drier period (1403±60 to 836±65 yr cal BP) and, finally, an increase in both cold conditions and hydrological variability, is deduced for the Middle-Late Holocene (191±97 to 127±82 yr cal BP). Archaeological excavations have shown the interest in this territory that humans has had since prehistoric times. The information obtained from paleoenvironmental studies (fauna and flora) made in several of these archaeological sites, makes evident the differences in climatic conditions, in comparison to the current dry landscape and semiarid Bardenas Reales. The Bardenas Reales had a residual occupation during Roman times, practically limited to White Bardena, rural settlements with second order devoted to farming. The excavation in the rural village of Cantera Pichón has yielded a sequence of centuries II- III A.D. The intensification of human activity in the territory of the Bardenas Reales, especially from the Middle Ages, has implied a deterioration of the landscape, so that the natural resilience of the primitive vegetable coating has significantly decreased (apparition of substrate and consequently, higher incidence of erosion), reaching even to the steppe-formation in parts of the territory occur.

## POSTER

## 9. ENVIRONMENTAL CHANGES AND HISTORICAL PROCESSES DURING THE LATE PREHISTORY IN THE MIDDLE EBRO VALLEY. THE EXAMPLE OF THE HUERVA VALLEY.

*Pérez-Lambán, Fernando (Universidad de Zaragoza) fperezlamban@gmail.com*

*Picazo Millán, Jesús V. (Universidad de Zaragoza) jpicazo@unizar.es*

*Rodanés Vicente, José María (Universidad de Zaragoza) jrodanes@unizar.es*

*Peña-Monné, José Luis (Universidad de Zaragoza) jlpena@unizar.es*

The relationship between environmental changes – mostly climatic – and historical processes is a recurrent topic in certain explanations of the social change. These explanations have been accepted differently depending

on the real data behind them but also on the prevailing theoretical positions of each moment. Nowadays, circumstances seem favorable for the exploration of this relationship. On one hand this is a consequence of the present social sensibility to environmental change. On the other hand, it is due to the increasing availability of paleo-environmental and archaeological data. Therefore, recently it has been proposed again that slight climatic changes could be the cause of crisis that led to the extinction of certain societies (cfr. Hsiang et al. 2013, Drake 2012...). Some of these climatic changes are well recognized through the Holocene, as it is the case of the Bond events or Mayewsky's Rapid Climate Changes, and it is possible to imagine more climatic short episodes that could had a significant impact in societies dwelling fragile environments.

In this work we explore this relationship between the available paleo-environmental data and the historical processes identified through the final stages of the Prehistory in the geographic region of the Middle Ebro Valley, focusing our attention in one of its southern tributaries, the Huerva Valley. Interdisciplinary studies carried out in the last years gave a paleo-environmental dataset that is the framework for this research. Geomorphology has been the basis of these studies revealing the existence of erosive and sedimentation stages that are materialized in slope and bottom valley deposits. These stages are related to climate episodes as climate is one of the main factors driving the geomorphological processes. The climate episodes are also compared to the environmental data provided by anthracology, palynology and C12/C13 ratio analysis carried out in archaeological contexts from the Bronze Age (Los Collados) and Iron Age (Cabezo de la Cruz).

According to the data obtained from these analyses, climatic conditions were somehow variable and their variations can be related to the rapid transformation of the landscape suffered in this time period. Human activity is the other main factor in the environmental change. Recent archaeological studies in the area provide a well-established chronological framework based on C14 dating and the settlement trends: the changes in the segmentary societies of the Late Chalcolithic to the emergence of complex and unstable societies in the Early Iron Age and the irruption of Rome during the Late Iron Age. Through the parallel study of the changes in societies and in the environment we are able to distinguish that some of the anthropo-environmental processes are related to regional and global trends, while others are acting at local scale.

## 1. THE USE OF QUARTZITE IN THE EARLY STONE AGE AT OLDUVAI GORGE, TANZANIA.

*Proffitt, Tomos (Institute of Archaeology, UCL) t.proffitt@ucl.ac.uk*  
*Arroyo, Adrian (Institute of Archaeology, UCL) a.arroyo@ucl.ac.uk*  
*de la Torre, Ignacio (Institute of Archaeology, UCL) i.torre@ucl.ac.uk*

Quartzite was the primary raw material utilised by early hominins within the Olduvai basin during the Early Stone Age, as such it constitutes a significant proportion of the archaeological record and was readably available within 6km of the majority of Olduvai sites. Its extensive presence in the archaeological record warrants its use as an investigative tool in order to better understand archaeological sites and hominin behaviour at Olduvai Gorge.

Current research is focusing on experimental approaches designed to investigate the analytical and functional aspects of quartzite and its place in the archaeological record at Olduvai Gorge. Raw material used in the experimental approaches is sourced directly from Olduvai Gorge, Tanzania. A series of multi-disciplinary approaches have been utilised, including technological analysis, blind analysis, use wear analysis, and GIS analysis in order to better understand the analytical and functional issues relating to this raw material.

Results from these studies have highlighted the inherent difficulties in the analysis of this raw material as well as providing tentative suggestions for frameworks which will aid in the analysis and interpretation of quartzite in an Early Stone Age context.

This collaborative research provides a more complete picture of our understanding of the archaeology of Olduvai Gorge during Beds I and II times.

ORAL

## 2. QUARTZ AND QUARTZITE USE IN THE MIDDLE PALAEO-LITHIC BISON KILL AND BUTCHERY SITE OF COUDOULOUS I (SOUTHWESTERN FRANCE)

*Mourre, Vincent (Inrap, UMR 5608) vincent.mourre@inrap.fr*  
*Venditti, Flavia flavia.venditti@gmail.com*  
*Lemorini, Cristina clemorini@hotmail.com*  
*Jaubert, Jacques (Université de Bordeaux, PACEA) jacques.jaubert@u-bordeaux.fr*

The site of Coudoulous I provided one of the most important late Middle Pleistocene sequence in Southwestern France. The stratigraphic sequence is divided into 10 main units and shows the transition from a closed cave room to a sinkhole more and more opened towards the limestone plateau. This communication will focus on the lithic industry of the layer 4 bone bed. This unit dates back to MIS 6 and is a 40 cm thick layer mainly composed of steppe bison bones. The large number of individuals (NMI = 232 in 25 excavated m<sup>2</sup>), the presence of all the skeletal elements, the catastrophic mortality pattern with dominant juvenile and young adults, the recurrent late spring to early summer acquisition (based on wear studies and skeletochronology), the numerous anthropic modifications (green fracture, cut-marks and burnt bones) are good indicators of repeated human occupations targeted toward hunting events within a frame of organized planned activities of structured human groups using the natural sinkhole to trap bison.

The layer 4 lithic industry is dominated by quartz and quartzite (97%) supplemented by flint (2.5%) and a few other raw materials (0.5%). Almost all the lithic resources used in the site were available in the alluvial deposits of neighboring rivers. The use of flint imported from an outcrop located about 30 km away was documented for one single tool. Three flaking methods were: Discoid, bipolar-on-anvil and Levallois flaking (the latter only on flint), typical of the Early Middle Palaeolithic. Most of the flint flakes were used without any retouch but a few of them were retouched into Mousterian tools (namely scrapers and points). Only a few quartz and quartzite flakes were retouched.

Use-wear analysis has been carried out on a sample of 79 artifacts made of quartz and quartzite. Given the heavy alteration, no artifact made of flint was selected. As can be expected from such an archaeological context, butchering was the activity most frequently carried out. The hunting-oriented character of Coudoulous is further corroborated by the lack of other activities except for few cases of scraping or cutting of wood and dry hide that could be related to the making and the maintaining of the tool-kit used for hunting. The presence of possible hunting tools has been questioned through an experimental program in the framework of the "des Traces et des Hommes" collective project. A small number of archaeological artifacts with convergent edges show traces consistent with a use as spear points.

Coudoulous lithic industry thus confirms the importance of quartz and quartzite in the Middle Palaeolithic subsistence strategies and shows, as it still seems to be

necessary, that those materials should no longer be considered as second-rate and poorly informative ones.

Navalmaíllo rockshelter, a Mousterian site at Pinilla del Valle in the Madrid region of central Spain, was discovered in 2002. Over time the shelter was completely buried by sediments.

Our work describes a preliminary study of the site's lithic industry. The most characteristic feature of the lithic sample at Navalmaíllo is that the artifacts are mostly made of quartz. Chert and other good raw materials, such as quartzites—found in river terraces—are relatively abundant in the central Iberian Peninsula, where Navalmaíllo rockshelter is located. Quartz cobbles are also common locally, but this material was usually avoided during the Middle Paleolithic period. The few exceptions are always in rockshelters or caves. Although archaeological assemblages dominated by quartz are not common in the central Iberian Peninsula, they are more common in peripheral areas such as Catalonia and Galicia.

As documented in other European sites, the abundance of quartz led to its becoming the main raw material used in tool-making in the area, even though it seems to be more difficult to knap than other, more homogeneous types of rock that fracture conchoidally.

The cores found at the Navalmaíllo site appear to have been intentionally worked to a very small size, a finding also reported for other European assemblages of similar age. The other raw materials found at the site include chert, quartzite, porphyry, rock crystal, and sandstone, all of which appear to have been worked in the same manner as the quartz. The scarcity or quality of raw materials is not the reason for this behavior.

The lack of any clear traces of soft-hammer percussion is notable. On the contrary, a large number of percussion marks that correspond to bipolar knapping on an anvil were identified on tools and cores of all materials. These are particularly visible on the quartz artifacts. Working small cores via the bipolar knapping technique is the best method for making small tools since the core is easily held in place when striking it.

A cultural explanation for this "microlithism" can be proposed in the sense that the Neanderthal groups that occupied the Navalmaíllo rockshelter may have followed a "microlithic-like" tradition of tool-making. To conclude, we have undertaken the use-wear analysis of some quartz implements to resolve, among others, questions related to the use of the small tools, as well as determining the possible intentionality of *Siret* fractures.

Traditionally, quartz has been considered as a second-rate resource for the Paleolithic communities and as

prove of their subordination to the environmental constraints. The petrological and mechanical characteristics of this raw material become a handicap for fully develop their technological skills. Hence, these lithic assemblages are defined by the ambiguity of their technical features, in some cases, interpreted as archaism.

The cave site of Cova Eirós (Triacastela, Lugo) has a stratigraphic sequence yielding archaeological layers related to the Middle Paleolithic, Early Upper Paleolithic and Late Upper Paleolithic. The technological study of these assemblages allows us to compare the different lithic management strategies played by two hominin species within the same territory and with a restricted lithological offer.

Hominins make a rational and differential management of this lithic resource by applying selective raw material procurement strategies. Secondly, they adjust the different *chaînes opératoires* to the petrological and mechanical properties of the quartz varieties. Although the lithic assemblages are dominated by expeditive knapping strategies, they reflect technological features parallel to those identified in other coetaneous flint lithic assemblages.

For the Upper Paleolithic levels the presence of specialized and standardize reduction sequences for bladelet production on rock crystal, show the high knowledge of these communities about the mechanical particularities of this material, as well as their adaptative strategies carried out to overcome the lithological constraints.

The sequence of Cova Eirós shows that behind the apparent homogeneity of quartz lithic assemblages, complex technical behaviours can be identified. The Middle and Upper Paleolithic societies adapt their procurement strategies and knapping methods for fully develop their technological requirements.

## 5. UTILISATION DU QUARTZ AU PALÉOLITHIQUE : DÉPASSER LES ÉTUDES TECHNIQUES, ANALYSER LE SYSTÈME.

*Bracco, Jean-Pierre (LAMPEA - Aix-Marseille Université) jean-pierre.bracco@univ-amu.fr*

Studies on the Paleolithic quartz material have mainly concentrated for 30 years on technical analysis and reconstruction of "chaînes opératoires". This work now allow a technical understanding of quartz tools, often diffi-

cult to analyze. A new phase of research can now begin, to understand the reasons for the use of quartz during the Palaeolithic. Several recent studies suggest that the raw material availability is not sufficient to explain the use of this material. The resolution of this question is certainly in a comparative study of all mineral raw materials used for the manufacture of lithic technical equipment and the place of quartz within industries. Supported on current research, this paper will propose lines of research.

ORAL

## 6. CONTEXTUALIZING QUARTZ RAW MATERIAL SELECTION AT ESPADANAL, PORTUGAL

*Paul Thacker (Department of Anthropology, Wake Forest University) thackep@wfu.edu*

Espadanal is a deep, stratified archaeological site located in a low terrace along a sand-bed tributary to the Rio Maior in central Portugal. The Early Upper Paleolithic assemblage from the site is comprised of more than 7,000 lithic artifacts. Consistent with the EUP of central Portugal, over 20% of debitage consists of blades or bladelets. Espadanal's assemblage is unusual for the UP of the Rio Maior area because of the combination of a very high percentage of chert blades (5%) and quartz bladelets (>10%).

Large blades and bladelets were manufactured from single platform prismatic chert cores, usually single platform convergent or opposed-lateral platform types. Chert bladelets were occasionally retouched but no backed bladelets, retouched points, or microgravettes are present. A very different and highly-developed quartz reduction strategy accompanied chert technological organization at Espadanal. Thin quartz bladelets and small flakes were removed from single platform, unidirectional bladelet cores. Many thick quartz "endscrapers" display parallel removals more typical of bladelet cores and probably should be considered as such.

Chert and quartz cortical flake frequencies are nearly equal and there is no evidence that either raw material was used more expediently or, conversely, intensively at Espadanal. The size variability of local quartz, quartzite, and chert cobbles was measured and contrasted with EUP debitage patterns. Results show a wide range of flake, blade, and bladelet sizes were manufactured on chert. However, the quartz assemblage is dominated by small flakes and bladelets. Quartz artifact size distributions are skewed to a substantially smaller range than

the possible debitage that could have been manufactured on local quartz cobbles. This finding contextualizes the complex prehistoric decision-making that occurred within both quartz and chert technological organization. Small quartz bladelets were 1) not equivalent to chert ones and 2) were not small because of quartz cobble size constraints. Small quartz bladelet dimensions were desired and cobbles were reduced using a distinctive technology to obtain them.

Assemblage analysis results from Espadanal challenge existing models of lithic raw material use. The EUP technological organization of chert and quartz are different and equally complex. Debitage of chert and quartz apparently were utilized for different functions and as blanks for fashioning different tool forms. These two radically-different chaînes opératoires are unrelated to on-site or provisioned raw material availability, a conclusion made possible by characterizing occurrence frequencies and size variability in local raw material cobbles.

Within lithic analysis more broadly, the interface of reduction strategies and raw material variability is frequently described using implicit or explicit concepts of supplementary or complementary technological behavior. At Espadanal, chert and quartz were both essential to the toolkit, and neither raw material can be considered expedient, supplemental, or equivalent to the other. Thus understanding stone tool technology at Espadanal requires consideration of the synergistic relationships between reduction strategies and procured raw material types.

The industry assemblages associated to prehistoric occupations from the interior regions of Western Iberia show a majority of quartz presence, traditionally interpreted as a raw material availability issue. Recent studies in Trás-os-Montes region, north of Douro river, can bring new light to the discussion since the sequence of human occupations spanning from the Upper Pleistocene to the Early Holocene show a range of reduction strategies associated to specific types of quartz, as is the case of Terraço Foz do Medal site.

With this presentation we intend to discuss the use of quartz, not only as a replacement for chert but also as a chosen raw material to achieve specific desired products.

Located in the Sabor valley, Douro Basin, Terraço da Foz do Medal is an open air site intensively occupied. With very few organic remains, stone tools provide the main target of the site's study. From its large Pleistocene and Holocene lithic assemblages, about two thirds are made using quartz. Contrary to chert, quartz is an abundant raw material in the Sabor valley and exists in various contexts and types. The many varieties of quartz with different knapping properties resulted in different approaches towards its reduction.

Until now we have been able to identify several quartz reduction strategies, like simple unidirectional methods as well as bipolar percussion using anvil technique for the production of a large quantity of flakes and small chips. We also found other strategies, traditionally more associated with chert, such as prismatic or carinated, and specific to quartz crystal morphology methods, used for the production of bladelets and small chips.

Quartz is the most represented raw material in every single layer of both Pleistocenic and Holocenic occupations of the Foz do Medal fluvial terrace. It seems clear that it has been in some circumstances a prime choice raw material. Its preponderant use cannot be justified only by its relatively large availability, but as deliberate selection towards the developing of more or less specific lithic reduction strategies.

*Fullola, Josep Maria (SERP, Universitat de Barcelona) fullola@ub.edu*

Over the past 30 years researchers have approached the analysis of quartz stone tools from a number of perspectives, with an especial focus on experimental knapping to understand the fracture mechanics of quartz. However, there has been little attention on the effects of trampling on quartz assemblages and how such post-depositional processes may affect a given analysis of a lithic assemblage with quartz. In order to remedy this, a large scale human trampling experiment was carried out over two weeks in 2013 at the Upper Palaeolithic rock shelter at Cova del Parco in the Iberian Pre-Pyrenees. A total of 500 artefacts were selected for the trampling experiment, with slightly less than a quarter being chert artefacts which acted as a baseline to analyse the quartz. The results of the experiment have demonstrated the significant difference in the fracture patterns, and fracture rates, between quartz and chert, and suggest that post-depositional processes such as trampling need to be taken into account when analysing quartz stone tools.

**9. QUARTZ IN CONTEXT: HOW FLINT USING GROUPS MOVING INTO SCANDINAVIA IN THE EARLY HOLOCENE ADAPTED TO QUARTZ**

*Knutsson, Helena (Stoneslab) stonesslab@gmail.se*

*Knutsson, Kjell (Uppsala University) kjell.knutsson@arkeologi.uu.se*

*Molin, Fredrik (National Bureau of Antiquities) fredrik.molin@raa.se*

*Zetterlund, Peter (National Bureau of Antiquities) peter.zetterlund@raa.se*

As the first hunter-gatherer societies settled in Scandi-

navia in the wake of the melting Weichselian ice some 11 000 yrs ago, they encountered a landscape that forced them to restructure their tool technologies considerably, from a developed blade technology to something less complex.

As it stands now, there seem to be a western and an eastern route into Scandinavia ultimately relating back to the Late Glacial Ahrensburg tradition in the west and Butovo/Veretye type material in the east during the Early Mesolithic. Both groups had developed their blade industries based on the presence of good flint. As they entered the new landscape devoid of flint, they had two options; to find alternatives to flint with similar characteristics or to change the technology to a more appropriate type to deal with the new materials encountered. Recent research has actually shown that both strategies were used by the pioneers.

In this paper we will focus on the result of our own research using use-wear and technological analysis to show in some detail how this adaptation to new circumstances may have taken place. Based on how quartz flakes were used in recent stone using societies and quartz flakes found in closed contexts (inserts in bone points and daggers from Scandinavia), we discuss and understand from a set of over 500 quartz flakes found on Mesolithic settlement sites in Sweden and Finland more generally how quartz may have been used.

It seems that quartz, the most common tool raw material in the region, albeit hard to control during knapping, was surprisingly easily integrated into the existing flint based tool systems.

A microwear analysis of a set of well contextualized quartz edged tools indicates that it was the edge qualities, not the knapping qualities that were important when tools with quartz edges were constructed.

ORAL

**10. THE USE OF QUARTZ AS RAW MATERIAL IN HUNTER-GATHERERS LITHIC ASSEMBLAGES: NECESSITY OR CHOICE?**

*Mansur, María Estela (CADIC-CONICET) estelamansur@gmail.com*

The study of lithic assemblages of hunter-gatherer societies constitutes one of the key tools to understand their technological organization and to propose hypotheses about aspects of the economic and social organization.

From this point of view, it is essential to try to understand the reason for the selection of specific raw materials for the manufacture of certain instruments. In order to approach this subject, we chose to address the analysis of the lithic assemblages from the perspective of the techno functional analysis, allowing to discuss three aspects closely interlinked: the selection of raw material, its transformation into consumer goods of mineral nature and the use of these tools to process various types of resources.

The lithic record of the southern sector of the southern cone is a great field to explore the relationships between these three aspects. Indeed, the archaeological sites of hunter-gatherer societies have provided extensive lithic series characterized by the diversity of raw materials represented in the assemblages, including quartzite, silicified tuffs, rhyolites, quartz, etc. The analysis has been developed on the basis of the techno morphologic characterization and the microscopic functional analysis.

A review of the representation of raw materials reveals that quartz is often represented. However, we noted that its representation is frequently a minority, but it is very common that it is present. It has also been observed that its use is related to the application of certain knapping techniques. Products made on quartz are different regarding the morphology of the edges, and they have frequently been used for specific tasks.

Therefore, their analysis allows us to discuss the interrelationship between raw material, technology, morphology and function.

## 11. QUARTZ AND SILCRETE RAW MATERIAL USE AND SELECTION IN LATE HOLOCENE ASSEMBLAGES FROM SEMI-ARID AUSTRALIA

*Holdaway, Simon (University of Auckland) sj.holdaway@auckland.ac.nz*

*Douglass, Matt (University of Nebraska) matt.j.douglass@gmail.com*

Both quartz and silcrete cobbles are abundant in the stony desert regions of western New South Wales, Australia and were used by Aboriginal people who occupied these regions from the mid to late Holocene. Archaeologists often characterise quartz as an inferior material for flaking when compared to silcrete yet Aboriginal people made intensive use of both materials. In this paper we

investigate the degree to which archaeologists can draw inferences about the choices people made in the past when considering different raw materials.

Different types of raw material were flaked more or less intensively but it is the utilization of the products of this flaking that allows inferences to be made about past intentions.

ORAL

## 12. THE EFFECTS OF QUARTZ FLAKE FRAGMENTATION ON THE ORGANIZATION OF LITHIC TECHNOLOGY

*Manninen, Mikael A. (University of Helsinki) mikael.manninen@helsinki.fi*

*Tallavaara, Miikka (University of Helsinki) miikka.tallavaara@helsinki.fi*

*Hertell, Esa (University of Helsinki) ehertell@gmail.com*

*Rankama, Tuija (University of Helsinki) trankama@gmail.com*

In addition to being difficult to “read”, vein quartz is notorious for its tendency to easily break into pieces during lithic production and use. Therefore an understanding of quartz fracture mechanics and the properties of quartz in lithic production are essential for an understanding of prehistoric lithic technology in the quartz rich areas of the world. It has been shown that the high fragmentation tendency of vein quartz can be controlled to some degree by favourable technological choices.

Previously (Tallavaara *et al.* 2010, *JAS* 37:2442-8), we have suggested that due to its fragmentation proneness vein quartz should have been avoided by highly mobile groups when raw materials of better flakeability and controllability were available because of higher transportation costs and greater risk of raw material failure when using quartz. In this paper we present cases indicating that strategies that reduce quartz fragmentation in lithic production and use were indeed employed in prehistory and show that support for the expectation that less fragile raw materials were favoured by mobile hunter-gatherers in the most critical tasks can also be found. However, in some situations a trade-off between raw material availability and raw material quality seems to have led to the use of vein quartz even in highly mobile toolkits.

ORAL

### 13. ASSESSING THE EFFECTS OF ANISOTROPY ON THE KNAPPING OF AUTOMORPHIC QUARTZ

*Rodríguez-Rellán, Carlos (Universidad de Santiago de Compostela) carlos.rellan@usc.es*

Researchers have overcome their traditional disinterest on quartz lithic industries, as this session perfectly evidences. Still, most approaches are focused on the xenomorphic or vein quartz, while the automorphic variety of this raw material, known as rock crystal, has received less attention. Automorphic quartz shows several specificities during the knapping, caused not only by the morphology and size of the blanks –single crystals of prismatic habitus– but also by its anisotropic nature.

That scarcity of specific studies has resulted in a certain lack of knowledge about the general problems of the knapping of automorphic quartz. Due to its conchoidal fracture and homogeneity, it was initially considered to have a good quality, comparable to chalcedony or jasper. Thus, its knapping would be constrained only by the small size of the crystals, which –on the other hand– have a natural shape similar to a prismatic core. This view changed when researchers noted that the knapping of automorphic quartz was quite different from that on cryptocrystalline rocks, mainly due to its anisotropic nature that led to a remarkable variability in the ease of fracture depending on the direction it was worked. This was seen as a serious hinder and a reason for its allegedly anecdotic use in prehistoric times. In truth, the archaeological record shows that the industries made on ‘rock crystal’ are found worldwide, being even subjected to complex chaînes opératoires.

Therefore, a re-examination of the effects of anisotropy on the knapping of automorphic quartz seems appropriate, especially in order to see how this could have affected the characteristics of the archaeological assemblages recovered everywhere. An experimental protocol was designed in order to reconstruct the strategies of exploitation of this type of quartz and assessing the effects of its peculiar physical properties, showing how these are not an insurmountable obstacle for its knapping.

ORAL

### 14. IDENTIFICATION OF KNAPPING TECHNIQUES FOR MICRO-BLADE PRODUCTION APPLIED TO HYALINE QUARTZ DURING THE LATE NEOLITHIC IN NORTHERN GREECE (DIKILI TASH AND PROMACHONAS-TOPOLNI'A)

*Tardy, Nicolas (Archéorient 5133 CNRS) nicotardy@hotmail.com*

Two Late Neolithic sites, both situated in northern Greece, delivered small amounts of hyaline quartz products within a diversity of other lithic raw materials such as chalcedony, different types of flint and chert, vein quartz, jasper and obsidian. These hyaline quartz artefacts indicate a technology based on micro-blade production. The presence of these elements poses the question of the knapping techniques applied to this type of unusual raw material in prehistoric lithic industries.

The archaeological assemblage consists of a small amount of pieces, mostly represented by micro-blades and fragments of micro-blades. After a short summary concerning hyaline quartz's petrology as well as its mechanical properties, a technological analysis of the products gives information about the specific attributes of this micro-blade production. Then, the setting up of a knapping experiment, using various knapping techniques on hyaline quartz crystals allows identifying the knapping techniques used for the production of micro-blades.

This study demonstrates that, among the variety of tested knapping techniques, only a few modes of pressure flaking techniques are likely to produce micro-blades on this specific type of raw material. However, the technomorphological characteristics of some both archaeological and experimental products diverge markedly from the attributes that commonly characterize blade production made by pressure flaking on obsidian or flint. These divergences are mostly due to some mechanical properties of hyaline quartz, such as its anisotropic character.

The results of this analysis undertake a reflection on the problems associated with the identification of pressure knapping techniques on hyaline quartz, and in a more general way, on the variability of blade production made by pressure flaking techniques. On the other hand, the presence, amongst these archaeological assemblages, of some flakes, cores and technical pieces questioned the possibility of a “*in situ*” pressure debitage

in a regional and chronological context in which pressure blade products are generally considered as imported products, and exclusively found in consumer sites in the form of finished by-products (blades or tools made on blades).

### 15. WEAR FEATURES ON QUARTZ, ROCK CRYSTAL AND QUARTZITE: A COMPARATIVE STUDY COMBINING OPTICAL LIGHT AND SCANNING ELECTRON MICROSCOPY

*Ollé Cañellas, Andreu (IPHES) aolle@iphes.cat*  
*Pederagnana, Antonella (IPHES) apederagnana@iphes.cat*  
*Martin, Sabine (Univ. Exeter) sajm201@exeter.ac.uk*  
*Fernández Marchena, Juan Luis (IPHES) juanl.ferna@gmail.com*  
*Borel, Antony (MNCN Paris) borel@mnhn.fr*  
*Aranda Sánchez, Victoria (IPHES) victoriaraandasanchez@gmail.com*

Quartz and in general most of non-flint rocks have not been very extensively studied from a functional point of view. Very frequently the definitions of micro-features connected with flint surfaces have been used to describe those encountered on non-flint tools. This circumstance has repeatedly posed serious methodological problems for evaluating the accuracy of functional results when analysing use-wear on quartz and quartzite implements. This is due to the intrinsic divergences in morphology and distribution of use-wear with regard to the different lithic raw materials.

A review of the experimental and archaeological literature dealing with this issue points out that efforts to systematize use-wear features on quartz have been done. Even so, there continues to be confusion and lack of standardization regarding terminology in this aspect.

We try to make progress in this research field by means of an extensive experimental program involving different raw materials, from the purest form of quartz found in nature (hyaline quartz and milky quartz) to rocks with a very high quartz content and extensively used for knapping throughout Prehistory (quartzites and quartzarenites). For data recording, we resorted to both Optical Light and Scanning Electron Microscopy.

The results obtained allowed to assess the different mechanical behaviour under the stress of a group of raw materials with the same chemical composition but very different in structure. Furthermore, we were able to assess the inefficiency of applying the methodology and

terminology developed for flint use-wear analysis to those rock types.

We finally propose an updated terminological selection of terms to be employed when documenting micro-wear on quartz, even recurring to external concepts coming from materials and geological sciences (e.g. tribology, quartz exoscopy...).

ORAL

### 16. IDENTIFICATION AND EVALUATION OF MECHANICAL WEAR TRACES ON QUARTZ ASSEMBLAGES: AN EXPERIMENTAL INVESTIGATION.

*Venditti, Flavia (University of Rome) flavia.venditti@gmail.com*  
*Tirillò, Jacopo (University of Rome) jacopo.tirillo@uniroma1.it*  
*Garcea, Elena*

The evaluation of the state of preservation of archaeological lithic artefacts is the first step before starting a functional analysis. If lithic artefacts show a variety of damage of many contact materials, they are also subject to modifications from "natural" causes, such as water transport, soil abrasion, trampling etc..(Levi Sala 1986, van Gijn 1980). Studying alteration features gives us information to reconstruct the life story of lithic tools after their abandon and helps us to better understand formation processes of archaeological sites. Prolonged movements under soil could be responsible for post depositional surface modifications that sometimes look like wear traces due to use. This alteration could have chemical and/or mechanical origin. Recognizing them is of paramount importance especially on quartz assemblages where use wear analysis requires a long and complex methodology that differs to a certain extent from the protocol applied to other manufactures produced with raw materials such as flint, obsidian etc...

For this reason, the use wear and post-depositional surface modification analysis on quartz and quartzite tools have been undertaken by very few researchers until now (De Araujo Igreja 2009, Conte & Gibaja Bao 2009, Eigeland 2009, Knutsson 1988). The aim of this poster is to increase the experimental field through the attempt to recreate mechanical contact between quartz flakes and sediment such as in archaeological contexts. Through the use of a Polishing Machine MECAPOL P320 equipped with two counter-rotating platens, it was possible to wear out two experimental flakes in a sandy quartzite sediment coming from island of Sai (Sudan) for about 240 hours.

After the experimentation, the two flakes showed no edge damage or other visible modifications, but some micro traces on the crystal surface were present. The micro traces definable as abrasions on some parts of the crystal surface, have been analysed by a metallographic microscope and compared with the same crystal portion of this latter taken before the experiment. Although and demanding, this step sharply reduces possible errors in the recognition during the experimental stage.

Even if it is difficult to reconstruct post depositional processes in a laboratory, this attempt shows that the contact between sediment and stone tools in a continuous movement can randomly abrade the crystal surface.

### **17. MICROSCOPIC ANALYSIS OF THE TECHNICAL AND FUNCTIONAL STIGMAS AS A METHOD FOR THE USE-WEAR ANALYSIS OF ROCK CRYSTAL TOOLS.**

*Fernández Marchena, Juan Luis (IPHES, Institut Català de Paleoeologia Humana i Evolució Social, Zona educacional 4 (Edifici W3), Campus Sescelades URV, 43007 Tarragona, Spain / Àrea de Prehistòria, Universitat Rovira i Virgili, Fac. de Lletres, Av. Catalunya 35, 43002 Tarragona, Spain) juanl.ferna@gmail.com*

Rock crystal is a quartz variety of very good quality and excellent aptitudes for knapping. Although it is a infrequent raw material, in certain geological contexts, as in our case study, it can assume a large part of the tooling. Despite this, it is a material very little researched. The reasons for this lack of interest may be various, from the difficulty of analyzing a translucent material to its direct attachment to the symbolic world.

Here we propose a methodology combining macro and microscopic analysis of knapping and use stigmas in order to establish a better approximation to the functionality of rock crystal artefacts. We integrally analyzed a series of experimental tools before use, with different microscopic equipment (low magnification microscopy, SEM and OLM with a Nomarski prism). After a first documentation, the tools were used in a sequential experimental program in order to observe the evolution of the use-wear. Fourteen experiments were done on different materials and with different actions, documenting the different traces of use with their respective orientations and sizes that appeared in each of the times recorded.

The set of experiments resulted in different associations of use-wear traces (striations, chipping, roundings and polish) characteristic of the various worked materials and actions employed. We have also documented the lancet as a stigma of a technical character, which can also provide functional information. This is due to the formation process of this stigma, either by percussion or pressure. While those formed from the impact point on the ventral side are distributed radially, those created into the chipped follow the kinematics of the tools.

Finally, we demonstrated that rock crystal is a material that offers many possibilities for use wear analysis. For this purpose, an analysis the association of a set of technical and functional stigmas is necessary. Furthermore, although the OLM with Nomarski prism is the best optical media to analyze rock crystal, the combination with other media can provide even more information.

**SCALES OF CHANGE. CASE STUDY OF A PHASE TRANSITION DURING THE WEICHSELIAN LATEGLACIAL IN NORTH-WEST EUROPE.**

*Grimm, Sonja B. (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) grimm@rgzm.de*

The Late Pleistocene is characterised by significant climatic and environmental changes in north-western Europe. The onset of the Weichselian Lateglacial Interstadial represented the most intense climatic shift since the Last Glacial Maximum. In the context of this important climatic change, the transition from the Upper Palaeolithic Late Magdalenian to the Final Palaeolithic established Azilian (Federmesser-Gruppen) occurred. Nevertheless, the role of the climatic change and the associated environmental developments in this transition remained uncertain. Moreover, defining a limit between the Late Magdalenian and the established Azilian continues to be difficult because the latter certainly arose from a substratum of the former. Thus, both traditions were considered as parts of a continuum. However, without identifying clear limits and dating those limits, questions relating to causal relations of significant change in human behaviour with a changing environment remain speculative. Therefore, these observations raised several questions: How to describe a continuous change? How to quantify change? Where to set a limit within a transition?

Based on the concept of archaeological taxonomic units (ATU, Foley / Lahr 1997), a hierarchy originally designed to study population history (Gamble et al. 2005) was refined and coupled with a high-resolution chronology to study changes in human behaviour. This hierarchical approach allowed changes to be observed at different levels of the archaeological record and also on different levels of human society.

This approach was used on the Weichselian Lateglacial record from North-West Europe. For this record, a high-resolution chronostratigraphy was created to make a reliable succession of behavioural changes and of climatic and environmental events possible.

In this example, changes at different levels of the archaeological record were recorded in a summed diagram according to their chronological appearance. Several smaller, some intermediate, and one larger leap in this

diagram can be observed. The hierarchical position of changes contributing to the large leap range from low, individual levels to very high, societal levels. Compared to the climatic and environmental record, this large leap is not concomitant with the most significant climatic shift but with a later, much smaller fluctuation which initiated a major environmental change.

In more detail, the transition from the Late Magdalenian to the established Azilian could be described as phase transition based on the above mentioned approach. Furthermore, a relation to changes in the surrounding environment were suggested which makes this process understandable as a part of an adaptive cycle in the Weichselian Lateglacial.

Nevertheless, uncertainties of this approach remain as a matter of discussion such as: Which steps should be registered? How should observations in the archaeological record be coupled with a hierarchy of behaviours to increase the observed impact of changes on the human society?

ORAL

**A BIOSOCIAL APPROACH TO UNDERSTANDING THE MODE 2/3 TRANSITION.**

*Barham, Lawrence (University of Liverpool) l.s.barham@liv.ac.uk*

The Mode 2 (Acheulean) to Mode 3 (Middle Palaeolithic/Middle Stone Age) transition took place in Africa and Europe in the latter part of the Middle Pleistocene. Archaeologists have focussed on when and where the transition took place with less attention given to how and why it happened. The Mode 3 Hypothesis (Lahr and Foley 2001) argues for a single African origin of prepared core technology and subsequent dispersal into south-west Asia and Europe. Others argue for a process of independent convergent technological change in Europe among populations of early Neanderthals (White and Ashton 2003; Moncel 2011). This paper avoids a primarily lithic based analysis of the transition and argues that it should be examined as a part of a longer-term process of social, cognitive and developmental evolution with deep roots in the genus *Homo* (Barham 2013). The biosocial perspective offered incorporates cultural transmission theory, life history data, and cognitive neuroscience and integrates these with a model of technological change rooted in complexity theory (Arthur 2009). A small set of 'integrative technologies' are identified in the Acheulean that serve as the social and cognitive pre-

cursors to the Mode 2/3 transition, where ever it takes place. These technologies, which include fire and the making of thinned bifaces, integrate knowledge of materials with differing properties and involve extended hierarchical planning and constructive memory (Ambrose 2010). Cooperative social groups are inferred to be a necessary context for the transmission of these technologies and invention of Mode 3 technologies (i.e., prepared cores and hafting).

The social, cognitive and technological precursors of Mode 3 were in place in parts of Africa, southwest Asia and Europe by ~ 400ka and the transition may have taken place independently in more than one region and with more than one species of hominin. The chronological resolution of the transition, however, is too poor - especially in Africa - to identify a place of origin and for now the question of origin cannot be answered. The biosocial perspective shifts our attention to the co-evolution of mind, body, society and technology. Stone tools by necessity remains a focal point of much of our research, but our analytical frameworks need to situate them in an expanded analytical framework if we are to understand the complex processes that underpin technological change.

### **DOPAMINERGIC SYSTEMS EXPANSION AND THE ADVENT OF HOMO ERECTUS.**

*DeLouize, Alicia (University of Colorado, Denver) ALICIA.DAVIS@ucdenver.edu*

*Coolidge, Frederick (University of Colorado, Colorado Springs) fcoolidg@uccs.edu*

*Wynn, Thomas (University of Colorado, Colorado Springs) twynn@uccs.edu*

It is well accepted that a grade shift occurred in hominin evolution approximately 1.9 million years ago with the appearance of *Homo erectus*. With the challenges of complete terrestrial life, new cognitive abilities were selected for that allowed this species to thrive for the next million and a half years. It has also long been recognized that there was a change in diet with the advent of *Homo erectus*, that is, a greater reliance on meat. However, the relationship between additional meat and the cognitive abilities of *Homo erectus* has mostly remained unclear. The present paper proposes and presents extensive evidence that an increase in dietary meat protein and fats may have led to an increase in dopamine and dopaminergic systems, a critical chemical neurotransmitter in the brain. This purported change in dopaminergic sys-

tems may have played a key role in many of the traits and abilities exhibited by *Homo erectus* at that time, including increases in body and brain size, dispersion, and a greater aptitude for spatial and social cognitions.

ORAL

### **TEMPO AND MODE OF THE MP/EUP SHIFT IN MEDITERRANEAN EUROPE.**

*Longo, Laura (Musei Civici Fiorentini) longoflint@gmail.com*  
*Condemi, Silvana (UMR 7268 CNRS / Université de la Méditerranée/EFS) silvana.condemi@univ-amu.fr*

Until recently only Middle Paleolithic or Early Upper Paleolithic sites of northern and central Europe were brought into the discussion of the shift from Neanderthals to modern humans. The role played by Mediterranean Europe was weak and, due to the lack of articles dealing with southern Europe in English, the archaeological evidence on this topic was not readily available and was not cited in the leading scientific journals. Nonetheless, many southern European sites have been yielding consistent and reliable stratigraphic sequences, as well as human fossils associated with behavioral activities like the production of stone tools and intentional transformation of fauna and other "raw materials". PaleoDNA analysis, new protocols for reliable radiocarbon dating, and paleoenvironmental reconstructions of MIS 3 which are now also applied to the Mediterranean sites present a wholly different scenario concerning the role played by Mediterranean Europe in the demise of Neanderthals. It is necessary to obtain reliable chronological datasets and archaeological sequences for which the relation of both behavioural and environmental conditions can be proved. Investigation must also be carried out in reliable sites where human findings can be related to their activities. It is in other words essential to apply proxies considered to be fundamental for drawing further conclusions concerning acculturation or its absence. These proxies should be: (i) reliable conditions for distinguishing between feasible/probable/certain attribution of human remains to the cultural horizon with which they are associated; (ii) reliable species attribution of the human findings; (iii) AMS methodological extraction for radiocarbon dating; (iv) reliable sampling of humanly modified animal remains or charcoal; (v) in view of ascertaining the reliability of the relation established between human remains and their activities, the unquestionable association of the human remains with their cultural assemblages (Mousterian or EUP); last but not least, (vi) carrying out of radiocarbon dating on human genetically typified bone collagen. Radiocarbon dating

made from bone collagen is very important and, due to lack of human remains or of collagen on those that are found, it is often absent from the MP/EUP sites, and proxies (i) and (iv) cannot be applied to them. This is a crucial issue regarding future efforts to develop reliable protocols to enhance genetic and morphological analytical techniques. If we are to advance in our discussion of the role played by Neanderthals and modern humans in the evolutionary sequence, a consideration of the contemporary incidence of these proxies in a given site is of central importance. This paper presents the situation of the northern Mediterranean basin and focuses specifically on the Italian Peninsula and on its relationship with presently available data from western and eastern regions of Europe.

### **COMPARING MOUSTERIAN AND PROTO-AURIGNACIAN USE OF SPACE AT RIPARO BOMBRINI: IMPLICATIONS FOR THE MIDDEL-UPPER PALEOLITHIC TRANSITION**

*Riel-Salvatore, Julien (University of Colorado Denver) julien.riel-salvatore@ucdenver.edu*

*Ludeke, Ingrid (University of Colorado Denver) iludeke800@gmail.com*

*Negrino, Fabio (Università di Genova) fabio.negrino@unige.it*

Aurignacian sites are often claimed to differ from Mousterian ones on the basis of their showing clear evidence for spatially discrete activity areas and, by extension, where various types of discarded archaeological remains cluster within them. On the other hand, with a few notable exceptions, Mousterian sites have been generally argued not to show clearly separated activity areas. Assessing the true significance of these differences is difficult, however, when site size, shape, and functions cannot be controlled for. This highlights the need to conduct spatial analyses at sites that contain levels accumulated by both modern humans and Neanderthals to directly compare their degree of intrasite organization. To this end, this study uses piece-plotted finds (lithics, bones, shells, ochre) to contrast hominin use of space in proto-Aurignacian and late Mousterian levels from Riparo Bombrini (Liguria, Italy), where only a few hun-

dred years separate the two types of occupations. To date, spatial analyses at the site have been largely impressionistic though recent efforts at quantification have shown suggestive evidence of distinct activity areas in the Mousterian levels. The present analysis employs unconstrained cluster analysis to explore the distribution of co-occurring sets of artifacts in both the Mousterian and proto-Aurignacian levels. This allows us to conclude that 1) both Neanderthal and modern human occupations varied in their spatial organization across levels attributed to a single industry; 2) in the proto-Aurignacian, lithic manufacture, shellworking, and butchering activities appear to have been concentrated in different areas when the site was occupied by logistically- vs. residentially-organized *Homo sapiens*, with level A2 showing strong evidence for systematic sweeping/debris removal; and 3) that the organization of activities in the Mousterian also vary as a function of site use modalities over time, reinforcing the idea that Neanderthals also purposefully segregated different tasks within the rockshelter. In contrast, to previous studies, this suggests that Neanderthals and modern humans did not have a qualitatively different way of organizing their use of Riparo Bombrini. The implications of these patterns for the process of the Middle-Upper Paleolithic Transition at the site (and NW Italy more broadly) are also discussed.

**1. BIRDS IN THE FIGURATIVE IMAGERY OF UPPER PALEOLITHIC POPULATIONS. EXPLORING THE RELATION BETWEEN ART, ZOOARCHAEOZOOLOGY AND ETHNOARCHAEOLOGY.**

*Cestari, Martina (University of Ferrara) martina.cestari@student.unife.it*

*Peresani, Marco (University of Ferrara) marco.peresani@unife.it*

The depictions of birds in the Paleolithic art are uncommon compared to the large repertory of big mammals and predators, but are attested in many Eurasian Paleolithic sites where avifaunal resources are often an integral part of the diet and the ornament of the hunter-gatherers groups. Many studies have tried to explain these representations for identifying species represented and their frequency in some contexts, but their investigations have been limited only to some countries. This contribution wants to present a synthesis of old and recent interpretations in a wider geographical area. For this purpose we have created a database taking data from the literature and directly from some collections of archaeological remains.

Data from as many as possible sites, levels, culture, chronology have been collected also taking into account the type of context: burial, cave art, residential site. The depictions have been classified according to the current taxonomic identifications and, when ambiguous or uncertain, we have tried to identify the figured birds at the order or family levels, in relation to the anatomical or the ethological features. The data have been statistically analyzed for establishing the frequency of the represented families. Subsequently, materials have been studied in relation to the species present in the faunal assemblages, with consideration of the geographical and chronological extensions of each techno-cultural area. Finally, the ethnoarchaeological record has been taken into account by identifying some ethnic groups of the subarctic regions, where the birds constitute part of the diet and of the artistic and ceremonial manifestations.

The compared reveals higher frequency of specific orders of Aves as Anseriformes, Gruiformes, Strigiformes and Passeriformes (Corvidae), compared to other: Galliformes, Charadriiformes and Accipitriformes that can be found only in a few contexts. The comparison with zooarchaeological remains have shown that only few

species are represented compared to those hunted, specifically stand out owls and aquatic birds frequently attested in Magdalenian sites in Western Europe, but also in Paleolithic sites of the Eurasian steppe.

Relations between environment, avian ethology, the species of birds depicted and hunted by the Late Paleolithic hunter-gatherers have been found. Implications are here proposed.

**2. BIRD CONSUMPTION IN COVA NEGRA MOUSTE-RIAN SITE (XÀTIVA)**

*Martínez Valle, Rafael (Laboratorio de Arqueología y Paleontología. IVC+R. CulturArts Generalitat) martinez\_rafval@gva.es*

*Villaverde Bonilla, Valentín (Prehistory and Archeology Department. Universitat de Valencia) valentin.villaverde@uv.es*  
*Guillem Calatayud, Pere M. (Archeology and Paleontology Laboratory. IVC+R. CulturArts. Generalitat Valenciana) martinez\_rafval@gva.es*

Since the end of the XIX century there has been an ongoing debate about the hunting of birds during the Paleolithic, about the importance that it might have had as a source of food and for the use of feathers and bones for personal ornaments (Bouchud, 1953; Mourer Chauviré, 1975, Vilette 1983). There is still debate regarding the Middle Paleolithic, particularly concerning the study of the Neanderthals' capabilities (Blasco y Fernández, 2009; Finlayson et al, 2012).

The excavation campaigns carried out in Cova Negra between 1981 and 1991 have yielded a large number of bird remains. In the area known as the North Sector, which contains the most recent levels of the sequence (OIS 5e-d), 1,594 remains, from 42 taxa, have been recovered. Doves (*Columba livia/oenas*), choughs (*Pyrrhocorax pyrrhocorax* and *Pyrrhocorax graculus*), and partridges (*Alectoris rufa*) predominate (Martínez Valle, 1996).

The taphonomic study of these remains has shown that a substantial part of bone remains correspond to human contributions. In a significant part of these remains human marks of fracture can be found, such as disarticulation incisions and scraping for flesh removal, made with lithic implements. These marks are related to the processing of the piece and to teeth marks made by consumption.

This paper describes the remains that show evidence of human manipulation. The process of selection and consumption of birds in the site is reconstructed and results are contrasted to patterns observed in the treatment of bird bones in Paleolithic sites in the region.

ORAL

### 3. POTENTIAL EXPLOITATION OF AVIAN RESOURCES BY EARLY HUMANS.

*Negro, Juan José (Estación Biológica de Doñana (CSIC) negro@ebd.csic.es*

Human consumption of bird meat in modern societies comes in two ways: as embryos –i.e., eggs- and as hatched individuals, either young or adults. Compared to the available species, about 10,000 in the world, the number of avian species domesticated for their eggs or meat is however very reduced at a global scale (two galliforms -the chicken and the turkey-, a few waterfowl -geese and ducks-, and the pigeon. But even if birds provide today only a relatively small fraction of the animal proteins in human diets, the bird-human interface is possibly an ancient one and has remain important until today. Hundreds of species are kept as pets, a few others are used themselves as hunting or fishing weapons (the falconry birds, and the cormorants, respectively), and non-edible products, such as feathers or eggshells are used by traditional cultures in all continents as body ornaments, headdresses or jewelry.

Regarding early humans, it has been proposed that Neandertals decorated themselves with raptors and corvid feathers, with a preference for dark colours. It is also known that they consumed birds, including pigeons, according to cutmarks in bone remains. Even if birds may be perceived as elusive prey due to their flight capabilities, they are forced to incubate their eggs in a fixed position, the nest, where the nestlings grow until they reach full size. This makes eggs, nestlings and brooding adults easy prey. Even roosting birds are practically defenceless against stealth predators. And humans may become such when they learn to interpret cues left behind by a flock of birds. Birds share a common sensitive world with humans. Most birds are diurnal as we are, and they rely on visual and auditive cues for communication, that we may learn to interpret, or that we can even imitate.

ORAL

### 4. AN ATTEMPT TO CHARACTERIZE LITHIC USE-WEAR AND RESIDUES RELATED TO THE AVIFAUNAL RESOURCES EXPLOITATION

*Pedergrana, Antonella (IPHES) apedergrana@iphes.cat  
Blasco, Ruth (Gibraltar Museum) rblascolopez@gmail.com*

The proposed issue of the interaction between humans and the avifaunal species is here approached from the lithic studies perspective. Pilot experiments on the treatment of bird carcasses employing flint flakes were performed. The executed actions comprised skinning and de-feathering different avifaunal species (*Circaetus gallicus* and *Gyps fulvus*), connected with the migratory routes crossing the Gibraltar Strait.

The main aim of this experimental program was to document use-wear traits on flint implements related to the avifaunal carcasses management for then being able to recognize those actions in the archaeological record. An additional effort is done concerning the experimental organic residues associated with the bird species included in the experiments (skin, meat, feathers). For each residue type a detailed chemical and morphological characterization is provided, with the aim of creating an experimental database to be comparable with micro-residues possibly found on the archaeological stone tools.

For microscopic observations, we employed both Scanning Electron Microscopy (SEM) and Optical Light Microscopy (OLM). A detailed description of use-wear features and residue types is done through a systematic comparison of micrographs taken with both techniques. In addition, EDS (energy-dispersive x-ray spectroscopy) is applied to obtain elemental composition of residues.

Future developments of the research will improve the methodology by expanding the experimental program and through its further application to archaeological collections (at sites where the processing activity of this kind of animals has already been identified). Subsequently, the taphonomic analysis of the bones of the carcasses used in the experimental program will be added. In fact, it will be interesting to compare the cut marks distribution on bones with the use-wear pattern on the employed lithic implements.

Therewith, by crossing data coming from different disciplines, we hope to suggest an innovative point of view for better understanding the exploitation of the avifaunal resources by human groups throughout Prehistory.

ORAL

**5. AN ASSESSMENT OF THE EXPLOITATION OF BIRDS IN THE LATE MIDDLE PALAEOOLITHIC BASED ON NEW EVIDENCE FROM GROTTA DI FUMANE.**

*Romandini, Matteo (University of Ferrara) matteo.romandini@unife.it*

*Fiore, Ivana (Museo Nazionale Preistorico Etnografico L. Pigorini) iva\_fiore@yahoo.it*

*Gala, Monica (Museo Nazionale Preistorico Etnografico L. Pigorini) monarix@yahoo.it*

*Tagliacozzo, Antonio (Museo Nazionale Preistorico Etnografico L. Pigorini) antonio.tagliacozzo@beniculturali.it*

*Cocca, Enzo (University of Ferrara) enzo.cocca@unife.it*

*Peresani, Marco (University of Ferrara) marco.peresani@unife.it*

In the debate on the Neanderthal behavior and its dietary habit, a role is played by the taphonomy of avifaunal complexes. However, data suggesting deliberate exploitation of this resource are still sparse across western Eurasia. To reinforce this scenario, new data have been recently achieved at Grotta di Fumane, a site in the North of Italy known for producing important material for the study of Neanderthal behavior, especially during the latest Levallois Mousterian complex A5-A6 (Peresani et al. 2011). To confirm the deliberate extraction of remixed feathers from large raptors and, at the same time, to enlarge the body of evidence, the bird bone assemblage of the Mousterian unit A9 is here presented.

A taxonomic determination of over 500 bird bones has been based on comparison with the zoological collection of the Quaternary Palaeontology and Archaeozoology Section of the Pigorini National Ethnographic Museum. Microscopic analyses of the bone surfaces have been carried out using Nikon 1000 (Rome) and Leica S6D Green Ough (L.A.T. of Ferrara) stereomicroscopes (20-220X). Experimental butcherings on large raptors have been conducted for a better understanding of the striae formation on the bones and the gestures performed. The spatial distribution of the bones has also been taken into account, integrated by statistics, database and GIS.

Over 29 species have been identified. Mostly are Passeriformes, mainly Corvids, with numerous Gruiformes and Galliformes. Diurnal and nocturnal raptors are also present. Species from mountain cleared and forested environments dominate the assemblage and, in comparison to unit A6-A5, unit A9 records less harsh climatic signatures. Taphonomical traces show anthropic modifications like cut-marks and fractures ascribable to the frag-

mentation of bone when fresh. These traces have been observed of species of different size and positioned on various anatomical zones, suggesting that the carcass was exploited according to a well experienced process. The spatial distribution of the bones, when related to the taphonomical traces, hearths and other structures reveals that the bird exploitation in the cave was planned in a different way than the ungulate fauna was.

Besides backdating the acquisition of valuable elements of avian plumage in human history, this and other new evidence from the final Mousterian levels increases the variability in exploitation of different species of birds, so strengthening our view of behavioral complexity among Neanderthals.

*Giles Pacheco, Francisco (Gibraltar Museum) pacogiles@hotmail.es*

*Rodríguez-Vidal, Joaquín (Universidad de Huelva) jrvidal@dgeo.uhu.es*

*Finlayson, Clive (Gibraltar Museum) clive.finlayson@gibmuseum.gi*

Pigeons (*Columba*) are species of rocky habitats, nesting typically on cliff ledges and at the entrance to large caves. Corvids are forest birds, and a few colonial species, such as choughs (*Pyrrhocorax*), can also breed in rocky outcrops or cliffs; nevertheless, choughs do not seem capable of reaching the high population densities of doves. At Gorham's Cave, Gibraltar, the Neanderthals exploited pigeons and choughs for a period of more than 40 kya, with the earliest evidence dating to at least 67 kya. We show that the exploitation was not occasional, having found repeated evidence of the practice in different layers within the cave. The Gibraltar sites seem to

provide the ideal conditions to broaden the spectrum of prey during MIS 3. The high diversity of avian species identified in the faunal assemblages could be related to the location of the caves, which enable exploiting coastal and rocky habitats. This fact seems to argue for the unique circumstances and foraging opportunities at this particular locality, where the available prey and environmental conditions seem to be conditioned to the Neanderthal diet.

### **7. WHO IS BRINGING BIRDS? AN APPROACH FROM THE MIDDLE AND EARLY LATE PLEISTOCENE ACCUMULATIONS FROM PAYRE AND ABRI DES PÊCHEURS (ARDÈCHE, FRANCE)**

*Rufà, Anna (Institut Català de Paleoecologia Humana i Evolució Social (IPHES) - Àrea de Prehistòria, Universitat Rovira i Virgili (URV) arufa@iphes.cat*

*Blasco, Ruth (The Gibraltar Museum) rblascolopez@gmail.com*

*Moncel, Marie-Hélène (Département de Préhistoire, Muséum National d'Histoire Naturelle - Institut de Paléontologie Humaine) moncel@mnhn.fr*

*Thierry, Roger (Laboratoire de Préhistoire du Lazaret) trogier@lazaret.unice.fr*

The acquisition of quick-flying small prey has been a wide discussed topic during last decades, especially since the emergence of archaeological bird collections more ancient than expected with evidence of anthropic processing. The acquisition and processing of birds is different from those done on larger fauna. For its small size, it may be difficult to find human activity on bird bones in form of cut-marks, since they could be eaten directly without using tools. This added to the fact that bird specimens might be also deposited in archaeological contexts by natural causes and/or by other biological agents (such as raptors or mammal carnivores) makes their association with human consumption difficult.

In the archaeological site of Payre (end MIS 8/beginning MIS 7 to end MIS 6/beginning MIS 5), human activity on birds has been suggested thorough the residue analysis made on stone tools from the site but, up to now, further analysis have not been carried out on avian remains from the site. In the same way, no detailed taphonomic data from bird bones has been obtained from the near site called Abri des Pêcheurs (MIS 5-3). These data could be interesting to have a global point of view from the Ardèche region, in relation with the Neanderthal subsist-

ence. For this reasons, the main objectives of this work are: (1) to demonstrate whether birds are consumed or not by hominids in these archaeological sites; (2) to establish subsistence patterns, in case human consumption of birds exist. If it is not, it will be important to (3) detect the taphonomical agents which could intervene on the remains, to find the origin of the accumulations. Payre and Abri des Pêcheurs correspond to the Middle Palaeolithic period. Payre is divided in 8 archaeological levels, in turn divided in sub-levels. Bird remains come from levels A, D, F and G. On the other hand, Abri des Pêcheurs is composed by 4 archaeological levels (from Sector 1 to 4). In both sites, human activity was demonstrated on large and medium fauna.

To achieve the goals established above, bird bones from both sites were analysed on the framework of the Taphonomy methodology. Bone representation, fragmentation, tooth-marks, corrosions and other taphonomical processes were considered.

As a result of this analysis, a wide variety of avian species from different families were identified. Despite of that, human activity does not seem to be present on any of them. The presence of carnivore tooth-marks, beak-marks and digestions pointed out carnivores (nocturnal raptors and small mammal carnivores) as possible accumulator agents. Initially, it can run into contradiction with stone tool residue results, but it should be taken as new data which complements the previously proposed. In summary, bird bones analysis pointed out carnivores as the main accumulator agents in both sites. Even so, it could be used as an example of Neanderthal adaptation in front of different ecological circumstances.

### **8. EATING CROW OR A FEATHER IN ONE'S CAP: THE AVIFAUNA FROM THE MAGDALENIAN SITES OF GÖNNERSDORF AND ANDERNACH (GERMANY).**

*Street, Martin (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) street@rgzm.de*

*Turner, Elaine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) turner@rgzm.de*

The Central Rhineland Magdalenian sites Gönnersdorf and Andernach produced an extremely rich corpus of diverse archaeological finds, including some 14,500 faunal remains at Gönnersdorf and some 4000 at Andernach.

Faunal studies have focussed on the large game, mainly horse, however favourable conditions of preservation at both sites provide an opportunity to examine not only smaller mammal taxa, but also for detailed analyses of the avifauna. Here we present results of these analyses with particular emphasis on the economical and social role of birds in Magdalenian life.

Standard zooarchaeological methods were used to establish NISP and MNI and to identify presence of butchery traces on avian bones. By applying a holistic approach we were able to attribute remains with details of individual stages of carcass processing of birds to a specific location within site area, providing a combination of information relevant to settlement organisation and site formation.

Bird bones at Gönnersdorf are from large to medium-sized species, the majority of them ptarmigan / willow grouse and raven, but also swan, snowy owl, goose and gull. Here, some of the most complete late Upper Palaeolithic settlement structures in western central Europe are interpreted as four distinct dwellings, with birds recovered from three of these (K I - K III). The smaller assemblage of bird bones from Andernach is identified to ptarmigan / willow grouse, raven and goose. Post-settlement disturbance leads to a less clear picture here.

Selection for wing elements of swan and goose suggests these large birds may have been primarily of interest in terms of their pinion feathers or wing bones. In contrast the skeletal representation of ptarmigan or willow grouse suggests that complete carcasses were brought to the site for processing / consumption. Cut marks on raven phalanges probably result from the detachment of the feet and claws. A complete praemaxilla and dentary of a raven from a pit in Gönnersdorf K II represent a complete head. Its location, together with the overall representation of raven bone, perhaps suggest non-utilitarian motives for the presence of entire feathered skins of ravens within Gönnersdorf dwelling structures.

In view of the large numbers of horse hunted at both sites, the relatively small number of bird remains show that they did not play major role as a food resource. Other uses for body parts such as feathers and claws must be considered.

Combining zooarchaeological analysis with spatial data provides insights into Magdalenian economic and social organisation practically down to a household level. Ravens have played a major role in the spiritual life of many northern peoples and an engraving from Gönnersdorf

shows that their character and probably their significance were clearly appreciated by the artist. Insight into Magdalenian perception of birds is also provided by an inspired carving of a bird from Andernach.

*Tomek, Teresa (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska 17, 31-016 Kraków, Poland) tomek@isez.pan.krakow.pl*

*Roblickova, Martina (Anthropos Institute, Moravian Museum, Zelný trh 6, 659 37 Brno, Czech Republic) mroblickova@mzm.cz*

*Oliva, Martin (Anthropos Institute, Moravian Museum, Zelný trh 6, 659 37 Brno, Czech Republic) moliva@mzm.cz*

Dolní Vestonice I and Pedmosti are one of the largest and best known Pavlovian sites known from Moravia (Czech Republic). They have yielded extraordinary assemblages of osseous and lithic artefacts, as well as animal remains, subsequently addressed in innumerable publications. The presentation briefly summarizes the results of the analysis of bird bone remains from Dolní Vestonice I and Pedmosti. Analysis of features such as species composition, representation of anatomical remains, and fragmentation of bones, confirms that rather than being natural these accumulations took form as a result of human activity. The observable domination of the remains of Raven (*Corvus corax*), which is confirmed also in other Gravettian sites in Moravia, may be a feature distinctive for the Pavlovian culture/Gravettian of Moravia.

## 10. HUMAN CONSUMPTION OF BIRDS AT BOLOMOR CAVE (VALENCIA, SPAIN, MIS 9-5)

*Blasco, Ruth (Gibraltar Museum) rblascolopez@gmail.com*  
*Fernández Peris, Josep (SIP (Servei d'Investigació Prehistòrica), Museo de Prehistòria) josep.fernandez@bolomor.com*

The diversification of subsistence in pre-Upper Palaeolithic periods has developed over the past 40 years, and is one of the main topics of discussion in Europe. Environmental and socio-cultural aspects invite us to reflect on the characteristics that delimit the meat diet and the correct assessment of this in relation to human behaviour and the availability of prey. The ecological context in which sites are located and the environmental characteristics of the period in which human occupations occur must be considered to correctly assess how diet has evolved throughout time. This proposal leads to the suggestion that more than one diet could exist because it could vary according to the locally available resources as well as socio-cultural variables. Bird predation was practised since at least the Early Middle Pleistocene and seems to be directed towards edible species, with clear evidence of consumption in Mediterranean Europe in the Bolomor Cave layers. Bolomor Cave, dated between 350 and 100 kya, emerges as some of the clearest and earliest evidence of hominin use of birds. Here, we present a general taphonomical view of bird assemblages from Bolomor through its stratigraphic sequence by presenting a bird record from sublevels XVlla and XVllc (lower sequence, MIS 9), levels XII and XI (middle sequence, MIS 6) and level IV (upper sequence, MIS 5e). Bolomor is an example of how the subsistence strategies across the Middle and early Late Pleistocene may display significant variability based on local environmental adaptation, occupational pattern—mobility and site functionality—as well as other possible socio-cultural factors.

**11. FLUTE OF ISTURITZ? EXPERIMENTAL REPRODUCTION AND ARCHAEMUSICOLOGICAL ANALYSIS.**

*García Benito, Carlos (University of Zaragoza) cgb@unizar.es*  
*Mazo Pérez, Carlos (University of Zaragoza) cmazo@unizar.es*  
*Alcolea Gracia, Marta (University of Zaragoza) malcolea@unizar.es*

The prehistoric archaeological remains interpreted as flutes of Cave of Isturitz, are they really this particular type of wind instrument?

Through the research that being carried out on the experimental reproduction of the only complete aerophone of Isturitz -1914 F3a 75252/A3-Ist. III 83 888 1939-, made using replicas of prehistoric flint tools (blades, chisels and drills) in a bone of griffon vulture (*Gyps fulvus*), this study suggests that this object can be up to

three different kind of aerophone: end-blow instrument (*ney flute*), reed instrument (*clarinet*) or reep lip instrument (*brass*).

In this sense, it will mostrate the first results of this archaeomusicological analysis demonstrating this sound and musical ability, along with all previous research that has allowed us to know what is the manufacturing process.

**12. BIRD-BONES MODIFICATIONS CONDUCTED BY IBERIAN LYNX: TAPHONOMIC ANALYSIS OF NON-INGESTED RED PARTRIDGE REMAINS**

*Rodríguez-Hidalgo, Antonio (IPHES) ajrh78@gmail.com*  
*Saladié Balleste, Palmira (IPHES) palmira.saba@gmail.com*  
*Marín Hernando, Juan (EPPEX) juan.marin.hernando@gmail.com*  
*Canals Salomó, Antoni (IPHES) acanals@iphes.cat*

Bird-bones accumulations may be due to multiple origins. Understanding the taphonomic signal of different bone accumulators (agent and processes) is important to establish whether or not anthropogenic origin of birds in the fossil assemblages. The Iberian lynx (*Lynx pardinus*) must be a significant taphonomic agent in Iberian ecosystems. Their diet is based mostly on rabbits complemented mainly with birds of the family of Phasianidae, Anatidae and Corvidae.

Here we present the results of a taphonomic research conducted to assess the modifications produced by this predator on non ingested red partridge (*Alectoris rufa*) remains after the meal. Through the anatomical representation, breakage pattern and bone surface modifications we were able to establish the main characteristics of the taphocoenosis of Iberian lynx regarding to one of its complementary preys.

The entire skeletons show very low survival, mainly leaving offal entrails and feathers, which can hardly be preserved in the archaeological fossil record. Anatomically there is greater survival of thorax (especially synsacrum and adjoining ribs), and distal areas of the upper and lower limbs. The breakage is low and presents a lot of whole elements although none of the major long bones has preserved complete. The bones in the meaty portions (wings/humerus, drumstick/femur and tibia, and breast/sternum), appear very fragmented. The tooth marks are rare and occur mainly in the form of notches in

fracture edges. It has been documented midshaft bone cylinders.

This pattern can be used for archaeological purposes.

## 1. ARCHAEOLOGICAL FIELD SURVEY GOES INTERDISCIPLINARY!

*van Leusen, Martijn (Groningen Institute of Archaeology)  
p.m.van.leusen@rug.nl*  
*de Neef, Wieke (Groningen Institute of Archaeology) w.de.neef@rug.nl*

The organizers of this session propose that archaeological field survey has come of age as a research method and that it is now time to bring the seeming multiplicity of approaches and terminology into a single, internally consistent and comparable, framework. We support this proposal and will present recent experiments conducted in central and southern Italy that probe the meaning of commonly used surveying concepts, such as that of the 'transect sample' and the 'visibility correction factor'. We will argue that archaeological survey in the 21st century must, at a minimum, become geoarchaeological survey - that is, all surface surveys must be accompanied by studies of the geological and anthropogenic processes that 'produce' the surface archaeological record.

The end of the 20th and the beginning of the 21st centuries are characterized by the development of New Information Technologies applied to survey data. A bad use of these NIT has led to a neo-positivism in which the power of computers and apparent splendor of their results have fulfilled with self-confidence to some young researchers. In some cases, a Doctoral Thesis has been fully based in data provided by regional archaeological databases without field contrast and verification, relying on the assumed "objectivity" of the data contained in these databases.

Against this tendency we must continue to defend the need to push forward the archaeological survey and analysis strategies. For more than 30 years, our research group applies geoarchaeological methods in the fieldwork, with an increasing concern of the importance of the great alterations suffered by the physical environment and, consequently, the archaeological evidences.

In semiarid environments, as it is the Mediterranean, erosive and sedimentary processes cause large landscape transformations, even in the recent stages of the Holocene. Consequently, most archaeological sites are seriously affected by erosion and deposition of sediments. Therefore, it is necessary to develop a methodology focused in the detection and interpretation of these landscape alterations, which span in a range that goes from complete erosive destruction to disappearance under several meters of sediments.

In this work we present several cases of geoarchaeological analysis from the Ebro Valley and Iberian Ranges (NE Spain). The experience of these studies is condensed in a methodological proposal for the reconstruction of the archaeological evidence and paleo-environmental processes. In this way, it is possible to give a better reliability to the data before it is included in databases or analyzed with NIT.

*Jordá Pardo, Jesús F. (UNED) jjorda@geo.uned.es*

As we all know, archaeological surveys have progressed from a secondary discipline to a solid, consistent working method that is evolving in step with the goals of prehistoric research. Almost 60 years have passed since New Archaeology began to point out the importance of archaeological surveys for the study of prehistoric settlement patterns, and many meetings and communications have discussed this issue. Now, it is not only

individual sites that matter. In order to understand the lives of human groups, we know we also have to study their interactions with other sites and the environment in which they operated, i.e., their territory. In this context, we began a survey aimed at documenting all the prehistoric settlements in Sierra de Atapuerca and its environs that had been preserved.

A full-cover, high intensity archaeological survey was conducted in a 314 km<sup>2</sup> area (Navazo 2006). The study area was defined by a 10 km radius circle centred on one of the excavated caves in Sierra de Atapuerca, *Cueva Mayor*. A total of eight surveys were conducted over a 5 year period, structured on the basis of the natural areas in the zone defined with geoarchaeological methodology (Navazo et al. 2005).

In all, 181 archaeological sites were located. For the purposes of the in-depth study, we distinguished the 31 Middle Paleolithic sites (Navazo et al. 2011; Navazo and Carbonell, i.p). These sites were studied from different perspectives, focusing on raw materials (Navazo et al., 2008), lithic industry, stratigraphy, geoarchaeology, etc. The results are presented in this communication in order to discuss two issues that remain outstanding after such a large-scale survey: 1. There seem to be as many surveys as research projects, and indeed as many methodologies as there are surveyed natural areas. From the experience of our work, we wish to defend/support the unification of methodologies.

2. Lack of a global vocabulary. Terms such as records, landscape, site, location, etc., mean different things to different authors and studies.

Additionally, in order to discuss the feasibility of one method or another, we will design different survey methods for our study area to assess the suitability of each one with a view to ascertaining the settlement patterns of prehistoric groups.

The issues that we share in this communication haunt us from our own experience. We will explain our research goals, methodology and results as an introduction to the discussion of the two proposed issues.

*Martínez-Moreno, Jorge (CEPAP-UAB) jorge.martinez@uab.cat*

We present the survey project "Settlement of transversal valleys between Serra Llarga and Serra de Montclús (Noguera)". This project is carried out by the Centre for the Studies of Prehistoric Archaeological Heritage (CEPAP-UAB) since 2007. Its main objective is to dig deeper in the knowledge of the prehistoric settlement of a geographical sector located in the region of La Noguera (Eastern Pre-pyrenees, Iberia) from a multidisciplinary point of view: the discovery of new archaeological findings and the location of raw material sources.

The archaeological potential of this geographic sector has been historically ignored, although several examples revealed an exceptional richness in this aspect. After eight survey seasons (2007-2014), new findings enrich the prehistoric conception of this region. The use of current data recovery field techniques (GPS, SIG) has led to a systematic and consistent work.

The contribution of new data is considerable: new archaeological sites, surface materials and prehistoric engravings have been documented. These findings increase the prehistoric interest of this region from older (Middle Palaeolithic) to modern chronologies (recent Prehistory). On the other hand, the study of raw materials sources has been carried out in two directions: location of primary geological outcrops and the study of "secondary deposits". To date, multiple new outcrops and rock types that were potentially exploitable have been documented.

Current data suggests a repeated occupation of shelters and caves through side valleys of the two major rivers (Noguera Ribagorçana and Noguera Pallaresa – Segre) and the use of these valleys as secondary circulation routes.

*Teira, Luis C. (Universidad de Cantabria) luis.teira@unican.es*

Since the very beginning of the twentieth century, several generations of archaeologists have investigated about one of the most characteristic manifestations of the Mesolithic of Atlantic Europe, the *Asturian*. Yet the available information for this archaeological entity is clearly biased, as the research has focused on shell midden deposits in the mouth of caves and rock shelters, in most cases providing scarce, if any, evidence that suggest that they may be considered living places. Thus, one of the most relevant issues that are currently opened to discussion is the location of the main settlement areas corresponding to the *Asturian*. The hypothesis has been posed that those hunter-gatherers groups might have been mainly established in open-air camps close to the caves where the shell middens have been preserved. However, so far, no systematic attempt has been made to test it. This paper exposes some preliminary results of a programme of research aiming to solve that problem.

In 2013 a systematic geophysical survey of the surrounding of a group of selected *Asturian* sites was started, looking for Mesolithic remains in the open air. They were chosen attending to both Geomorphological and Archaeological criteria, attempting to define the places with the highest probabilities of preserving Mesolithic sites. One of the areas that were chosen was close to the cave site of El Alloru, right in the core area

of the *Asturian*, in Llanes (northern Spain). A surface of 1670 m<sup>2</sup> was surveyed using magnetic gradiometry methods. That permitted the location of some anomalies that were judged to be potentially related to prehistoric human activity. Four test pits were opened to validate that hypothesis.

Both geological and archaeological features were found in the test pits, confirming the hypothetical interpretations of the survey. The Mesolithic open air site includes a high density of Holocene marine molluscs and *Asturian* picks. Unlike the typical *Asturian* ensembles, evidence of knapping and other kinds of artefacts, such as bone and antler tools, and pendants were recovered. Besides two small pits possibly corresponding to postholes were identified. It appears to be the first *Asturian* dwelling structure discovered.

The hypothesis that the shell middens could be linked to nearby areas where the greater part of everyday activities were performed has found confirmation through the combined use of geophysical surveying and archaeological excavations.

## 6. ARCHAEOLOGICAL SURVEY AFTER FOREST FIRES: THE EXAMPLE OF THE NATIONAL PARK OF GARAJONAY 2012 (LA GOMERA, CANARY ISLANDS, SPAIN).

*Hernández-Marrero, Juan Carlos (Museo Arqueológico de La Gomera (Cabildo Insular) museoarqueologico@lagomera.es*

*Rodríguez-Mendoza, Mario (Museo Arqueológico de La Gomera (Cabildo Insular) mariocgb@hotmail.com*

La Gomera is the second smallest island within the Canary Archipelago. It has a surface area of 369.76 kms<sup>2</sup> with the highest point at El Alto del Garajonay (1,487 metres). The island has a very steep topography and its central area is relatively flat and is occupied by a thick forest that was declared, as of 1981, the National Park of Garajonay (3,986 hectares).

In 2012, there was a violent forest fire in the South-center of the island that destroyed 3,617 hectares (almost 10% of the total island). From then till the present year, there have been an archaeological survey project within the limits of the National Park (741 hectares), besides visits to

the known archaeological sites to see what impact the first fire heat has had upon the same.

The conditions observed in the latest campaign of surveys (2002-2004) had offered low visibility, low perception and great difficulty in access and linkage. Now the fire modified radically those conditions. This was the considerable advantage of this year over previous campaigns: the burning atmosphere was depressing, but it was also a unique opportunity.

The survey was superficial and intensive, corresponding to a sample over eleven selected areas or polygons, according to their geomorphological and cultural criteria. Coverage in said areas was almost 100%.

We use methods not previously used in La Gomera: systematic probes with parallel bands that overlap in altitude whose breadth depended on the topographic profiles and vegetation; so we covered whole selected polygons. The survey system that is often used in the Canary Island and, above all, on the more mountainous islands such as La Gomera, is performed by movements that cover lineal vectors, rather than polygons, centring on specific geomorphological units.

We did not detect the significant impact of the fire on the archaeological materials, although there was an impact. The surrounding vegetation, the geomorphological host units and the nature of the material explain, to a certain extent, this outcome. In fact, the archaeological material founded was mainly lithic artefacts and, therefore, low conductivity, low quality as fuel and very resistant to thermal alterations.

With respect to the archaeological sites earlier projects in the highlands of La Gomera (1974, 1994, 2002-2004) marks a few archaeological sites with a total of 25 archaeological sites. This draft has greatly increased the number of sites: about 100 new archaeological places.

What is most interesting is the new types and heterogeneity detected after the forest fire, allowing for a more extensive and complex interpretation of the use of the forest by the original inhabitants of La Gomera. Previous results said that most of the sites corresponded to religious sites used for ritual services. Now, quarry and stone tool workshops, shepherd shelters, possible areas of woodworking, new ritual places, etc., have been located inside the forest.

We believe it is necessary that subsequent legal protocols to any fire on the island, take the need to incorporate

this type of study on the cultural heritage of these areas that have been burned.

ORAL

## 7. IN SEARCH OF A LOST VILLAGE. PROSPECTING TECHNIQUES AT THE SITE MARIANO MIRÓ (LA PAMPA ARGENTINA, EARLY TWENTIETH CENTURY).

*Tapia, Alicia (Instituto de Arqueología, Universidad de Buenos Aires) aliciahtapia@yahoo.com.ar*

*Doval, Jimena (Conicet, Instituto de Arqueología, Universidad de Buenos Aires) jdoval84@hotmail.com*

*Montanari, Emanuel (Instituto de Arqueología, Universidad de Buenos Aires) emanuelmontanari@gmail.com*

*Pineau, Virginia (Instituto de Arqueología, Universidad de Buenos Aires) virpineau@gmail.com*

*Landa, Carlos (Conicet, Instituto de Arqueología, Universidad de Buenos Aires) carlosglanda@gmail.com*

*Caretti, Florencia (Instituto de Arqueología, Universidad de Buenos Aires) florenciacaretti@gmail.com*

In 2011, called by Culture Department of La Pampa province government we began the archaeological investigations at Mariano Miró site (Chapaleufú, La Pampa, Argentina). In this archaeological site there are material culture remains of a country village, which emerged in 1901 in front of a train station. This Railway goes to Buenos Aires city. This village was inhabited by about 500 people and had a number of typical shops of agricultural and livestock settlements (stores, bakery, hairdresser, etc.), as indicated by historical documents. Around 1911 the village had to be forcibly abandoned because the owner of the land did not renew the rental contract. Since then, the owners of the land used for agricultural labors. Because of that there are not standing structures of the ancient village. The archaeological study of the site Mariano Miro is included within a goal of broader research, which aims to know the population dynamics of the area in the late nineteenth and early twentieth century; when these lands were incorporated into the country after the military campaigns, which annihilated and subdued the indigenous people who occupied them. In this paper we present the results obtained from the various prospecting techniques used to delimited the area occupied by the old town.

While structures are not observed at the present, there is in the superficial a large amount of glass, ceramic and metal fragments from which a study area of 240 x140 meters was defined. All the surface of this area -that covering 39,200 m<sup>2</sup>- was surveyed from transect

using metal detector and a systematic collection of surface materials was performed. The diversity of data was processed using Geographic Information System (GIS) software with ARCGIS10 that allow us to correlate different analysis variables. Also the use of documentary sources (aerial photos, maps and plans of the layout of the town) facilitated the identification of some of the site formation processes, as ancient buried structures and sectors related to specific activities or social practices.

The systematic collection made in transects allowed us to register 11,407 artifacts from different raw materials. From this data we generated potential excavating areas. We excavated 19m<sup>2</sup> at the moment and were recovered 2460 artifacts.

The prospection design applied allowed us to guide the interventions in a vast area, and from the analysis of the distribution and density of the findings helped us to differentiate areas, that respond to deliberate social practices during the occupation of the people (eg landfills) from those that would result from anthropogenic and natural post-depositional processes.

## 8. RAW MATERIAL FILE - LITHIC SOURCING AND COLLECTION MANAGEMENT.

*Siegeris, Markus (Collaborate Research Center 1070, University of Tuebingen) markus.siegeris@uni-tuebingen.de*  
*Floss, Harald (WG Early Prehistory and Quaternary Ecology, University of Tuebingen) harald.floss@uni-tuebingen.de*

Both lithic sourcing and management of lithic raw material collections are a field of accurate but also time saving work. In the last decades a few different kinds of files had been created to source lithic raw material in the field. But the practical site of the files had not been good enough to cover all the needed aspects while describing a source and its materials.

Working on my thesis I created a new file for describing the sources and lithic raw materials both in the field and the collection. The file contains information about the geography and geology, about the source and its characteristics and information about the lithic raw materials themselves.

After publishing the file in the new lexica about lithic artifacts by Prof. Harald Floss in 2012, it also became an open access product in the internet. The file fits on a regular DIN-A4 page and is available as a PDF in several languages like German, English, French and Spanish. Other languages will follow.

ORAL

## 9. CARACTERIZACIÓN Y APROVISIONAMIENTO DE MATERIAS PRIMAS DE LOS GRUPOS NEANDERTALES DE LA CUEVA DE PRADO VARGAS.

*Vallejo Rodriguez, Santiago (UPV/EHU) svallejo\_rodriguez@hotmail.com*

*Navazo Ruiz, Marta (UBU) mnavazo@ubu.es*

Se ha llevado a cabo una prospección sistemática en el área entorno a la cueva de Prado Vargas (Cornejo, Burgos), la cual presenta evidencias de ocupación humana en el Paleolítico Medio (Navazo et al, 2005). El objetivo del estudio es localizar afloramientos de materias primas que puedan haber sido utilizadas para la fabricación de herramientas líticas por estos grupos neandertales.

Se prospectan 46,6 Km<sup>2</sup> entorno a la cueva recorriendo todos los pisos geológicos, en donde se recogen materiales y se registran todo tipo de evidencias antropicas. Posteriormente con los materiales líticos se utilizan diferentes técnicas analíticas (Espectroscopía de Infrarrojos con Transformada de Fourier [FT-IR], Difracción de Rayos X [DRX] y Espectrometría de Masas con Plasma Acoplado Inductivamente [ICP-MS], con el fin de caracterizar los materiales líticos localizados en diez muestras seleccionadas de sílex en posición primaria en caja caliza y diez muestras seleccionadas de sílex en posición secundaria en caja de arcilla. También se han realizado análisis sobre nueve muestras de lascas arqueológicas procedentes de las excavaciones de la cueva.

Se lleva a cabo el trabajo de campo durante 33 jornadas, invirtiendo un total de 214 horas, de las cuales 130 horas son de prospección efectiva, recorriendo 313 Km de transectos, localizándose 94 lugares donde se recogen sílex y otros materiales de interés arqueológico y etnográfico. Se caracterizan las muestras de sílex natural y se interpretan los resultados de los datos de FT-IR, DRX e ICP-MS, se observa una similitud entre muestras de origen natural y arqueológico, localizando las posibles áreas de captación de recursos líticos. Se presentan a continuación los resultados de la prospección en donde

se han documentado diferentes áreas de captación de materia prima, así como se localizan posibles yacimientos arqueológicos.

La prospección en superficie aporta información de interés para comprender las relaciones entre los grupos humanos y el medio ambiente en el que vivieron. Se caracteriza el material lítico que utilizaron, pero los análisis geoquímicos y mineralógicos efectuados no fueron concluyentes con la existencia de marcadores netos, aunque el tratamiento estadístico sí que aporta información muy interesante entre analogías de las muestras. Estas correlaciones entre muestras de sílex natural y arqueológico proyectan unas ubicaciones espaciales en el territorio muy interesantes para su estudio, por lo que el análisis geoquímico también puede ser utilizado como herramienta de prospección selectiva para localizar yacimientos arqueológicos en superficie.

## 1. THE LITHIC ASSEMBLAGES AT THE MIDDLE PALEOLITHIC ONSET: THE UNCHANGED SUBSTRATUM AND THE NEW NEEDS

Arzarello, Marta (*Università degli Studi di Ferrara*) [marta.arzarello@unife.it](mailto:marta.arzarello@unife.it)

Moncel, Marie-Hélène (*Muséum National d'Histoire Naturelle de Paris*) [moncel@mnhn.fr](mailto:moncel@mnhn.fr)

Peretto, Carlo (*Università degli Studi di Ferrara*) [carlo.peretto@unife.it](mailto:carlo.peretto@unife.it)

The Holstanian period covers a large period of time, from the MIS 11 to the MIS 9 (from 427 to 301 ka) if we refer to the chronological curves. Archaeological data and human activity all over Eurasia show an increase of the number of sites following the Anglian or Elsterian glaciation (MIS 12) which is considered as a main crisis. It is often considered otherwise difficult to distinguish the two interglacial periods because they are short and share common climatic and environmental features. This period of time is though crucial; it's characterized by a wide biodiversity, a large faunal dispersion associated to a regionalization of mammal communities and variability of hominin morphology.

Our aim is to focus on the main well-dated sites all over Europe to identify the common features and the main innovations in their environmental and climatic framework. Sites from Spain, Italy, France, Great-Britain, Belgium, Germany and Poland will be documented and compared. We will take in account the technological behaviors but also the related subsistence strategies and the environmental and faunal patterns. We will focus also on the sites that have dates consistent with Late Acheulean but have not bifacial tools.

Large behavioral variability is observed with both Late Acheulean and onset of Early Middle Palaeolithic assemblages with sometimes some remaining bifacial tools, fire use generalization and structured living places. Management of local resources leads to another type of land use with seasonal settlements and evidence of specialized hunting into a territorial network. A new core technologies appear (Levallois) or previous ones are more and more complex (discoid-type).

The unchanged component that remains rooted for environmental constraints or cultural reasons is often overlooked and continues in some sites till MIS 7.

Through an interdisciplinary approach, the comparison will allow us making an overview of the main changes that occurred in relation to the unchanged substrate.

The Holstanian period indicates that changes obey by a mosaic of new behaviors which occurred at different scales and speeds. It opens to the Neanderthal world from MIS 8.

ORAL

## 2. THE END OF THE LOWER PALEOLITHIC IN THE LEVANT: THE ACHEULO-YABRUDIAN LITHIC TECHNOLOGY AT MISLIYA CAVE, ISRAEL.

Zaidner, Yossi (*Zinman Institute of Archaeology, University of Haifa; Institute of Archaeology, The Hebrew University of Jerusalem, Israel*) [yzaidner@research.haifa.ac.il](mailto:yzaidner@research.haifa.ac.il)

Weinstein-Evron, Mina (*Zinman Institute of Archaeology, University of Haifa, Israel*) [evron@research.haifa.ac.il](mailto:evron@research.haifa.ac.il)

The end of the Lower Paleolithic in the Levant is marked by the emergence of a new technocomplex known as Acheulo-Yabrudian (400-250 Ky). Stratigraphically placed at the transition between the Acheulian and Mousterian technocomplexes, the Acheulo-Yabrudian is crucial for the understanding of biological, cultural and behavioral evolution from the Lower to the Middle Paleolithic in the Levant. While some suggest that emergence of the Acheulo-Yabrudian is accompanied by arrival of new populations, others see continuity within the Levantine Lower Paleolithic and suggest that major technological and behavioral change occurred only with the onset of the Middle Paleolithic.

Misliya Cave, Mount Carmel, is one of the rare Levantine sites in which both the Acheulo-Yabrudian and Early Mousterian are present, allowing direct comparison between the two industries. Here we present the analysis of an Acheulo-Yabrudian lithic assemblage from the site and discuss its place within Levantine technological and cultural frameworks. Three technological systems were identified in Misliya Acheulo-Yabrudian assemblage:

- 1) Bifacial shaping
- 2) Production of thin flakes from unidirectional cores and cores with one preferential flaking surface and prepared striking platform. The flakes were usually left unmodified.
- 3) Production of large and thick, often cortical, flakes from unprepared cores. The flakes were used for manu-

facturing large scrapers by Quina or semi-Quina retouch. The two former systems are well-known from the Lower Paleolithic assemblages in the Levant, indicating regional continuity from the Acheulian, while the production of Quina scrapers seems to be a major technological innovation of the Acheulo-Yabrudian.

The three Acheulo-Yabrudian technological systems described above were not identified in the Early Middle Paleolithic assemblages of Misliya Cave. Moreover, Levallois and laminar technologies, and production of retouched points that mark the emergence of the Middle Paleolithic in the Levant, are absent from the Acheulo-Yabrudian of Misliya Cave, further supporting the view that a marked technological break in the region occurred ca. 250 ky ago with the onset of the Middle Paleolithic.

ORAL

### 3. THE LOWER TO MIDDLE PALEOLITHIC TRANSITION AND THE DIVERSIFICATION OF LEVALLOIS TECHNOLOGY IN THE SOUTHERN LEVANT: EVIDENCE FROM TABUN CAVE, ISRAEL

*Shimelmitz, Ron (University of Haifa and David Yellin Academic College of Education) ronishim@gmail.com*

*Weinstein-Evron, Mina (University of Haifa) evron@research.haifa.ac.il*

*Ronen, Avraham (University of Haifa) aronen@research.haifa.ac.il*

*Jelinek, Arthur (University of Arizona) ajelinek@email.arizona.edu*

*Kuhn, Steven (University of Arizona) skuhn@email.arizona.edu*

The transition from the Lower to the Middle Paleolithic has received renewed attention recently following the realization that many traits once thought to be characteristic of the Middle Paleolithic in fact appeared already in Lower Paleolithic assemblages. In the Levant, the Acheulo-Yabrudian complex constitutes the latest part of the Lower Paleolithic, preceding the Levantine Mousterian. It is dated from 415 to 250 kyr at Tabun Cave. However, the nature of the transition between the Lower and Middle Paleolithic in the Levant remains highly controversial with a range of opinions. While some suggest lines of continuity others claim a complete separation between the two complexes. Considering the fundamental transformation in human behavior that occurred during the Acheulo-Yabrudian complex, which includes the use of habitual fire and the intensive use of predetermined blank technology among the emer-

gence of other traits, it is of significance whether these transformations continued in the Levant from the Lower Paleolithic to the Middle Paleolithic or whether they were completely swept away by a new wave of humans bringing with them similar as well as different sets of behaviours. This question can be best elucidated through a search of continuity in technological choices which can reflect socially-learned traditions of stone knapping. Our study is carried out on the long 16 m deep archaeological sequence of Tabun Cave, by combining results from Ronen's and Jelinek's excavations, which comprise ca. 100 superimposed layers, ranging from the Lower to the Middle Paleolithic. An overview of various reduction sequences, i.e., the Yabrudian scraper-blank production, the blade production of the Amudian, the exploitation of various types of cores on flakes, the variable exploitation of handaxes as cores and the Levallois technology at the site, indicates that although the Acheulo-Yabrudian and the Levantine Mousterian complexes exhibit marked differences in the macro level, there are also some significant features of similarity in the micro level, as reflected in particular technological choices within the reduction sequences that suggest some continuity in technological tradition. Exploring all ranges of reduction sequences can also provide new insights regarding the development of Levallois technology that burst at the Middle Paleolithic and demonstrate how particular technological choices that were already embedded in the knapping tradition of the Acheulo-Yabrudian are manifested in the particular method of Levallois that characterize the Mousterian of Tabun Cave.

---

ORAL

### 4. THE END OF LOWER PALAEOOLITHIC AND THE BEGINNING OF MIDDLE PALAEOOLITHIC IN EAST EUROPE AND THE CAUCASUS.

*Golovanova, Liubov (Laboratory of Prehistory) labprehistory@yandex.ru*

*Doronichev, Vladimir (Laboratory of Prehistory) labprehistory@yandex.ru*

In East Europe, and the Southern and Northern Caucasus, the border between the Lower and Middle Palaeolithic is currently marked during MIS 6, after which the archaeological record shows the appearance of Middle Palaeolithic industries in MIS 5e.

In the **Southern Caucasus**, the available chronological data from cave sites document a late age (between 350 and 200 ka) for the Acheulean, comparable to the

final stage of Late Acheulean or Acheulo-Yabrudian in the Levant. The most representative Late Acheulean assemblages of Acheulo-Kudarian variant are dated from MIS 10 through MIS 7. In the Lesser Caucasus, Acheulean assemblages are known from many locations in volcanic uplands of southern Georgia and Armenia. During the last decade, Dashtadem-3 and Nor Geghi-1 open-air sites – the first stratified Late Acheulean occupations – were excavated in Armenia. The lithic assemblages of Kudaro-Djruchula Mousterian represent the earliest Middle Palaeolithic industry in the Southern Caucasus. Until recently, the chronological estimates suggested that Kudaro-Djruchula Mousterian appeared in the Southern Caucasus no earlier than the Last Interglaciation (MIS 5e, 130-115 ka). The recent TL dating in Djrchula Cave has produced the earlier unexpected dates between 260-210 ka for Layer 2. Our most important point of disagreement with the TL dates is that hominids could not occupy the cave during that time. This is because the cave entrance, opening now at the elevation of only 40 m above the modern riverbed, did not exist that time in the Djrchula River canyon. The geomorphologic studies suggest that the lower parts (at elevations less than ~100 m above modern channels) of river valleys in this part of the Caucasus formed during the Upper Pleistocene.

In the **Northern Caucasus**, the age of Late Acheulean industries is now estimated no younger than the beginning of MIS 6, and a chronological hiatus separates local Late Acheulean and Middle Palaeolithic industries. The initial stage of the North-west Caucasian Middle Palaeolithic is present by the assemblages from lower levels 5-7 at Matuzka Cave, dated to MIS 5 – MIS 5. In the end of MIS 5, the Eastern Micoquian appeared in the Northern Caucasus.

In the **Eastern Europe**, the lithic industries of Pre-Mousterian complex survived until the end of Lower Palaeolithic, beyond the distribution range of the Acheulean complex in West Europe and West Asia, including the Southern Caucasus. A large-scale hominin colonization of Eastern Europe began with the spread of leaf point assemblages in the later Middle Pleistocene (MIS 7 – early MIS 6). Later, the earliest industries representing Eastern Micoquian appear in the region since MIS 5e.

Thus, the now available data provide no evidence for the transition from Lower to Middle Paleolithic in the Caucasus and Eastern Europe. The earliest Middle Paleolithic assemblages appeared here as completely formed technological traditions and likely originated from different centers, West Asia for the Middle Palaeolithic in the

Southern Caucasus, and Central and the south of Northern Europe for the Middle Palaeolithic in the Eastern Europe and Northern Caucasus.

ORAL

## 5. THE PRE-MOUSTERIAN INDUSTRIAL COMPLEX IN EUROPE AND THE CAUCASUS BETWEEN 400-300 KA

*Doronichev, Vladimir (Laboratory of Prehistory) labprehistory@yandex.ru*

Since the onset of intensive Acheulean expansion within Western Eurasia at about 0.8-0.75 Ma, the frontier for the maximum distribution of the Acheulean assemblages changed through the time as the Acheulean-making populations of *H. heidelbergensis* expanded northward in the West Europe and West Asia, and the distribution area of non-Acheulean assemblages reduced. The continuity of stone-working traditions suggests the Middle Pleistocene non-Acheulean hominids originated from the earliest pre-Acheulean hominin population to enter Western Eurasia, and thus the first present the hominin population separated in Europe by at least 1.0 Ma years from the Acheulean-making *H. heidelbergensis* first penetrated to Europe from Africa at about 0.8-0.7 Ma. The unquestionable archaeological records also indicate that the non-Acheulean hominids were the first *Homo* to settle in continental Europe north of Alps and between the Alps and Caucasus since ca. 0.7–0.6 Ma or earlier.

In the late stage of Early Palaeolithic, between 400-300 ka, when the Acheulean expansion reached its maximum spread in Europe, as far eastward as the Rhine River in Northern Europe and the Po River in Mediterranean Europe, and as far northward as the Greater Caucasus in the West Asia, exclusively industries of flake-tools and choppers (defined as Pre-Mousterian complex) were spread in the Central and Eastern Europe, and the Balkans, beyond the Acheulean distribution area.

The assemblages of Pre-Mousterian complex are variable due to their functional differentiation and other reasons, but generally comprise the next three components: (1) simple (mostly primary and orthogonal, and also rare unipolar and centripetal) cores with short reduction sequences, consisting of flaking of 1-3 flakes from one platform, followed by the core rotation or discard; (2) flake-tools, which are made mostly (but not exclusively) on small-sized flakes with beveled platforms and include varieties of simple side-scrapers, denticulates, notches,

thick end-scrapers, awls, and convergent pieces, as well as small numbers of tools with flat ventral retouch or bifacial retouched edges; and (3) large-sized tools are always present and include mostly unifacial choppers, and more rare chopping-tools and proto-bifaces (or pointed choppers) with partial bifacial processing. Nevertheless, despite the absence of complex technologies for blank and tool production, the hominids that produced lithic industries of Pre-Mousterian complex acquired a high behavioural plasticity to settle in most uncomfortable (within Western Eurasia) forested and forest-steppe environments with cold winters in Central and Eastern Europe. The hominids developed tool inventories well suited for bone- and woodworking, made real wooden throwing spears found in Schöningen 13 and composite tools with wooden hafts that are found in Schöningen 12.

In contrast to the Acheulean complex in West Europe and West Asia, assemblages of Pre-Mousterian complex do not show a transition (temporally being placed now during MIS 8 – MIS 7, between ca. 300-200 ka in both the regions) toward the Middle Palaeolithic technology and typology. In contrast to the Acheulean to Middle Palaeolithic transition, which is associated with final neanderthalization of *H. heidelbergensis* and the origin of *H. neanderthalensis*, the assemblages of Pre-Mousterian complex disappear with the spread of early Middle Palaeolithic Neanderthals.

ORAL

## 6. MIS 11-9 LOCALITY OF MEDZHIBOZH, UKRAINE : ARCHEOLOGICAL AND PALEZOOLOGICAL EVIDENCE

*moigne, anne-marie (MNHN.Paris) moigne@mnhn.fr*  
*Stepanchuck, Vadim (Institute of NIAS Kiev) vadimstepanchuck@yahoo.com*  
*Rizhov, Sergei (Kien taras Schevchenko Nat Univ) seryzh@gmail.com*

Lower Paleolithic localities near Medzhibozh town, Khmel'nitsky region in the west of Ukraine, represent a group of multilayered sites on southern Bug River. Two localities Medzhybozh 1 which age is defined as the beginning of Zavadovka episode MIS 11 and Medzhybozh A Lubny time MIS 13-15 contain Early and Middle Pleistocene deposits, remains of fauna, stone artifacts and presumable trace of hearths

Multidisciplinary studies stratigraphy, micromorphology, paleontology (large mammals micro-mammals, shells)

techno-typology and zooarchaeology are combined/ Medzhybozh studies are directly relevant of study of reconstruction of the ancient migration paths at the territory of the North western Eurasia in the East European segment

Faunal large Mammals list (NISP= 450) reveal few carnivores, *Ursus deningeri* and *Ursus thibetanus*, a typical association for interglacial middle Pleistocene period. Dominance of cervids as *Cervus elaphus*, *Dama clactoniana* and *Capreolus suessenbornensis*, *Sus scrofa*, *Stephanorhinus kirchbergensis* and *Castor fiber* confirm the temperate climate as well as biochronological attribution. Faunal list correspond to the humid and forest environment already described from the microfauna and shell analysis (Rekovetz, 2009). Cervid are mostly represented by adult animals. Bones are characterised by systematic intentional breakage with percussion notches and cutmarks. Rhino ribs and vertebra present also long and deep cutmarks. Carnivore activity is rare.

From archaeological point of view, six distinct assemblages of Medzhibozh 1 and Medzhibozh A horizons should most adequately be defined as belonging to the industries of technological Mode 1 (Oldowan). Materials cultural horizons despite of relatively late age (about 400 Ka) are characterized by the predominance of choppers, choppings, isolated retouched flakes, few flake and knapped, broken and fragmented pieces of various raw materials showing a minimum of secondary working. Available inventories contain no good instances of core knapping, as well as almost no morphologically stable shaping of flake tools and no signs of bifacial technology. The upper culture-bearing horizons provide likely remains of hearths. By its parameters the first culture-bearing horizon of Medzhibozh A resembles a living floor. This human occupation could be one the most ancient in Ukraine. Human activities, as subsistence can be compared to western sites as Orgnac 3 or Cagny l'Épinette but technological sequence is different. During Mis 11 and 9, a large variability can be observed in Europe.

ORAL

## 7. THE ONSET OF THE MIDDLE PALAEOOLITHIC IN THE CENTRAL BALKANS

*Mihailovic, Dusan (Faculty of Philosophy, University of Belgrade) dmihailo@gmail.com*  
*Marin-Arroyo, Ana Belen (Instituto Internacional de Investigaciones Prehistóricas de Cantabria (IIIIPC), Universidad de Cantabria) anabelen.marin@unican.es*

Recent investigations in Serbia shed some more light on changes in the settlement pattern, technology and economy at the time of transition from the Lower to the Middle Palaeolithic in this part of Europe.

In the course of site surveying of the right bank of the Zapadna (Western) Morava river, in central Serbia, a whole series of sites, which could be dated to the end of Lower and the beginning of Middle Paleolithic have been recorded on the highest river terrace. There, to the more or less extent, choppers, Levallois and Kombewa cores and blanks, denticulated and notched tools on asymmetrical flakes, Quinson points and Clactonian elements were discovered. All that indicates the possibility that river valleys in the central Balkans had been intensively settled during the end of Middle and the beginning of Upper Pleistocene.

Settlements on hilly and mountainous areas had been recorded already half a million years ago. This is confirmed by the discovery of mandible of *Homo erectus* s.l. in Mala Balanica near Niš for which it has been established a minimum age between 397 and 525 ka. In the same cave, as well as in the nearby Velika Balanica cave, stratigraphic levels with Charentian-like assemblages, dated to the Middle Pleistocene according to the microfauna found, have been confirmed. On the meantime, macrofaunal results show evidence of regular use of fire and many elements of Middle Palaeolithic behavior like hunting middle-sized game (red deer and ibex), orientation to prime age individuals and suboptimal transport strategy of hunted animals has been confirmed at this site.

ORAL

## 8. FIRST SETTLEMENTS IN CENTRAL EUROPE: BETWEEN ORIGINALITY AND BANALITY

*Rocca, Roxane (UMR 7041 ArScAn AnTET) roxane.rocca@gmail.com*

The situation of Central Europe during Lower Palaeolithic seems to be original. Evidence of human occupations before 0.5 million years ago is sparse and handaxes are absent during the entire duration of the Lower Palaeolithic. Despite being located on the Out of Africa route towards Europe, this region has not yielded the archaeological evidence that could have been expected.

At the end of the Lower Palaeolithic, between 400 and 300 ka in Central Europe the lithic industry are charac-

terized by a small tool production. We will analyse this typical production thanks to two lithic assemblages (Vértesszölös in Hungary and Bilzingsleben in Germany). If those assemblages are original compared to the Western Acheulean, some elements can be likened to some other industries in Southern Europe.

The results of this study of the first lithic industries from Central Europe, allow a reconsideration of settlement dynamic in Europe at the end of Lower Palaeolithic. The classical division between Eastern and western Europe, can be discussed, according to the criteria taken into account in the definition of the different Lower Palaeolithic cultural entities and technological systems.

ORAL

## 9. MENEZ-DREGAN I, LAYER 4: A TRANSITIONAL LAYER BETWEEN THE LOWER AND MIDDLE PALAEOLITHIC IN BRITTANY

*Ravon, Anne-Lyse (Université Rennes 1) annelyse.ravon@voila.fr*

*Monnier, Jean-Laurent (CNRS) jean-laurent.monnier@univ-rennes1.fr*

Menez-Dregan I is a lower palaeolithic site situated at Plouhinec, Finistère, in Brittany. It is an ancient marine cave whose roof has gradually collapsed. Layer 4 from the site of Menez-Dregan I is the last occupation of this deposit, at the boundary between the lower and middle palaeolithic. Geological correlations tend to place layer 4 in OIS 9 or 11, although the only TL dating available for this level gave an age of 270 ky.

This study focuses on the lithic industry from the 1991-2004 excavations and was undertaken in order to capture the various types of technical behaviour that could communicate the transition between lower and middle palaeolithic. We present the lithic industry of this layer, which simultaneously combines lower palaeolithic characteristics, such as large quantities of pebble tools (due to the environment of the site), and the emergence of characteristics that are common to the middle palaeolithic, such as standardisation of flake production, or adapting knapping methods to the dimensions of the raw materials (discoid knapping for quartzite, bipolar flaking on an anvil for small flint pebbles).

The lithic industry from layer 4 and its three levels (4a, 4b and 4c) has been analyzed. The lithic industry includes flakes (33.1%), flake fragments (28.4%), debris

(21%), retouched flake tools (7%), cores (4.3%), pebble tools (3.2%), pebble fragments (1.7%); 1.3% are miscellaneous pieces. The raw materials used in layer 4 are flint (71%), quartz (13%), sandstone (10%), microgranite (5%), quartzite (0.8%) and glossy sandstone (0.5%), and were collected from the fossil beaches in or nearby the deposit. Retouched flake tools are mostly denticulates (68.2 %), scrapers (19.7 %) and notches (12.1 %). Layer 4 of Menez-Dregan I has been attributed to the "colombianian" by J.-L. Monnier on the basis of the composition of its lithic industry: a predominance of cobble tools among the heavy-duty tools, retouched light-duty tools on flake-supports comprising mostly notches and denticulates, and knapping method akin to the "clactonian" (wide butts rarely faceted, prominent bulbs, wide open flaking angles). The Levallois method is absent, bifaces are absent or extremely rare, and there are few scrapers. The colombianian proves to be a facies of the lower palaeolithic, contemporary with classic acheulean but typologically distinct.

However, standardisation of flake production leads us to foresee a change in the lithic industry of layer 4, and allows us to highlight a transitional period from the lower palaeolithic to the middle palaeolithic in the latest occupation of this deposit. This study is a contribution to the documentation of the diversity and variability of lower and middle palaeolithic lithic industries, demonstrating that the large amount of cobble tools in layer 4 are an unchanged component due to environmental constraints.

## ORAL

### 10. A NEW KEY-SITE FOR THE END OF LOWER PALAEO-LITHIC AND THE ONSET OF MIDDLE PALAEO-LITHIC AT ETRICOURT-MANANCOURT (SOMME, FRANCE)

Hérisson, David (UMR7194, INRAP) davidherisson@yahoo.fr  
 Goval, Emilie (INRAP, UMR7194) emilie.goval@inrap.fr  
 Loch, Jean-Luc (INRAP, UMR8591) jean-luc.locht@inrap.fr  
 Coutard, Sylvie (INRAP, UMR8591) sylvie.coutard@inrap.fr  
 Antoine, Pierre (UMR8591) pierre.antoine@cnsr-bellevue.fr  
 Chantreau, Yoann (INRAP, UMR6566) yoann.chantreau@inrap.fr  
 Debenham, Nick (Quaternary TL Survey) n.debenham@qtl.globalnet.co.uk

Rare are new testimonies for the MIS 11 to 9 in Eurasia. The discovery and the excavation of a new site in 2012 at Etricourt-Manancourt (Somme, France) in a very large area was an exceptional event.

In 2010, at the place of the future retention basin, a palaeolithic trial excavation was carried out by Emilie Goval on 170 000 square meters. It produced many flint artefacts, proving the existence of at least two important Middle Palaeolithic sites. In 2012, an excavation on the first favourable sector was conducted by David Hérisson over 6 months on 4500 square meters. This excavation has been led by a multidisciplinary scientific team, including prehistorians, geomorphologists. This allows us to apply a reliable chronostratigraphical approach based on the sequential analysis of glacial-interglacial deposit successions.

Five palaeolithic occupations have been excavated *in situ*, dating from 330 to 80 ky. The youngest occupation dates from 70-80 ky and corresponds to a recent phase of the Middle Palaeolithic. The next two layers belong to the Early Middle Palaeolithic during the Saalian, between 190 and 240 ky. Finally, the two oldest layers have dates between 330 and 280 ky and belong to the Lower Palaeolithic. In addition to this archaeological wealth, the sedimentary sequence is very dilated (11 meters high) and presents for the first time in Northern France a continuous record of the three last interglacial-glacial cycles. This talk will present archaeological and chronostratigraphical results of the excavation of Etricourt-Manancourt and its input with high resolution data to discuss behavioural changes occurring at the end of the Lower Palaeolithic and the onset of the Middle Palaeolithic.

## ORAL

### 11. IS IT POSSIBLE TO RECOGNIZE STRUCTURED LIVING-PLACES AND ACTIVITIES AT CAGNY-L'EPINETTE, SOMME BASIN ?

Tuffreau, Alain (université de Lille) alain.tuffreau@univ-lille1.fr  
 Lamotte, Agnes (université de Lille) agnes.lamotte@univ-lille1.fr  
 Auguste, Patrick (CNRS) patrick.auguste@univ-lille1.fr  
 Moigne, Anne-Marie (Muséum d'Histoire Naturelle) moigne@tautavel.univ-perp.fr  
 Peudon, Floriane floriane.peudon@gmail.com

Fine Fluvial deposits (end of MIS 10 and MIS 9) from Cagny-l'Épinette site permits the discovery of numerous bones of big mammals (*bos primigenius*, *cervus elaphus*, *Equus caballus mosbachensis*) which show us many signals of anthropic activities and acheulean artefacts, all both records in different stratigraphic units. Refittings have been made between lithic, bones and teeth in

different of those units. Pieces have been damaged by taphonomic aspects underlined by the orientation of artefacts. Nevertheless, a great part of lithic and bones discoveries are well preserved (absence of patina and rolled edges). A spatial analysis associated with stratigraphy try to treat taphonomic aspects correlated to anthropic activities.

ORAL

## 12. THE ACHEULIAN OF THE SOMME BASIN (FRANCE) : VARIABILITY AND CONVERGENCE IN PRODUCTION SYSTEMS

*Lamotte, Agnes (université Lille 1) agnes.lamotte@univ-lille1.fr*

*Tuffreau, Alain (Université Lille 1) alain.tuffreau@univ-lille1.fr*

Around Amiens, several acheulean sites dated between stages MIS 12 to 9, are located in the Somme Valley. We are dealing with the sites of Cagny-la-Garenne I, Cagny-la-Garenne II, Cagny-la-Ferme de l'Épinette, Cagny-l'Épinette, Revelles and Gentelles. The aim of the communication is to present in each site, and during time and space, the raw material procurement, the core status, the biface and tool-flake status, but also many aspects of shaping and knapping like the hammer presence or specialized aspects of lithic classes. We'll present a synthesis of datas which will underlines changing in lithic main categories of artefacts, variability or convergences in the production systems. Some focus will be made in/or between main artefacts with the care to quantify those phenomenon.

ORAL

## 13. COMPORTEMENTS TECHNIQUES DES ACHEULÉENS DE LA GROTTÉ D'ALDÈNE (CESSERAS, HÉRAULT, FRANCE).

*Rossoni-Notter, Elena (Musée d'Anthropologie préhistorique de Monaco) elenarosso@hotmail.fr*

*Notter, Olivier (UMR 7194, Muséum National d'Histoire Naturelle) notterolivier@hotmail.com*

*Simon, Patrick (Musée d'Anthropologie préhistorique de Monaco) fburle@gouv.mc*

*Simone, Suzanne (Musée d'Anthropologie préhistorique de Monaco) suzanne\_simone@libello.com*

La grotte d'Aldène (Cesseras, Hérault, France), aussi appelée grotte de la Coquille ou de Fauzan se compose

d'un vaste réseau karstique s'étendant sur plusieurs niveaux étagés. Ce site est remarquable par la conservation de ses gravures et tracés digitaux pariétaux attribués au Paléolithique supérieur mais aussi par ses empreintes de pas d'ours, d'hyènes et d'Hommes (Mésolithique). Cependant, les plus anciens témoignages d'occupation anthropique se situent au niveau du porche effondré et de l'entrée de la grotte.

Cette zone fut fouillée par le Musée d'Anthropologie préhistorique de Monaco, entre 1971 et 1991, puis de 1996 à 1998. Le remplissage, tronqué par l'exploitation industrielle des phosphates, a néanmoins conservé plusieurs témoins stratigraphiques (T1 à T9) attestant d'une longue séquence d'occupations acheuléennes (cf. Taya-cien) et pré-moustériennes, depuis la fin du stade isotopique 13 jusqu'au stade 5.5.

Les études interdisciplinaires conduites (paléobotanique, paléontologie, micropaléontologie, paléoclimatologie, sédimentologie, datations radiométriques par U/Th et ESR) ont permis de mettre en place un cadre paléoenvironnemental et chronostratigraphique pour chaque unité archéostratigraphique. Certaines de ces unités, appartenant à différents témoins sédimentaires, ont pu en outre être corrélées.

L'étude de l'ensemble des industries lithiques caractérisée, par différentes approches (pétroarchéologique, structurelle et technologique), la diversité des comportements techniques des groupes ayant séjourné aux abords de la Cesse et propose une interprétation réactualisée des technocomplexes en présence. Par ailleurs, le vaste développement stratigraphique d'Aldène donne l'occasion de décrire et positionner chronostratigraphiquement les principales innovations techniques de ces périodes telles que l'apparition du concept Levallois, du feu, ainsi que des structurations de l'espace (foyer, dallage).

Ces résultats, confrontés à ceux de sites pénécotemporains de l'arc méditerranéen franco-ligure, contribuent à la connaissance des comportements techniques, à la charnière du Paléolithique inférieur et moyen (Modes 2-3).

ORAL

## 14. BONE RETOUCHERS FROM MIDDLE PLEISTOCENE SITES. A FOCUS ON ORGNAC 3, CAGNY-L'ÉPINETTE, CUEVA DEL ANGEL AND LAZARET CAVE

*Moigne, Anne-Marie (MNHN) anne-marie.moigne@cerp-tautavel.com*

*Lamotte, Agnès (Université de Lille) lamotte@univ-lille1.fr*

*Barroso, Cecilio (Cueva del Angel Project) barroso.cecilio@gmail.com*

Boen retouchers are common for the Middle Palaeolithic (from MIS 7 to 3) and are now considered as a part of the tool kit of Neanderthals. They exist in Middle Pleistocene sites even they are few and attest to the scarcity of use of bones for shaping tools. Some sites allow us describing the onset of bone use. Our aim is to present details about the bone retouchers in assemblages yielding bifacial tools and often described as Late Acheulean.

The sites studied are Orgnac 3 and Cagny-l'Épinette (MIS 9 in France), Cueva del Angel (Spain, MIS 11-7) and the Lazaret cave (MIS 6, France). We will examine the number, supports, types of species, size and types of marks of the retouchers; The results will be compared to retouchers already published (Cueva del Bolomor and Gran Dolina TD10 in Spain, Qesem in Israel, La Micoque and Payre in France).

Our corpus yielded between 1 and 6 retouchers by level in one or several layers for each site. They are made on fragments of bones of the main species hunted on the site. Marks indicate specific processes for selecting bones and allow us suggesting hypotheses for their use: for retouching bifacial tools and flake-tools and for direct percussion.

The onset of the bone use is one of the features attesting behavioral changes from MIS 9 in Europe. Data will be discussed in relation to the characteristics of the lithic assemblages and the subsistence strategies.

### **15. FUNCTIONAL CHARACTERISTICS OF HANDAXES FROM TERRA AMATA (SOUTHERN FRANCE, MIS11)**

*Viallet, Cyril (UMR 7194 - UPVD - MNHN) cyril.viallet@cerp-tautavel.com*

We present preliminary results of handaxes structural and functional analysis. Artifacts come from Terra Amata in southern France and are assigned to the MIS 11. Terra Amata deposit reveals one of the oldest traces of fire-place in Eurasia.

On a structural point of view, all handaxes (n=16) are 'cortical basis', little shaped and only four are retouched. Structural analyses show that handaxes are designed as "handaxes-tools". Nearly half (n=7) are shaped to obtain a distal bevel or a thick tip (n=3). The others are structured for travel with edge (n=4) or tip-edge (n=2).

One handaxe, with an edge as active part, shows use-wear in relation to a tool motion longitudinal translation. For handaxes with distal bevel or thick tip, functional analysis of active part shows chipping and crushing marks, associated with a percussive tool-motion. On the opposite part, the cortical basis, pits and scratches are typical of percussion use. The contemporaneity of the two types of use-wear is unprovable. However this association between the use of percussion and handaxes with distal bevel or thick tip is constant and reflects a specific use for these tools.

In the case of Terra Amata, handaxe is not a unique or multifunctional tool, it is apprehended like a matrix, from which a minimum of three types of tools can be produced. These results should be compared with the functional characteristics of other tools – especially cleavers and pecks – to understand the role of handaxes at Terra Amata.

### **16. NOTABLE TECHNICAL CHANGES IN WESTERN EUROPE BETWEEN MIS 11 AND MIS 9 AS TOLD BY THE BIFACIAL INDUSTRIES**

*Nicoud, Elisa (Ecole française de Rome) elisa.nicoud@gmail.com*

Bifacial industries in Western Europe between MIS 11 and MIS 9 indicate technical changes that may be interpreted as technical invention and innovation. That informs us on previously unseen diffusion of population within Europe at this time.

Conventional technological studies do not offer a comprehensive enough approach for analyzing these ancient industries due to the absence of well-developed "chaînes opératoires". We performed a technical study

of 36 lithic assemblages from France, England, Italy and Spain.

During what we usually call "Acheulean" in Western Europe, the biface as a typological entity actually consists of three different technical structures. We identify the "biface used as a blank for tools", the "biface as a tool" and "pebbles/blocks with bifacial removals". Other tools are made on flakes – by-products of bifacial shaping or from core reduction sequences – but also on small pebbles and various natural fragments.

The bifacial structure changes together with the rest of the production. This major change of the bifacial structure as well as the rest of the production seems to occur around MIS 10. The rhythms and occurrences of this change could reveal a new diffusion of populations within Western Europe, going South, during Middle Pleistocene. In any case, the biface is a secondary phenomenon within Lower Palaeolithic in Europe.

ORAL

### 17. NEW ESR DATINGS OF ACHEULIAN LEVELS AT ATAPUERCA DOLINA AND GALERIA SITES AND THEIR POSITION IN THE EUROPEAN PREHISTORIC CONTEXT

Falgueres, Christophe (CNRS) [falguere@mnhn.fr](mailto:falguere@mnhn.fr)  
Moreno, Davinia (MNHN) [moreno@mnhn.fr](mailto:moreno@mnhn.fr)  
Bahain, Jean-Jacques (MNHN) [bahain@mnhn.fr](mailto:bahain@mnhn.fr)  
Voinchet, Pierre (MNHN) [pvoinch@mnhn.fr](mailto:pvoinch@mnhn.fr)

The Sierra of Atapuerca, Northern Spain, has yielded many prehistoric and palaeontologic data documenting the human history in Eurasia during the last million years. The stratigraphical sequences of three major sites, Gran Dolina, Galería and Sima del Elefante, cover almost the entire period of the Pleistocene from the oldest Hominin bearing levels of Western Europe dated to 1.1 to 1.3 Ma at Elefante (Carbonell et al., 2008) to c.a. 0.2 Ma on the top of the Galería archaeological sequence (Falguères et al., 2013). The upper levels of Dolina and the entire sequence of Galería have provided a rich Acheulian assemblage documenting the earliest stage of the second human settlement of south-western Europe.

Recent results obtained by combined ESR/U-series dating on 20 herbivorous teeth from different levels at the Galería site allow a chronological comparison with upper levels of Dolina site. For these levels, several data were obtained using independent methods (TL, ESR/U-series,

TIMS) yielding a more accurate idea on the chronology for the first Acheulian levels in these major sites of Middle Pleistocene.

The obtained ages range between 300 and 500 ka and are contemporaneous with the lower part of Arago (France) and Visogliano (Italy) stratigraphical sequences. They succeed from one hand to La Noira site (France) in which Acheulian tools have been identified at more than 650 ka (Moncel et al., 2013) and in the other hand to Mauer (Germany), Pakefield (England) and Isernia la Pineta (Italy) sites recently dated to 600 ka or more and which do not contain Acheulian artefacts.

The Atapuerca sites offer a long series of hominin occupations since the Lower Pleistocene. In this sense, it becomes a key site for understanding the continuity and discontinuity of the technological and settlement dynamics in Western Europe.

The thick sedimentary record from Gran Dolina site comprises 11 stratigraphic units that cover the last million years. The level TD10 is located in the upper part of the sequence and divided into four lithostratigraphic units (T10.4 to TD10.1, from bottom to top) dated between less than 480 ky and 240 ky. In this work we present the study of the whole lithic assemblage belonging to TD10.1, the uppermost unit.

The archeostratigraphic studies have identified the existence of several occupations within its approximately 1.5 meters thickness. Their artifact densities and occupational models differ; some of them related to base camps and others to sporadic and opportunistic occupations. However, no remarkable technical differences are observed among them, showing a great technological homogeneity. Nevertheless, they show more evolved features compared to other Mode 2 assemblages from Atapuerca, and even to the lower section of the TD10 level, currently under excavation (namely TD10.3). These changes are reflected in a selective raw material management strategies; an increase of the hierarchized and predetermined reduction methods; the progressive detriment of LCT in the lithic assemblages with respect to light-duty tools, the latter defined by a greater morphological and typological standardization; and the evidence of tool-hafting. These technological changes do not suppose a clear-cut rupture with respect to previous technological models, although they are accompanied by other punctuated but significant changes in subsistence and behavioral strategies (bone tools and retouchers) that later will be consolidated during the Middle Paleolithic.

Hence, the archaeological record from TD10.1 points to a local transition from Mode 2 to Mode 3 technocomplexes in Atapuerca, parallel to that observed in other European sites.

ORAL

## 19. THE CUEVA DEL ANGEL (LUCENA, SPAIN) - A COMPARATIVE ANALYSIS WITH GALERIA OF ATAPUERCA AND COVA DEL BOLOMOR

*Barroso, Cecilio (Director of the Cueva del Angel research project.) cecilibarroso1@hotmail.com*

*Caparros, Miguel (Muséum National d'Histoire Naturelle. Département de Préhistoire, Paris.) capmig@aol.com*

The Cueva del Angel (Lucena, Spain) site is an archaeological open-air sedimentary sequence remnant of a collapsed cave, part of a karst complex. Taphonomical characteristics of the herbivore faunal assemblage, the well developed final Acheulean industry and a preliminary  $^{230}\text{Th}/^{234}\text{U}$  date of  $121 \pm 11/-10$  ky points to a chronology stretching from the end of the Middle Pleistocene to the beginning of the Upper Pleistocene (MIS 11 to MIS 5).?

Most of the well known middle Middle Pleistocene Acheulean assemblages of the Iberian Peninsula are located in terraces of major rivers and their industries, made essentially of quartzite cobbles, are far removed from the one encountered in Cueva del Angel. Two sites that would help to clarify where the culture of the Cueva del Angel hominins would fit are to be found in a cave context, such as Galeria at Atapuerca and Cova del Bolomor in the province of Valencia. These three caves stopped functioning during MIS 5 (Cueva del Angel cave probably collapsed, while Galeria and Bolomor were sealed off).

A comparative analysis of the three sites will illustrate how groups of *Homo heidelbergensis s.s./* Neanderthals took advantage of karst cavities before the MIS 5 discontinuous event. The reviewed sites illustrate the relative adaptive responses of these human groups to the diverse ecological environments and the faunal and raw material resources available, taking into account the fierce competition for animal nutrients that existed between them and carnivores.

From a comparison of the Acheulean lithic assemblage of Cueva del Angel with the the Acheulean ensemble of Galeria and the so-called non-Acheulean mousterian industry of Bolomor, it appears that there is no clear boundary between the Lower and Middle Palaeolithic in the Iberian Peninsula, and that tools made on flakes, once considered a feature of the Middle Palaeolithic are common in Acheulean industries. This diversity fits very well with the archaeological evidence encountered in other regions of Western Europe.

The Cueva del Angel archaeological site is a collapsed open-air cave, located on the outskirts of the town of Lucena, province of Cordoba, with an excavated and well preserved sedimentary sequence and a stratigraphy evidencing a Middle to Upper Pleistocene human occupation. In 1995, a team led by C. Barroso and D. Botella discovers a rich stratigraphy on top of the site. To date seven excavation campaigns have yielded numerous faunal remains and substantial late Lower Palaeolithic type lithic artifacts, including a number of handaxes, but so far no human fossil. The faunal assemblage dominated by equids, large bovinds and cervids has been subjected to intense anthropic actions reflecting selective predation. The fauna may be correlated with the end of the Middle Pleistocene to the beginning of the Upper Pleistocene. Further datations are presently being undertaken to assess more precisely the chronology of the sequence.

More than 80,000 lithic artifacts have been found in the site but about 5000 pieces have been extracted from the stratigraphy and coordinated. The assemblage is relatively well preserved though a given quantity of flints is highly desilicified. Evidence of fire is observed on about a third of the artifacts throughout the sequence. Three

main petrographical categories of raw material have been distinguished: flint, largely dominant, then quartzite and limestone. The source of flint raw material identified comes principally in the form of pebbles, and less frequently small slabs or cobbles. The lithic assemblage is dominated by non-modified flakes and abundant retouched tools with the presence of 46 handaxes. Many of the flakes show signs of use wear with thin or flat irregular retouch. Whole pebbles, percussion instruments and pebble tools are extremely rare. Side scrapers are largely dominant throughout the stratigraphy and the notched tools are the second most numerous retouched tools. Most of the cores were knapped from flint and the rest from quartzite, reflecting flake raw material distributions. Recurrent unipolar flaking dominates for flint pieces and bifacial discoidal flaking is most commonly observed for the quartzite ones. Levallois flaking methods are however absent in the site.

The present analysis will be based on handaxes, who were configured mainly on large flakes or fractured pebbles. Some conserve more or less cortical residue. The degree of raw material selection, the morphology and quality of blanks, the interaction between *débitage* and *façonnage* (shaping) and their operational sequence (similarities and differences in methods and techniques), the function of the site, are some of the conditioning or determining factors in the operational schema of bifacial shaping. These pieces allow us to produce a new way of understanding the way those bifaces are made and used. The technological approach through the diacritic analysis and a morphometrical study will present the different steps of productions and the identification of the functioning and the functional unities linked to the morphology and technology of the tools.

Many models have been established to show settlement dynamics in Europe and the Italian peninsula during Middle and Upper Pleistocene: the **Out of Africa** theory (Acheulian dispersal from Africa), the hypothesis of an evolution of bifacial industries within Europe around MIS 10, and the idea of a cultural mosaic in Italia.

But, these models need more technical data and accurate chronologies. This statement leads us to reopen researches at Valle Giumentina (Ecole française de Rome-project 2012-2016). Valle Giumentina is a little valley within the Majella mountain range that has been sealed during Pleistocene. Nine archaeological levels assigned to Clactonian, Acheulian and Mousterian cultures have been discovered during the 1950's excavations by A.M. Radmilli and J. Demangeot.

A technical study of lithic industries from ancient and new excavations give new results on this extraordinary open air site. Since 2012, hundreds of lithic artefacts have been discovered with few faunal remains. Use wear analysis shows well preserved marks. Lithostratigraphic correlations between the ancient and the new excavation are in progress thanks to a new stratigraphic section of 17m high and a 45 m sedimentary core. We try to characterize the environment and the age of human occupations. The morphology of the Quaternary deposits is known by electric resistivity. OSL and Ar/Ar dating are in progress on sands and volcanic deposits. Palynology and malacology are also started.

Valle Giumentina is of great interest both for Prehistory and Quaternary chronostratigraphy. It will help us to comprehend the Middle Pleistocene cultural evolution in Europe and the Mediterranean area.

Building a precise and accurate chronology for the cultural and hominins evolutions during the Lower Palaeolithic in Western Europe has always been a challenge. The Italian Peninsula, because of the quality, the number of sites from the Middle Pleistocene as well as the contemporaneous volcanic activity is a unique place in Western Europe. In the frame of a Italian-French multidisciplinary

team we started two years ago a program that aim at improving the chronology of some of the landmark sites of the Latium and Molise provinces using several methods ( $^{40}\text{Ar}/^{39}\text{Ar}$ , ESR-U/Th) and covering the period between 1 Ma and 300 ka.

In this contribution we will present the first  $^{40}\text{Ar}/^{39}\text{Ar}$  ages constraints we obtained using single sanidine crystal laser fusion method on three archeological sites: la Polledrara, Torre in Pietra, both located North East of Roma (Latium) and Guado San-Nicola found in the South of the Isernia la Pineta site (Molise).

These new ages show that all the investigated sites are all dated within a narrow time window between 400 to 310 ka that also encompassed the Devil footsteps that were found on the Roccamonfina volcano slope and the Ceprano calvarium (Scaillet et al., 2009, Nomade et al., 2012). Thank to these new chronological anchors we will discuss the cultural evolution in central Italy during the short period that covers the end of interglacial 11 and the interglacial 9. During our presentation we will also introduce a new approach we have developed based on the systematic  $^{40}\text{Ar}/^{39}\text{Ar}$  dating of sanidine single crystal in fluvial deposits.

Based on the first results we have we show that we are now able to evaluate the reshuffle of the volcanic materials within fluvial units, identify the sources (the volcano and sometimes a specific eruption) as well as give an maximum age to the deposition of these sediments. Our approach using the systematic dating of single crystal could be used in almost all archeological sites in Central and Southern Italy that contain primary volcanic deposits such as tephras or sedimentary layers containing feldspar crystals (Sanidine, Leucite).

Identifying the ecological niches occupied by diverse hominin taxa represents an important step in modelling early hominin distribution and dispersal. Several parameters have already been suggested as being of decisive impact, for instance seasonality and primary productivity. Apparently, it is not easy to link this parameters with human behaviour in a direct way. The concept of ecospace summarizes a set of descriptive parameters including mammal communities, vegetation, climate, and landscapes, and permits testing correlations among them.

The ecospace concept is designed to compare ecosystems inhabited by diverse hominin taxa, eventually located on different continents and situated in different latitudes. It allows for the evaluation of correlations between ecologically relevant parameters. The aim is to develop a set of predictive factors, which can be tested with the fossil record of hominins. Which factors are relevant for hominins? Which types of ecosystems are selected by specific hominin taxa?

We introduce the ecospace concept in its theoretical context and illustrate it by focusing on ecosystems around the mid-Pleistocene transition in tropical and sub-tropical latitudes.

rigf@uni-trier.de*

*Gutmann, Mathias (Karlsruher Institut für Technologie, In-  
stitut für Philosophie) mathias.gutmann@kit.edu*

There are currently four competing hypotheses for the human dispersal out of Africa, via the Bab al Mandab Route, along the Levantine Corridor, the Sicily Route and/or the Gibraltar Route (Bar-Yosef and Belfer-Cohen 2001; Derricourt 2005; Armitage et al. 2011; Abbate and Sagri 2012). Several factors play a role for the human dispersal such as ecological variations and demographic pressure (Abbate and Sagri 2012), climatic changes (Agustí et al. 2009; Leroy et al. 2011; Van der Made 2011), biological and social organization (Van der Made 2011), dispersal of megafauna in Asia (Hemmer 2001), carnivore competition (Turner 1992), vegetation (Leroy et al. 2011). The evaluation of the contributions of each of the factors is still ongoing.

In the last decades, agent-based modeling (ABM) has been established as innovative methodology for modeling and simulating of artificial societies (Davidsson 2002). Within this project we develop a new approach for modeling and simulation of various human dispersal scenarios out of Africa. ABM enables us to analyze dynamic effects within artificial societies, i.e., emergence effects, which represent global effects resulting from local interaction of actors, the so-called agents, and the environment (Timm et al. 2006). Applied to the dispersal scenarios, external conditions, like climate or nutrition resources, have to be identified, specified and represented in the environment and individual behavior, capabilities, and interactions of tribes have to be considered in the agent model. The main question is how early hominins dispersed from Africa into Eurasia. This implies the questions when, where and under which prerequisites, constraints and circumstances hominins dispersed out of Africa and which routes were taken. Furthermore we may ask whether out of Africa was limited to members of Genus Homo or not and include the dispersal potential of different Homo species. With ABM we will model various scenarios in which we can simulate and compare different hypotheses.

Many studies have assessed the relationship of Anatomically Modern Humans, AMHs, with climate and other megafauna species, including other Hominines, but a climatic niche-based perspective incorporating Community Ecology and Macroecology approaches has yet to be applied to the patterns and drivers of the great human expansion during the Late Pleistocene. The aim of this study is to describe and quantify climatic niche and range dynamics of Paleolithic Eurasian AMHs, from 46kya to 11kya (kya=thousands years ago), and to quantify the role of climatic forcing and technological/cultural transitions in those dynamics.

Using paleoclimatic simulations from AOGCMs (Atmospheric Ocean Coupled General Circulation Models) and 5,300 archaeologically associated radiocarbon dated materials we applied a community ecology framework to calculate metrics of niche overlap, niche breadth and marginality of the niche (distance of the mean conditions occupied by modern humans to the mean climatic conditions of Eurasia) between consecutive time periods. We also mapped the potential distributions of humans, calculated their range size for each time period using Climate Envelope Models (CEMs) and identified climatically stable areas through time as potential climatic refugia. Finally, we used General Additive Models to quantify the effect of climate forcing and techno-cultural changes on niche parameters and range size.

We can divide the climatic niche and range dynamics of AMHs for the time extent of the study into two periods,

largely coinciding with parts of Marine Isotope Stages (MIS) MIS3 and MIS2. In the first period (46kya – 24kya) humans' climatic niche was highly unstable, while the niche breadth was expanding with some time bins revealing an explosion of the niche, as humans occupied different climatic conditions. At the same time, we found that range size is increasing, and the distribution of humans is shifting into new areas, expanding from Europe towards the Far East through a mid-latitude belt, in South Siberia-China. In contrast the second period (24kya-11kya) revealed a much more stable niche, with a gradual decrease in niche breadth and continuous changes in range size.

The niche of Paleolithic Eurasian Anatomically Modern Humans drastically varied from 46kya to 11kya, with climate forcing being the most important factor driving these changes. During the climatically variable but less harsh MIS3, humans expanded their climatic niches and dispersed to new environments. Cultural transitions appeared to facilitate this expansion. In contrast, during the extreme conditions of the MIS2, which included the Last Glacial Maximum, the climatic niche of AMHs contracted and increased in marginality, in spite of technological transitions. It appears that AMH dealt with these extreme conditions by shifting geographically to track suitable climatic conditions instead of adapt to these new climatic conditions. This framework provides a quantitative reconstruction of AMH's spatiotemporal niche dynamics and allows quantification of the effects of climate forcing and cultural changes on the mode and tempo of the great expansion of modern humans across the planet.

### 4. A NEW HIGH-RESOLUTION MULTI-PROXY RECORD FROM THE CROMERIAN STRATOTYPE AT WEST RUNTON, UK: PALAEOENVIRONMENTAL AND ANTHROPOLOGICAL IMPLICATIONS

*Rowney, Francis (Plymouth University) francis.rowney@plymouth.ac.uk*

*Whitehouse, Nicola (Plymouth University) nicola.whitehouse@plymouth.ac.uk*

*Candy, Ian (Royal Holloway, University of London) ian.candy@rhul.ac.uk*

*Fyfe, Ralph (Plymouth University) ralph.fyfe@plymouth.ac.uk*

*Schreve, Danielle (Royal Holloway, University of London) danielle.schreve@rhul.ac.uk*

The early Middle Pleistocene (MIS 19-13, c. 780-474 ka) is a critical period in the Lower Palaeolithic of Northern

Europe, during which time southern Britain represented the north-western fringe of hominin habitation. The region is therefore regarded as an area of sporadic hominin presence and periodic extirpation, for which an understanding of the environmental context is of fundamental importance. Thus, through the analysis of palaeoecological (entomological and palynological) records, this paper aims to refine understanding of the palaeoclimatic and macroecological characteristics of early Middle Pleistocene interglacials in Britain. This will aid the development of a more nuanced understanding of the ecology of, and potential stresses on, these marginal populations. Additionally, this will also facilitate a broader investigation into the terrestrial expression of the Mid-Brunhes Transition (MBT) (c. 430 ka) in Britain; potentially the most significant climatic transition of the last 800 ka. However, in spite of its significance, its expression in Northwest European terrestrial environments remains relatively poorly understood, due to the limited nature of previous analytical approaches and a paucity of high-resolution records.

A new high-resolution, multi-proxy palaeoenvironmental record from the stratotype for the Cromerian stage of Northern Europe, the West Runton Freshwater Bed (WRFB) on the North Sea coast of England, is an ongoing aspect of this work. Previous palaeoclimatic and palaeoecological studies of the WRFB have concluded that it was deposited in a temperate climate, similar to modern Britain, in a predominantly lentic freshwater habitat, with areas of both open grassland and mixed deciduous-coniferous woodland in the vicinity. However, these have been based on low-resolution records, with little attention paid to stratigraphic change through the sequences, thus new approaches to the collection and analysis of palaeoentomological and palynological data will allow for more detailed reconstructions.

Both palaeoecological and palaeoclimatic analyses will be carried out, utilising entomological and palynological assemblages from the WRFB. Palaeotemperatures will be reconstructed using the mutual climatic range (MCR) technique, applied to insect assemblages, and an ecological functional-type approach will be utilised in the analysis of both insect and pollen assemblages in order to provide an ecologically-based palaeolandscape reconstruction.

Preliminary results from this new high-resolution multi-proxy palaeoenvironmental record for the WRFB will be presented, including sedimentology and outline palynological and palaeoentomological records.

The new palaeoclimatic and palaeoecological records will be summarised, and their significance regarding the character of early Middle Pleistocene interglacial environments in Britain, and the implications for Lower Palaeolithic populations, will be discussed and evaluated.

## 5. FITTING A SURVIVAL MODEL TO DESCRIBE THE AGE STRUCTURE OF FOSSIL POPULATIONS

*Martín-González, Jesús A. (UBU - CENIEH) [jesusangel.martin@ubu.cenieh.es](mailto:jesusangel.martin@ubu.cenieh.es)*

*Mateos, Ana (CENIEH) [ana.mateos@cenieh.es](mailto:ana.mateos@cenieh.es)*

*Rodríguez-Gómez, Guillermo (CENIEH) [guillermo.rodri-guez@cenieh.es](mailto:guillermo.rodri-guez@cenieh.es)*

*Rodríguez, Jesús (CENIEH) [jesus.rodriguez@cenieh.es](mailto:jesus.rodriguez@cenieh.es)*

Building mortality profiles to study age-at death patterns is a typical component of most faunal analyses. These age profiles are used to reconstruct aspects of a sample's taphonomical history, including prey selection or mode of accumulation. The attritional profile, produced by natural deaths by predation, disease, etc., reflects the animals dead by each age class in a living population. Several methods, like histograms, boxplots and triangular plots are currently used to describe and compare mortality profiles and living population profiles.

The main goal of this study is to reconstruct the age structure of fossil populations from attritional mortality profiles by assuming that this structure may be mathematically modeled by a survival model. Eventually, demographic parameters as life expectancy at birth, birth rate, mortality rate, etc, may be estimated from the model. Moreover, descriptions and comparisons between fossil and living populations can be developed.

Dental eruption, dental attrition, epiphyseal fusion and skeletochronology provide reliable estimations of the age at death from fossil samples. However, although some of these techniques are claimed to provide punctual age estimations, most of them provide interval age estimations. The age intervals may be equal for all life stages but more frequently they are different in length for different life stages. These type of data are called censored data in statistics analysis. The nature of censored data produce limitations in the estimations and require the use of specific statistical techniques.

If the age at death is reliably known with high accuracy (no censored data) several models can be easily

proposed by estimating the parameters using the maximum likelihood method. However, censored data make it more difficult to obtain a likelihood function.

Several models are fitted to a sample with interval censored data and the best one is selected. The set of models used are called Exponential, Weibull, Log-Normal, Extreme value, and Gamma and Rayleigh. These are typical models used in survival analysis.

All the tested models fit the data. However, Exponential and Weibull present better performance. Both of them exhibit a similarly good adjustment to the data, but the use of the exponential model is recommended because of its simplicity. Note that the Exponential model has only one parameter whilst Weibull has two. The parameter to be estimated in the case of the exponential model is  $\lambda$ . This can be interpreted like the mean time of death is  $1/\lambda$  years. Moreover, the Survival Function, i.e. the proportion of individuals alive at time  $t$ , or the Lifetime Function, i.e. proportion of individuals with more than  $t$  years, can be easily obtained. These functions, besides the mortality profile, are useful to compare populations.

Mathematical and statistical techniques have been found to be useful for the description, comparison and analysis of the age structure of fossil populations. In addition, the features of the fossil record, as the limitations in the size of the sample, and the nature of censored data, are properly dealt with using these techniques.

The presence of large predators is one of the main factors that probably affected the successive dispersal of humans across the Mediterranean area during the Pleistocene. In this respect, food acquisition must have been one of the key problems for these human populations to overcome in an environment subject to periodic glaciations. Several authors have suggested that the survival of these hominins during the cold seasons was probably made possible through the development of scavenging strategies focused on ungulate carcasses. The availability of these carcasses depends to a large extent on the internal structure of the carnivore guild and the intrinsic relationships between top predators.

Previous works have suggested, based on available taphonomical evidence, that sabertoothed and conical-toothed cats as well as bone-cracking hyenas developed complex social behaviors of hunting in packs. Concerning hyaenids, the degree of gregariousness among extant species is variable, with *Crocuta crocuta* being the most social hyena. For some extinct hyaenids, paleobiological inferences on social behavior have been made on the basis of bone accumulations in putative dens of *Pachycrocuta brevirostris* and *Crocuta spelaea*. Some studies have also relied on encephalization metrics (relative brain size) to infer social behavior on fossil carnivorans in general, or extant hyaenids in particular, although no study had previously focused on an extinct hyaenid.

A recent analysis focused on extant hyaenids, following a research line initiated by Holekamp and coauthors, established a positive correlation between the relative size of the anterior brain and group size—with the most social *Crocuta* displaying the greatest development of this region, and the solitary *Proteles* the least. Besides several other structures, the anterior region of the brain is mainly constituted by the frontal cortex. In primates and other mammals, the frontal cortex intervenes in complex cognitive processes related to social decision-making, such as the inhibitory behaviors required in complex fission-fusion societies. Therefore, a relatively larger frontal cortex may reflect the enhanced abilities required to process social information.

In the present study, the shape and size of the internal cranial cavities of *Pliocrocota perrieri* and *Crocota spelaea* are compared with those of extant hyaenids with the aid of computed tomography techniques. Our results indicate that *Pliocrocota* displays an anterior cerebrum relatively smaller than in all extant bone-cracking hyenas whereas *C. spelaea* shows an anterior cerebrum of the same relative size as the highly social *C. crocuta*. These facts suggest that *P. perrieri* possessed less developed cognitive abilities than extant bone-cracking hyenas and *C. spelaea* for processing the information associated with complex social behaviors.

The reported evidence supports previous taphonomical data, indicating a highly social behavior for *C. spelaea* and further suggesting the existence competition for food resources between this hyena and Pleistocene hominins. The results for *P. perrieri*, in turn, contradict previous assumptions of complex social behaviors for all Pleistocene bone-cracking hyenas. Further research based on other bone-cracking hyenas coeval with humans, such as *Pachycrocota brevis*, are required to further evaluate the role played by trophic competition between hyaenids and early *Homo* during the Pleistocene.

## 7. ASSESSING COMPETITION RELATIONSHIPS ON THE BASIS OF COMPETITION-FREE CARRYING CAPACITY

Rebekka, Volmer (Senckenberg Research Institute) rebekka.volmer@senckenberg.de  
Christine, Hertler (Senckenberg Research Institute) christine.hertler@senckenberg.de

The evolution of humans must be understood in their ecological context. Hominins had to cope with environmental conditions like climate, vegetation, resources and competitors.

Since meat played a key role in human evolution the impact of interspecific competition for prey in fossil carnivore guilds needs to be assessed.

To analyze guild structure and the role of guild members we introduce a model based on the theory of competition effects. In this model prey is considered as a limited resource. The guild depends on this resource and consumption of the resource by one guild member must

affect other guild members. To calculate the effects of competition we developed the concept of competition-free carrying capacity (CFCC). The ecological term 'carrying capacity' means the maximum population size of a specific species in a given habitat. The CFCC represents the population size a guild member could reach if all other guild members were absent and it consumed all available prey mass on its own. In this regard, only prey categories relevant to the specific guild member are used. To calculate the CFCC we characterize the guild member by its actual population size, prey mass requirements and prey spectrum. The prey spectrum is very important, because not all potential prey species constitute essential resources for each guild member. Thus the prey is characterized by its size and sorted into prey mass classes. The prey spectrum comprises the prey classes that a guild member hunts. Next we calculated the CFCC for each guild member. The prey consumption of each guild member in each prey category allows the calculation of the capacity loss of one guild member to another. We call the percentage loss of CFCC of one guild member to another 'competition effect'. The structures of carnivore guilds from the Pleistocene of the Indonesian Archipelago are assessed by the model. The results reveal new invaders are challenged to establish in an existing carnivore guild. Further it is discussed whether faunal changes in the prey guild can be responses to high predation pressure.

Mateos, Ana (Centro Nacional de Investigación sobre la Evolución Humana (CENIEH), Paseo Sierra de Atapuerca 3, 09002, Burgos, Spain.) ana.mateos@cenieh.es  
Rodríguez, Jesús (Centro Nacional de Investigación sobre la Evolución Humana (CENIEH), Paseo Sierra de Atapuerca 3, 09002, Burgos, Spain.) jesus.rodriguez@cenieh.es

The availability of resources and the competition with secondary consumer have been proposed as

key limiting factor for the European human dispersals during Early and Middle Pleistocene. However, to determine the actual influence of these factors on the distribution of human populations it is necessary to quantify them and compare the values among different sites or environmental conditions. A standard method to measure competition intensity and resource availability in different assemblages is thus required.

The ratio primary consumer biomass to secondary consumer biomass is commonly used to describe trophic conditions of a mammal community. However, this ratio is an oversimplification, since the feed habits and limitations of the secondary consumers are not taken into account. We present different indexes to measure the intensity of competition between secondary consumers in faunal assemblages with a standard approach using a mathematical model based on Leslie Matrices. In this way, competition intensity may be compared between different faunal assemblages. The mathematical model provides sustainable densities for each secondary consumer species in an assemblage, taking into account the available prey and the competitors, while expected densities are estimated from allometric equations. We apply several indexes to these results relating estimated and expected densities, number of individuals and biomass for secondary consumers.

The different indexes provide different information helpful to analyze competition intensity between secondary consumers. Comparing several faunal samples with these indexes would be a first step to get a standardized tool.

Several methods to estimate the intensity of competition between secondary consumer in faunal assemblages are presented. These methods are based on the estimated densities obtained from a mathematical model, which standardizes the estimations of competition intensity allowing comparisons between different assemblages to be carried out. However, the faunal assemblages included in the comparison should be complete enough, i.e. representative of the living community, in order to make these estimations reliable.

We present here a novel approach to study the interactions of Neanderthals and carnivores in the cave of Zafarraya by comparing the lithic archaeological and faunal records of the site with a statistical path analysis.

A multiple regression with independent variables such as for example lithic and carnivore elements could be used to explain herbivore accumulation, the dependent variable. The main drawback of multiple regression is that it assumes that the independent variables are direct unrelated causes of the dependent variable, disregarding the indirect causal relationship that might exist between them. Alternatively one could use the correlation coefficients between all the variables to make inferences on herbivore accumulation and Neanderthal – carnivore competition for nutritional resources. However, correlation analysis serves to determine only whether two variables are interdependent or co-vary, but does not assert a causal relationship between them. Path analysis, developed by Sewall Wright (1968), is a powerful statistical technique considered as an extension of multiple-regression that takes into account the effects of correlated independent variables. In light of the shortcoming of regression and correlation analyses, we used a statistical path analysis to infer the causal relationships between the herbivore prey accumulations and the presence of accumulators (carnivores and Neanderthals) in this site after taking into account the reciprocal influence of the accumulator variables.

The results of the statistical analyses confirm and shed further light on previous taphonomic and zooarcheological research. The findings concur with the two-species Lotka-Volterra competition model for resources which stipulates that when niche overlap is complete the species with the larger fitness excludes the other. Our analysis shows that in the immediate vicinity of the cave the fitness of *Panthera* was greater than Neanderthals', i.e. when *Panthera* was present it excluded Neanderthals as evidenced by the record of *Capra* and *Rupicapra* remains. It also shows that further in the southern hills and the polje where large herbivores roamed, Neanderthals had a greater fitness than carnivores which translated into their primary

ORAL

## 9. ANALYZING NEANDERTHALS AND CARNIVORES INTERACTIONS IN THE SURROUNDINGS OF THE CAVE OF ZAFARRAYA (SPAIN) BY MEANS OF A STATISTICAL PATH ANALYSIS.

accumulation in the cave of remains of *C. elaphus* and other large herbivores.

Coexistence from occasional niche overlap is apparent when one or the other predator scavenged, but from a time prospective it must have been short periods linked to seasonality, weather conditions and occupation randomness. In Zafarraya, the archaeological record would indicate that the degree of fitness of the herbivore prey accumulators, carnivores or Neanderthals, was related to the nature of the geomorphological domains in the vicinity of the cave and the favored foraging areas of hunted herbivores.

**10. EXPLORING PALEO FOOD-WEBS IN THE EUROPEAN EARLY AND MIDDLE PLEISTOCENE: A NETWORK APPROACH**

*Lozano, Sergi (IPHES & URV) - slozano@iphes.cat*

*Mateos, Ana (CENIEH) ana.mateos@cenieh.es*

*Prignano, Luce (IPHES & URV) luceprignano@yahoo.it*

*Rodríguez-Gómez, Guillermo (CENIEH) guillermo.rodri-guez@cenieh.es*

*Rodríguez, Jesús (CENIEH) jesus.rodri-guez@cenieh.es*

Food webs are networks of feeding (trophic) interactions among species. As any other network approach, research on food webs focuses its analysis on the structure of direct and indirect interactions among diverse species, rather than looking at the particularities of certain taxa. In recent times, scholars have collected an impressive amount of empirical food-web data to study present day terrestrial and aquatic habitats. Moreover, there is an increasing literature on the construction of theoretical models of food-web structure to understand dynamics of ecological communities (for instance, robustness to the extinction of certain species or introduction of new ones).

This approach has also been applied to trophic interactions represented in the fossil record of extinct ecosystems. Since the seminal paper by Dune *et al.* on Cambrian food-webs, several authors have reconstructed and/or modeled paleo or fossil food-webs. Nevertheless, to our knowledge, none of them has addressed the role played by the different Pleistocene hominin species as part of such food-webs. In this work, we aim at filling this gap (at least, partially) by focusing on the Early and Middle Pleistocene paleocommunities in Western Eurasia. Our goal is to improve our understanding on

changes experienced by large mammals' interactions during this period, and shed some light on the influence of and on *Homo* species of those changes.

We have constructed up to 25 paleo food-webs from the archaeo-paleontological record of European assemblages, covering from the Middle Villafranchian to the Late Galerian. Only large mammals have been considered, including a couple of *Homo* species that are present in 10 food-webs. In order to address our research questions, we will develop a two-steps analysis. First, we will calculate the main structural features of all the networks, and compare them across geographical areas, periods and cases with and without *Homo* species. Second, we will perform computational experiments on the obtained networks (and, eventually, also on synthetic ones generated from theoretical models) focusing on dynamical aspects of hominin interactions with other large mammals.

The Neanderthals are a typical European Middle and Upper Pleistocene population that emerged at around 400.000 BP and became extinct at around 30.000 years BP. The causes of their demise are the topic of heated scientific debate. Many hypotheses have been advanced to account for it, notably competition with modern humans following their arrival on the European continent, accompanied by major climate changes (OIS 3) that resulted in great changes in the availability of natural resources. Three scenarios have been proposed:

- 1) Modern humans replaced Neanderthals in Europe;
- 2) Modern humans assimilated the Neanderthal population;
- 3) Modern humans replaced and partly assimilated Neanderthals.

In order to test these scenarios, the NEDEMO project intends to create a network of pluridisciplinary research as a means of identifying the demographic parameters (fertility, survival, structure and variation in the size of the population) that brought about the Neanderthal demise. Although the Neanderthal demographic parameters are not known with precision, they can be inferred through the integration of genetic, environmental, fossil and archaeological data.

To determine which of the three proposed scenarios is most likely, we will use an approach based on demographic modeling, which is widely employed in ecology and has provided a powerful tool of strong heuristic value for the study of the dynamics of animal populations.

Each scenario will be translated in terms of mathematical functions (or demographic models). For this purpose, as in all modeling work, we will simplify and interlink biological, social and environmental processes that may explain the disappearance of Neanderthal. This approach will also enable us to test different hypotheses and, in addition, determine the value of *a priori* parameters that are not measurable.

In the framework of this section, we aim to present this resolutely pluridisciplinary project. At present, researchers are involved in diverse disciplinary fields (anthropobiology, genetics, ecology, paleoanthropology, paleoecology and archeozoology) and we hope to stimulate interest in this project among researchers from other disciplines in the hope of enlarging our network of collaboration.

POSTER

## FUNCTIONAL DIVERSITY, A TOOL FOR MODELING ECOSYSTEM RESPONSES TO CLIMATE CHANGES

*Palombo, Maria Rita (Dip. Scienze della Terra, Sapienza Università di Roma, Italy) mariarita.palombo@uniroma1.it*

Functional diversity (the amount of inter-specific variation in functional traits in an ecological community) has been receiving increased attention in ecological studies because it does not treat all species identically, as taxonomical diversity does, but rather according to the role they have within a community. Therefore, functional diversity can provide information capable of revealing the processes that structured past faunal complexes (FCs) (seen as "spatio-temporal" metacommunities) and promoted their dynamic changes. Each FC gathers faunal assemblages from different territories, thus species composition of local fauna may differ from site to site, though the ecological structure may be substantially the same. In such cases, it is appropriate to classify species into functional groups and study the changes in their relative abundance over time. This allows to quantify the functional aspect of biodiversity and to establish its relationships with ecosystem functioning and environmental constraints through changes in the amount of resource partitioning among species.

For analyzing functional diversity, the population density (that is marginally affected by climatic and geographical factors) can be regarded as a proxy for the abundance of individuals of a species in a FC. This approach proposed here has the advantage of avoiding the effects of time averaging on fossil data and other sampling issues that palaeontologists routinely face (e.g. taphonomic biases). During the past two decades, a number of studies have examined the relationship between body mass and population density across a wide variety of habitats and in various animal groups. A number of equations have been proposed to calculate density, trying to resolve inconsistencies in the observed scaling of mammal abundance among ecological and taxonomic groups. I estimated the population density for fossil species by using species-specific predictive equations based on the body-mass calculated for each species by averaging all the body masses obtained by the predictive equations with the lowest predictive errors, and the population density reported for its extant relatives. The research focused on the variation throughout the Pleistocene of the relative abundance of mammalian ecological groups in SW European FCs, examined in the light of climate

and environmental changes and perturbations of biotic interactions.

The analysis hints at different patterns in each studied sub-region (Iberian Peninsula, France and Italy), though some general trends can be detected in the changing ecological structure of FCs. In particular, results obtained show that the biomass of prey was high (especially in Italy and France) shortly before the Jaramillo submagnetochron, during the ensuing Early Pleistocene and, more markedly, during the Middle Pleistocene, following a pattern irrespective of prey and predator richness. Result obtained suggests that, at that time of first hominins appearance in SW Europe, a variety of resources were present for carnivores, reducing the intra-guild competition and giving any advantage to archaic hominins, viewed as opportunistic species with some scavenging behaviour.

A further developing of this analytical approach should help to answering the question about to what extent changes in environments had a role in shaping the dynamics of European hominin populations during the Early and Middle Pleistocene.

### 1. A DIACHRONIC REVIEW OF MACROFOSSIL EVIDENCES OF FIREWOOD RELATED TO NEANDERTHAL OCCUPATIONS AT ABRIC ROMANÍ

*Solé, Alex (IPHES) alexsole1@gmail.com*

Travertine sedimentary environment at Middle Palaeolithic layers from Abric Romaní has allowed a particular preservation of firewood remains. These firewood evidences (wood imprints charred wood and charcoal) permits to discuss wood gathering and management among Palaeolithic hunter-gatherers. The sequence dated using U-series (U/Th) spans from 70 to 40 kyrs, wooden remains were recorded from layer H to layer P. This work analyzes from a diachronic perspective how the variations related to the type of occupations, rock-shelter morphology and taphonomical agents along the sequence, could have an effect on the wooden assemblage.

Methodology was based on the typological analyses of the wood remains according to size and distribution patterns. Variables analyzed are mostly related to field data. Field record consisted in the documentation of the category, the stratigraphic setting, the position in the excavation grid, the measurements, the orientation and the inclination. The wooden imprints were also drawn in detail information of location and surface features. We carried out three approaches in spatial analyses: the distance from the wall, the relationship with hearth structures and the density of occupation.

Examination of spatial pattern permits to consider different incidence of natural and anthropic agents in the wood assemblage formation. This incidence can be related with two facts: The outer part of the rock shelter was more exposed to natural agents and the occupation core was located near the wall. There are several typologies of wood assemblages due to its measurements distribution and degree of combustion.

Using spatial distribution patterns and measurements of wood imprints recovered at Abric Romaní we have been able to draw conclusions concerning firewood management among Neanderthal human groups. Abric Romaní's firewood remains, are a useful and innovative tool to discuss issues as the variability of measures and morphologies of wood collected for fuel and the different exploitation patterns depending on the intrinsic characteristics of assemblage and spatial distribution reflecting a differential use of space. As anthropic related assemblage, the wood remains show variability, depending to the type of occupation mode and reflecting different activities and/or different moments of abandonment. Furthermore the changes of rock shelter morphology along the sequence were the main features affecting the incidence and variability of taphonomical agents.

ORAL

### 2. FIRING-RECORDS REVEALING ANCESTRAL PROCESSING OF PEAT-DERIVED ENERGY RESOURCES AND HIGH-VALUE FUEL BYPRODUCTS

*Courty, Marie-Agnès (CNRS) marie-agnes.courty@promes.cnrs.fr*

Ancient firing activities are now commonly investigated by high resolution analysis of charcoal-rich ash microfacies and combustion features. Their diagnostic features relate to the general assumption that fresh biomass fuels have been the major energy sources until the modern shift to fossil combustible. Fresh biomass fuels have been assumed to always produce fair amount of pyroresidues (carbonized charcoal, charred bones, calcinated ash) and combustion features. Therefore, their absence or scanty microcharcoal are commonly related to a loss of palethnological information by taphonomical processes. The common use in ancient times of matured hydrocarbon-rich fuel from transformed biomass sources seems to have been underestimated. Therefore, signatures of these energy resources in the archaeological fire records have remained so far unknown or misinterpreted. We intend here to establish the use for long time periods of peat-like fuel based on early Paleolithic to Middle age firing records.

The integrated field/multi-analytical that we have developed to tracing the unusual pyroresidues with distinctive mineral grains, specific of peat-like fuel, and for characterizing their origin is presented. This includes: films and filaments made of aliphatic polymers with

nano-sized metal inclusions; vitrous glassy carbon with barium sulphate and metal sulphide inclusions; glassy scoriaceous spherules and beads with native metal blebs; polyphased microbreccia, sandstones and angular quartz with refractory inclusions (zircon, rare earth phosphates) and sprayed nanostructured metallic ribbon.

We illustrate the range of peat-like sources with these particular characteristics which might have been easily available to ancient populations along incised valleys, small basins, coastlands or exokarst deposits. We explain how these peat-like geomaterials rapidly accumulated during particular episodes of enhanced cosmic activity, aerosol dust loading, lightning strikes and violent storms. We present the most remarkable properties of the peat-like fuel, i.e. high inflammability due to organic-rich volatile compounds, high calorific capacity, high thermal resistance, mechanical plasticity and high content in native metals, oxides and nanostructured graphite. Various archaeological situations illustrate how their spatial pattern at microscales helps to identify processing areas with particular hearths and material production for various purposes, i.e. constructions (bricks, floors, plastering), ceramics, surface treatment and high-value objects (carbon-rich clay, bitumen, organic ligands, hydraulic cement, organo-mineral-pigments, carbon-rich metals). We deduce from the high quality of the manufactured products and scarcity of the microresidues in living floors that the precious energy resource was meticulously used with minimal loss. We explain how the remarkable mechanical and thermal resistance of the carbonaceous byproducts has played a major role in the long-term preservation of the related living floors. This suggests that the integrity of all archaeological records is closely linked to the use of peat-like fuel. Based on archaeological situations, we present a typology of microresidues and related microfacies from peat-like fuel that is aimed to identify the collect of surface raw resources, from recycling of activity refuse and from the exploitation of subsurface aged sources.

This reveals a wide range of ancestral use of the peat-like fuel from rudimentary technology to well organized energy production systems that were probably under the control of complex pre-industrial societies.

ORAL

### 3. PHYTOLITH STUDIES APPLIED TO COMBUSTION STRUCTURES: THE CASE OF THE MIDDLE PALEOLITHIC SITE OF EL SALT (ALCOY, ALICANTE)

*Rodríguez-Cintas, Àgata (Universitat de Barcelona) agata.roci@gmail.com*

*Cabanes, Dan (Universitat de Barcelona) dancabanes@ub.edu*

El Salt is a Middle Paleolithic site (ca. 60 and 45 Kyr BP) located in Alcoy (Alicante, Spain). The presence of recurrent Neanderthal occupations are recorded by a succession of hearths and other remains derived from human activities. In this sense, the abundance of combustion structures allows to perform a detailed study of the Neanderthal fire technology. Here we present the results of the mineralogical (FTIR) and phytolith analyses for 10 hearths from the layer Xb.

Mineralogical composition was analysed using an iS5 FT-IR Nicolet Thermo Scientific Spectrometer. The phytolith extraction was made using the method of Katz et al. (2010) and identification was carried out using the standard literature and the International Code for Phytolith Nomenclature (ICPN).

Preliminary analyses show that the main mineral components are clay and calcite, with minor presence of quartz and autigenic dahllite. These results indicate that ashes and travertine forming the infilling are well preserved (calcite) with only minor diagenetic alterations (dahllite). The presence of interconnected phytoliths morphologies and the low number of weathered morphotypes indicate that phytolith preservation is good despite the calcitic nature of the deposit.

Phytoliths assemblages are mainly composed by monocotyledonous (C3 grasses), dicotyledonous (wood/bark and leaves), and especially *Celtis sp.* seed morphotypes in different amounts. *Celtis* presence was additionally confirmed by thin section and during the excavation. The phytoliths assemblages show differences between the hearths analysed.

The variability observed can be interpreted as the result of anthropogenic choices made on the vegetal material available at the moment of the combustion structures function. These choices are reflected in changes on the phytoliths morphotypes represented in the combustion structures (dicotyledonous leaves, fruits, etc.).

ORAL

### 4. AN ETHNOARCHEOLOGICAL STUDY OF LIVE-STOCK DUNG FUELS FROM COOKING INSTALLATIONS IN NORTHERN TUNISIA

Portillo, Marta (ERAAUB, Department of Prehistory, Ancient History and Archaeology, University of Barcelona) mportillo@ub.edu

Belarte, M. Carme (ICREA/ Institut Català d'Arqueologia Clàssica, ICAC) cbelarte@icac.cat

Ramon, Joan (GRACPE, Department of Prehistory, Ancient History and Archaeology, University of Barcelona) jrborrell@ub.edu

Kallala, Nabil (Institut National de Patrimoine de Tunisie/ Faculté des Sciences Humaines et Sociales, Université de Tunisie) nabilkallala@yahoo.fr

Sanmartí, Joan (GRACPE, Department of Prehistory, Ancient History and Archaeology, University of Barcelona) rmalbert@ub.edu

Albert, Rosa M. (ICREA/ ERAAUB, Department of Prehistory, Ancient History and Archaeology, University of Barcelona) rmalbert@ub.edu

Livestock dung is a valuable source of fuel in many rural communities around the world. Ethnographic evidence from northern Africa shows that in areas where the woody vegetation is sparse, the use of dung materials is more extended than in areas where there is no shortage of firewood. Such is the situation of our study area, the site of Althiburos and its surroundings, now el Médéina, located in a small fluvial valley on the northern edge of the Ksour massif, in northwestern Tunisia. Within the present-day rural communities in this region, sheep and goat dung is the main source of fuel for domestic use, including daily cooking in mud cylindrical *tannur* type ovens, namely *tabouna*. Mud constructed cooking and baking installations are also common in archaeological contexts belonging to the first millennium BC.

We present a study of cooking installations from the numidian site of Althiburos, primarily from microfossil evidence extracted from well-defined domestic hearths and cylindrical ovens similar to modern *tabounas*, using ethnoarchaeological approaches. Field work included ethnographic observations and interviews (dung production, management, storage, waste disposal and cooking and baking activities), time measurements from the initial fire lighting and the end of cooking and temperature measurements within the burning fuel, as well as modern material sampling for comparative purposes (ovicaprine fresh dung, burned pellets, dung ashes from *tabouna* ovens, trash paths and abandoned installations). Additionally, experimental samples obtained from controlled-burning dung pellets from the same animal producers are also analyzed to better understand taphonomic aspects dealing with dung microfossil preservation.

The results obtained from integrated studies of phytoliths (plant silica cells), dung spherulites (calcitic particles produced in the digestive tract of many animals) and calcitic ash pseudomorphs (primarily originating from wood), provided direct evidence from the type of fuel matter, a mixing of vegetal matter (wood and perhaps grass leaves and stems from agricultural by-products) and dung. Dung was used as source of fuel material across time (from the Ancient Numidian occupation phase, 10<sup>th</sup> century BC to the last centuries BC) and space (in different site areas and type of firing installations).

Such integrated studies demonstrate the value of combining different microarchaeological techniques and the use of ethnoarchaeological material from the site areas.

## ORAL

### 5. "FIRE-STICK FARMING": THE PLACE OF FUEL WOOD IN A MULTI-RESOURCE FIRE REGIME

Carah, Xavier (The University of Queensland) xavier.carah@uqconnect.edu.au

Clarkson, Chris (The University of Queensland) c.clarkson@uq.edu.au

Marwick, Ben (University of Washington) b.marwick@uw.edu

Fullagar, Richard (University of Wollongong) fullagar@uow.edu.au

Wallis, Lynley (The University of Queensland) lynley.wallis@wallisheritageconsulting.com.au

The tropical savanna of Northern Australia is a complex anthropogenic landscape, which has been dramatically altered through climatic and anthropogenic processes over the last 50,000 years. These changes have been driven by climatic, geomorphic and environmental changes, as well as anthropogenic impacts on flora and fauna. Fire regimes have been observed in Australia since European contact and there is strong evidence for their operation well into prehistory (termed by Jones [1969] as 'fire-stick farming'). The management of fuel wood availability in the landscape was almost certainly an integral part of any fire regime. However, previous research has focused only on the importance of management by fire of landscape productivity and subsistence systems. Research discussed in this paper seeks to address this oversight.

An anthracological analysis of hearth charcoal from the rock shelter site of Madjedbebe (Malakunanja II) in

Northern Australia, offers researchers an opportunity to explore the relationship between hunter-gatherers, climatic changes, and fuel wood selection strategies over the last 20,000 years. The research presented in this paper utilises methods of archaeobotanical recovery and anthracological analysis - techniques still in their infancy in Australia - and ethnographic work conducted with the Mirarr, the traditional custodians of Madjedbebe. The Mirarr continue to live in this landscape and still operate mosaic fire regimes which encourage growth and renewal.

Preliminary anthracological results from Madjedbebe suggest the fuel wood selection strategy at the site was governed by the Principle of Least Effort (PLE).

Fuel wood selection strategies informed by the Principle of Least Effort (PLE) remained relevant during dramatic shifts in vegetation over the last 20,000 years.

ORAL

## 6. COMBUSTION AND FUELS NEOLITHIC DEPOSITS FROM TIN HANAKATEN CAVE (TASSILI N'AJJER, ALGERIA)

*Amrani, Samira (Université d'Alger) amrani1.samira@gmail.com*

*Aumassip, Ginette (CNRS/CNRPAH) gaumassip@gmail.com*

This communication aims to present the archaeobotanical data and charcoal analysis from the five hearths discovered in Tin Hanakaten archaeological deposits. The archaeological materials from Tin Hanakaten site can address multiple issues, such as: fire-related activities, the management of fuel resource, the fire operating sequence, energy production and fire use, fuel sources, combustion processes, firing products and related residues and domestic hearths.

Tin Hanakaten archaeological cave is located in south-eastern Algeria at 1200 km from Algiers; Neolithic deposits from this site include several sequences of human occupation dated from around 9000 to 2000 B.P. The excavations (1974-1981) show a height of 2 to 3 meters of ash sediments in the eight layers. This study is based on Space archaeology description, from data base of the inventory and all literature description from different reports. For the charcoal analysis: The botanical identification was made using the wood anatomy atlas, and the reference collection of actual sahara woods charcoals. Moreover, an ethnological approach which is

based on our experience and knowledge of the current behaviour of the Touaregs society.

The ash deposits, gray, dark, whitish are probably result of intense activity entire combustion and/or partial; this is the result of a long process and operating production line of fire, for multiple use; The structure of a typical combustion main focus and will supply other areas of secondary firing said lenticular homes for a soft and long cooking.

The presence of twigs, bark and plants in scores of households suggest same behaviour in actual society ; The Touareg nomad, mastery of the territory and its phytogeographical knowledge, took their power measurements in wood especially for good food, therefore, some woods are selected and even picked up remote camping place so the notion of reserve wood. The activities related to fire are multiples including the presence of herbs, bark and wood which provide continuous fire management (fire burning for long time). Anthracological studies reveal that, the hearths are characterized by the presence of several tree species, except, the fire place "domestic hearth" 5, is characterized by fuel consisting on only two species (*Faidherbia albida* (98%) and *Olea laperrini*, (2%)); its best for good fire. Furthermore several domestic homes structures have been uncovered. The cookstoves are reported; most important, is the grasshoppers (*Schistocerca gregaria*) cooking hearth, which twigs and "stubble", appeared among the branches. The analysis of coals cooking indicate the use of several species whose *Olea laperrini* attained 80%. The best wood for make fire and cooking. Actually, in the sahara, Olive is relic specie protected by law ; Touaregs can use only the dry wood part, they reserved its specially for cooking.

Archaeobotanical content with several examples demonstrate behavior change, the type of wood and fire management during the different periods of occupation known in the cave. Ethnographic analogy, support our work by the many testimonies recorded. It shows that the behavior of the Touaregs nomadic society (exploitation of the landscape, culinary practices, heating and lighting) are ancient practices that dating from the Neolithic.

ORAL

## 7. PLANTS AND CULTURAL ACTIVITIES RELATED TO THE USE OF FIRE IN THE CALDEN FOREST, LA PAMPA, ARGENTINA

*Tapia, Alicia (Instituto de Arqueología, Universidad de Bue-*

*nos Aires) aliciahtapia@yahoo.com.ar*  
*Bogino, Stella (Departamento de Ciencias Agropecuarias, Universidad Nacional de San Luis ) stellabogino@gmail.com*  
*Dussart, Esteban (Facultad de Agronomía, Universidad Nacional de La Pampa) estebangdussart@yahoo.fr*  
*Doval, Jimena (Conicet, Instituto de Arqueología, Universidad de Buenos Aires) jdoval84@hotmail.com*

In this paper we discuss the fuel use of different typical plants of calden forest or caldenal, a particular environment located in the arid lands of central Argentina. In this forest there are species such as legumes like caldén (*Prosopis caldenia*) and algarrobo (*Prosopis flexuosa*), accompanied by a variety of low bushes like piquillín (*Condalia microphylla*) and grassland (*Stipa speciosa*, etc.). This problem is approached through two evidence lines: 1 - analysis and comparison of archaeological carbonized samples of vegetable macroremains, with thermoalteración as without it, corresponding to different human occupations; either hunter-gatherers of prehistoric times as ranqueles chiefdoms, military and early settlers of historical times; and 2 - the interrelationship between data written in documents about fire use by hunter-gatherers and activities of defense by ranqueles (end of the nineteenth century) and the presence of fire marks registered in a dendrochronological series made with calden samples.

First, we used data published by other researchers for taxonomic identification of plants used for light fires by hunter-gatherers, but for the subsequent populations that occupied the area, we used 82 vegetable samples that were recovered from the archaeological record. Such samples come from different types of sites: three ranquel settlements that were contemporaries from desert conquest (1878-1879); b-a military installation from 1883-1885; and c- two sites occupied between 1890 and 1911, where the first colonists settled. Taxonomic results indicate that the low bushes were most frequently used among some groups of hunter-gatherers, this could be linked to the location of settlements in more open areas or peripherals of a forest, where it is more auspicious for the hunting of gregarious animals. By contrast, in the samples recovered from the ranquel site there are more frequently the legumes, in the typical sector of dense forest with low bush and grassland, suitable for grazing and breeding of domestic animals (*Bos taurus* and *Ovis aries*), typical activity of these native groups. For the more recent sites, a close relationship between selected plants as fuel and functionality of settlements is observed. In the case of the early settlers, in addition to native species, are highlighted the introduction of other exotic species

such as *pinotea* and *quebracho colorado*, some of which are carbonized.

Moreover, by analyzing 37 calden samples collected in a forest sector (that was part of the ranquel territory), a dendrochronological series which covers 273 years, from 1738 to 2011, was established. Some marks of fire registered can be linked to intentional fires, that would have made the ranqueles as part of their defensive strategies during the desert conquest.

Finally, the data obtained through this interdisciplinary approach allow to discuss the sociocultural factors that have intervened at differential selections of plants used for combustion, even when they were potentially available species over time.

ORAL

## 8. ANTHROLOGICAL ANALYZES OF HEARTHES DATING FROM THE LATE PLEISTOCENE TO HOLOCENE DISCOVERED IN THE ROCK SHELTERS SANTA ELINA AND THE CIDADE DE PEDRA (CENTRAL BRAZIL, MATO GROSSO).

*Bachelet, Caroline (Museu Nacional, Universidade Federal do Rio de Janeiro) ac.bachelet@gmail.com*

In Central Brazil (Mato Grosso / MT), research in the rock shelters of Santa Elina (Cuiabá) and the Cidade de Pedra (Rondonópolis) revealed an important succession of occupation dating from the late Pleistocene to Holocene. Dating and material remains (lithics, ceramics, adornment, hearth) show that they were occupied continuously by various groups of hunter-gatherers. The discovery of many combustion structures in all levels of occupations indicates that the fire had a significant role in their daily activities.

This work presents the anthracological analysis results performed on several carbonized deposits (hearths, embers, concentrations). From the taxonomic identification of charcoal, the objectives are to highlight the practices of hunter-gatherers related to the collection and use of wood (firewood, fuel properties, medicinal / ritual uses, selection species, procurement areas, etc.) and the environment in which they have evolved for nearly 10,000 years. We also aim to identify modifications in the collection of firewood that could be directly related to climate changes, which occur around 9000 years BP in Brazil.

The results indicate that human groups practiced an opportunistic collection mainly focused on dry wood available in the vegetation around the sites. Woods of good qualities, fruit trees, species with medicinal properties have been identified in various combustion structures. They probably evolved in an environment similar to that currently characterizes the region, a typical flora of the Cerrado Biome.

Ongoing analyzes of hearths in Santa Elina site, dated 10000-9000 years BP, will provide new information on the behavior of the first prehistoric settlements and the environment of the region.

---

ORAL

### **9. ANTHRACOLOGY AS MEANS FOR ASSESSING HUMAN-ENVIRONMENT RELATION AT THE EXTREME ENVIRONMENTS DURING THE HOLOCENE: THE CASE OF THE HUNTER-GATHERERS AT CENTRAL WESTERN PATAGONIA.**

*Riquelme Toro, Isabella (CEPAM-CNRS Université de Nice Sophia-Antipolis) isabella.riquelme@cepam.cnrs.fr*

*Méndez Melgar, César (Departamento de Antropología, FACS Universidad de Chile) cmendezm@uchile.cl*

*Théry-Parisot, Isabelle (CEPAM-CNRS Université de Nice Sophia-Antipolis) isabelle.thery@cepam.cnrs.fr*

The relations between the human groups and their environment are of utmost importance when studying regional archaeologies that focus on the assessment of the knowledge and exploitation of the resources by past hunter gatherer societies. Anthracology, as subdiscipline that studies the archaeological wood charcoal, contributes to this research area, through defining operational chains analysis, where both the procurement of raw materials, and the knowledge of the environment and their natural resources, are major components of the human decisions.

The methods in anthracology are based on wood anatomy analysis, the taxonomic identification by comparative anatomy, caliber measurement, as well as other qualitative and quantitative attributes observed microscopically and macroscopically.

The Patagonian territory presents extreme and contrasting environmental characteristics, which offer diverse resources for past human societies. Central Western Patagonia is particular in that it shows biomes ranging from evergreen forests in the west to semiarid

steppes in the east, thereby providing a good case for assessing differential procurement of resources. The Cisnes and Ñirehuao river valleys, are located on an ideal are for studying such a problem since they connect this ecological diversity and yield human occupations starting at the onset of the Holocene.

Archaeological sites are located at different altitudes along the river courses; at the evergreen forest, the forest-steppe transition, and at the steppe. Thus, they are key for understanding differences in resource selection considering the evidences that suggest a connectivity network, at least during a limited period of time in the late Holocene (2800 cal. B. P.). The studied sites suggest some functional complementarity along these river valleys. In this paper we explore anthracological assemblages of El Chueco 1, Alero El Toro, and Baño Nuevo 1, in the evergreen forest and steppe, to analyse resource procurement strategies under the assumption that there must have been different and adaptive to environment for the same human groups.

This study (Fondecyt project 11301258) presents the first approach to the study of combustion of wood raw materials and fuel procurement strategies in Central Western Patagonia during the Holocene. Also, this study aims to discuss these results in the context of the network relations of hunter-gatherers in extreme environments.

ORAL

### **10. RESULTS OF WOOD CHARCOAL ANALYSIS AT KAMAN-KALEHÖYÜK, CENTRAL ANATOLIA, TURKEY.**

*Wright, Nathan (The University of Queensland) n.wright@uq.edu.au*

*Fairbairn, Andrew a.fairbairn@uq.edu.au*

*Hua, Quan (The Australian Nuclear Science & Technology Organisation) qhx@ansto.gov.au*

Very little is known of the extant woodland of the Bronze and Iron Age in Central Anatolia other than that revealed by regional pollen data and modern analogues. Today the region is a treeless steppe, a product of millennia of agricultural and pastoral use. Yet regional pollen data indicate a climax woodland cover consisting of open oak woodlands existed in the Bronze and Iron Age periods. This study utilises wood charcoal data of the site of Kaman-Kalehöyük in the heart of Central Anatolia to assess whether the local woodland surrounding the site matches that indicated by the pollen data during

the Bronze and Iron Ages and what, if any, changes in woodland composition occurred.

The results of wood charcoal identification and statistical analyses of over 24,000 fragments from 168 contexts are reported in this paper along with the first comprehensive absolute dating of the site. The results indicate both dramatic and more subtle and nuanced changes in the local woodland vegetation coincide with changes in occupation at the site. These changes in vegetation composition are chronologically tied to changes in land use and associated social changes including that of expansion in the use of land required for agricultural and pastoralist purposes. As both woodland and agriculture/pastoralism compete for space this research explores the issues around woodland resource management and woodland clearance for agricultural purposes.

54 pit (midden) contexts, 30 hearth contexts, 34 room fills and 50 in-situ construction contexts (posts, beams etc.). 24,000 wood charcoal fragments.

Taxa richness declines during the Late Bronze Age and into the Iron Age. A shift to pine occurs at the beginning of the Iron Age Oak is dominant throughout the sequence.

Possible detection of an anthracological signature for the Hittite occupation is detected.

## ORAL

### 11. FUEL USES IN CABEÇO DA AMOREIRA SHELLMIDDEN DURING THE MESOLITHIC: AN INSIGHT FROM CHARCOAL ANALYSES

Diogo Monteiro, Patrícia (ICArEHB Universidade do Algarve)  
patriciaadmonteiro@gmail.com

Bicho, Nuno (ICArEHB Universidade do Algarve) nbicho@ualg.pt

Zapata, Lydia (Universidad del País Vasco/Euskal Herriko Unibertsitatea) lydia.zapata@ehu.es

Cabeço da Amoreira is a shellmidden from the Mesolithic complex of Muge, Santarém, in central Portugal and dated to between c. 8000 and 7500 cal BP. The aim of this study is to provide an overview of the use of fuel, based on the evidence related to gathering of wood and production of fire at the site.

The previous studies provided a diverse set of archeological data allowing extended studies in different

areas of investigation (Ribeiro, 1884; Mendes Corrêa, 1933; Roche, 1972; Rolão et al. 2006; Wollstonecroft *et al*, 2006; Rocksandic, 2006). Since early times, evidence of charcoal has been noted, present most in burial reports. Only by Rolão's fieldwork charcoal had been properly recovered by flotation. Now, within a new research project by Bicho's new team, "The last hunter-gatherers in the Tagus valley", a new area of excavation in the shellmidden has provided new insights on Muge occupation, concerning the social complexity and subsistence of these populations (Bicho et al, 2010, 2011, 2012).

Its strategic location, in the estuarine basin of Tagus River and the access to inland resources, provided the exploitation of different natural resources, aquatic and from the surrounding forests.

The cultural processes related with fuel production are fundamental to understand the human selection and behavior towards the environment, the site organization and therefore the complexity of their economy and society (Piqué i Huerta, 1999).

Charcoal analyses from different contexts of Cabeço da Amoreira will provide an important insight on this matter, showing us the wood used for fuel and the variation of those uses diachronically and functionally.

Charcoal analyses began in 2011 allowing the taxonomic identification of more than 4000 charcoal fragments for Cabeço da Amoreira. The present paper will focus mainly in the burial contexts (Burial 2 and 3), hearths (shellmidden hearth and sand layer hearth) and pits. Other charcoal data, as well as palaeoenvironmental information will be taken into account to compare and discuss our results.

For anatomical identification was used the tree anatomy atlases (Shweingruber, 1990) and reference collection of modern charcoal. Some taphonomical observations were made that could be related with management of wood and fire, important to understand the fuel use within the site (Thery-Parisot et al, 2010).

The following *taxa* have been identified for Cabeço da Amoreira contexts: *Pinus pinaster*, *Pinus pinea/pinaster*, *Pinus tp. sylvestris*, *Pinus sp.*, *Quercus subg. Quercus*, *Quercus ilex/Q. coccifera*, *Quercus sp.*, *Arbutus unedo*, *Pistacia lentiscus*, *Salix sp.*, Monocotylodones, Indeterminate Gymnosperms and Angiosperms.

Preliminary results show us a clear predominance of pine suggesting that was the most used species to produce

fire. The results seem to point to a pattern combination of pine and oak wood to produce fire. Other minor *taxa* are present and have been used as fuel, but their relation with the burials needs further analyses to confirm a special use of these species. Taphonomical analyses have helped us to observe charcoal alterations that might indicate: 1) use of deadwood for fuel, 2) the use of wide calibre wood pieces.

---

ORAL

## 12. THE SELECTION OF FIREWOOD FOR DIFFERENT PURPOSES ? THE EXAMPLE OF MONTE MOZINHO (PORTUGAL)

*Costa Vaz, Filipe (CIBIO - Research Center in Biodiversity and Genetic Resources) filipe.mcvaz@gmail.com*

*Tereso, João Pedro (CIBIO - Research Center in Biodiversity and Genetic Resources) jptereso@gmail.com*

Located in the NW of Portugal, Monte Mozinho is a large roman settlement spanning over an area of 20 ha. Its occupation ranges from the beginning of the era until the late 5th century BC. Beginning in 2008, the excavation effort was centered in a new area – sector A-2008 – where several soil samples were collected in 3rd-4th centuries' levels, in order to obtain relevant archaeobotanical data. This communication focuses on the charcoal analysis carried out in four different combustion structures in this sector's compartment A and C.

Compartment A is a large rectangular space with a large stone slab used as a combustion place placed roughly in its center and a storage structure in its southernmost corner. 8 samples were recovered in this compartment in five different stratigraphic units. All but one was related to the stone slab. The other sample, collected in the NW corner of the compartment, was proved to have a different origin (see results). Compartment C is smaller and comprehends two distinct combustion structures: a large oven and a fireplace. The full content of the oven (16 samples) was recovered, while other five samples are related to the fireplace located in the compartment's easternmost corner. The sediment samples were processed through bucket flotation and the charcoal analysis was performed according to the standard methodology. Particular anatomical characteristics of the charcoal were also registered, such as radial cracks, vitrification, ring curvature, reaction wood and xylophages' galleries, among others.

In compartment A, *Castanea sativa* was the dominant species, followed at a great distance by *Quercus deciduous*, *Leguminosae* and *Populus*. In small numbers, several other taxa were identified such as *Erica spp.*, *Frangula alnus*, *Fraxinus*, *Prunus*, *Salix*, *Ulmus* and *Quercus evergreen*. The majority of the fragments analyzed in this compartment had weak ring curvature, indicating the preference of large and medium size wood pieces. In the northernmost corner, was identified a singular moment of combustion. Most of the charcoal collected was from *Pinus pinaster*, a species that was not identified anywhere else in the compartment. The results from compartment C relate to its structures. In comparison with the other compartment, despite the range of species remains roughly the same, its proportion, quantity and the anatomical characteristics of the charcoals were very different. This time, in the oven, *Leguminosae* fragments make up the majority of the analyzed charcoal, followed by the deciduous oak and chestnut. The remaining species show very limited numbers.

In Compartment C's oven it is clear the selective use of shrubby *Leguminosae* in comparison with the other analyzed structures. The architecture of the oven suggests it was used for food and ethnographic data demonstrates that *Leguminosae* was the preferred firewood for such usages. Additionally, the exclusive presence of cluster pine in a single context in Compartment A also demonstrates the selective use of firewood, although for unknown purposes. Hence, the results obtained made possible to verify different trends of usage of firewood depending on the structures and compartments where they were used.

POSTER

## AN APPROACH TO FUEL MANAGEMENT IN THE CONTEXT OF CENTRAL EBRO BASIN (NE SPAIN) DURING THE VIII-VII MILLENIUM CAL BC.

*Alcolea Gracia, Marta (University of Zaragoza) malcolea@unizar.es*

In this paper we present an approach to the study of fuel management by hunter-gatherer communities during the VIII-VII millenium cal BC in the central Ebro basin (NE Spain). The aim of this work is to value the influence of geographic and climate factors in the availability of firewood and their implications for human strategies

of fuel management. By this way, on the one hand, we propose a state of the current issue of anthracological studies for this territory and this chronology. On the other hand, we provide new data from four settlements with unpublished anthracological sequences located in different areas of this territory.

The object of study of this paper is charcoal remains from four mesolithic shelters: Forcas II (Graus, Huesca), Espanatalobos (Quicena, Huesca), Esplugón (Sabiñánigo, Huesca) and Arenal de Fonseca/Ángel I (Ladruñán, Teruel). The samples were recovered following different strategies for sampling and processing the sediment applied during excavation. For Forcas II, Peña 14 and Arenal de Fonseca/Ángel I charcoal remains were manually selected during excavation. For Espanatalobos and Esplugón we have processed whole sediment by flotation. For the anthracological analysis of charcoal we have used a metallurgical microscope that allows a magnification factors of 40 to 400 times. The anatomical patterns of each wood species are observed on three sections of wood. The botanical identification was possible comparing with anatomy atlases (Schweingruber, 1990; Vernet *et al.*, 2001) and current carbonized woods.

Conifers, especially pine, either in mediterranean (*Pinus halepensis*) in driest trend areas or mountain pines (*Pinus sylvestris/nigra*) in higher elevations, appear as the most widely fuel used at all archaeological layers studied. Consumption of *Quercus* sp. appears intermittently but always with very low percentages. The taxonomic diversity observed in the center of valley (*Acer* sp., *Pistacia* sp., *Fraxinus* sp., *Salix/Populus*, *Prunus* sp., *Buxus sempervirens*, *Rhmanus/Phillyrea*, *Rosmarinus officinalis*, *Leguminosae*, *Monocotiledoneae*) contrasts with the specific poverty in mountainous areas where we have only documented the consumption of pines and oaks.

The mesolithic is the last stage of an exclusively predatory economy based on hunting and gathering and also is a period of environmental change. The last hunter-gatherer communities in the Holocene period seem to use opportunistic strategies of fuel management and consume wood species in expansion. This work provides a picture of the surrounding vegetation to prehistoric settlements and relations between the hunter-gatherer communities and their environment in the context of central Ebro basin (NE Spain) during the VIII-VII millennium cal BC.

## POSTER

### PERSPECTIVES FOR THE STUDY OF FUEL AMONG EARLY PALEOLITHIC HUNTER-GATHERERS BASED ON EXAMPLES FROM THE NE OF IBERIA

Allué, Ethel (IPHES, Institut Català de Paleoecologia Humana i Evolució Social, C/ Marcel·lí Domingo s/n Campus Sescelades URV (Edifici W3), 43007-Tarragona, Spain, 2 Àrea de Prehistòria, Universitat Rovira i Virgili (URV), Av. Catalunya 35, 43002- Tarragona, Spain ) [eallue@iphes.cat](mailto:eallue@iphes.cat)

During prehistoric times humans undoubtedly used all available resources. However the interpretation of these resources as cultural records is impregnated sometimes with closed scientific conceptions. This might be the case in the study of fuel. Although fuel was one of the most important resources for people in the past, as it is at present its study is dispersed. Interest in understanding past fuels emerges from our interest in the study of humans and desire to set up a theoretical framework within which to approach research. Usually study of past human behaviour has focused on human evolution (palaeoanthropology), food remains and technological evolution. Obviously it is clear that fire (technology), culture (human) and nature (environment) interactions and time (evolution) are the ultimate objectives but the aim is to pursue them through fuel evidences. Most archaeological studies on fuel among hunter-gatherer's groups are isolated studies or studies about hearths with fire fuel having an insignificant role. Hence, it is only present day studies that show major interest in fuels with a focus on scarcity, deforestation or health. In the European territory during the Palaeolithic the most common fuel was probably wood; however other types of fuels might be also used due to scarcity of wood or for other specific purposes. The approaches for the study of fuel uses among hunter-gatherer's is mostly directed to the study of charcoal remains and based on anthracology and charcoal taphonomy. Fuel gathering as a major activity had an important role in daily activities and the determination of choices on site locations according to different strategies. In this study we present different examples to illustrate fuel gathering strategies according to different scales, cultural behaviours, wood properties and selection patterns. The sites under are located in different areas from the NE of Iberian Peninsula at altitudes from 900 m asl to the coast with a chronological frame between 60 to 30 kyr. BP. The Anthracological study show a homogeneous pattern related to the preference choice of wood among other possible fuels and this choice is determined by environmental constraints and the

characters of the species exploited. *Pinus sylvestris* type is the most recurrent species, present in 90% of the sites and values of this species are always the highest. The comparison, in some of the sites with burnt bone remains and grasses indicate the presence of other materials that might be forming part of the fuel; however the recurrence of wood clearly the most used fuel used.

In the frame of archaeological systematic surveys carried out at the Guéfait region (eastern Morocco) two isolated combustion structures were discovered at the Oued Za river bank. The erosion of the Upper Pleistocene terraces made it possible their discovery. Even if a part of them disappeared by fluvial post-depositional processes the good conservation of the remains made possible the whole excavation. They were dated by the C14 AMS method on charcoal remains around 4,000 (Cal BP). These two structures combustion were separate by four meters of distance and each one shows a different morphology

and type of construction. Both show important traces of fire impact, a single lithic tool and some snails associated to them.

An interdisciplinary program of analysis was developed on the archaeological remains in order to identify the specific use of each one of these structures: (1) charcoal, pollen and phytoliths analysis to identify the vegetal resources used as fuel and to reconstruct the environment, (2) malacological analysis to distinguish their possible anthropic origin and also to obtain palaeocological data, (3) mineralogical study performed by X-Ray diffraction and Fourier Transform Infrared Spectroscopy on sediments and on the stones used to structure the hearths in order to detect changes of composition induced by heating, temperatures and to identify fuel and materials burned, and lastly (4) spatial patterning and 3D reconstruction analysis to reconstruct the morphology of both structures specially the parts eroded by the fluvial post-depositional processes.

The preliminary results of the different approaches will be present in this paper to try to identify the fuel used, the activities carried out in them and to contextualize them into the frame of the cultural human activities developed in this geographic area during this chronological moment.

POSTER

**ZOOARCHAEOLOGY OF THE UPPER PALEOLITHIC SITE OF THE CUZOUL DE VERS: DISTINCTIVE SKELETAL PROFILES AND DIVERSITY OF BONE USE**

*Castel, Jean-Christophe (Muséum de Genève) jean-christophe.castel@ville-ge.ch*

The site of Cuzoul de Vers (Southwest of France) shows an exceptional stratigraphic sequence dated from the end of the Last Glacial Maximum and presenting Recent Solutrean and Badegoulian industries. About 30 archaeological levels were identified over a depth of three meters.

The preservation of faunal remains is excellent for the lower half and decrease thru the top. The faunal spectrum is dominated by the Reindeer, with generally some small ungulates (Chamois, Ibex) and more rarely bigger ones (Horse, Bison, Deer).

The first studies (Castel, 1999) showed an important percentage of identified burnt remains that indicate

a systematic use of the articular regions of the axial skeleton and limbs as secondary fuel. The precise identification of small fragments allowed a more precise reconstitution of the exploitation procedures than previously observed in Upper Paleolithic sites.

The bone assemblage shows other remarkable characteristics, notably associated with the production of bone industry and ornaments. Retouchers and needles are particularly abundant in the Badegoulian levels. The great abundance of incisors is also noteworthy. These elements lead to suspect that some identified secondary species sometimes don't have alimentary status although the identified remains don't show evidences of intentional modifications.

The zooarchaeological data of this site are a reference (i.e. Castel, Costamagno and Théry-Parisot works), but they have never been presented in an international symposium. They are nevertheless fundamental in the framework of discussions on the significance of skeletal profiles and on the real or suspected role played by prehistoric people concerning their origin.

POSTER

**A 25,000 YRS BP COMBUSTION STRUCTURE OF RIBEIRA DA PONTE DA PEDRA OPEN AIR SITE.**

Ferreira, Cristiana (Universidade de Trás-os-Montes e Alto Douro (UTAD-PT), Centro de Geociências - Grupo Quaternário e Pré-História (UC, Pt), IPHES, Institut Català de Paleoecologia Humana i Evolució Social (Tarragona, Esp) ferreira.cris.00@gmail.com

Cura, Sara (Museu de Arte Pré-Histórica de Mação) saracura0@gmail.com

Pierluigi Rosina - prosina@ipt.pt (Instituto Politécnico de Tomar)

Outside karst system, Upper Palaeolithic sites in Portugal are almost unknown. Particularly in Central Portugal, the few evidences are represented by rock art (Vale do Ocreza) and the open air site at Ribeira de Ponte da Pedra, where a combustion structure was recorded.

The combustion structure was found in/at a colluvium of Ribeira da Ponte da Pedra located in Vila Nova da Barquinha, Central Portugal. This archaeological site presents a long chronology, from ~300000 yrs. BP until ~25000 yrs. BP, located in a fluvial terraces system. The last deposition is represented by colluviums that

cover all the sequence with sediment, abundant lithic implements and burnt material dated at ~25000 Ka BP.

The combustion structure was formed by a sub-circular shape presenting burnt sediments and stone elements. No lithic implements were found in association with the combustion structure, the only exception is represented by a worked pebble. The sampling of the combustion structure has yielded charcoal remains that are the object of this study.

Although the taphonomic alteration of charcoal, results of the antracological analyses show the presence of *Erica sp.*, *Prunus* and *Pinus sp.*. This vegetation should characterize the pre-pleniglacial phase during final Gravettian, just before the HE2. These taxa were probably the wood used for fuel in the hearth.

This association is also described in other Portuguese archaeological contexts with the same chronology. Particularly, the presence of *Pinus pinaster* was described on the Gravettian archaeological site of Porto Marinho (Rio Maior) (Figueiral et al. 1995). These data suggest that in this area (in SW Europe) the presence of a diversity of trees and shrubs/tree cover determined the use of woody fuel, whereas in other areas other fuels such as bone are suggested to be complementary fuels.

---

POSTER

**LANDSCAPE PRACTICES AND THE EVERYDAY LIFE IN DOMESTIC SPACES: PERSPECTIVES FOR AN ARCHAEOLOGY OF FUEL AND FIREWOOD IN BRONZE AGE MALLORCA (BALEARIC ISLANDS)**

Picornell Gelabert, Llorenç (Universitat de les Illes Balears) tokelau24@gmail.com

Human societies obtain the material resources necessary for its development and reproduction from natural resources. This is one of the core elements in the establishment of the complex networks of interactions performed in socio-environmental systems. In this context, fuel constitutes a primary element, as it satisfies the energetic social demands. Since the very recent and partial generalization of fossil fuels, wood has been the main energetic resource for human groups. Firewood management and consumption is, thus, a central component of the organization of maintenance and subsistence activities of human societies, but it has to be understood from a contextual perspective that analyzes the relations between firewood practices and all the

other social and environmental elements that plays a role in the socio-environmental system.

This viewpoint points to the construction of a theoretical and methodological perspective that allows analyzing charcoal assemblages not as isolated datasets, but as the result of society-landscape/vegetation interactions performed in its ecological, social and historical backgrounds. In this sense, we propose to explore the perspectives for the study of firewood management and consumption among domestic groups of sedentary pastoralists and agriculturalist societies through the archaeological record. The main goal is to test a theoretical and methodological approach that allows the integration of firewood practices in the context of the economic organization of human groups and the development of the everyday maintenance activities carried out in domestic spaces.

On the one hand, firewood gathering has to be understood as a landscape practice integrated in the organization of the mobility, the sense of place and landscape and the organization of the economic activities of the group. On the other, firewood consumption in domestic structures has to be analyzed as a component of the everyday life related with the different household activities and the creation, use and abandonment of domestic spaces.

In order to discuss and test a theoretical and methodological approach that allows reaching such a contextual comprehension of firewood management and consumption in household organization, different examples from Bronze Age sites of the island of Mallorca (Balearic Islands) will be presented. During this period of the Balearic Prehistory particular domestic buildings were generalized, the so-called *navetiformes*, cyclopean, megalithic buildings with boat-shaped plant. These buildings constitute the material expression of the household groups and the domestic space. A diverse range of everyday, routine activities were organized around the *navetiformes*, which presents a complex organization of the different spaces. In two Bronze Age sites in Eastern Mallorca, Closos de ca'n Gaià and Hospitalet Vell, a systematic sampling strategy for the recovery of bio-archaeological materials have been applied and resulted in the availability of representative charcoal assemblages. The contextual analysis of such charcoal record allows analyzing the role of firewood management and consumption as landscape practices integrated in the structuring of household maintenance activities and the configuration of domestic space.

POSTER

### SELECTION OF WOOD FUELS IN THE SOUTH OF ÁLAVA (BASQUE COUNTRY, N IBERIA): ARCHAEO-BOTANICAL DATA

*Ruiz-Alonso, Mónica (CCHS, CSIC) moruizalonso@hotmail.com*

*Zapata, Lydia (Universidad del País Vasco) lydia.zapata@ehu.es*

*Pérez-Díaz, Sebastián (Université Toulouse-Le Mirail) sebas.perezdiaz@gmail.com*

*López-Sáez, José Antonio (CCHS, CSIC) joseantonio.lopez@cchs.csic.es*

*Fernández-Eraso, Javier (Universidad del País Vasco) javier.fernandeze@ehu.es*

Within the present situation of archaeological research in the Basque Country, archaeobotanical analyses (Plant macro remains, both wood and seeds, pollen and phytoliths) start to be a standard procedure. However, there are still few examples that combine all these archaeobotanical disciplines, not only in the Basque Country but also in nearby regions. However, an integrated approach of the different archaeobotanical analyses offers interesting possibilities. Even if they provide different types of information, they are complementary, an integrated approach being the ideal scenario.

This work presents different case studies from the Sierra de Cantabria (Province of Álava, Northern Iberia) with the aim of establishing the composition and evolution of the vegetation, the anthropic impact as well as the management and use of forest resources by prehistoric communities. The main results focus on three archaeological sites where different types of analyses can be discussed: the rock-shelters of Peña Larga, Peña Parda and San Cristóbal, which span a chronological sequence from the Neolithic to the Iron Age. Significant differences can be seen from what pollen analyses show and the way plant resources were used according to the analyses of plant macroremains –both, wood charcoal and seeds-. Pollen analyses point to a spread of deciduous forest dominated by hazel. However it is mostly deciduous oak that is used for fuel at the sites with a very limited presence of *Corylus*. Besides, from the Neolithic to the Chalcolithic yew wood is the most used wood whereas its presence in pollen data is extremely limited. Together with this, other dynamics can be discussed, such as Beech (*Fagus sylvatica*) that appears very clearly from the Bronze Age.

The remains of crops, wherever they have been found, are also present in these chronologies, both in pollen and plant macros, wild plants being also present.

All these questions will be discussed emphasizing the selection of specific woodland resources in the studied area, as well as the possibilities and limits of using different types of archaeobotanical evidence.

POSTER

**BURNING BONES ALONG PRE AND PROTOHISTORY.**

*Vidal, Aixa (Universidad Complutense de Madrid) aixa-vidal@gmail.com*

*Estaca Gómez, Verónica (Universidad Complutense de Madrid) vestacag@hotmail.com*

Amongst the myriad of fuels available for human use, the ones of a mineral origin have lately been the most appreciated, whereas firewood has traditionally been standard. However, several fuels derived from animals should not be neglected. Although their properties have some limitations regarding ignition and quick burning, their caloric value and omnipresence in all cultural developments are advantages which were surely not unknown to people in Pre and Protohistory.

Based on the specific properties of animal secondary products (particularly, bones, dung and grease) a diachronic discussion is proposed regarding the many different uses they could have been applied to. From the dawn of Humanity and the manipulation of fires for warmth to metallurgy activities in the Bronze Age, burnt and charred bones has been recorded and in some cases their presence could be link to heat producing processes.

In this sense, the discussion presented here is not case-specific but deals on the possibilities of these materials to satisfy human needs, including their use for heat, lighting, defence, building and crafts such as pottery, rock thermal alteration and wood-hardening. Thus, it aims at been comprehensive and cover most of the activities related to the need for fuel in early societies.

## 1. AROUND THE CATEGORY "PRESTIGE" AND THE ARCHAEOLOGY OF THE "SOCIAL COMPLEXITY" IN PREHISTORIC SOCIETIES.

*Pedraza Marín, Diego (Universitat Autònoma de Barcelona)  
diegopedraza.antropos@gmail.com*

Under the paradigms of neoevolucionism, cultural ecology, social functionalism and systemic approaches, since the middle of the last century, the study of the social evolution of societies has been enriched with new methodologies and categories of analysis, for example "social complexity", or the use of descriptive classificatory typologies of this social evolution. Ethnographers and archaeologists looked for evidence of "big men" or "chiefs", among others, who were associated with certain functions and social behaviors, as well as "prestige". We argue that it is necessary to analyze the epistemological and ideological implications of these approaches and categories in the scientific process of knowledge creation. We will also try to provide new perspectives of analysis from historical materialism and feminist studies, focusing on the category "prestige", which is understood as a social production.

ORAL

## 2. KINSHIP ORGANIZATION REFLECTED FROM THE SETTLEMENT OF THE XINGLONGWA CULTURE AT BAIYINCHANGHAN SITE

*Xiyun, Yu (Department of Archaeology School of History  
Wuhan University) yuxiyun@aliyun.com*

Baiyinchanghan site is located in Shuangjingdian town, Linxi County of Inner Mongolia, about 500 meters southwest of Baiyinchanghan village on the hills, and near the north bank of Xar Moron River. The settlement of the Xinlongwa Culture at this site consists of two separate living areas (A and B) surrounded by their own enclosure ditches and each living area has its own cemetery. The age of this settlement is cal.7000BP.

In this paper, the author mainly uses these materials which had already published. Like *Excavation brief report of Baiyinchanghan Neolithic site in Linxi County, Inner Mongolia* (1993), *Excavation brief report of Baiyinchanghan Neolithic site in Linxi County, Inner Mongolia in 1991* (2002). *Baiyinchanghan—Excavation report of the Neolithic site* (2004).

The author mainly adopts the method of settlement analysis to analyse the settlement patterns of Baiyinchanghan site and the method of analogy to make explanations.

Using indigenous villages like Kejara in Rio Vermelho valley of central Brazil in South America as an analogy, which is described as "a primitive culture society unaffected by the modern civilization" and "a strong bastion of indigenous cultures exist independently" settlements of bipartite structure like that of the Xinglongwa Culture at Baiyinchanghan site are reflections of moiety which is the same as phratry of Indians in North America in the nature of social organization. Drawing an analogy with ancient Chinese literature the kinship organization reflected in the settlement of the Xinglongwa Culture at Baiyinchanghan site should be "the surname family".

Settlements of bipartite structure like that of the Xinglongwa Culture at Baiyinchanghan site should be reflections of a village constituted by two stable intermarriage "surname family".

ORAL

## THE SOCIETY OF PRE-YANGSHAO PERIOD IN CHINA (7000BC--5000BC)

*Jinying Cai (Anyang Normal University) caijinying12@hotmail.com*

Pre-Yangshao period belongs to the early Neolithic age in China. Its radiocarbon dates range is 7000BC-5000BC. During this period, there were many cultures in China. The Peiligang culture, the Cishan culture, the Laoguantai culture and the Houli culture were distributed in the Yellow River Valley. The Pengtoushan culture and the Kuahuqiao culture were distributed in the Yangtze River Valley. The Xinglongwa culture was located in the northern region of China. Among those cultures, the Peiligang culture appeared to be the strongest. And the society began to be complicated at this time.

There were many sites and cemeteries excavated in every culture. In this paper, the author mainly uses these materials which had already published. Like *Peiligang Neolithic site in Xinzheng, Henan* (1978). *Excavation of Peiligang site in 1978* (1979). *Wuyang Jiahu* (1999). *Excavation report of Peiligang cultural relics in Tanghu site in 2007, Xinzheng City, Henan* (2010). *Excavation of Cishan Neolithic site in Hebei* (1977). *Cishan site in Wu'an, Hebei* (1981). *The first and second excavation report of Houli*

*site in Linzi, Shandong (1992). The third and fourth excavation report of Houli site in Linzi, Shandong (1994). Excavation report of Xiamengcun site in Bin County, Shaanxi (1960). Lijiacun Neolithic site in Xixiang, Shaanxi (1961). Pengtoushan and Basidang (2006). Excavation report of Xinglongwa site in Aohanqi, Neimenggu (1985). Excavation report of Baiyinchanghan Neolithic site in Linxi County, Neimenggu (1993).*

The research methods are mainly stratigraphy analysis, typology analysis and pedigree analysis. By using the stratigraphy analysis and typology analysis, we can understand the spatial and temporal distribution of each culture. And by using the pedigree analysis, we can analyze the relationships among those cultures.

The analysis shows that the Peiligang culture is the strongest among those cultures in Pre-Yangshao period. Combination of the stratigraphy and typology analysis, the Peiligang culture was divided into three phases. By using the pedigree analysis, the Peiligang culture originated from the Jiahu culture. Because of the early Cishan culture, the Jiahu culture transferred into the Peiligang culture. The Peiligang culture was influenced by the Houli culture in phase ?. It affected the Houli culture, the Cishan culture, the Xinglongwa culture, the Pengtoushan culture and the Laoguantai culture with varying degrees in phase ?. It had less control in phase ?.

During Pre-Yangshao period, the Peiligang culture played a very important role. It was the strongest among those cultures and it had a great impact on surrounding contemporary cultures with different degrees, especially on phase ?. The Peiligang culture were mainly distributed in the central plains region. It played an important role in the foundation of the Chinese Civilization development. Judging from the development of the Peiligang culture, we can say that the society began to be complicated at Pre-Yangshao period. Pre-Yangshao period, especially the Peiligang culture, was a key step in the process of social complexity.

ORAL

#### 4. CRAFT PRODUCTION AND SPECIALIZATION DURING THE THIRD MILLENNIUM IN THE SOUTHWEST OF IBERIAN PENINSULA

*Inácio, Nuno (University of Huelva) nuno.inacio@gmail.com  
Nocete, Francisco (University of Huelva) nocete@dhis1.uhu.es  
Bayona, Moisés R. (University of Huelva) moises.rodriquez@dhis1.uhu.es*

Since Gordon Childe that economic and craft specialization has been analyzed within the historical process that led to the emergence of the so-called "complex" societies. In the Iberian Peninsula, this topic has been preferably debated by technological paradigm, emphasizing the lack of economic and craft specialization during the Third Millennium BCE. In recent years, an intense research about the first specialized mining and metallurgy in southwestern Iberia, highlighting the theoretical and empirical limitations of the postulates based on sophistication or complexity technological criteria. This is the opportunity to discuss the economic and social models of metallurgical and ceramic production during the Third Millennium BCE.

ORAL

#### 5. SOCIAL COMPLEXITY IN THE THIRD MILLENNIUM BC IN SOUTHERN PORTUGAL

*Soares, Joaquina (MAEDS) cea.maeds@mail.telepac.pt*

The author proposes a complex tribal organization model for communities that inherited their social kinship structure from the megalithic societies, at the first half of the III millennium BC, in Southern Portugal. This social and economic model began to collapse in the second half of the same millennium, as a result of the development of the arsenical copper metallurgy (copper-arsenic alloys) and craft specialisation.

The control of metallurgy made it possible for the elites to legitimate the accumulation of the political power, and gave them a coercive capacity to impose an unequal and very hierarchical social structure based on chiefdom. This theoretical construction has been tested in the analysis of the settlement system at Triângulo da Luz (in the middle Guadiana valley), during the III millennium BC. The stratified social organization seems to be preceded by the chiefdom that raise in the second half of the III millennium BC and developed in the Bronze Age.

By the end of this period the chiefdom society reached its most complex structure. In opposition with other authors, that defend the emergence of the state in the III millennium BC with a centre based in the lower Guadalquivir region, this paper proposes that the state took place in the South of the Iberian Peninsula only at early Iron Age, in the context of the orientalising process.

## 6. MATERIAL VS. IMMATERIAL EVIDENCES OF INTERRELATIONS. POPULATION SIZE, MATING NETWORKS AND TECHNOLOGICAL TRANSFER IN SICILY DURING EARLY AND MIDDLE BRONZE AGE

*Cantisani, Matteo (UTAD) matteo.cantisani@gmail.com*

The evaluation of indigenous communities development in southern Italy, through the analysis of the dynamics of interaction with the eastern Mediterranean during the Bronze Age, is one of the most significant issues in the later prehistory for the central Mediterranean. A long tradition of studies (Vagnetti 1983; Peroni 1983; Bietti Sestieri 1985; Kilian 1983; Smith 1987; Jones et alii 2005) influenced by the world system theory and the concept of peer polity interaction, claimed a socio-economic interdependence in structuring indigenous socio-cultural complexity. The preliminary results of on-going research, here presented, provide a complementary perspective, focused on indigenous behavioral patterns' development in structuring socio-cultural complexity in Sicily, since the later early Bronze Age. Through the analyses of settlements and specific ceramic assemblages' as well as observations on exploitation of raw material sources, hypothesis on interaction patterns between local communities are suggested.

Typological analyses carried on RTV-style ceramic assemblage from Mursia, as well as other works, showed coexistence of different stylistic pottery assemblages within the same context, as in Serra del Palco di Milena (Palio 2006), Manfria (Orlandini 1960). Settlement/households spatial analyses have been personally conducted (e.g. Mursia). Other datasets concerning settlement dynamics have been acquired from well-preserved multiphase sites, as Muculufa, by bibliographical tool. Site catchment analysis using fixed-radii method (Higgs et alii 1967) permitted to identify presumably exploited raw material sources within the "exploitation territory".

Typological analysis results suggest interaction phenomena, especially in central-southern Sicily, on the base of co-occurrences of different pottery assemblages within the same site. Mursia datasets show Pantelleria has been involved (see also Secondo et alii 2011). Spatial analysis showed increasing complexity in organizing spaces both between households and within them. Population growth, even difficult to assess, can be proposed for such dynamics. Similarly, scholars hypothesized population growth trends both in Etna

district (Cultraro 1997) and in southern central Sicily at La Muculufa (McConnell and Bevan 1999) in the same chronological framework. On the other hand, buffering zone elaborations demonstrated that several sites could have had easy access to local raw material sources for pottery production.

Although population growth and ceramic assemblages suggest interaction patterns, site catchment analysis results do not appear to support this hypothesis. As provenance studies on pottery vessels from Ramacca district demonstrated, indeed, previously identified RTV-style imported objects were produced instead by using surrounding clay sources (Agodi et alii 2006). Taking into account population dynamics and typology results, this aporia can be solved by hypothesizing interactions involving not only objects but potters themselves and mating strategies. Type-groups variability in ceramic assemblages within the same site shall be interpreted as innovative products of "outlander" potters -likely married to local people- forced to deal with new exploitation strategies. In this perspective, technological changes in pottery production shall be useful to explain socio-cultural complexity by extrapolating behavioral patterns developments related to them, and linked to cultural transmission variability phenomena, affected by modes and contexts of technological transfer, interaction and population size dynamics.

## 7. DYNAMIC SOCIAL CHANGES IN THE BRONZE AGE SOCIETY OF SARDINIA (ITALY)

*Gradoli, Maria Giuseppina (PhD researcher in Ceramics Technology, School of Archaeology, University of Leicester (UK) ggradoli@yahoo.it*

The present work is based on my current PhD research 'Dynamic Social Changes and Identity. A petrological study of Bronze Age ceramics in Nuragic Sardinia' carried out with the aim of investigating the pattern of pottery production, consumption and exchange at an inter-site level on the one hand, and the complex sequence of social changes accompanying the appearance of megalithic towers (nuraghi) during the Middle Bronze Age (1600 BC) and their later complexity during the Recent and Final Bronze Age (around 1000 BC), on the other hand. Major phases of growing settlement complexity in a case-study area are studied in relation to 450 sherds of domestic pottery, looking deeper beneath their apparent 'static cultural homogeneity'

through continuity and change in technology with the help, when possible, of the historical data and the anthropological and ethnographic approaches.

In Sardinia since now, local practices of prehistoric ceramic production and consumption have largely remained understudied, or have only focused on stylistic attributes and their use in assessing a chronological typology. The methodology here used - analysing ceramic fabric variability among selected common vessel forms and domestic architectures - represents thus an innovation. After the adoption of a broad theoretical context, based on both the physical and the social sciences, the process of pottery manufacturing is studied under the petrographic microscope considering: 1) 'pottery fabric' or the arrangement, size, shape, frequency and composition of clay, minerals, and other materials added intentionally to improve the workability and firing performances of ceramic pastes; 2) the concept of 'chaîne opératoire' and its individual steps to reconstruct part or the whole sequence of technical, physical and mental actions performed by potters, starting from the way natural resources were acquired in the area, mixed together, fashioned and then physically transformed by the process of firing; 3) the 'raw material provenance analysis', using analytical and geological approaches, to establish whether the sampled vessels were produced using raw materials obtained from the investigated area or far away from it; 4) the 'experimental archaeology', that provides the opportunity to confirm potential hypothesis and conclusions with multiple trials and repeatable tests in a chemical/mineralogical laboratory and will be used for the reproduction of the ceramic pastes (according with the different proportion of mineral/rock inclusions and clays estimated under the microscope and their comparison with the archaeological ones under study).

The petrographic study, supported by the clay chemical/mineralogical analyses, is helping to investigate whether similar pottery manufacturing, especially during transitional periods, accompanied observable architectural changes. Moreover, the role of technology in shaping social structures, the micro-scale context of production, the cooperative process of vessel manufacture, the expression and passing down of practical knowledge, are being emphasized.

In Sardinia since now, ceramic studies have mainly focused on stylistic attributes and their use in assessing a chronological typology. Analysing ceramic fabric variability among selected common vessel forms and domestic architectures inform on the way mundane pottery were manufactured, used, exchanged or

circulated across the wide landscape through social networks.

ORAL

## 8. MIDDLE BRONZE AGE COMPLEXITY IN SOUTHERN PORTUGAL.

*Tavares da Silva, Carlos (MAEDS) maedscea@gmail.com*

The social inequalities of the Middle Bronze Age societies of Southern Portugal are the main objective of this paper.

The focus will be the funerary record from the second and third quarters of the II millennium cal BC; the social hierarchisation displayed on the burial material culture as well as on the architectural features will be analysed. In accordance to this archaeological evidence it is proposed a chiefdom social organization model. The improvement of the centralisation of the politic power generated a high capacity to rule over large territories, comprehending the Southwest of Iberian Peninsula.

The Bronze Age political structure could create common cultural trends throughout the provinces of Alentejo, Algarve, Badajoz and Cáceres, which can be read mostly in the ceramic style, metallurgical technology, funerary rituals, cemeteries architectures and engraved stone steles.

## 9. TECHNIQUE AND SOCIAL COMPLEXITY: DEVELOPMENT TRAJECTORIES OF PEASANT SOCIETIES WITH METALLURGY DURING THE BRONZE AGE OF WESTERN IBERIA.

*Senna-Martinez, João Carlos (Centro de Arqueologia (uni-arq) Universidade de Lisboa) smartinfl@ul.pt*

*Luis, Elsa (Centro de Arqueologia (uniarq) Universidade de Lisboa) elsavluis@gmail.com*

Metallurgical practice from the ancient peasant societies was for a long time perceived as a "motor" for social development. Such a perception revealed itself not only inaccurate but it must also be seen as largely varying according to geographical place and civilization characteristics.

Nevertheless, in ancient peasant societies technological development remains one of the most promising

indicators of the growing of social complexity even if such growth must always be analysed accordingly to regional constraints.

In what concerns the Iberian Peninsula, and particularly its western facade, first metallurgies seem to appear as consequence of socioeconomic developments leading to first social elites coming into being. The metallurgical products can then be perceived to fulfil the need to express social status, lacking real technomic significance. Development of metallurgical technologies and products will, nevertheless, accompany and interact with parallel developments in social complexity from the Chalcolithic to the Early Iron Age when, for the first time, metals seem to assume a technomic role.

Pastoralism, a way of life followed by many groups in the present day as well as in the past, has encompassed an extraordinary variety of relationships between animals and humans across time and space that have been an expression of social and territorial organisation.

Prehistoric pen accumulations in rockshelters and caves can provide rich evidence of pastoral practices from the Neolithic through to the Chalcolithic/Bronze period.

Given the specific cultural and environmental dynamics involved in the formation processes of these sites high-resolution analysis of sediments and particularly micromorphology, has become a remarkably reliable tool for the identification and characterisation of early livestock-keeping practices.

The objective of this paper is to characterise the stabling practices and the syn/postdepositional formation processes of sediments from Cova Gran de Santa Linya through a combination of microstratigraphical analyses, macroscopic observations and radiometric dating of the Late Neolithic-Chalcolithic/Bronze pen deposits recorded at the site.

Samples for sedimentological and micromorphological analyses and radiocarbon dating were collected from stabling accumulations and interspersed runoff sediments. The stratigraphic sequence was recorded using aerial photography and lithostratigraphic

descriptions of the sediment texture, structure and composition.

In the laboratory, bulk samples were sieved and subjected to XRD and the organic content were calculated.

Thin sections for micromorphological analysis were manufactured from hardened blocks of undisturbed sediments and observed with a petrographic microscope at magnifications between 10x and 400x using Plane Polarised Light (PPL), Crossed Polarised Light (XPL) and Oblique Incident Light (OIL) applying international standard terminology.

To obtain a chronometric record for the sequence points that were linked to stratigraphic markers that corresponded to the roof and the base of the pen accumulations were selected. When possible, samples for radiocarbon dating were collected adjacent to block samples for micromorphology to temporally correlate the microfacies identified.

Sedimentological and micromorphological data enabled characterisation of the formation processes of a sequence holding two superimposed stabling accumulations and interbedded runoff episodes between 5.050-4.620 calBP/3.320-2.720 calBP.

Penning of sheep/goats has been documented at the site, mainly in the form of completely and partially combusted residues.

Postdepositional physico-mechanical features as bio-reworked sediments, erosive contacts and traits of water circulation allow assessment of the patterns of occupation at the site and the palaeoenvironmental dynamics involved in the degree of preservation of the stratigraphical record.

This study confirms the cyclical stabling of ovicaprids in the rockshelter. Other activities, such as the repeated burning of residues, add to our understanding of pen management and the upkeep of pen deposits in the past. The topographic characteristics and extensive use of the site over a long period of time, along with contextual data from other cave sites in the South-Eastern Prepyrenees where pen deposits have also been documented, allow discussion of the role played by Cova Gran in the establishment of long distance transhumant herding between the Ebro Basin and the Pyrenees during the Prehistory.

The particular dynamis involved in the formation processes of prehistoric pen deposits documented in caves and rockshelters entails that interdisciplinary approaches coupling microstratigraphical and palaeobotanical analyses have the potential to provide highly reliable and detailed results regarding the activities carried out and the settlement patterns of the sites in their palaeoenvironmental context.

Investigation of stabling practices through interdisciplinary analyses addressing the study at microscopic level of sedimentary accumulations during the Chalcolithic period in the Iberian Peninsula have remained scarce or lacking until now. This paper presents the first results of the micromorphology, phytolith, charcoal and pollen analyses of the chalcolithic layers IV-VIII (4.470 ± 40 BP - 4.030 ± 40 BP) recorded at the site of San Cristóbal (Upper Ebro Basin, Spain).

Micromorphological data provide evidence of penning activities, management of waste material through fire and discontinuity in the occupation of the site.

Phytolith analysis indicates strong presence of grass-related phytoliths together with much weaker evidence of leaves and woody plant fragments, which have been documented through all the sequence investigated.

Charcoal analysis suggests a clear contrast in the plant remains preserved between the earliest and the later archaeological layers: layer VIII is mainly represented by Pine wood while Quercus genus overtakes in layer VII and becomes strongly predominant in layer V.

Assessment of microstratigraphical and palaeobotanical results within their broader archaeological and chronological context allow interpretation of the use of the space, management of residues, palaeoenvironment and occupation patterns of rockshelters in the Western Pyrenees area during the Chalcolithic period.

## 3. EL ABRIGO DE LA CASTAÑERA (OBREGÓN. VILLAESCUSA. CANTABRIA). A CATTLE STABLE?

*Vega Maeso, Cristina (Universidad de Cantabria) cvega-maeso@gmail.com*

*Carmona Ballester, Eduardo (Universidad de Burgos) educarmonaball@gmail.com*

*Sierra Sainz-Aja, Alejandro (Universidad de Cantabria) asierasainzaja@hotmail.com*

*Marín Arroyo, Ana Belén (Universidad de Cantabria) anabelen.marin@unican.es*

The work is aimed to describe the archaeological record site of El Abrigo de la Castañera. This site, situated in a little rock shelter, is known since the middle of the sixties and, after more than a decade, the site was excavated by a team of the "Sanz de Sautuola Archaeological Seminar". Since 2011 a team, headed by C. Vega-Maeso and E Carmona-Ballester, is working in this site and in its immediate surroundings, with the support of the Consejería de Cultura, Turismo y Deporte of the Cantabria Government.

Until now, we have conducted two sounding campaigns (2011-2012) and a regular excavation (2013) that covers an area of 10 m<sup>2</sup>. The excavation procedure has followed the stratigraphic principles enunciated by Harris and developed by Carandini. This method provides a well-defined sequence of events that have formed the site.

This is essential in sites like La Castañera' shelter with a complex stratigraphic sequence. Besides fieldwork, some

specific studies are been carried out in order to know better the people who lived and were buried within the shelter. One of them is focused on the faunal remains collected since 2011, which preliminary conclusions will be presented here.

This new research has demonstrated the existence of extraordinary of Bronze Age deposits, with funerary practices, and a Chalcolithic previous occupation with evidence of livestock corrals and living areas in the site. The Chalcolithic strata are formed by little lenses of gray or black ash rich in charcoal and organic matter. This kind of sedimentation is usual in caves or shelters that served as stables and where burning dung is a common practice, repeatedly done, to avoid parasites. Under these strata there are a hearth and some postholes that suggest a cabin was constructed. In consequence, a complex stratigraphic sequence is preserved. The preliminary results of the zooarchaeological study show that the cattle is the dominant species, followed by pig. One of the most remarkable results is the low representation of ovicaprines remains identified until now.

There is no doubt that site was used as stable during the Chalcolithic. The livestock composition is similar to what Sainz de Sautuola Seminar previously documented in their Chalcolithic level. Nevertheless, this is not an isolated case in the region, cattle were also very important during the Chalcolithic in the nearby Miron Cave, a site with a similar stratification to La Castañera. But, the high representation of cattle is not usual in the caves used as stable in the Iberian Peninsula, where is more common the ovicaprines. The research will resolve this matter and others such as livestock managing or the relationship between livestock and deposits formation.

ORAL

#### **4. PERINATAL OVICAPRINE REMAINS AND EVIDENCES OF SHEPHERDING ACTIVITIES IN ENCLOSURE CAVES. THE CASE OF EL MIRADOR CAVE (SIERRA DE ATAPUERCA, SPAIN).**

*Martín Rodríguez, Patricia (IPHES/URV) patrimr9@gmail.com  
García-González, Ricardo (Instituto Pirenaico de Ecología (IPE) rgarciag@ipe.csic.es*

During Early Holocene, some caves were used like livestock enclosures. In these archeological contexts, sheep and goat remains are very abundant and the study of their remains can help to reconstruct shepherding activities at these sites.

El Mirador cave (Sierra de Atapuerca, Burgos) was used like stable cave and present early Holocene succession with a high number of ovicaprine remains (NR: 1987).

This work reports the analysis of El Mirador cave ovicaprine remains, in particular, the study of perinatal postcranial bones and decidual fall teeth. The aim is to study shepherding practices developed inside the cave and to study their evolution during Neolithic and Bronze Age.

Firstly, we identified perinatal and decidual fall teeth. Fetal bones are difficult to distinguish from neonatal ones. For this reason we have employed three identification methods: comparative osteological collection of Raza Rasa Aragonesa (current domestic sheep breed), osteometric analysis of postcranial elements and different bone ontogeny sequences works.

When it was possible, we have distinguished sheep bones from goat ones. Results were interpreted by quantification units: number of identified specimens (NISP) and minimum number of individuals (MNI).

In total, perinatal individuals were identified in 26 levels. Fetal and neonatal individuals show shepherding practices inside the cave. El Mirador cave was used to enclose ovicaprine herds, at least during the last gestation weeks, births and the first month of life of the offspring.

Few decidual fall teeth were identified. These teeth usually falls in graze areas, while the herd graze or chew. Considering fall teeth shortage, El Mirador cave could be used like livestock enclosure each night but during the daylight livestock would be moved to outdoors graze areas.

Wood fodder is an important income of food for herds in agro-pastoral communities. It is usually grazed and some species are specially appreciated by goats or sheep. The identification of wood charcoal in archaeological contexts has been suggested as part of woody fodder to feed animals inside caves overall during winter periods. El Mirador cave has yielded a continuous sedimentary deposit of burnt sediments identified as "fumier" layers, corresponding to burnt sheep and goat dung. The study of the charcoal assemblage from El Mirador has been based on an anthracological traditional approach and a dendrological analysis. This multiapproach has permitted to characterize the charcoal assemblage. The anthracological analyses is based on the study of 3868 charcoal remains from 16 layers covering a chronological span from 7030 ±40 to 4760 ±40 yrs BP. Layers 6 to 24 correspond to the Neolithic whereas layers 3 and 4 correspond to the Bronze age. The results of the anthracological analyses show that oaks (evergreen and deciduous oaks) were the most used species along the sequences showing >60% in all layers. Other taxa were also present in low percentages *Pinus sylvestris* type, *Fraxinus*, *Corylus* among others showing a more humid environment. At the top of the sequence evergreen oaks show higher values, with lower values of *Fraxinus* and *Corylus* indicating an increase of aridity. Finally, *Fagus* and Fabaceae are only present in the Bronze Age layers. The dendrological analyses could be only applied to a small sample, as charcoal fragments are usually small and number of rings needed for the study is not always available. The results show that most of the analyzed samples show much curved growth rings and mean value of 6 to 10 rings. These results suggest that the used wood corresponds to young branches and tree rings rapid growth rhythm which might be indicating that trees have been pruned regularly. Both analyses suggest that oak was probably used for woody fodder and was burnt during the combustion process that was carried out repeatedly.

**6. PASTORAL PATHS AND THE HERDING WORLD: THE ROUTES OF THE SHEPHERDS FROM ANTIQUITY TO MODERN AGE ACROSS THE MOUNTAINS OF SICILY.**

---

*Forgia, Vincenza (Università di Palermo, R-Evolution) vincenza.forgia@gmail.com*  
*Vergès, Josep Maria (Universitat Rovira i Virgili, IPHES) jmverges@iphes.cat*  
*Ollé, Andreu (Universitat Rovira i Virgili, IPHES) aolle@iphes.cat*  
*Di Simone, Giovanni (Università di Ferrara) giovannidisimone86@gmail.com*

One of the topics of the Madonie research project is the origin and development of pastoralism in the island. The possibility to cross archaeological, archaeo-zoological and palaeobotanic record is giving an idea of the development of pastoralism since its establishment in Sicily and in its developing.

After years of field survey we are finally able to process the different types of data using a GIS platform, particularly useful in the computation of least-cost paths. Our attention is focusing over one particular topic: the possibility to virtually draw the local trails followed in prehistoric and historic times, by pastoral groups.

Traces of pastoral activity are scattered all around the mountains. They embrace:

- 1) caves or rock shelter used, or (more rarely) still in use by shepherds or as resting place for herds.
- 2) Modern "pagliai" with a single or multiple pens
- 3) Modern building of cheese making.

Caves, "pagliai" and pens offer the possibility to analyse the development of pastoralism in this part of the Island with a diachronic approach. Since the study of Brochier, Villa and Giacomarra, it was clear that pastoral sites of Madonie offered a good opportunity to study pastoralism traditions and way of life.

Our work is documenting, within all altimetric zone, every pastoral place indicated by aerial photography or historical and recent cartography, by toponomastic layer, by direct survey, dedicating a particular attention to still in use places, where it's possible to recognize also the human passage in the past, as in the case of caves, showing stratified deposits and/or polished walls or signs that recall pastoral uses.

The chronological and cultural grid we are documenting within one of the pastoral rock shelter, at Vallone Inferno, is giving us the possibilities to contextualize the territorial pattern.

## 7. INTERDISCIPLINARY STUDY ON THE HISTORY OF PASTORALISM ON LA GOMERA (CANARY ISLANDS, SPAIN): ARCHAEOLOGICAL SOUNDS

*Hernández-Marrero, Juan Carlos (Museo Arqueológico de La Gomera (Cabildo Insular de La Gomera) museoarqueologico@lagomera.es*

*Navarro-Mederos, Juan Francisco (UDI de Prehistoria, Arqueología e Historia Antigua. Universidad de La Laguna) jnavarro@ull.edu.es*

*Trujillo-Mora, José Miguel (Museo Arqueológico de La Gomera (Cabildo Insular de La Gomera) josemigueltrujillo@gmail.com*

*Jeannine Cancel, Sandra (Servicios Integrales de Patrimonio Histórico SL.) dsaanr@yahoo.es*

The present study is aimed at charting the historical development of pastoralism on the island of La Gomera (Canary Islands), from prehistoric times through to the present, from socio-economic, cultural and territorial perspectives.

This project allows for the interplay of three different subject areas: ethnography, documental history and archaeology. This overlap of historical research allows for significant areas of existing demand to be covered, not only from the purely historical perspective but also from the viewpoint of cultural heritage management.

In particular, archaeological research is aimed at a deeper perception of the problems of management, transformation and consumption of livestock and derived products from prehistoric times. We should, thus, be able to respond to the question: ¿How can archaeology traces data that derive from this activity? So it was proposed to study the habitat caves which are significant since, to date, there are no studies on these archaeological contexts on the island.

Other kind of work relating to the aim of the project, and approached from varying perspectives, include: the zooarchaeological analysis, above all, the remains of domestic fauna such as goats, sheep, pigs and dogs; archaeological survey and territorial analysis of husbandry to reconstruct bridel paths and grazing grounds; paleodiet studies, archaeoastronomical research and studies relating to symbolic sphere, as funeral and sacrificial places.

The initial difficulties encountered when excavating was to locate caves that had not been subject to

serious transformation and yet were easily accessible for an extensive study, given the natural and historic characteristics of the island. The constant use of caves through to our present times has caused a marked lack of archaeosedimentary matrices that have not undergone substantial perturbation and, to a much more marked extent, the extreme scarcity of powerful stratigraphic records. Therefore, we decided to carry out a first wave of sounds previous to extensive excavation which is still pending. The pre-excavations were spread over four campaigns (2009 and 2010) with thirteen sounds or probes carried out over eight archaeological sites in cave, distributed over the whole of the island of La Gomera.

The results were much more than what had been initially expected, since six of the sites offered fine perspectives for extensive excavation. Sedimentary samples were taken from the same together with archaeological material which, as yet, has not been duly registered and far less stratigraphically referenced. There were many outstanding examples of sheep and goat coprolites plus bone remains of domestic fauna and organic matter which may have formed part of the manure which is typical of barns and pens. Likewise, there were elements that seemed to have been common to cave settlements such as vertical and horizontal post holes.

One of the sites of greatest interest for an extensive excavation is the area formed by the site Las Cuevas de Herrera González (Vallehermoso), where we have located an important stratigraphic package that dates from prehistoric times through to the period of contact between the natives of the island and europeans at the end of the XVth century.

Burnt anthropogenic cave sediments of holocene age (fumiers) represent a great source of data to reconstruct agro-pastoral human occupations since the Neolithic, mainly in the Mediterranean area. The diversity of techniques applied to their study is allowing the compilation of valuable archaeological, environmental and chronological data about these prehistoric communities. The particular succession of burnt levels at these sites (ash – carbonaceous couplets), well-preserved in more or less continuous sequences and usually well-dated, is proposed as a suitable context for archaeomagnetic studies. The information that can be obtained has both geophysical and archaeological interest. Archaeomagnetism is mainly known as a dating method. It is based on the small (few degrees) directional and intensity variations undergone by the Earth's magnetic field at regional scale (palaeosecular variation, PSV) and also on the ability of burnt archaeological materials to record such variations during heating through the acquisition of a thermoremanence (TRM). However, it also has many other applications of archaeological interest such as determination of palaeotemperatures, reconstruction of environmental conditions during burning (e.g.: type of atmosphere) or evaluation of post-depositional processes in burnt materials, among others. Here we report different examples of these applications from our research in anthropogenic cave sequences.

First, we present the results obtained from the study of multiple burnt levels at three caves from Northern Iberia, reporting 26 new archaeomagnetic directions ranging from ~ 5.500 to 2.000 yr BC. These data represent the oldest archaeomagnetic directions currently existing in Western Europe. Their combination with Mid-Holocene Eastern European archaeomagnetic records has allowed the design of the first directional European PSV curve, thus extending back-in time the use of archaeomagnetism as a dating method until Neolithic times. Dating

resolution of this curve reaches precision comparable to radiocarbon, making it a tool of great interest for the archaeological community. Second, a case-study about the application of archaeomagnetism as a tool to assess post-depositional mechanical processes in cave fires is shown from two burning events at El Mirador Cave (Sierra de Atapuerca, Burgos). Finally, it will be shown how the identification of maximum unblocking temperatures ( $T_{UB}$ ) of partial thermoremanences (p-TRM) can be used as a method to estimate the last heating temperature undergone by burnt archaeological materials. Despite its versatility, archaeomagnetism has barely been explored to study burnt anthropogenic cave sequences and this contribution aims to show its applications and limits to the study of this type of contexts.

The obtaining of referential data from present day herders is the basis to contribute to the correct interpretations of archeological records from prehistoric livestock spaces. In February 2014, we have started an experimental program in a fold where a herd is kept for the cleaning of the undergrowth in the frame of a fire prevention control program at Parc Natural d'Interès Nacional de Poblet (Tarragona). This herd was selected because, concerning its management, is similar to those from prehistoric periods and it is not fed with any other supplementary food as industrial fodder. The herd is mainly composed by goats with a small quantity of sheep. The herd is kept in the enclosure which is attached to a rocky wall, and has a roof and an open-air area, which provides contextual variability for this case study. The protected area is limited by walls and is covered with a roof and a small natural rock-shelter. In the frame of the experimental project we have agreed not to clean up the excrements, as we are burning them periodically with the aim to reproduce the management observed in the prehistoric folds. One of the main aspects of this research are the botanical studies with the aim of documenting the representativeness of the botanical content of these dung deposits in relation to the surrounding vegetal cover and the pasture areas. For this, we are developing a vegetation catalog of the pasture areas and the nearby surroundings, then we study the herd choices and we record the actual pollen deposition in the different areas of the shelter. Afterward, we aim to compare this data with the results of the dung analysis in relation to the presence of different plant species and their percentages in relation to the ones in the environment.

Another objective is related to the formation processes of the deposit. With this aim, we are documenting the increase of the total excrement deposition and by activity areas in relation to the number of animals and the time the herd is inside the enclosure. The periodical burning of the excrement permits also to estimate the volume reduction due to this activity, and the temperature and chromatic changes. We are carrying out periodical samplings to characterize different aspects of the deposits using micromorphology related with season or activity changes. In the frame of the formation processes we are studying the horizontal and vertical movements related to the fold activity of different materials (lithic tools, ceramic, bones, etc.). Furthermore we are studying the taphonomy of the natural and cultural materials of the deposit. Also, in relation to the burning activity of the excrement, we are sampling the combustion episodes to obtain data to contextualize the data obtained by the archeomagnetic studies. Finally we are documenting the development of polish of the rock produced by the herd. In this communication we are presenting the methodology and the experimental protocols used in the designing and control of the experimental program and the results obtained during the firsts months of development.

**1. LJUBI EVA CAVE (CROATIA, ISTRIA): EXCAVATIONS 2008-2011**

*Percan, Tihomir (Croatian Conservation Institute) tpercan@h-r-z.hr*

*Plestina, Ivica (Croatian Conservation Institute) iplestina@h-r-z.hr*

*Jerbic Percan, Katarina (Archaeological museum of Istria, Pula) katarina.jerbic@gmail.com*

Due to its exceptional geographical position on the crossroads of ancient paths, the Istrian Peninsula was an important link between east, west, north and south ever since the prehistoric times. The Ljubi eva cave is situated in southern Istria (Croatia) near the village Marana and only 15 kilometres east of Pula, the peninsula's largest city. The cave itself is positioned on the bottom of a large sinkhole, making itself almost unnoticeable in the peaceful landscape. Sinkholes are very common in a karst region such as Istria. In the area around the Ljubieva cave there are many other recorded caves and pits. One of the most important Late Paleolithic sites in the northern Adriatic, the Šandalja cave, is also situated nearby.

Since 2008 to 2011 archaeological excavations were carried out in cooperation between Musée d'Anthropologie préhistorique de Monaco (Principality of Monaco) and The Croatian Conservation Institute (Croatia). Four trenches were excavated: two in the deepest part of the cave (inside of a pit), one in the largest hall and another in a smaller room (Room 2, trench B). The surface of this trench was ultimately 10 m<sup>2</sup>. The entire excavated sediment was carried to a secondary location where the water sieving and flotation were carried out. The large and small fractions were later analysed in a laboratory. The reason for this rather complicated chain of actions was the cave's very moist and wet sediment and the lack of daylight, making it very difficult to notice all the findings. Measurements and other usual archaeological recordings were taken to those artefacts that we were able to find on site.

Using these methods, we collected and analyzed a large number of valuable data related to nutrition, husbandry and lifestyle. These analyses were executed by a range of scientific experts like archaeologists, geologists, zooarchaeologists, speleologists. By collecting all the scientific research, we were able to reconstruct that the cave was continuously in use from Late Paleolithic (Epigravettian) until the Bronze age. This thesis was confirmed with radiocarbon dates (C14) and the archaeological material that can typologically be placed in the mentioned periods. Recorded findings, specially ones from the Neolithic period, implied that some activity connected to husbandry was held in the cave. Different kind of seeds and nuts were found, as well as a grindstone with a pestle which was used for processing the grains.

These findings are showing that in the Neolithic period the fields around the cave were used for husbandry and that was one of the most important food sources for the people that were inhabiting the Ljubieva cave and nearby caves. By continuing with a variety of different scientific approaches and with future researches, this site has the potential to become one of the significant reference sites for the Epigravettian and Neolithic period of Northern Adriatic.

**2. VESSELS OF THE SHEPHERDS: THE NEOLITHIC POTTERY SEQUENCE AT EL MIRADOR CAVE (SIERRA DE ATAPUERCA, SPAIN) C. 6300 - 4760 BP**

*Oms Arias, F. Xavier (SERP Universitat de Barcelona) xaviroms@gmail.com*

*Marsal, Roser roser.marsal89@gmail.com*  
*Moral, Sergio sergiomoral@hotmail.com*  
*Fontanals, Marta (IPHES) mfontanals@iphes.cat*  
*Vergès, Josep M. (IPHES) jmverges@iphes.cat*

El Mirador cave has a sequence comprising the Early Neolithic period to the Bronze age. Most of this wide occupation was dedicated to the livestock keeping. In this work we will focus on analyzing the ceramic Neolithic equipping of the site (MIR6 to MIR23) with a double aim: (a) to determine the type and measurement of ceramic vessels to establish functional possibilities and (b) to initiate the decorative-formal study of the remains to establish a cultural affiliation of each chronological phase.

The whole of the pottery record (c.2300 fragments) has been analyzed to establish the minimum number of vessels (plain and decorated). From a macroscopic analysis, type of finished, mineral inclusions and cooking have been studied. Furthermore decorative matrices of the available sample have been analyzed.

Greater number of ceramic vessels have been observed in the layers of Early Neolithic and Late Neolithic than the intermediate phase. Also subtle differences in the volumes between the phases and morphologies have been observed. This would imply the possibility that the occupations had unequal intensities and at the same time the duration was also different.

In turn, the decorations are documented mostly in the earliest levels, while they are anecdotal from the Middle Neolithic. This fact indicates that the same tendency is followed in the peninsular Neolithic than the center of the Iberian Peninsular sites.

Rodríguez, Anna (IPHES, Institut Català de Paleoecologia Humana i Evolució Social, C/ Marcel·lí Domingo s/n Campus Sescelades URV (Edifici W3), 43007-Tarragona, Spain ) an.rodriguez.cruz@gmail.com

Plant macroremains including charcoal, fruits and seeds from El Mirador contribute to the study of different aspects related to human groups using the cave. The study of the plant assemblage contributes to uses of this type of evidence that were probably related to different activities. Food, fuel and fodder are the main uses of plant evidences identified at El Mirador. For the study all sediments recovered during the field work were sieved using a flotation machine or bucket flotation using 4, 2 and 0,5 mm meshes. Between 166 and 0,5 liters per sample were floated since 1999 when we first started the excavation. The anthracological study is based on the identification of 3868 charcoal remains from 16 layers (MIR3 to MIR24). The study of seeds and fruits are based on a sample from square Q22 including layers from MIR6 to MIR24. A total of 2061 remains were recovered. The anthracological results shows a continuous sequence where oaks are dominant along the deposit. At the bottom of the sequence the assemblage show more important values of humid environments such as deciduous oaks, *Fraxinus*, *Corylus*, *Cornus* as well as *Pinus sylvestris* type. At the top of the sequence evergreen oaks had more significant values and there is a decrease of *Fraxinus* and *Corylus*. According to the seed and fruit analyses results the most significant crops are *Triticum aestivum/durum* and *Triticum diccocom*; other taxa such as *Avena*, *Hordeum*, *Pisum* and *Vicia* are also present. Overall at the bottom of the sequence there is an important number of rachis and the spikelet forks remains mostly related to crop threshing activities. Synanthropic vegetal species (adventives and ruderals) are also abundant along the sequence. Finally, fruit seeds such as *Cornus*, *Rubus*, *Quercus*, *Prunus* and *Sambucus* are also present in low values. These results suggest that crop fields were probably close to the site and, in some cases, activities related to harvesting and crop processing were developed in the cave. According to this data and taking into account pollen and phytolith records, the landscape at the surrounding areas was a mosaic of woody areas, crop fields and open prairies. Along the sequence there are no critical changes, however charcoal data show a decrease of humid environment taxa and an increase of aridity along the sequence. This would be related to environmental variation that might occur along the mid-Holocene. The increase of the intensity of anthropic activity could be affecting landscape changes.

The uppermost layers of El Mirador Cave infilling are formed by a succession of burnt dung accumulations. Dung was accumulated during the Neolithic and Bronze Age (6320 ±50 to 3040 ±40 BP) when the cave was used as a pen and the dung was periodically burned for hygienic reasons. These activities produced an exceptional accumulation of vegetal microremains, including phytoliths, pollen and non-pollen palynomorphs.

The detailed sampling strategy and high resolution analyses allowed us to reconstruct formation processes, human activities, palaeoecology and the nearby landscape of the site through vegetal microremains.

Both disciplines palynology and phytolith analysis agree with the anthropic origin of the deposit and with the landscape degradation related with the development of pastoralism and agricultural practices.

The archaeological site of *El Mirador* is located in the southern slope of the *Sierra de Atapuerca*. The works developed at the site are providing a substantial set of data from the Upper Palaeolithic and Early Neolithic to the Middle Bronze Age. Throughout these at least about 4000 years of occupations, the cave was used for various activities, among burial, habitation and animal stalling. The practices related with this last use is at the moment, the main origin of the archaeological deposit, mainly composed by burnt animal dung with vegetal, potsherds, lithic and faunal remains. Also it is characterized by elevated high sedimentation rate that has enabled an individual and clear record of different episodes, providing a high chronological resolution data. Due to these particularities, we have developed a specific methodology of excavation and interdisciplinary study of the archaeological data in order to understand the genesis of this archaeological sequence and, at the same time provide information about the introduction and development of the production economy in the *submeseta norte* region.

Since the work of Brochier, Villa & Giacomarra (JAA 1992) the use of caves and rock shelters, for pastoral purpose, in this area of Sicily since antiquity, has been attested, but the attention of the mentioned study focused mainly on recent and subrecent deposits and the lack of an archaeological record within the sites presented, reduces the impact of it, with respect to our investigation, despite an accurate sedimentological analysis. Today we want to present and discuss the results of an interdisciplinary investigation of a site that, up to date, is the first pastoral settlement of the area covering the entire history of pastoralism development, from Neolithic to modern age (with some gap, of course) in one of the main Mediterranean islands: Sicily. Our research documents the born and the development of pastoralism from different point of view: chronological, technical and cultural.

We are documenting the interest for a mountain range, dating back to Neolithic until present. The site shows a stratigraphy that embraces the whole Holocene. The deposit was covered by a subactual level of use, with a modern pastoral pen and goes back to Neolithic, crossing medieval, late roman, middle and early Bronze age levels.

Up to date, actually, Vallone Inferno rock shelter and the Neolithic painted pottery found here represent the first stage of a constant and uninterrupted mountain exploitation (mainly for pastoral purpose, we suggest) opening this extreme range to human peopling from all over the region. Even if the rock shelter is sited in a mountainous context, the place is opened directly on one of the main fluvial valley of the Island – the Himera river valley, connecting, with the Southern Himera river, the Northern coast of Sicily to the inner and Southern part of the region.

This geographical feature and the altitude reached by these mountains, the only real mountains (except Mt. Etna) of the Island, are the more probable explanations for

the presence in the site of cultural element coming from all over Sicily, especially during recent prehistory, when the pastoral activity probably involved both horizontal (North-South and East-West) and vertical (from valley to the top of the mountains) shifts of livestock. Our speech aims to show a detailed report of an interdisciplinary analysis, as knew by the ongoing excavation, with particular attention to the dynamics of formation of the archaeological deposit and to the technical choices linked to the pastoral activity we can interpret by data of anthropic and natural derivation, originating by different chrono-cultural stages. Vallone Inferno rockshelter is a rare place where herding activity and its socio-cultural features can be seen in their evolution from the first stage of Holocene until contemporary days, that's a unique chance! Our attention will be focused on seasonality of the site (suggested from analysis of carpological remains), cultural provenance of herding groups (with some implication for regional culture and economy development), technical choices resulting by intra-site spatial analysis at a diachronic level of investigation, especially of pens and areas or levels of burnt manure.

**7. POLISHED WALLS: INDIRECT EVIDENCES OF USE OF CAVITIES AND STONE CONSTRUCTIONS AS LIVESTOCK FOLDS**

*Vergès, Josep Maria (IPHES: Institut Català de Paleoecologia Humana i Evolució Social. C/ Marcel·li Domingo, s/n, 43007, Tarragona, Spain. URV: Àrea de Prehistòria, Facultat de Lletres, Universitat Rovira i Virgili. Av. Catalunya, 35, 43002, Tarragona, Spain.) jmverges@iphes.cat*

*Morales, Juan Ignacio (IPHES: Institut Català de Paleoecologia Humana i Evolució Social. C/ Marcel·li Domingo, s/n, 43007, Tarragona, Spain. URV: Àrea de Prehistòria, Facultat de Lletres, Universitat Rovira i Virgili. Av. Catalunya, 35, 43002, Tarragona, Spain.) jmorales@iphes.cat*

In prehistoric caves or shelters used as a livestock folds, flock uses to scrape continuously against the rocky walls generating, in many cases, wide polished surfaces. The polish development degree and its distribution depend on the size of the flock, the animal species variety, the time spent on the fold, the wall topography or the rock lithology among others.

The study of this kind of evidences derived from the uses of caves as folds could provide us relevant information about the place history, especially in those cases where the sedimentary filling related with the livestock activities

has not been preserved. Sometimes cave sediments are not preserved, either by natural causes or anthropic interventions, but normally walls are always remaining. In this work we present historical and ethnographic observation used to characterize this kind of rock polishes, and subsequently we use this information to hypothesize about the absence of the sedimentary record of the most recent occupation episodes of Cueva de El Mirador site (Atapuerca, Burgos).

---

POSTER

**8. BONE ALTERATIONS IN FUMIERS: EXPERIMENTAL APPROACH AND ARCHAEOLOGICAL USE**

*Martín Rodríguez, Patricia (IPHES/URV) patrimr9@gmail.com*

*Vergès, Josep Maria (IPHES/URV) jmverges@iphes.cat*

Dung and vegetal remains burning was an usual practice in Early Holocene stabling caves. By burning the caves were cleaned from parasites due to livestock penning. El Mirador cave (Sierra de Atapuerca, Burgos) is one example of this sort of sites and present an important Neolithic and Bronze Age archaeological succession of stabling burnt layers with abundant faunal remains.

The first aim of this work is to analyze the alterations that this burning process causes in the macromammal bones, buried in the dung. Another point of interest is to observe the relationship between these bones and its archaeological context. Finally, experimental results were compared with El Mirador cave archaeological patterns.

With this purpose, we have developed two experimental works that consisted in goat's dung piles burning. Different bone fragments were introduced into these dung piles, placed to different layers. Bone fragments were from different sheep, goat and pig skeletons and presented different treatments: fresh, dry and boiled bones.

Experimental resulting sample was analyzed macroscopically and microscopically, following the same methodology used in archaeological sample analysis. Finally, experimental and archaeological results were compared.

We observed different burning, color and fragmentation stages on bone surfaces. These different stages were dependent on three variables: previous bone treatment, bone positioning into the dung pile and dung features. Bone burning stage is directly linked with dung burning stage. Nevertheless, in El Mirador cave, we observed that

non burned bones located in non thermal altered "facies" and just like the inverse pattern. These observations let us to set out different interpretations:

- Burned bones, located in non burned layers, could be interpreted like cooking process remains.
- Non burned bones, located in burned layers, could be the result of movements of the remains, caused by herd trampling or by the dung pile volume loss, produced during the burning process.

This is a preliminary study that precedes futures experimental works that consider other new variants.

---

POSTER

**9. EARLY TO MIDDLE HOLOCENE SHELTER DEPOSITS IN NORTHERN MOROCCO ? A MICROSCOPIC PERSPECTIVE**

*Kehl, Martin (Institute of Geography, University of Cologne) kehl@uni-koeln.de*

*Linstädter, Jörg (Institute of Prehistoric Archaeology, University of Cologne) joerg.linstaedter@uni-koeln.de*

*Weniger, Gerd-Christian (Neanderthal Museum) weniger@neanderthal.de*

The transition from hunter-gatherers to early food producing communities in Northwestern Africa is documented in few archaeological sites. Recently the sediment sequence of Ifri Oudadane gave insights into Late Epipalaeolithic/Early Neolithic occupations at the Moroccan coast documenting the onset of livestock penning in the area (e.g., Linstädter and Kehl 2012). New excavations at the rock shelter of Ifri N'etsedda yield information on contemporaneous occupations in the Moroccan hinterland. We here present results of micromorphological investigations on both sequences, which shed light on mineral and organic constituents of the sediment sequence, as well as processes of sediment formation and post-depositional alteration. This information should help elucidating the usage of these rock shelters and subsistence practices during the early to middle Holocene.

Undisturbed sediment samples were extracted from selected profiles of both sequences and thin sections of 6 cm x 8 cm prepared. Micromorphological analyses included standard procedures using a petrographic microscope. A thin section reference collection of herbivore dung from Northern Africa was prepared to improve identification of different dung types.

Subsistence practices at the coast included the consumption of sea mollusks as documented in abundant seashell fragments, local occurrences of external skeletons of diatoms and bryozoans as well as the penning of ovicaprids proved by the presence of dung pellets including calcite spherulites. At Ifri N'Etsedda, land snails were the dominant part of the diet, whereas evidence for animal husbandry in the shelter is sparse and remains of marine mollusks are generally lacking. At both sides, the degree of compaction of the shell-rich deposits and shell preservation vary considerably, indicating differential intensities of trampling and the presence of living floors or dumping of shells in small heaps. Gypsum precipitates at Ifri Oudadane probably relate to import of sulfate by sea-spray.

Micromorphology facilitates the identification of stratigraphic boundaries as well as the types, source and nature of sedimentary components and supports the findings of palaeobotanical and faunistic analyses. The shelters document diachronic and regional differences in subsistence strategies and land use in coastal and interior areas of Northeastern Morocco. While mollusks were important dietary components in both areas, the penning of animals could be testified for the coastal area only.

**1. GOPHER AND BARKAI: QESEM CAVE IN RETROSPECT ? A SHORT SUMMARY (OPENING THE SESSION)**

*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*  
*Barkai, Ran (Tel Aviv University) barkaran@post.tau.ac.il*

Qesem Cave is a Middle Pleistocene site in Israel dated to 420,000-200,000 kya (Barkai et al. 2003; Gopher et al. 2010) and assigned to the Acheulo-Yabrudian Cultural Complex (AYCC) of the late Lower Paleolithic. The cave reveals a rich and well-preserved array of lithic and faunal remains as well as human teeth. It provides a good context in which to test hypotheses concerning the intriguing liaison between the environment, culture, and biology. We summarize our research in the cave suggesting that the unique cultural transformation seen at Qesem Cave might actually be related to local human evolutionary processes and the appearance of a new hominin lineage.

The 9.5 m stratigraphy of Qesem Cave offers a detailed background of sediment deposition that occurred as the karstic chamber cave was aging. The AYCC is a unique, local cultural entity clearly differing from the preceding Acheulian and the preceding Mousterian. It shows a suite of innovative behaviors including: the habitual use of fire; hearth-centered activities and functionally distinct activity areas; sophisticated raw material acquisition (flint quarrying); intensive and systematic blade production employing an innovative, and thoughtful technology involving meticulous raw material selection; a noticeable presence of 'ahead of their time' Quina scrapers; and intensive flint recycling activities.

The faunal *chain* indicates cooperative hunting targeted mainly at prime age fallow deer followed by transportation of selected body parts to the cave after which was conducted on-site butchering by use of a tool kit comprising blades and small recycled flakes before eventual consumption. Patterns of cut marks seem to indicate unique habits of on-site butchering and meat sharing.

The study of human dental remains concluded that these mostly resemble the Skhul-Qafzeh samples of the Middle Paleolithic Levant while a *Homo erectus* assignment is clearly not tenable (Hershkovitz et al. 2011). Assuming this is the case, two questions arise – why did this evolution

occur in the Levant, and why ca. 420 kya ago. Based on a newly developed bio-energetic model conjoined with the cultural developments demonstrated at Qesem Cave, we offer an explanation accounting for the demise of *Homo erectus* and the appearance of a new hominin lineage some 400 kya (Ben Dor et al. 2011). The model suggests that the disappearance of elephants from the human diet around this time triggered selection in favor of those who were better adapted to the hunting of larger numbers of smaller, faster animals. Consistent with a recent evolutionary model concerning Pleistocene human populations of Europe, the Levant appears to be a Central Area of Dispersals of Eurasia, an "origin region" for human species biodiversity (Bermúdez de Castro and Martínón-Torres 2012). Acknowledging we are challenging a well-established paradigm, our (as yet) insufficiently comprehensive hypothesis is offered with the intention of opening new vistas for discussion.

ORAL

**2. NEW ESR/U-SERIES DATES IN YABRUDIAN/AMUDIAN LAYERS AT QESEM CAVE, ISRAEL**

*Falgueres, Christophe (CNRS) falguere@mnhn.fr*  
*Mailys, Richard (MNHN) mailys.richard@mnhn.fr*  
*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*  
*Ran, Barkaran - (Tel Aviv University) barkaran@post.tau.ac.il*

Qesem cave is a Middle Pleistocene site situated 12 km east of the Mediterranean coast of Tel Aviv, Israel. It is attributed to the Acheuleo-Yabrudian Cultural Complex, (AYCC) of the late Lower Paleolithic period, dated to ca. 420-200 ky (Gopher et al. 2010; Mercier et al., 2013). This site exhibits a unique prehistoric sequence where the Amudian blade dominated industry is the main cultural component, however the scraper-dominated Yabrudian industry is also represented in distinct contexts at the cave, The chronology established by TL applied on burnt flints, ESR/U-series on herbivorous teeth and U-series dates on sphenothems, suggests that Qesem cave is one of the oldest sites yielding such an early blade industry.

This work presents new ESR/U-series dates on four animal teeth unearthed from a central hearth recently published (Shahack-Gross et al. 2014) which presents an Amudian industry and four other teeth from the shelf area in which a Yabrudian industry was found.

This work presents new ESR/U-series dates on four animal teeth unearthed from a central hearth recently

published (Shahack-Gross et al. 2014) which presents an Amudian industry and four other teeth from the shelf area in which a Yabrudian industry was found.

### 3. ON ANACHRONISM, OR STONE BALLS IN THE AMUDIEN: THE STRANGE PRESENCE OF SPHEROIDS/POLYHEDRONS AT QESEM CAVE, ISRAEL

*Barkai, Ran (Tel-Aviv University) barkaran@post.tau.ac.il*  
*Gopher, Avi (Tel-Aviv University) agopher@post.tau.ac.il*

The Acheulo-Yabrudian cultural complex (AYCC) is represented at Qesem Cave by two major lithic industries: The blade-dominated Amudian and the scraper-dominated Yabrudian. The typological and technological characteristics both lithic industries were thoroughly studied, as well as the very interesting phenomenon of lithic recycling which is significantly present at all assemblages of both industries.

In this presentation we would like to add another aspect, yet unpublished, of the Qesem Cave lithic assemblages, which is rather surprising and in our opinion deserve special attention.

Within one of the Amudian horizons of the lower stratigraphic sequence of Qesem Cave, a group of stone balls was discovered. Another stray stone balls, one or two, were found within other Amudian assemblages of the cave, however this specific Amudian assemblage exhibits an unprecedented number of such remarkable items.

In this presentation we would like to describe the stone balls (spheroids, polyhedrons) found at Qesem Cave, discuss the archaeological context of these items and explore the significance of their presence within the AYCC in terms of continuity and change that characterize this interesting cultural complex of the terminal Lower Paleolithic period in the Levant.

### 4. SPATIAL ASPECTS AS SEEN FROM A DENSITY ANALYSIS OF LITHIC CATEGORIES AT QESEM CAVE

*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*  
*Barkai, Ran (Tel Aviv University) barkaran@post.tau.ac.il*

This paper focuses on the results of a preliminary study of flint items density in different areas of Qesem Cave and different parts of the stratigraphic column.

Qesem Cave is a chamber cave with a 9.5 m stratigraphic sequence assigned to the Acheulo-Yabrudian Cultural Complex (AYCC) of the late Lower Paleolithic in the Levant. After a brief introduction presenting the 420-200 ka Qesem Cave, we show the range of lithic densities in the cave.

Significant differences in lithic densities are shown for both the total number of lithic items per volume or for selected artifact categories within these assemblages.

These densities are tested against and incorporated with other sets of data, mainly horizontal (spatial) distribution aspects, assemblage composition, functional data on different categories in the assemblages, and the relation of these densities to natural or human made features.

One example of our results is that the highest flint density is directly related to a constructed hearth in the center of the cave. Moreover, while some parts around the feature show a blade-dominated industry (Amudian), another part shows a Quina scraper dominated industry (Yabrudian). This may indicate functionally related differences between areas around this feature and may be significant in understanding variability within the AYCC.

### 5. PRELIMINARY EVALUATION OF RAW MATERIAL CHOICES IN THE AMUDIEN VERSUS THE YABRUDIEN AT QESEM CAVE.

*Wilson, Lucy (University of New Brunswick in Saint John) lwilson@unbsj.ca*  
*Agam, Aviad (Tel Aviv University) aviadkra@post.tau.ac.il*  
*Barkai, Ran (Tel Aviv University) barkaran@post.tau.ac.il*  
*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*

The lithic assemblages recovered from Qesem Cave can be divided into two distinct industries, the Amudian and the Yabrudian, based on different uses of raw materials to produce different proportions of end products (blades vs. scrapers, for instance). The goal of our study is to try to determine whether those differences extend to different uses of the landscape and its resources. Do the two assemblages differ only in terms of technology and typology, with the same raw materials being used

for both, or do they also differ in terms of raw materials used, either in proportions or in sources exploited? Starting in summer 2013, we have undertaken a petrographic examination of a large sample of the pieces in each assemblage, categorizing each distinct raw material. Different raw materials are identified on the basis of rock type, and, since most of them are varieties of flint, of criteria such as colour, cortex characteristics, homogeneity, any visible fossils, etc. Our goal is to separate the raw materials into as many defined types as possible, with the full knowledge that some types are varieties of each other which will be regrouped later. Each lithic piece examined is therefore recorded as to typological category, assigned a raw material type, and weighed. We are thus able to examine the differences in proportions of use of the raw material types in each assemblage, by typological category, and in terms of number of pieces and of weight of material used. In addition, we have started field work aimed at locating the sources of the flint varieties, comparing samples from geologic sources with samples from the site assemblages.

This will give us a view of the extent of the territory exploited by the hominins at Qesem, and will show us for instance whether different territories were used by the hominins who created the two assemblages, or whether different raw material qualities were preferentially exploited in creating the industries.

We will be presenting the results of our work to the end of the summer 2014 field season in the Special Session on Qesem Cave.

## **6. THE TRANSMISSION OF KNOWLEDGE AND APPRENTICE FLINT-KNAPPERS IN THE ACHEULO-YABRUDIAN CULTURAL COMPLEX: A CASE STUDY FROM QESEM CAVE, ISRAEL**

*Assaf, Ella (Tel-Aviv University) ellaassa@gmail.com*  
*Barkai, Ran (Tel-Aviv University) barkaran@post.tau.ac.il*  
*Gopher, Avi (Tel-Aviv University) agopher@post.tau.ac.il*

In recent years, researchers have been showing great interest in issues relating to knowledge transmission among early humans. Being an important component of the general picture of the Acheulo-Yabrudian Cultural Complex (AYCC), the site of Qesem Cave provides an opportunity to address these issues in the context of an early human occurrence in the Levant.

During the 2009-2011 excavation seasons in "The southern area", Amudian assemblages were recovered.

Following the special characteristics of these assemblages and beyond presenting a detailed analysis of the techno-typological characteristics of the assemblages, we decided to search for evidence concerning lithic knowledge transmission in these assemblages. This is attempted through a detailed analysis of cores from the southern area assemblages and a comparison of this data to two Amudian assemblages from other parts of the cave.

The results of the study suggest that processes of learning and knowledge transmission were indeed present in the southern area. The techno-typological analysis indicates that in contrast to other areas, knapping activities focused on the production of "simple" items (like flakes). The analysis of cores indicates that various levels of knapping skills are represented in the assemblages including skilled and unskilled knappers, or knappers who were in the process of learning. It is likely that knowledge transmission has taken place in other areas of the cave too and was not restricted to a single area of the cave. However, a comparative analysis of these results to cores originating from two other Amudian assemblages in the cave shows that the transmission of knowledge related to knapping (following our criteria) was more prominent in the southern area than in other areas of the cave, thus indicating a spatial pattern.

The number of studies attempting to identify lithic learning processes in Lower Palaeolithic assemblages is very low. As for today, there are no studies that explore knapping skills in AYCC sites. This study sheds some light on the subject and expands our understanding of knowledge transmission mechanisms in early human societies – an issue that might be of significance and relevance for our present time.

ORAL

## **7. AMUDIEN VERSUS YABRUDIEN UNDER A ROCK SHELF: A STUDY OF TWO LITHIC ASSEMBLAGES FROM QESEM CAVE, ISRAEL**

*Parush, Yoni (Tel-Aviv University) yoniparush@gmail.com*  
*Gopher, Avi (Tel-Aviv University) agopher@post.tau.ac.il*  
*Barkai, Ran (Tel-Aviv University) barkaran@post.tau.ac.il*

In this presentation we will present new results from two distinct lithic assemblages from Qesem Cave - A Yabrudian and an Amudian assemblage. The two assemblages originated from the same location within the cave - underneath a rock "shelf" located at the north-western part of Qesem Cave, and are dated to older than 299 kyr. Both assemblages exhibit clear

stratigraphic relations, as the Yabrudian layer is on top of the Amudian layer and thus at this part of the cave and in this stratigraphic unit the Yabrudian is later than the Amudian.

In this presentation we will present the general characteristics of the two assemblages (both assemblages include a total of ca. 30,000 artifacts) and will focus on the similarities and differences in lithic characteristics between the two assemblages. In addition, the results of a technological analysis of hundreds of recycled items will be presented.

In all, it seems that the Yabrudian and Amudian of the "shelf" area are part of the same technological system - sharing the same techno-typological features; differ mainly in frequencies as well as in densities. It seems that the differences might be related to human activities that took place at the different strata of this area and not to different technological operations, conceptions or choices.

In addition, flint recycling at Qesem Cave seems to represent a significant technological component that is a constant and repetitive mode of production within the technological repertoire aimed at the production of distinctive flakes/blades, most probably for specific purposes. Reconstructing the Chaîne Opératoire of the production of these items helps understanding human behavior at the cave. It appears that products of lithic recycling at Qesem Cave reflect a decision-making scenario that follows a repetitive set of rules and conceptions.

## 8. CONTINUITY AND CHANGE IN AMUDIEN BLADE PRODUCTION THROUGHOUT THE QESEM CAVE SEQUENCE

*Shimelmitz, Ron (The David Yellin Academic College of Education and University of Haifa) ronishim@gmail.com*

*Barkai, Ran (Tel Aviv University) barkaran@post.tau.ac.il*

*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*

Amudian blade production at Qesem Cave reflects a predetermined debitage technology in which blade production is both systematic and serial. The rich lithic assemblages of the almost ten meters stratigraphic column of Qesem Cave are all attributed to the Acheulo-Yabrudian cultural complex, dating to ca. 420-200 kyr. Although the Amudian is found in several Acheulo-Yabrudian sites in the Levant, only at Qesem Cave it constitutes the dominant industry throughout the stratigraphic sequence. Significantly, while the

technological variation in the Acheulo-Yabrudian Cultural Complex is predominately manifested by its three industries (Amudian with a dominant blade production, Yabrudian with flake production and Quina scrapers, and Acheulean with numerous handaxes), the long sequence of Amudian layers at Qesem Cave makes it an ideal candidate to examine diachronic changes in the late Lower Paleolithic by tracking variations within a very particular technology - blade production. This is of importance since one of the features differentiating the Lower Paleolithic Acheulean and the Middle Paleolithic Mousterian is an assumed faster rate of technological changes in the Mousterian. In order to shed new light on this issue we present a comparative study addressing characteristics of blade production from five Amudian assemblages retrieved from different areas and different elevations within the stratigraphic sequence of Qesem Cave. The results indicate that blade production intensity differs in Amudian assemblages and while many of its characteristics are quite stable, some significant changes are witnessed as well. This suggests that the Amudian blade production of the Acheulo Yabrudian Cultural Complex and that of Qesem Cave in particular can provide a yardstick for measuring the pace of change in late Lower Paleolithic technologies and may indicate flexibility in decision making and technological choices at this early, pre-Mousterian stage as well.

## 9. A SCRAPER LIFE HISTORY: USE WEAR ANALYSIS OF YABRUDIEN AND AMUDIEN SCRAPERS FROM QESEM CAVE (ISRAEL)

*Lemorini, Cristina (Universita' La Sapienza di Roma) cristina.lemorini@uniroma1.it*

*Bourguignon, Laurence (INRAP) laurence.bourguignon@inrap.fr*  
*Zupancich, Andrea (Tel Aviv University - TAU) a.zupancich@gmail.com*

*Gopher, Avi (Tel Aviv University - TAU) agopher@post.tau.ac.il*

*Barkai, Ran (Tel Aviv University - TAU) barkaran@post.tau.ac.il*

Quina and demi-Quina scrapers are well represented at Qesem Cave, mostly associated to the Yabrudian levels of the site, dated between 420,000 and 230,000 years ago.

These types of tools are characterised by a long retouched edge, where invasive scars are generally visible over the dorsal surface. The retouched edge is characterised by scars exhibiting different length, where shorter ones are superimposed to the earlier longer ones, thus generating different lines of retouch.

Here we propose the results generated by the application of an integrated approach, including both a techno-morpho-functional analysis of the samples and use wear analysis of these latter.

The former takes into consideration the overall tool morphology, including the blank features and the edge retouch characteristics in order to provide an evaluation of the technological choices involved within the production, use and re-use of Yabrudian and Amudian scrapers at Qesem Cave.

The use wear analysis of the tools is performed throughout the exploitation of both a low and high power approaches. Through the analysis of edge removals, polishes, abrasions and striations, present on the tool we are able to determine the worked materials and the activities carried out with these tools at Qesem Cave.

Throughout the application of a techno-morpho-functional approach it is possible to investigate the use of Quina and demi-Quina scrapers within their life history, underlining the possible use and re-use of these tools to performing different activities and processing various materials, in relation to the different retouch steps to which the tools have been subject to during their life cycle.

Furthermore, this latter aspect will take in consideration the fact that several of these tools represent distinct recycling phenomena, where the tools are modelled on throughout the exploitation of older patinated blanks.

## 10. ON SCRAPERS HANDLING: PRELIMINARY RESULTS FROM THE LOWER PALAEOOLITHIC SITE OF QESEM CAVE (ISRAEL)

*Zupancich, Andrea (Tel Aviv University - TAU) a.zupancich@gmail.com*

*Lemorini, Cristina (Universita' La Sapienza di Roma) cristina.lemorini@uniroma1.it*

*Barkai, Ran (Tel Aviv University - TAU) barkaran@post.tau.ac.il*  
*Gopher, Avi (Tel Aviv University - TAU) agopher@post.tau.ac.il*

Most of the studies carried out so far, related the function of lithic tools have merely focused on the worked materials and the activities performed with these latter. Very few works (eg. Rots 2010) included, other than the investigation of the processed materials and the activities performed, an analysis of the traces related to handling and prehension of the tools.

Here we propose the results coming from an experimental frameworks related to this matter, focused

on the prehension and hafting of different types of flint scrapers (eg transversal, double, Quina, demi-Quina etc.), associated to the ones unearthed at the late Lower Palaeolithic site of Qesem Cave (Israel).

Throughout the microscopic analysis of experimental replicas, used both as hafted and hand held implements we underline the efficiency of different types of prehension (hafted, hand held and wrapped), isolating diagnostic wear related to each adopted solution.

We are able to personally test the efficiency of the hafted tools to perform various activities (hide working, wood working etc). Different types of hafting and prehension solution are adopted, in accordance to the ones observed on a scraper sample coming from Qesem Cave.

The experiments allow to define edge removals or micro wear related to different handling solutions, creating a hafting and prehension use wear replicas collection, to be compared to the traces identified on the archaeological sample included in this study.

Thus, it is possible to define the prehension and hafting solutions adopted by the human groups at Qesem Cave, in regard to the use of flint scrapers underlining the overall high level of technological knowledge characterising the Middle Pleistocene inhabitants of Qesem Cave.

## 11. WHO LIVED IN THE QESEM CAVE? THE DENTAL PERSPECTIVE

*Hershkovitz, Israel (Department of Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University) anatom2@post.tau.ac.il*

*Sarig, Rachel (Department of Orthodontics, The Maurice and Gabriela Goldschleger School of Dental Medicine and the Department of Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University) sarigrac@post.tau.ac.il*

*Weber, Gerhard (Department of Anthropology, University of Vienna) gerhard.weber@univie.ac.at*

*Fornai, Cinzia (Department of Anthropology, University of Vienna) cinzia.fornai@univie.ac.at*

*Gopher, Avi (Institute of Archaeology, Tel Aviv University) agopher@post.tau.ac.il*

*Barkai, Ran (Institute of Archaeology, Tel Aviv University) barkaran@post.tau.ac.il*

When the first study on the Qesem Cave human teeth was published (eight teeth, deciduous and permanent; Hershkovitz et al. 2010), it initiated a debate on questions such as: To whom did these teeth belong?

Were they some form of AMHs, Neanderthals, *Homo heidelbergensis*, or *Homo erectus*? Apart from a quite clear negative answer concerning their assignment to *Homo erectus*, one could find at least some support for any of the other possibilities. Continued work at Qesem Cave in recent years revealed additional human teeth at the site. These include an upper right deciduous canine, a lower right first deciduous molar, a lower right first permanent molar, a lower left third molar, an upper right first permanent premolar, and an incomplete tooth (represented by a single root). The current study presents new metric and morphological data on these additional teeth from Qesem cave. We will argue that the Qesem teeth manifest a mosaic combination of archaic and modern traits and, in fact, cannot be attributed with reasonable certainty to any of the above-mentioned morphs. Furthermore, teeth from different layers at the cave vary in size and shape. Therefore, the answer to the question of who occupied the Qesem Cave during the late Lower Paleolithic will have to await further discoveries and analyses of human remains.

ORAL

## 12. HOW DID THE QESEM PEOPLE USE THEIR TEETH?

*Sarig, Rachel (Department of Orthodontics, The Maurice and Gabriela Goldschleger School of Dental Medicine and the Department of Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University) sarigrac@post.tau.ac.il*

*Gopher, Avi (Institute of Archaeology, Tel Aviv University) agopher@post.tau.ac.il*

*Barkai, Ran (Institute of Archaeology, Tel Aviv University) barkaran@post.tau.ac.il*

*Weber, Gerhard (Department of Anthropology, University of Vienna) gerhard.weber@univie.ac.at*

*Hershkovitz, Israel (Department of Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University) anatom2@post.tau.ac.il*

The study of dental wear can be an important source of information regarding dietary habits, methods of food preparation, and human behavior.

Studying the dental wear patterns of the Qesem Cave teeth has led to several observations that may shed light on the habitual behavior of the occupants of this cave.

Five wear types were identified on the Qesem teeth:

- The first is represented by fine, non-oriented scratches located on the buccal surface of the crown. These features are usually considered to be micro-wear elements resulting mainly from the introduction of external ingredients in to the food.
- The second appears in the form of vertical grooves (small furrows), semicircular in cross-section, on the interproximal wear facets.
- The third, coarser scratches were noted on the labial aspect of the root.
- The fourth is occlusal wear.
- The fifth is interproximal wear facets that appear in the proximal contact area of adjacent teeth.

These wear categories comprise different elements with unique characteristics such as groove (scratch) length, depth, location and orientation, and they represent different etiologies. Occlusal and buccal micro-wear scratches may reveal dietary habits and food consistency; vertical grooves and interproximal facets relate to the force of mastication; and the coarser scratches can be the result of hand tools used for food cutting and processing. The picture obtained from the analyses of all wear types on the Qesem Cave teeth is of people with a strong masticatory system who were exposed to unprocessed food, and who used small flints to cut pieces of flesh.

## 13. THE QESEM CAVE HOMININ MATERIAL (PART 1): A MORPHOMETRIC ANALYSIS OF THE MANDIBULAR PREMOLARS AND MOLAR.

*Weber, Gerhard W. (University of Vienna, Department of Anthropology) gerhard.weber@univie.ac.at*

*Fornai, Cinzia (University of Vienna, Department of Anthropology) cinzia.fornai@univie.ac.at*

*Gopher, Avi (Tel Aviv University, Institute of Archaeology) agopher@post.tau.ac.il*

*Barkai, Ran (Tel Aviv University, Institute of Archaeology) barkaran@post.tau.ac.il*

*Sarig, Rachel (Tel Aviv University, Sackler Faculty of Medicine, Department of Anatomy and Anthropology) rachel.sarig@gmail.com*

*Hershkovitz, Israel (Tel Aviv University, Sackler Faculty of Medicine, Department of Anatomy and Anthropology) anatom2@post.tau.ac.il*

A first description of eight hominin teeth from the Middle Pleistocene Qesem Cave (QC) in Israel has been published by Hershkovitz et al. (2011). Based on qualitative assessments and linear measurements they pointed out the ambiguous morphological affinities to anatomically modern humans (AMH) and Neanderthals (NEA). The teeth were associated with an Acheulo-Yabrudian Cultural Complex. Since then, some other teeth have been found. Of particular interest for the present paper here are the mandibular P3 and P4 (from the same individual) dated to ~350ka, and a lower M2, at least post-dating 300ka, because they represent the oldest material from the cave falling in a time period when the two lineages leading to NEA and AMH would differentiate or could already show different traits.

The QC teeth and comparable material were  $\mu$ CT scanned at the Vienna Micro-CT Lab, other comparable material was obtained from existing data bases. Enamel and dentine surfaces were segmented and surface models created. Data were collected from these 3D models of dental crowns. We used Geometric Morphometric methods based on landmarks and semilandmarks to analyse shape and form of three different traits: 1) the enamel-dentine-junction (EDJ), 2) the cervical outline, and 3) the crown outline.

Morphometric analysis shows that QC premolars are quite small compared to Mauer (*H. heidelbergensis*) and NEA, but they are in the range of modern humans. NEA and AMH separate well in terms of size. The QC molar, to the contrary, is large and in the size range of NEA and Mauer. Turning to shape (no size considered), the QC premolars are intermediate between NEA and AMH, and similar to Mauer. The QC molar is in all features very close to NEA (different to Mauer), and features a grade 3 trigonid crest on the EDJ, described as being absent in modern humans (Bailey et al. 2011). Molar EDJ shape generally separates extremely well AMH and NEA.

We find a dissociation of shape and size for premolars – an intermediate shape between NEA and AMH combined with a significant size reduction. Martinon-Torres et al. 2013 also found Neanderthal-like shape and sapiens-like size in Sima des los Huesos material, though in upper M1s. With the current data, we cannot assign the oldest QC remains to any existing taxon, nor exclude that it belongs to one of them, nor that it is a new taxon. However, premolars and molar show different trends. If they are representative for this past population, there are two hypotheses possible. H1: they are from different populations inhabiting QC at slightly different times.

Nevertheless, culturally (including lithic economy, technology, hunting and butchering patterns, or faunal composition) QC context provides no reason to support this hypothesis. H2: if they are from the same population, premolars show a clear tendency towards size reduction, at the same time featuring an intermediate shape between NEA and AMH, while molars are similar to NEA in size and shape. This represents a pattern of postcanine dentition that is neither NEA nor AMH. Supported by A.E.R.S.DentalMedicineOrganisationsGmbH, DanDavidFoundation.

### 14. THE QESEM CAVE HOMININ MATERIAL (PART 2): A MORPHOMETRIC ANALYSIS OF I/12A DECIDUOUS LOWER SECOND MOLAR

*Fornai, Cinzia (Department of Anthropology, University of Vienna) cinzia.fornai@univie.ac.at*

*Benazzi, Stefano (Department of Cultural Heritage, University of Bologna; Department of Human Evolution, Max Planck Institute for Evolutionary Anthropology) stefano.benazzi@unibo.it*

*Gopher, Avi (Institute of Archaeology, Tel Aviv University) agopher@post.tau.ac.il*

*Barkai, Ran (Institute of Archaeology, Tel Aviv University) barkaran@post.tau.ac.il*

*Sarig, Rachel (Department of Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University) rachel.sarig@gmail.com*

*Hershkovitz, Israel (Department of Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University) anatom2@post.tau.ac.il*

*Weber, Gerhard W. (Department of Anthropology, University of Vienna) gerhard.weber@univie.ac.at*

The Qesem Cave Middle Pleistocene hominin site (QC) has yielded a well preserved lower second deciduous molar (dm2) labeled I/12a, among several other teeth. The latter has been previously qualitatively described by Hershkovitz et al. (2011) as a rather large, taurodontic tooth, with mesial cusp tips inclined inward and a rather expanded talonid, presenting an anterior fovea but lacking a mid-trigonid crest. The authors pointed out that some of these characteristics typical of Neanderthals (NEA) are shared also with other Late Pleistocene Homo (e.g. Qafzeh), while the lack of a mid-trigonid crest would differentiate it from NEA. Since a definitive taxonomic assessment for I/12a dm2 has not yet been made, we carried out a comparative geometric morphometric (GM) analysis of crown and cervical outlines from 3D

surface models in order to contribute to this issue. I/12a was compared to a sample of 31 anatomically modern human (AMH) and NEA specimens. 3D surface models for the dental crowns were obtained from  $\mu$ CT data. The virtual crowns were oriented on the bases of their best-fit plane (parallel to the X-Y-plane) and lingual margin (parallel to the X-axis) before crown and cervical outlines could be collected (Benazzi et al., 2012). Each outline was resampled using 24 pseudo-landmarks placed at the intersection between the outline itself and equiangularly spaced radii originating from the centroid of the outline. After superimposition of the landmark configurations, we ran a Principal Component Analysis for the cervical and crown outlines separately, both in shape and form space.

Our GM analyses of crown (PC1=38.45%; PC2=28.43%) and cervical outlines (PC1= 37.76%; PC2=22.86%) distinguished AMH from NEA in shape space. Only Qafzeh 15 represents an exception for its crown outline, and plots within the NEA distribution, while Skhul I is always within the range of variability of AMH. I/12a allied with NEA for both outlines. The main crown outline variation responsible for the separation between the two hominin groups is in the relative dimension of the distal and mesial regions, where NEA and I/12a possessed a relatively broader distal aspect. NEA cervical outline is rather squared, while in AMH the bucco-distal aspect is reduced. The between groups separation is less clear in form space (crown outline' PC1=87.04%; cervical outline' PC1=83.78%). I/12a and Qafzeh 15 plot at the highest end of the size range of variability for the very large sizes of both outlines.

Based on the shape and size of both crown and cervical outlines, I/12a showed morphological affinities to NEA. This is in line with Weber et al. (2014) who found similar results for QC permanent lower second molar. Yet, other results in shape and form space for the QC premolars, but also our results showing Qafzeh 15 dm2 crown outline' closeness to NEA, suggest caution in interpreting Middle Pleistocene dental morphological variability. The investigation of further dental features and the inclusion of more Middle Pleistocene specimens in our sample would possibly provide clearer insights on the taxonomic assessment for QC hominin material.

*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*

*(modificado en mail 01/08 17h. Mer)*

Dental plaque is formed by the activity of bacteria which are energised by sugars in carbohydrates. If it is not removed, it rapidly calcifies. Adhering strongly to the tooth, it can survive indefinitely and is common on archaeological skeletons from all periods. Samples of material were found adhering to three human teeth from Qesem Cave. These were extracted and, following characterisation, two of these samples were found to be dental calculus.

Two samples were degraded to extract microfossil material embedded in the calculus. Samples were processed according to standard techniques, using low concentration HCl before being centrifuged at room temperature. An Olympus IX 71 inverted microscope was used at between 50-200 magnifications for viewing and imaging was conducted using a Colour View camera and Cell D imaging system. One sample was analysed by sequential thermal desorption-gas chromatography-mass spectrometry (TD-GC-MS) and pyrolysis-gas chromatography-mass spectrometry (Py-GC-MS). This technique facilitates the identification of both free/unbound and bound/polymeric organic components.

Analysis of the material embedded in the calculus has revealed a range of items including micro traces of charcoal, starch granules, and other plant microfossils, all of which may be evidence for plant ingestion, as well as paleo-environmental indicators. Evaluation of the potential for survival of chemical compounds, offers markers for their endurance in dental calculus over extended time periods.

Even at the extensive time depth of Qesem Cave, a range of material was found in the dental calculus. Here we present these findings and we explore the pathways, including food items, which may have led to the ingestion of this material.

**16. WHAT HAPPENS AROUND A FIRE: FAUNAL PROCESSING SEQUENCES AND SPATIAL DISTRIBUTION AT QESEM CAVE (300 KYA), ISRAEL**

*Blasco, Ruth (Gibraltar Museum) rblasco@rblascoperez@gmail.com*  
*Rosell, Jordi (Universitat Rovira i Virgili (URV)-IPHES, Institut Català de Paleoecologia Humana i Evolució Social) jordi.rosell@urv.cat*  
*Sañudo, Pablo (Universitat Rovira i Virgili (URV) pablo.sañudo@bolomor.com*  
*Gopher, Avi (Tel-Aviv University) agopher@post.tau.ac.il*  
*Barkai, Ran (Tel-Aviv University) barkaran@post.tau.ac.il*

The technological innovation involving the controlled use of fire represents a decisive change in the hominin subsistence. Hearths and the spatial distribution patterns associated with them constitute a valuable element to deepen our knowledge about human behaviour and its evolution. Studies focussed on the use of fire are approached by different disciplines and through different points of view. Thus, hearths were studied for their meaning in the diet, the caloric and light capacity, spatial organisation and their role as communication and socialization focal points. The site of Qesem Cave (Israel) shows evidence of the controlled use of fire as early as 400 kya. A particular superimposed central hearth that was repeatedly used as a focus for human activities ca. 300 kya is the topic of this presentation. This succession of hearths at the same location in the cave yields dense faunal and lithic remains as well as evidence for spatial differentiation of activities around it. Here, we present faunal taphonomical data from this specific archaeological context, which includes not only the hearth area (approximately 4 m<sup>2</sup>), but also surrounding areas (approximately 11 m<sup>2</sup>). The most common prey species is the Mesopotamian fallow deer (*Dama cf. mesopotamica*), whose wide age range and anatomical profile (marrow-rich bones such as long limb bones) led us to propose the development of social hunting techniques and seasonal occupations. Here, we will provide data on human subsistence behaviour during the formation of this archaeological unit as well as compare it to other areas from a taphonomical point of view. Elements such as taxonomical attribution, size (length) of bone fragments and intensity of burning are used for spatial differentiation of activities around the hearth. This study is designed to contribute to our understanding of subsistence strategies and hominin behaviour during the Acheulo-Yabrudian Cultural Complex in the Levant.

ORAL

**17. THE MICROVERTEBRATES OF QESEM CAVE: A COMPARATIVE STUDY OF THE TWO MAIN CONCENTRATIONS AND THEIR MODE OF ACCUMULATION**

*Smith, K.T. (Senckenberg Research Institute) krister.smith@senckenberg.de*  
*Maul, Lutz Christian (Senckenberg Research Institute) lutz.maul@senckenberg.de*  
*Barkai, Ran (Dept. of Archaeology, Tel Aviv University) barkaran@post.tau.ac.il*  
*Gopher, Avi (Dept. of Archaeology, Tel Aviv University) agopher@post.tau.ac.il*

At Qesem Cave, huge numbers of small vertebrates have been excavated from two main concentrations: (1) an eastern concentration in quadrats L-N/13-15, and (2) a western concentration in quadrats H/16-17. The density of finds reaches 10,000 per excavation unit of 50x50x5 cm. Thus far, ca. 10,000 specimens (of more than 233,000 microvertebrate remains in total) have been identified at least to the genus level.

The faunas of the two concentrations are quite similar, with the exception of a few taxa present in only one of the areas (indicated below with (1) or (2)). The following taxa have been identified: Actinopterygii indet.; Amphibia - Anura indet. (three species); Reptilia - *Stellagama stellio*, *Chamaeleo chamaeleon*, *Gekkonidae* indet., *Lacertidae* indet. (two species), *Scincidae* indet., *Pseudopus apodus*, *Colubroidea* indet. (at least three species); Mammalia (micromammals) - *Suncus etruscus*, *Crociodura cf. leucodon*, *Crociodurinae* indet. (large form), *cf. Roussettus sp. (2)*, *Rhinolophus ferrumequinum*, *R. euryale*, *R. mehelyi*, *Miniopterus cf. schreibersii*, *Myotis blythii (1)*, *Procyon sp.*, *Lepus cf. capensis*, *Sciurus cf. anomalus*, *Eliomys cf. melanurus (2)*, *Cricetulus cf. migratorius*, *Microtus guentheri*, *Nannospalax ehrenbergi*, *Dipodillus cf. dasyurus*, *Meriones cf. tristrami*, *Gerbillidae* indet. (large form), *Mus cf. musculus*, *Rattus cf. haasi (2)*, and *Apodemus cf. flavicollis*. Judging from the faunal content and from morphometric data on molars of Guenther's Vole (*M. guentheri*), the remains of the two areas were not accumulated at the same time, and concentration (2) is older than concentration (1).

The taphonomic data obtained thus far suggest a Barn Owl as the predominant accumulator, although natural history observations on Barn Owls and chameleons are strongly at odds with this actualistic inference: Barn Owls are nowhere recorded as a major predator on chameleons. We argue that this represents an example of non-analog behavior in the extinct Barn Owl populations and propose a scenario that harmonizes actualism and

natural history. We further pinpoint a possible owl roost in Qesem Cave, the first time such a roost has been identified in a collapsed cave setting.

ORAL

### 18. PALAEOECOLOGICAL AND BIOSTRATIGRAPHICAL IMPLICATIONS OF THE MICROVERTEBRATES OF QESEM CAVE

*Maul, Lutz Christian (Senckenberg Research Institute) lmaul@senckenberg.de*

*Smith, K.T. (Senckenberg Research Institute) krister.smith@senckenberg.de*

*Barkai, Ran (Tel Aviv University) barkaran@post.tau.ac.il*

*Gopher, Avi (Tel Aviv University) agopher@post.tau.ac.il*

Extant species of microvertebrates are eminently suited for drawing inferences on past environmental conditions, because their remains are closely bound (for ecological and taphonomical reasons) to the areas in which they lived. The ecological preferences of the nearest living relatives of the microvertebrate taxa recorded at Qesem Cave allow us to infer a palaeoenvironment with a mosaic of open and woodland habitats. Additionally, palaeoenvironmental conditions have been inferred from climatic parameters of the current distribution areas. Most overlaps of recent geographic ranges of the species recorded at Qesem Cave have been found in the northern Levant. Additional range overlaps can be seen in areas in recent Turkey, Marmara region and East Anatolia. The data suggest slightly higher precipitation for the time range covered by the microvertebrate-bearing layers than at present around Qesem Cave. A comparison of the Qesem Cave microvertebrate-bearing layers to one another suggests more forested conditions in the upper part of the stratigraphic microvertebrate-bearing sequence in comparison to the lower part. However, to some extent taphonomical influences could be responsible for these fluctuations (e.g., selective prey intake of the raptors responsible for the fossil accumulation) too.

It cannot always be assumed that a species' present habitat requirements are reflective of the entire history of a lineage. The *Sheltopusik*, *Pseudopus apodus*, is a case in point. The lineage *Pseudopus* arose in the early Neogene in more mesic environments in Europe, before the extant species spread southward. Its present habitat preferences are an autapomorphy of the species. Qesem Cave contains the earliest records of the lineage in the Levant, documenting a time of range-expansion and habitat shift. Accurate palaeoenvironmental estimation

on the basis of these early fossil populations of *Pseudopus apodus* will first require appraisal of their phylogenetic position with respect to the crown.

Among microvertebrates, micromammals are most suitable for biostratigraphic purposes. With the exception of *Rattus cf. haasi*, the small mammal fauna of Qesem Cave comprises only taxa that live today in the Levant. However, *Rattus haasi* occurred in Israel in the Early and Middle Pleistocene, and its latest known record is from the site of Oumm Qatafa. Morphometric data on molars of Guenther's Vole from Qesem Cave show that it was similar to Middle Pleistocene populations of this species in other faunas. The data further indicate a more primitive state of the *Microtus* finds in the western (older) concentration at Qesem Cave (quadrats H/16–17) than in the eastern one (quadrats L–N/13–15).

ORAL

### 19. ANCIENT DNA ANALYSIS OF MIDDLE PLEISTOCENE FAUNAL REMAINS FROM QESEM CAVE, ISRAEL

Recent developments in ancient DNA extraction and library preparation methods have enabled the generation of sequencing data from Middle Pleistocene samples. In Qesem Cave (Israel), dated to 420-200kya, large numbers of faunal remains and a small number of hominin teeth have been found. The abundance of faunal remains offers the opportunity to study ancient

DNA preservation in different areas of the cave. This preliminary study could then be used to select hominin remains for further genetic analysis, thus diminishing destructive sampling of these valuable fossils. Moreover, many of the faunal remains from Qesem Cave are too fragmentary to enable identification at the species level based on their morphology. Identification of species based on their genetic material would help shed light on the environment and hunting patterns of the inhabitants of Qesem Cave.

Forty-two faunal remains from six distinct areas in the cave were selected for this study. 25-50mg of bone/tooth were removed from each sample. DNA was extracted, converted into libraries and enriched for mammalian mitochondrial DNA using the most sensitive techniques currently available. Mammalian sequences longer than 30bp were identified and evaluated for the presence of C to T substitutions, which derive from deaminated cytosines and constitute a signal typical of ancient DNA. Most sequences detected originated from contaminating modern mammalian DNA, such as human and pig. However, a small number of libraries showed sequences similar to Persian fallow deer (*Dama mesopotamica*), a species found abundantly in Qesem Cave, albeit with inconclusive deamination signals.

A secondary stage of screening, focused on these "promising" libraries, is now being carried out in order to detect whether DNA is differentially preserved in different layers of the site. Deeper sequencing of these libraries and further analysis of the reads will be beneficial to assess the feasibility of extracting ancient DNA from hominin and faunal remains from Qesem Cave.

# B19 Aquatic resource consumption by prehistoric humans

**1. THE PROCUREMENT OF THE CLAM *DONAX SERRA* RÖDING (BIVALVIA: DONACIDAE) DURING THE MIDDLE STONE AGE OF SOUTH AFRICA.**

Jerardino, Antonieta (ICREA/ Spanish National Research Council (CSIC) [amsjerardino@gmail.com](mailto:amsjerardino@gmail.com)

Navarro, Rene (University of Cape Town) [rene.navarro@uct.ac.za](mailto:rene.navarro@uct.ac.za)

Galimberti, Mariagrazia (University of Cape Town) [mgrazia.galimberti@gmail.com](mailto:mgrazia.galimberti@gmail.com)

South Africa Middle Stone Age coastal sites have played a prominent role in documenting early evidence of systematic shellfish collection and adaptation to aquatic environments in the context of anatomically modern humans. Pinnacle Point 13B cave is important among these Middle Stone Age sites not only because it holds the earliest yet known evidence for human use of marine resources (~162 ka), but because shellfish observations have been integrated more fully into discussions of Middle Stone Age adaptations. This is particularly the case of *Donax serra* procurement on sandy beaches, where skills that are usually indicative of an aspect of behavioural modernity (in the context of hunting) were apparently used.

*Donax serra* from 110-91 ka old assemblages have been studied in detail by way of metrical analyses and relevant biological and ecological literature of this species. Existing seasonality studies derived from Oxygen isotope analyses on the same molluscs are incorporated into this reconstruction.

Shellfish appear to have been collected in winter over many millennia when *Donax serra* are most nutritious due to high gonad content. A dramatic change in collecting strategies took place during this millennia-long period. Earliest systematic collection of *Donax serra* consisted of almost unselective procurement of animals in terms of shell size along the tidal gradient and beach depth. In later visits, people collected mostly larger individuals by narrowing their collection to the mid-intertidal. This change increased the efficiency of *Donax serra* collection which reflects a positive adaptive behaviour that endured into Later Stone Age times.

ORAL

**2. FROM ARCHAEOLOGICAL FRAGMENTS TO SUBSISTENCE STRATEGIES. BIOMETRICAL STUDIES OF MARINE INVERTEBRATES: THE COMMON MUSSEL (*MYTILUS EDULIS*) AND THE VIOLET SEA URCHIN (*PARACENTROTUS LIVIDUS*)**

Mougne, Caroline (University of Rennes 1) [caroline.mougne@free.fr](mailto:caroline.mougne@free.fr)

Dupont, Catherine (University of Rennes 1) [catherine.dupont@univ-rennes1.fr](mailto:catherine.dupont@univ-rennes1.fr)

Some biometrical studies have been realized on the common mussel (*Mytilus edulis*) and on the violet sea urchin (*Paracentrotus lividus*), which are regularly discovered on archeological sites along the French Atlantic coast. The fragmentation rate of the mussel valves and of the sea urchin test is generally high in archaeological contexts. In fact, their mineralogical nature, their shape and their thickness did not resist to a mechanical pressure of sediments and the shells and the tests are regularly found crushed. In order to reconstruct the original lengths of these two marine invertebrates from archeological fragments, a specific methodology has been settled.

As far as the *Mytilus edulis* is concerned, a series of measures has been carried out on 2500 valves (1250 right and 1250 left). Those valves come from four archeological sites and from six stations located on the present seashore. The shape of the mussel changes according to its environment, that is why the shells studied have been collected on several areas localized all along the French Atlantic coast, in various environments (rocky and muddy) and at different tidal ranges (middle and low seashore). Three measures allow to reach a correlation statistically reliable in order to reconstruct the original size of this bivalve: the width, the length of its hinge and a small part near the teeth.

Another series of measures has been taken on 55 individuals of *Paracentrotus lividus* coming from the present seashore of the western part of France. Four measures allow to obtain a high correlation in order to reconstruct the original diameter of the test: the length and the width of its rotula, the total length of the hemipyramid and a intermediary length of the hemipyramid.

These biometrical approaches aim to reconstitute the subsistence strategies of archeological human populations. Their application allows to describe the gathering methods, the diet and economical practices.

Mollusc shells and avian eggshells found in archaeological sites represent direct evidence of how people in the past chose to exploit their environment. Aquatic resources in particular appear to have played an important role in the development of early human behaviour. However, molluscs (and eggs) were not only exploited as a food resource; their shells were valued for their aesthetic qualities and material properties, and were therefore used (and traded) for making personal ornaments, or useful tools.

Taxonomic identification of the raw material is key for reconstructing the selection process and the network of exchange of these prehistoric goods, but morphological identification is often hampered by degradation and/or working processes (e.g. for shell beads). Here we present a new methodological approach for the identification of these materials, based on ancient protein analyses.

Shells and eggshells are biominerals that are able to retain a stable fraction of proteins trapped within the calcium carbonate crystals (intra-crystalline). We target this fraction and analyse it by mass spectrometry (MS/MS) and liquid chromatography (RP-HPLC) to obtain information on both protein sequence and bulk amino acid composition.

We report the use of pattern recognition methods on a large dataset (777 samples) of bulk amino acid compositions from mollusc shells to demonstrate that taxonomic identification can be achieved at genus level.

This has important implications for the interpretation of large and fragmentary shell assemblages, as well as for shell personal ornaments, including worked shell beads from the Early Bronze Age site of Great Cornard, UK.

Furthermore, we present the first in-depth proteomics study on avian eggshell; this comprises more than twenty bird taxa (both wild and domestic), and allows unprecedented insights into the patterns of eggshell protein preservation, enabling not only taxonomic identification of the shell, but also an understanding of the role of proteins in the process of biomineralization itself.

The stable intra-crystalline fraction of proteins is shown to be preserved in archaeological shells and eggshell. Protein sequence and composition can be used for the taxonomic identification of these materials and therefore increase our understanding of the patterns of exploitation of natural resources in prehistory.

ORAL

### 4. PREHISTORIC AQUATIC RESOURCE USES IN THE SCOTTISH NORTH ATLANTIC ISLANDS: INTEGRATING DATASETS.

*Jones, Jennifer Rose (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) jenniferrose.jones@unican.es*  
*Mulville, Jacqui (Cardiff University) mulvilleja@cardiff.ac.uk*

The Mesolithic-Neolithic transition in the Scottish islands has been a major focus of interest. Past human isotopic evidence demonstrated a sharp shift away from consuming marine foods with the arrival of farming to the islands in the Neolithic. Aquatic resources were thought to be abandoned until the Vikings arrived in the Norse period. These original models were based solely on human isotopic evidence, and little attention had been paid to the zooarchaeological data, or to the faunal isotopic baseline. Specifically the direct and indirect uses of aquatic resources such as their role in animal foddering is little understood. This paper presents a chronological overview of the importance and uses of marine food from the Neolithic to the Norse period in the Scottish Islands combining isotopic and traditional zooarchaeological techniques.

Carbon and nitrogen analysis of 622 faunal specimens was undertaken from the Neolithic, Bronze Age, Iron Age and Norse Period sites in Orkney and the Western Isles. These values were compared statistically to generate

a baseline and to characterise faunal diets. These results were compared to human isotopic values and zooarchaeological datasets to determine the changing importance of aquatic resources within these islands through time.

During the Neolithic human isotopic evidence and zooarchaeological data shows aquatic resources were not being consumed directly at this time. However, faunal isotopic evidence demonstrates that some animals were being grazed on the shorefront. During the Bronze Age there is a small increase in fish bones in the Outer Hebrides, although it was not being consumed in sufficient quantities to register in human bone collagen. Marine consumption may have been infrequent, or occasional. During the Iron Age in the Outer Hebrides there is an increase in fish bones present in the archaeological record, and humans at the Broch site of Dun Vulcan exhibit marine isotopic signatures. Similarly pigs at Dun Vulcan have isotopic signatures consistent with being fed fish. This is possibly linked to the high status of Brochs, and the role of fish in feasting activities at the site. During the Norse period there is evidence of extensive fish consumption in both Orkney and the Western Isles as seen isotopically. Zooarchaeological evidence demonstrates that herring were the main species exploited in the Western Isles, whereas cod and saithe were more commonly exploited in Orkney, showing differences in the economic strategies employed.

An integrated approach toward is crucial to understand nuances of aquatic resource use. Combining human and faunal isotopic evidence with zooarchaeological data allows an holistic understanding of aquatic resource use. Despite not being directly consumed aquatic resources were utilised in animal management during the Neolithic and Bronze Age. During later prehistory greater evidence of marine food consumption is observed within both human and animals, indicating their increasing importance through time.

## POSTERS

### POSTER

#### **5. DO FISH ACCUMULATIONS IN CAVES REPRESENT HUMAN FISH CONSUMPTION? A SYNTHETIC APPROACH.**

Guillaud, Emilie (Muséum national d'Histoire naturelle (UMR 7209) [eguillaud@mnhn.fr](mailto:eguillaud@mnhn.fr))  
Béarez, Philippe (Muséum national d'Histoire naturelle

(UMR 7209) [bearez@mnhn.fr](mailto:bearez@mnhn.fr)

Primault, Jérôme (Ministère de la Culture et de la Communication, DRAC de Poitou-Charentes/Service Régional de l'Archéologie (UMR7041) [jerome.primault@culture.gouv.fr](mailto:jerome.primault@culture.gouv.fr))

Fish remains are abundant in some upper Pleistocene sites, but the origin of such assemblages is generally poorly known. Potential accumulators of fish bones include humans as well as other kinds of predators, such as birds and carnivores, separately or together.

*Quantification:* Information on the number of fish represented by the remains is important in other analyses, such as subsistence evaluations.

These would include establishing known element representation, element fragmentation and bone surface modification.

*Spatial distribution:* Spatial distribution can be used to show if the fish remains are concentrated near human activities areas or if the accumulation is exogenous.

*Weight and size estimation:* Estimates of the original size and weight of fish represented in archaeological samples are used to reconstruct the relative contribution of fish to the overall diet.

The size of fish acquired depends on fishing technique and the carrying capacity of the predator.

*Traces of predation and digestion:* Fish remains preserved in archaeological contexts have the potential to inform us about past diets, but it is essential to identify the agents of accumulation by their taphonomic signature based on surface modifications, breakage and digestion traces, as well as element representation.

*Season of capture:* With the aid of a modern reference collection and standardized measurements, sclerochronology can be applied to archaeological scales or bones. This method allows us to reconstruct the season when fish were captured.

This methodological framework has been applied on the fish remains found at the cave "Le Taillis des Coteaux" (Vienne, France). This had permit to develop a methodology consisting to identify the part of freshwater resources in human diet during paleolithic period.

POSTER

**6. ISOTOPIC EVIDENCE (C, N, S, O) FOR A HIGH AQUATIC DIETARY CONTRIBUTION FOR A PRE-DORSET MUSKOX HUNTER FROM UMINGMAK (BANKS ISLAND, CANADA)**

Carbon, nitrogen and sulphur stable isotopes differ among different food resources in the high arctic (terrestrial, freshwater, marine) and these variations are recorded by humans according to their diet and thereafter preserved in fossil bone collagen.

Basis of this study is a human mandible associated to the Pre-Dorset site of Umingmak (Banks Island, N.W.T., Canada) and directly dated to 3875±45 BP (GrA-38561). The carbon, nitrogen and sulphur isotopes of the bone collagen of this individual were measured, together with those of coeval fauna (muskox, reindeer, polar fox, wolf, geese) as well as modern ones (polar bear, reindeer). The main species in the Umingmak kill site is the muskox. The intra-tooth variations of carbon and oxygen isotopes were measured on several individuals to test whether they were killed in one or several episodes.

The C and N isotopes of the human bone collagen are consistent with a high marine dietary contribution, with values close to those of polar bear. Using a Bayesian mixing model (SIAR), the contribution of marine resources ranges from 60 to 75% depending on the values estimated for freshwater resources. However, the S isotopes are much closer to the terrestrial/freshwater range, and when S isotopes are incorporated in the SIAR model, the contribution of marine resources decreases to 50-60%, while the contribution of freshwater resources increases. In any case, the contribution of terrestrial

resources ranges from 20 to 40%, significantly lower than the 50% estimated from archaeological remains. The C and O isotopic data of muskox teeth indicate that the different individuals lived under different environmental conditions, precluding them to have lived as one herd. Therefore the accumulation of muskox corresponds to several hunting episodes. The tooth eruption of the muskox calves give evidence of hunting during the cold season, around November/December.

The multi-isotopic approach used on human and faunal remains of Umingmak allowed a precise dietary reconstruction of a Pre-Dorset human living in arctic conditions around 4000 years ago. The contribution of aquatic resources appears higher than expected, with a significant contribution of freshwater resources usually difficult to evaluate from zooarchaeological remains only. The ungulate bones correspond to an accumulation lasting several years, probably providing limited amount of meat to the humans in this environment.

POSTER

**7. USE OF AQUATIC RESOURCES IN THE BOTHNIAN BAY, NORTH BALTIC SEA? A CASE STUDY AT IIN HAMINA**

*Lahtinen, Maria (Durham University) m.lahtinen@durham.ac.uk*

The use of bulk collagen isotope analysis in archaeology has been based on differences in isotope signals between marine and terrestrial diets. However, little is known of the carbon and nitrogen isotope ratios of the north Baltic Sea, the Bothnian Bay. Furthermore, evidence of organic sediment and fish muscle carbon isotope ratios from the Bothnian Bay area suggests that the marine signature is not as distinctive as in oceans. As part of this study, seal bones were analysed from various archaeological sites in the Bothnian Bay coastal area in order to estimate the marine signal. For comparison, wild and domesticated terrestrial animals were also measured for  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values. The identification of the marine signal is important, because fish are very likely to be a significant protein source in northern latitudes, where the growing season is short. This is because fish are available year round and productivity of farming is low. As already known from Europe, the freshwater signal can overlap with the carbon isotope ratios of a terrestrial diet. This is a dilemma in isotope bulk collagen reconstruction and is especially problematic in Fennoscandia, an area with a great number of lakes and

ivers. The use of coastal resources was studied with bulk collagen isotope analysis from a case study site at Iin Hamina, a cemetery in Northern Finland, where people might have used both marine and freshwater fish as a main protein source. This would be logical considering the location of the site: it is situated in the mouth of the river Ii on the coast of Bothnian Bay. The results of the bulk collagen analysis from Iin Hamina support this assumption. However the human data from Iin Hamina range across the range expected for terrestrial and marine diets. The study investigates whether the bulk collagen nitrogen and carbon isotope ratios of human bone are simply not enough to reconstruct diet in the northern Fennoscandia.

---

POSTER

**8. ZOOARCHAEOLOGY OF THE RIVERINE SHELL MOUNDS CARAÇA, ESTREITO, TATUPEVA AND LAGEADO IV: A READING OF THE SAMBAQUI LANDSCAPE IN THE REGION OF ITAOCA RIBEIRA VALLEY OF IGUAPE.**

*Tognoli, Anderson (Museu de Arqueologia e Etnologia da Universidade de São Paulo MAE-USP) ar.tognoli@gmail.com*

The Caraça (1607-1300 years BP), Estreito (4124-3655 years BP), Tatupeva (4800-4770 years BP) and Lageado IV (1500-1280 years BP) riverine shell mounds – called Sambaquis – are located in the Ribeira Valley, in the South portion of Brazil, specifically in the Itaoça area. This region has a great spatial partitioning and micro-environment, and a prevailing warm and humid climate, characteristics that contributed to the existence of a great diversity of fauna and flora. In this sense, the purpose of this communication is to present the preliminary results of this Archaeofaunistic analysis in order to identify the diet of these groups based on Archaeofaunistic remains, and thus its main catchment areas, as well as understanding the paleoenvironmental conditions in which they were inserted.

The Archaeofaunistic analysis showed that the materials that compose the sambaquis are formed of bones, teeth and shells, in different proportions. These samples were subject to two primary methods of analysis for quantification and identification. The Number of Identified Specimens (NISP), that in one hand, allowed us to identify the taxonomic classes present at each site, the anatomical part, the degree of fragmentation, processing marks, and the rate of change of the material, and in

the other hand, the Minimum Number of Individuals (NMI) that allowed us to estimate the number of species present in each of the sambaquis, and their contribution into the diet.

During the analysis specimens of vertebrate animals belonging to the *mammals*, *birds*, *reptiles*, *amphibians* and *actinopterygii* classes were identified, besides the invertebrates animals of *gastropoda* and *bivalvia* classes.

The Archaeofaunistic samples of these sites have a high degree of fragmentation and thermal alteration marks, resulting from the use of fire in the process of preparing these animals for consumption.

From these results it was possible to develop a framework for analysis of animal species present in these sambaquis, and so, understanding the behavior of these groups in relation to the environment, and possible areas of resource catchment.

In terms of identified species of animals, the noteworthy presence of the *actinopterygii* at the Tatupeva and Estreito sambaquis are related to the proximity of these sites with the Ribeira river. Already the Caraça and Lageado IV sambaquis that are located further away from Ribeira, showed a high rate of Mammals remains. The fragmentation of these materials are the result of both processing activities of animals for consumption, as well as the modification by thermal action, which weakened the remains, besides the post-depositional processes such as trampling by historical reoccupations.

The Archaeofaunistic configuration demonstrates that these groups have developed certain types of adaptability in these diverse environments, with a strictly generalist and opportunistic behavior.

*Goude, Gwen elle (Laboratoire M diterran en de Pr his-  
toire Europe Afrique, UMR 7269, CNRS) goude@mms.h.univ-  
aix.fr*

The aim of this paper is to present and integrate new and existing archaeological, archaeozoological and isotopic data from the Mesolithic-Neolithic sites in the Danube Gorges of the Balkans. It has been hypothesised that fishing must have played a significant, if not crucial role in the prolonged stay of human communities in this region in the Early Holocene (10<sup>th</sup>-8<sup>th</sup> millennium BC), and consequently in the formation of first (semi) sedentary settlements (c. 7.300-5.900 cal. BC). The significance of aquatic resources in this particular context is amply manifested in the archaeological record - namely by considerable amounts of fish remains, isotopic signatures of human remains, and by distinctive sculpted sandstone boulders displaying elements of fish anatomy. However, even though the economic and social role of fishing has been recognised and emphasised in previous archaeological publications, a detailed archaeozoological analysis of fish remains had not been undertaken. Consequently, the great potential of cross-referencing archaeozoological and isotopic data has not been exploited.

This research employs a multidisciplinary approach which includes ichthyoarchaeology, stable isotope analysis of human remains, archaeological indicators of fishing and its importance (i.e. fishing and fish processing gear, sculpted and engraved representations of fish), and landscape studies which focus on the location of sites within the wider landscape. Case studies utilised in our research include the sites of Lepenski Vir, Padina and Vlasac, which were located on river terraces in the vicinity of whirlpools and small river tributaries, and could have therefore been recognised as attractive fishing spots.

The results of ongoing archaeozoological analysis of fish remains from these sites suggest that its inhabitants were oriented towards fishing freshwater species (large catfish, carp, roach, huchen), but also very large anadromous sturgeons (beluga, Russian sturgeon, stellate sturgeon) during their spawning migrations to and from the Black Sea. Existing isotopic data ( $\delta^{13}\text{C}$ ,  $\delta^{15}\text{N}$ ,  $\delta^{34}\text{S}$ ) show that the diet remained largely based on aquatic resources throughout the sequence, with no dramatic shifts documented in other European transitional populations. However, an ongoing study suggests that the dietary patterns were much more complex than previously thought, considering that different socio-biological

categories might have had various preferences and/or access to aquatic resources.

By integrating various disciplinary approaches, this research aims to provide new insights into the strategies of fish procurement and consumption - species selection and availability, the size of caught specimens, seasonality and fishing techniques, the role of fish in human diet and among different categories of the population, as well as the relationship between humans and the aquatic environment in this particular context. On a larger scale, the Danube Gorges sites, occupied by (semi)sedentary fishermen over a long time span between the 10<sup>th</sup> and 6<sup>th</sup> millennium BC, offer great possibilities for studying and understanding various aspects of Mesolithic-Neolithic transformations.

ORAL

## 10. SULPHUR-34 AS A TRACKER OF AQUATIC RESOURCES CONSUMPTION: INSIGHTS FROM THE LATEGLACIAL AND EARLY HOLOCENE OF NORTH-WEST EUROPE

*Drucker, Doroth e G. (Department of Geosciences, Biogeologie, University of T bingen, Germany) dorothee.drucker@ifg.uni-tuebingen.de*

The aquatic dietary resources are considered as high quality food that provided ancient humans with beneficial nutrients to brain development and alternative subsistence advantages. Due to its low archaeological visibility, the contribution of fish and other aquatic preys to the diet of past populations has been investigated using direct trackers such as carbon and nitrogen isotope abundances in bone collagen. In contrast with marine resources, freshwater resources cannot always be distinguished from terrestrial ones based on carbon-13 and nitrogen-15 abundances. To go beyond this limitation, sulphur-34 analysis of collagen has been recently applied to archaeological remains.

In continental context, collagen sulphur-34 abundances have been proved to be a potential tracker of freshwater contribution to the diet as well as a marker of the geographical origin. These two aspects were explored in the context of the Epipaleolithic and Mesolithic cultures extending from about 14,000 to 8000 years cal BP in northwest Europe. Those late hunter-gatherers were living in a changing environment with a succession of warm and cold episodes. During the Epipaleolithic, the Lateglacial interstadial (ca. 14,700-12,800 cal BP)

was a period of global warming with the progressive replacement of some emblematic species of the Pleniglacial, such as reindeer, by more temperate species, such as red deer. At that time, human populations seemed to have broadened their dietary spectrum to small game as well as aquatic resources. After the last major cold event of the Younger Dryas (ca. 12,800-11,600 cal BP), the environment witnessed a global warming leading to the early Holocene climatic optimum around 9000 cal BP. During this temperate phase, hunter-gatherers had access to a high diversity of terrestrial and aquatic resources, while their land use pattern was suggesting a reducing mobility over time.

The isotopic results ( $^{13}\text{C}$ ,  $^{15}\text{N}$ ,  $^{34}\text{S}$ ) obtained so far on human and faunal remains from Epipaleolithic and Mesolithic sites in northern France, eastern France, Luxembourg and Germany were examined to decipher the potential of sulphur-34 to identify the consumption of freshwater resources. A significant difference in sulphur-34 abundances between terrestrial and freshwater ecosystems was confirmed in the late Mesolithic context of northern France. In contrast, evidence or strong suspicion of aquatic-based diet was not reflected by a clear pattern in sulphur-34 in the studied Epipaleolithic and early Mesolithic cases. Finally, sulphur-34 appeared as a promising tracker of mobility in the context of terrestrial-based subsistence in the middle part of the Mesolithic.

The possibility to discriminate between freshwater and terrestrial resources using sulphur-34 abundances in collagen is not systematic as underlined by previous works and case-by-case studies are necessary. So far, the end of the Lateglacial interstadial and the transition to the early Holocene provided negative results on the use of sulphur-34 as an aquatic consumption tracker. The temperate context of the early Holocene seems more promising for the application of  $^{34}\text{S}$  either for diet or mobility tracking.

*Zarina, Gunita (Institute of Latvian History at the University of Latvia) gunitaz@latnet.lv*

Aquatic food resources (fish and molluscs) were exploited intensively at Rinnukalns, a Neolithic shell midden at the outlet of Lake Burtnieks, north-eastern Latvia (Berzins et al. in press). Stable isotope data from a rich fish-bone assemblage (Schmölcke et al. submitted) and isotope data from a wide range of terrestrial species complement results on faunal samples from the prehistoric settlement and cemetery at Zvejnieki, on the opposite shore of the lake (Eriksson et al. 2003; Eriksson 2006). Stable isotope data from human remains at Zvejnieki and Rinnukalns indicate that freshwater food resources made substantial but varying contributions to human diets throughout the Mesolithic and Neolithic.

Our results also show significant radiocarbon reservoir effects in aquatic species from Lake Burtnieks, which must be reflected in the radiocarbon ages of human remains, and may explain some unexpected dates from Zvenieki burials (Meadows et al. 2014). Radiocarbon is therefore another dietary proxy, albeit one which can only be used if the date of burial is constrained by other evidence: radiocarbon dates of organic grave goods, radiocarbon ages of other individuals buried simultaneously (but having different diets), and radiocarbon ages of different components of the same individual, if these are isotopically labelled by individual dietary history or the metabolism of different nutrients. We consider examples of the first two situations, and argue the inconsistencies between dietary reconstructions based on stable isotopes alone and those incorporating radiocarbon evidence may be due to mobility patterns rather than the use of incorrect local isotopic baseline values.

*Smith, Colin (Department of Archaeology, Environment and Community Planning, La Trobe University, Melbourne, Australia) colin.smith@latrobe.edu.au*

Hunter-gatherer societies have lived along the coast of the Atacama Desert in northern Chile for millennia. The complexity of these early sedentary societies (notably the Chinchorros) was manifested in the manifold practices of mummification given to the dead. The archaeological evidence suggests that these coastal populations were highly specialized in exploiting aquatic resources (especially marine), with only minimal use of terrestrial resources.

We have employed a novel stable isotope approach, taking advantage of the exceptional preservation of the mummies, to investigate individual subsistence patterns using liquid chromatography – isotope ratio mass spectrometry (LC/IRMS) analysis of sequential hair samples. LC/IRMS enables the analysis of  $\delta^{13}\text{C}$  values from amino acids of protein acid hydrolysates from small samples and the results can be interpreted to discriminate between terrestrial and aquatic resources, and further distinguish between marine and freshwater resources. Single hair strands sampled from seven mummies from the Late Archaic Period (~6000-4000 BP) to the Late Intermediate Period (~950-1476 AD) were cut into 0.5cm lengths and analysed to provide detailed fortnightly discrete palaeodietary profiles of these individuals. We will discuss the results in terms of how the individual amino acid results from hair keratin are interpreted and discuss the advantages and disadvantages to our approach. The subsistence strategies of individuals from different time periods and different locations (inland and coastal) will be discussed and what the implications are for the persistence of aquatic resource exploitation in pre and post-agricultural periods in the region.

Stable isotope analysis of human remains enables an estimation of food habits in ancient times. Among others, aquatic resource consumption is especially important as it is considered to be a recent innovation in hominid evolution thus providing insights into the adaptive strategies of modern humans. However, studies of bulk collagen have showed that nitrogen isotopic composition could significantly vary even within the same animal species depending on environmental conditions, making a dietary reconstruction of human remains difficult without enough number of referential prey animal specimens. Nitrogen isotope analysis of individual amino acids in bone collagen has recently been proposed as a potentially useful tool for the detection of not only marine resources but also freshwater ones. In this paper, we further test its applicability to human populations in a variety of regions and chronological time periods in the world and discuss whether it is possible to detect aquatic resource consumptions based on the isotopic composition of human remains only.

We compiled published and unpublished data of nitrogen isotopic composition of amino acids for more than 150 archaeological samples from 23 sites located in various environments (e.g. temperate and cold regions in Japan, mammoth steppe in Europe, inland and coastal regions in South Africa) to decipher a general trend in the terrestrial  $\text{C}_3$ -plant-based, terrestrial  $\text{C}_4$ -plant-based, freshwater, and marine ecosystems and compare them with the human realms. Furthermore, a generalized linear model was developed based on those data in addition to isotopic compositions of bulk collagen in order to blindly assign a human remain to either of the above categories. Finally, we applied these models to published literature data to test their robustness and to see how human remains are categorized.

Major findings are: independently of climatic conditions, nitrogen isotopic compositions of glutamic acid and phenylalanine of terrestrial animals group similarly; these

two amino acids are particularly useful to detect marine or freshwater resource consumptions; the developed models successfully distinguish freshwater, marine and terrestrial animals though separations between freshwater and marine ecosystems could be imperfect; most of the human remains were assigned to predicted categories while only a few of them were not.

Nitrogen isotopic composition of amino acids is useful for the detection of aquatic resources. In the future, it would be possible to more precisely categorize human remains by combining other indicators such as sulphur isotopic composition and carbon isotopic composition of individual amino acids.

**1. ARGUMENTS FOR THE CHARACTERIZATION OF THE (PRE)HISTORIC REALITIES DURING THE NEOLITHISATION OF THE WESTERN MEDITERRANEAN: AN INTRODUCTION TO THIS DEBATE.**

*Manen, Claire (CNRS) clairmanen@univ-tlse2.fr*

From an historical point of view, the Neolithic transition constitutes a fundamental period during which people changed their relationship with the environment, establishing – in diverse ways – an economy based on farming and agriculture. In archaeology, the approaches to the study of this 'Neolithisation' process are extremely varied, since what changed was the entire range of elements making up the human-environment system. For Europe, the study of Neolithisation has focused on the vectors of this change (i.e. cultural diffusion via the indigenous hunter-gatherer societies vs. demic diffusion by the migration of a population from the Near East, where most of the animal and plant species in question had been domesticated). Equally, the study of Neolithisation in Europe involves examining the rhythms of emergence of novel techno-economic traits (considering the greater or lesser favorability of the natural and cultural milieu within which such novelties appeared).

Thanks to multidisciplinary researches, data of the last years have shown that the Mesolithic-Neolithic transition in the western Mediterranean is a very complex phenomenon that linear models cannot explain. Indeed, relations between the latest hunting societies and the earliest agro-pastoral societies may have had an impact on the dynamics of the spread of the agro-pastoral economy and on the reshaping of cultural expressions. Furthermore, the first farmers appear to have regularly transformed their technical and economic systems (thanks to adaptation to new environments, to social dynamics...). Even more, if we widen the perspectives and consider the southern shores of the Mediterranean, the situation is further complicated by the fact that the model of the diffusion of the Neolithic package does not fit to the archaeological situation.

Thus the restrictive duality between a world of mobile hunter-gatherer and a world of sedentary agriculturalists is no longer valid. And a lot of intermediary situation have to be taken into account to draw a patchier picture. But from an archaeological point of view, it must be

recognized that the definition and characterization of the criteria that allow to distinguish, in an objective way, the different socio-economic situations of every context is very difficult (farmer communities of colons, Mesolithic communities with evidences of exchange, "mixed" system, in which the weight of the predatory and producing activities is similar, functional variability of the Neolithic expressions...). This difficulty can be explained by the fact that no archaeological element defines for itself the hunter-gatherer or farmer nature of the context. This is in particular due to the fact that the presence / absence of certain archaeological elements respond to multiple factors: functionality of the deposits, interaction / exchanges between different groups, importance of the activities of subsistence ...

The aim of this introduction is to explore the variability of situations through practical examples or case studies taken from different kind of geographical, technical and archaeological contexts.

**2. NEOLITHIC PROCESS OF THE IBERIAN PENINSULA THROUGH OF ABSOLUTE DATING**

*Sanz González de Lema, Sofía (Universidad Técnica Particular de Loja (Ecuador) ssanz@utpl.edu.ec*

In this paper I would like to take the opportunity to present the result of my doctoral research about the Neolithic process of Iberian Peninsula through the absolute dating (*Dating to a Historical Process: Absolute dating in the Iberian Neolithic. Analysis and Cultural Assessment*, Universidad Autónoma de Madrid, 2012). Our first aim is to contribute an interpretation about the Iberian Neolithic process through absolute dating.

The method of working commences in the collecting published absolute dating (radiocarbon and thermoluminescence dating) at archaeological context with Neolithic technology (the domestication of animals and plants, ceramic and polished stones). The dates are examined in depth including the method of detecting radiocarbon, type of sample, error term, alteration effects, contamination, sedimentary analysis and taphonomy. The result of the test is one absolute dating group with a safe age. In this manner there is a safe chronology of archaeological context and materials.

On the one hand, 1091 absolute dates has been analyzed from 364 archaeology sites with Neolithic

context and the 32% of data only could be seen as safes. In most problematic cases has relation with: method and site of recollecting sample, high error term, taphonomic problems and little published information about the sites. On the other hand, the percentage of safe dates vary according to the geographic regions, the Iberian Peninsula is divided in sixth regions: Northeast, Ebro Valley, Meseta, Levant, Baetic-Guadalquivir Axis and Atlantic coast. On third place, according the archaeological record the population model could be mosaic model.

In the light of the research and his results, it is possible to propose the Neolithic process as an "Inland phenomenon", not as "Coast phenomenon"; where the mountain ranges had an important part in this process. So, the traditional models about the Neolithisation of Iberian (Maritime Pioneer Colonization, Dual Model and Acculturation Modell) look upon the Mediterranean route as only Neolithisation route, but dates show other different order. Finally, a chronologic-cultural table about the Neolithic process in Iberian Peninsula has been made by mean of results.

### 3. BACK TO THE MESOLITHIC-NEOLITHIC TRANSITION IN NORTHERN SPAIN: THE ABSOLUTE CHRONOLOGY

*Fano, Miguel Ángel (Universidad de La Rioja) miguel-angel.fano@unirioja.es*

*Wood, Rachel (The Australian National University) rachel.wood@anu.edu.au*

*Cubas, Miriam (IIIIPC - Sociedad de Ciencias Aranzadi) mcubas@aranzadi-zientziak.org*

Thanks to investigations in northern Iberia during the last two decades, it is now possible to establish models for the Mesolithic-Neolithic transition (5th millennium cal BC). This requires a critical evaluation of the archaeological evidence, and agreement on which criteria allow discrimination between context with evidence of hunter-gatherer groups and those corresponding to Neolithic groups. In northern Spain a traditional criteria based on technology was used to identify the new *way of life* until the 1990s. Currently, well-established but scant data about farming and stockbreeding is available, and a consensus exists about the importance that should be given to the introduction of artificial techniques in food production. However, this criterion can be difficult to apply and the cultural

attribution (Mesolithic vs. Neolithic) of distinct contexts is complex. After a consideration of these difficulties, this paper presents a model for the transition to the Neolithic based on the statistical treatment of the radiocarbon dataset.

In order to analyse the Neolithisation process from the chronological point of view, published dates for the period of time covering the process have been compiled ca. 9500-2500 cal BC. Bayesian statistical models have been constructed to investigate the transitional process and assess the value of radiocarbon dates in understanding this period.

Using published dates, the chronological models show an overlap between the final Mesolithic and the Early Neolithic archaeological deposits. The final hunter-gatherer societies appear to have disappeared after the Neolithic groups were present in the region. This result is in accordance with the complexity displayed by the Early Neolithic in archaeological terms.

Results support the hypothesis of a "mosaic" Neolithisation process, with groups of hunters and farmers living together in the region during the first half of the fifth millennium, at least in the eastern part of Cantabrian Spain.

Reading and interpreting the archaeological record (archaeography) is a very attractive challenge in those sites with important "entropy", such as cave contexts

submitted to numerous taphonomic processes with postdepositional alterations of the archaeological layers. This results in different interpretations about the type of occupation or the function of the archaeological contexts in different periods.

In this communication we will describe and interpret the prehistoric record of the Els Trocs cave as a perfect example of the combination of several analyses to analyze different contexts during the Neolithic. The key elements to be analyzed are the following:

- The environment, and especially the singular location of this cave in a high mountain area (1500-2000 meters above the sea level), with the evident connections with traditional livestock tracks.
- Evidences of mobility: through the study of sources of raw materials (flint) and the comparison of pottery styles in the Neolithic contexts of this cave.
- Evidences of seasonality: clearly reflected by the study of the faunal and microfaunal remains, and the micro-morphology and palaeobotanic analyses.
- Palaeo-environment: together with the study of the archaeological evidences inside the cave, sondages were made outside, in the surroundings, where interesting deforestation events have been documented, probably related with the anthropic impact of the inhabitants of the cave and their activities.
- Habitation evidences inside the cave: presence of numerous hearths, pits, and above all a spectacular pavement made of potsherds (with more than 25.000 pieces), which are crucial to interpret the domestic use of the cave.
- Finally, the ritual use of the cave would be also analyzed through the study of human bones discovered in the domestic contexts (with marks of violence, *peri mortem* treatment, etc.).

To sum up, the global analysis of these multiple evidences would be very useful to propose hypotheses about the interpretation of the different contexts of the cave. In other words the complete study of the archaeometric and archaeological data would help us to understand the life forms of the first settlers of the Central Pyrenees and the environment in which they lived, in the general framework of the Iberian and regional Early Neolithic.

ORAL

## 5. THE NEOLITHISATION OF INNER IBERIA: ANALYSIS OF THE ARCHAEOLOGICAL CONTEXTS AND ITS HISTORICAL INTERPRETATION.

*García-Martínez de Lagrán, Íñigo (Postdoctoral Programme of the DEUI of the Basque Government, Spain - University of the Basque Country, U.P.V./E.H.U. - IT622-13 Research Group in Prehistory, Basque System of Research, Spain - Laboratoire TRACES UMR5608, Université de Toulouse Le Mirail 2) igmtzl@gmail.com*

The Neolithisation as a historical process has the great handicap to interpret and identify on the archaeological record different types of societies and historical situations that have been defined from ethnographic and anthropological models: pioneers, groups in transition, "low-level food production", "mixed communities", "hunter-gatherer with ceramic", etc. In the case of the Iberian Peninsula, especially in the Ebro Valley and the Northern Meseta, this has also been conditioned by the dominant cultural historical theory, which usually interprets as Neolithic any context with any archaeological remain defined as such.

In this communication we will try to overcome these problems classifying the contexts identified in this territory between ca. 6000-5000 cal BC. This classification is based on a hierarchy of archaeological, chronological and theoretical criteria:

- Archaeological:
  - Quantitative and qualitative importance of Neolithic elements in each context;
  - The presence / absence in the same site of previous Mesolithic occupations;
  - The type of site and its functionality: shelters and caves exploited as logistical camps and open-air settlements defined as residential camps;

- Chronological:

Based on current data two "chronological limits" can be proposed: 1) ca. 5700-5600 cal BC as the beginning of the Neolithic, and 2) ca. 5400-5300 cal. BC as the end of the above process and starting the Early Neolithic.

- Theoretical:

Neolithic concept based on agriculture and livestock as historical and archaeological genesis is assumed. Also we consider the Neolithic as allochthonous to the Iberian Peninsula and, therefore, different processes of colonization and population movements for its explanation are proposed.

The analysis of these criteria results in the definition of three groups of contexts. Each of them will respond to different historical situations: Neolithic pioneers, Mesolithic contexts with neolithic elements obtained by exchange, and, finally, farming communities that will

begin the Early Neolithic and that will result from the previous interaction, mentioned above.

Each of these definitions present particular features in the archaeological record and a specific chronological frame defined above.

From this classification we will try to define the different historical situations that might occur during the Neolithisation and to characterize the Early Neolithic communities as the final result of it. All this will serve as argument for the approach of a specific hypothesis about the Neolithisation of this Inner Area and the Iberian Peninsula as a whole, which, at its core, is characterized by the importance of interaction between Mesolithic and Neolithic populations, and the need for certain processes of colonization of the territory.

ORAL

## 6. MESOLÍTICO, NEOLÍTICO, CONTEXTOS, COMPLEJIDADES Y PROCESOS. REFLEXIONES EN LA CUENCA DEL EBRO

*Alday, Alfonso (Universidad del País Vasco) a.alday@ehu.es*  
*Perales, Unai (Universidad del País Vasco) perales.unai@gmail.com*  
*Soto, Adriana (Universidad del País Vasco) kurajadri@yahoo.es*

La pregunta clave que nos planteamos en nuestra reflexión es conocer cuál es la aportación de un contexto arqueológico neolítico en la definición de la cultura neolítica. La respuesta arranca en el momento que sustentamos el concepto de Neolítico, priorizando unos caracteres sobre otros.

La dinámica histórica neolítica no puede analizarse sin comprender el episodio anterior, el Mesolítico, que en el Alto Ebro, se significa por unas sociedades flexibles en sus planteamientos, y consolidados en su relación con el entorno. Desde fines del tardiglaciario las poblaciones se instalan aquí, dialogando con el medio a través de una red de yacimientos. Los lugares tipos responden al modelo de abrigos bajo roca, injustamente simplificados como altos de caza a partir de una industria lítica retocada con alta participación de armaduras, la posición estratégica que ocupan y el registro de su fauna. Esta visión debe ajustarse, por derivar de unas políticas de prospección sesgadas, de problemas de conservación diferencial y porque la serie de actividades que en ellos se realizan sobrepasa las propias de un cazadero. La polivalencia

es uno de sus caracteres más notables, observada en las dinámicas de talla, la variedad, proporcionalidad y funcionalidad de los instrumentos (deslegitimando la vinculación entre industria lítica y caza). Las estrategias de caza de los grupos les permite un control de los recursos que, en las condiciones medioambientales imperantes y dada la gestión desarrollada, son predecibles. Las sociedades mesolíticas están engarzadas en la región y alcanzan una organización social compleja en un claro proceso sedentarizador.

Caracteres similares ofrecen los registros neolíticos: talla del sílex, elaboración de cerámica, multiplicación de acciones, molinos en soportes alóctonos y láminas de hoz como evidencia de agricultura, animales domésticos... Hay cambios profundos en las industrias líticas: en los módulos (suponen nuevos planteamientos tecnológicos), en los proyectiles, en la proporcionalidad de las categorías retocadas, en la gestión de las materias primas... Los inventarios de estos abrigos no se diferencian, fuera de detalles, de los catálogos de los clásicos registros neolíticos del mediterráneo peninsular. Reflexionamos también, sobre la fauna: en el Mesolítico la gestión es diferencial según la especie, argumento que confirma la complejidad de las decisiones de los grupos. No es sorprendente, en esta situación, la detección prematura de ganadería que, a partir del último tercio del sexto milenio, pone en práctica un nuevo tipo de gestión, con rediles como yacimientos especializados.

La continuidad mesoneolítica en los abrigos deviene del hecho de que las comunidades prehistóricas materializan sus estructuras económicas, sociales e ideológicas en estos y otros lugares: ahí expresan su esencia e identidad. Defendemos la existencia de un vínculo entre los grupos y los lugares, que trasciende la perspectiva económica, para transferir un mensaje social que se traslada a otros aspectos del registro, y argumentan la participación local en el proceso neolitizador.

---

ORAL

## 7. INSIGHTS INTO THE PREHISTORIC TOOLKIT: TRACEOLOGICAL ANALYSIS OF LITHIC ASSEMBLAGES FROM MESO-NEOLITHIC CONTEXTS IN THE NEW MEDITERRANEAN

*Mazzucco, Niccolò (IMF-CSIC) nicco.mazzucco@gmail.com*  
*Gibaja, Juan Francisco (IMF-CSIC) jfgibaja@imf.csic.es*

The traceological analysis of archaeological artefacts has a great potential in prehistoric studies. Apart from

defining the functionality of determinate categories of objects, traceological analysis can strongly contribute to the understanding of the overall economic organization, of the productive processes which took place in each site and of the role they had in the overall site organization. During the last decade, the study of an increasing number of archaeological contexts of Neolithic and Mesolithic period, has allowed to establish comparisons between settlements of diverse functionality and cultural affiliations. As result, both Mesolithic and Neolithic 'toolkits' have been investigated by means of traceological analysis.

In this communication, we are going to present the results of the traceological analysis realized on the chipped stone assemblages from a number of case studies dated to the VII-VI millennium calBC, in the Western Mediterranean. Our aim is to highlight which are the key-elements that can help us understanding the site functionality and its cultural affiliation. All the lithic collections considered, have been studied through an integrated approach, including also data from technological and provenance analysis.

Typical 'Neolithic' tools are for example harvesting tools (among which the so-called sickle blades), tools associated with hide processing (endscrapers or blade scrapers) or related with working processes on clay/ceramic. On the contrary, 'Mesolithic' toolkit is generally characterized by a much larger production of projectile inserts (e.g. geometric tools), but also by notched blades often related with crafting activities on wood or bone/antler materials and a large set of scarcely elaborated blanks related to butchering and animal substance processing.

Even if some qualitative differences can be remarked both from a technical and functional point of view, is not always easy to establish a clear boundary between a 'Mesolithic' and 'Neolithic' assemblages. The patterns of resource exploitation can vary notably from site to site during Neolithic and Mesolithic, depending from the economic organization, the site functionality, the geographical and environmental settings.

ORAL

## **8. BETWEEN MESOLITHIC AND NEOLITHIC: WHICH STATUS FOR THE MATERIAL PRODUCTIONS OF AVEYRON (FRANCE) DURING THE VITH MILLENNIUM B.C.**

*Defranould, Elsa (EHESS-UMR5608 TRACES) [elsa.defranould@yahoo.fr](mailto:elsa.defranould@yahoo.fr)*

*Caro, Joséphine (Université Toulouse 2 - Le Mirail-UMR5608 TRACES) [josephinecaro@hotmail.fr](mailto:josephinecaro@hotmail.fr)*

During the VI<sup>th</sup> millennium B.C., the French department of Aveyron shows few settlements attributed to a specific Early Neolithic currently named «Roucadourien». Defined at the end of the 60's, the Roucadourien is a large cultural group which spreads out from Aquitaine to the Pyrenean and the Massif Central piedmonts. Its particularity is to associate various Mesolithic and Neolithic's components from an economic as well as material point of view. These associations have, until now, been interpreted as a "cultural group" of transition from the last indigenous hunter-gatherers to the Neolithic (with the first farmers and practice of animal husbandry). Among those specific data, ceramic and lithic productions were the main arguments for a theory where this cultural group was largely influenced by Mesolithic traditions. The ceramic productions, often defined as clumsy and coarse, could result of a local invention by Mesolithic hunter-gatherers. On the other end, the association of 2<sup>nd</sup> Mesolithic and Early Neolithic lithic assemblages, could also show signs of an acculturation process of the indigenous populations.

Consequently, because of their geographic situation on the margin of the Cardial culture emergence and because of early <sup>14</sup>C datations (up to VII<sup>th</sup> millennium B.C.), the settlements taken into account in this study, play a crucial role in the current debate on the neolithisation process. Different hypothesis may be stated:

A pole of indigenous neolithisation, independent from the Cardial group.

Acculturated Mesolithic groups, but still preserving some of their cultural backgrounds.

A phenomenon related to the expansion of the Epicardial complex.

The results of stratigraphic mix and/or the lack of chronological resolution.

Thus, today, the reliability of the archaeological contexts as well as the definition of a vast and homogenous cultural entity, are called into question. From this statement, it seems very important to study again all data material from selected main settlements. Recent typotechnological studies on lithic and ceramic assemblages from Aveyron (Combe-Grèze, Clos de

Poujol, Roquemissou, Les Usclades, La Poujade) allowed us to renew our perception of these continental contexts. It is now possible to consider these sites in a more functional perspective and not only according to culturalist approach. Thus, this study may be considered as a further step to the understanding of cultural relations and technical know-how between the 2<sup>nd</sup> Mesolithic and the Early Neolithic.

ORAL

### 9. BURIED STRUCTURES IN BARCELONA PLAIN NEOLITHIC SETTLEMENTS: A GENERAL REVISION, MORPHOLOGICAL ANALYSIS AND FUNCTIONAL APPROXIMATION

Vicente, Oriol (UAB) [oriol.vicente@uab.cat](mailto:oriol.vicente@uab.cat)

The discovery of occupations in the underground of the actual city of Barcelona is one of the most significant news in North-east recent Iberian prehistory. During the last two decades, thanks to a right preventive archaeology policy, the number of archaeological findings has been multiplied, this defining a set of settlements in the proximity of the sea shore.

In the present communication the structural evidences from the Neolithic settlements (located in the lower part of the Montjuïc mountain, in the actual Raval quarter (Caserna de Sant Pau del Camp, Conservatori del Liceu, Reina Amàlia...) will be analyzed both jointly and generally. In particular, buried structures will be revised (pits, slumps,..) whose morphological characteristic and its filling has allowed a functional analysis (hearts, combustion structures, used silos...). The spatial analysis at macro level, all along with archaeological type variables, chronology in particular, will allow an approximation to the characterization of the settlement.

In a methodological level, the search for digging and register systems is, together with the interesting collaboration between public and private professionals, one of the important variables taken into account.

Ferrer García, Carles (SIP, Museu de Prehistòria de València) [carlos.ferrer@dival.es](mailto:carlos.ferrer@dival.es)

In this paper we present the preliminary results of new studies carried out in Cueva de la Cocina, a major site to study the Neolithic transition in Western Mediterranean. Early fieldwork was conducted in the 1940s (directed by L. Pericot) and in the 1970s (directed by Fortea), but only a partial analysis, referred to the sector E1 (1945), has been published in detail since. In there, Fortea concludes that the better hypothesis to understand the pass between pre-ceramics and ceramics levels is an acculturation process. Recently, has been pointed out the possibility of a gap between late Mesolithic and Early Neolithic occupations from the techno-tipological analysis of lithic industries (García Puchol 2005).

Currently we are processing all information of previous excavations according with archaeometric analysis (including zooarchaeological and pottery studies in a new radiometric framework) in order to obtain new data with the idea of contrasting this explanation framework. In this paper we put attention in zooarchaeological and radiometric analysis referred to immediate preceramic levels and ceramic contexts at the site (Fortea's excavation) with the goal to generate relevant infor-

mation for understanding this complex archaeological context and to achieve relevant information about the Neolithic transition process in Mediterranean Iberia.

ORAL

## 11. BEYOND THE SYMBOLISM: CONTRIBUTION OF THE GRAPHIC RECORD TO THE STUDY OF THE NEOLITHIC EXPANSION IN THE IBERIAN MEDITERRANEAN BASIN.

*López-Montalvo, Esther (CNRS UMR5608-TRACES) esther-montalv@gmail.com*

The Iberian Mediterranean basin shows an exceptional graphic record as a result of the expansion of the Neolithic communities. Up to three different graphic horizons can be documented in this territory.

So far, the study of these graphic horizons, especially in the case of the Spanish Levantine paintings, has paid little attention to those aspects that could contribute both to reach a better comprehension of this cultural process and to assess the role of these graphic expressions in the Neolithic communities.

In this sense, the naturalism of depictions and the narrative content of Levantine paintings must be considered as a significant tool in our goal of characterizing the cultural dynamics of their authors.

However, the multiple and opposed readings and interpretations of the social and economic activities portrayed in the Levantine panels have fuelled the discussion concerning chronology and authorship.

We propose a new approach to the thematic content taking into account temporal variables as well as the territorial distribution of the activities portrayed. These two variables will allow us to define the continuities and ruptures concerning these activities in order to characterize the cultural dynamics of these groups. Besides, the exhaustive analyse of these scenes will allow us to make an anthropological approach focused in some aspects concerning the social organisation that have few or none archaeological evidences.

This new approach to Levantine scenes allows us to get new data about their authors, their social and economic dynamics. These new data questions the use of the thematic content as an argument to justify a Mesolithic authorship of Levantine paintings.

Our goal is to show that rock art can contribute to reach a better understanding of prehistoric societies, digging for some social and economic aspects that have no material remains.

ORAL

## 12. INTERPRETATION OF DOMESTIC SITES AND TRANSITION INTO THE PRODUCTION PROCESS IN VALE DO TEJO (PORTUGAL)

*Cruz, Ana (Instituto Politécnico de Tomar) anacruz@ipt.pt*  
*Graça, Ana (Instituto Politécnico de Tomar) anagrace@ipt.pt*

The debate on the neolithisation process in Alto Ribatejo continues on the table due mainly to the discovery and excavation of new archaeological contexts in which the presence of material culture typically considered to be Neolithic appears truncated and where we can find material culture with very peculiar characteristics such as the Holocene macrolithic industries.

The taphonomic issues affecting these archaeological contexts contribute to some extent to hinder archaeographical reading, particularly the migration of artefacts. However, the stratigraphies and the positive and negative structures are obvious and can clearly be seen *in situ*. Both Amoreira and Fontes boast material culture, stratigraphy, structures and datings.

The outdoor sites of Amoreira and Fontes bring new data to the discussion implying a review of the existing models in order to understand a phase of change that may have taken different paths in Alto Ribatejo and may, or may not, match other contexts in Portugal.

Both Amoreira and Fontes data strongly suggest a "change" from a form of predation to a form of production, which is not exhaustive and deterministic.

Any of these sites, contemporary of the estuarine shell-middens, undermines the maritime pioneer colonisation model created in the 90s of the 20th century, which claimed the existence of a *cardinal enclave* in Estremadura Limestone Massif, on the one hand, and inland desertification during the Epipalaeolithic, on the other.

Rather than deconstructing paradigms or interpretative models new archaeographical readings should be implemented as records are revealed through facts and

these are in line with a reality where the producer is also collector and where the collector can also take up new technologies.

ORAL

### 13. UNDERSTANDING THE LANDSCAPE OF NEOLITHIC GROUPS IN THE TAGUS INNER BASIN (EXTREMADURA REGION, SPAIN)

*Cerrillo Cuenca, Enrique (CSIC, Instituto de Arqueología - Mérida) enrique.cerrillo@csic.es*

*Almeida, Nelson J. (ITM, Instituto Terra e Memória.) nelson-jalmeida@gmail.com*

The Early Neolithic of the inner Tagus has only been systematized during the last decade (Cerrillo 2005) after a revision of material culture, stratigraphies and the development of new excavations. The proposal of a complex neolithisation process has gradually replaced the traditional view of a marginal and late process linked to a migration of peasant groups from the Atlantic or the Andalusian shores, as some scholars claimed during the previous decades.

The sequence has been established after the excavation of a few sites and a limited number of C<sup>14</sup> absolute datings that confirm that the region was inhabited around the middle of the 5<sup>th</sup> millennium cal BC (ca. 7500 cal BP). Although the signals of Early Mesolithic (Epipalaeolithic) habitats are being recognised in the region, particularly from the 8<sup>th</sup> millennium cal BC (ca. 9500 cal BP), at this moments it does not seem possible to provide a clear understanding on how both communities interacted.

More than thirty locations with presence of Neolithic artefacts have been recorded alongside the different units of landscape that compose the region, sharing common patterns, but also many differences in terms of geology and possible models of resource exploitation. In this sense, the currently on-going survey projects are providing data about how complex it is to detect the archaeological evidence in the region and what are the barriers that bias the recognition of both Mesolithic and Neolithic sites. The preliminary results are also offering information about surface scatters that can be relevant when performing comparisons with other territories.

From our point of view, a holistic approach on how landscape is organised can aid in offering a regional vision of the Neolithic in the area by jointly analysing patterns of settlement, palaeoenvironmental data and

faunal remains. In this sense, these data are providing a renewed framework with new arguments that point to a diversified strategy of territorial exploitation.

In this paper the question that we want to address is if the current picture of Neolithic landscape(s) can collaborate in understanding the transition to farming, by considering that the aforementioned approaches can describe the first materialization of such a process in the landscape. Wide-spectrum exploitation strategies and a low anthropization of landscape suggest the possibility that cropping practices and livestock were introduced and managed as complementary strategies since the first archaeologically evidenced indicators of productive economies.

### 14. DEFINING THE NEOLITHIC OF SEMIARID NE-MOROCCO

*Linstädter, Jörg (University of Cologne) joerg.linstaedter@uni-koeln.de*

The traditional European understanding of the Neolithisation process, in which agriculture and animal husbandry play a dominant role, is difficult to apply to the semiarid Mediterranean zone of NW-Africa. Here, the introduction of food production indeed represents an important economic innovation. However, recent studies show that in NW-Africa this specific mode of subsistence is integrated within a wider spectrum of complex subsistence strategies which are better described by concepts such as "broad spectrum economy" or "low level food production".

Recent excavations in shelter deposits from the middle of the 8<sup>th</sup> millennium calBP in the Eastern Rif area in Morocco have given us the opportunity to study such concepts in more detail. The application of innovative analytical methods such as black carbon analysis, micromorphology, and pollen analysis of the abri deposits have permitted us to detect the appearance of new economic features. In addition, sediment flotation has produced comprehensive data that allow palaeomalacologists and palaeobotanists to define the particular adaptation of Early Neolithic groups to a climatically sensitive and therefore challenging environment.

**15. DEFINING NEOLITHIC ARCHAEOLOGICAL CONTEXTS USING POTTERY VESSELS IN A VOLUMETRIC APPROACH.**

*Alberch Calm, Pau (UAB) pau.alberch@gmail.com*

*Gómez Bach, Anna (UAB) anna.gomez@uab.cat*

*Molist Montañá, Miquel (UAB) miquel.molist@uab.cat*

This poster aims to address the relationship among the first groups of farmers with their territory in the central coast of north-eastern Iberian Peninsula analysing ceramic production. The geographical context chosen includes the maritime coastal between Besós and Llobregat rivers, including stretch Catalan coastal, Garraf-Ordal littoral mountains and Barcelona's plain.

To approach this problem we decided to apply a double methodology: volumetric pottery shapes and settlement patterns analysis. With the aim to check if there is a causal relationship between intentionality in the ceramic use and stratigraphical depositions we would focus our work to define an initial economic and functional proposal by sites; analysing the volume of ceramic vessels and identify if there is any relationship between pottery shape, intentionality and its context where it has been repaid.

The methodology of the present work is bibliographic and it provides us a first approach to this subject thanks to the field works of different archaeological teams (giving us an whole of 76 archaeological contexts). It made essential the elaboration of a united database focused on the analysis of specialization and production of the ancient Neolithic. Specifically, the chronology goes from 5.480 to 3.500 cal BC and it is attributable to the cultural groups known by the name of "cardial", "epicardial" and "postcardial".

This way allows us a practical approach of each site thanks the partial landscape study, as well as lay down the divergences and similarity among the ceramic material of each archaeological context with the intention of proposing some specialization or opportunism criteria for this containers. Besides this general and theoretical introduction, the present paper tries to test the analysis of the landscape of a limited territory. The combination of different landscapes and sceneries is going to provide a view of a possible pattern of coastal and alluvial exploitation during the firsts steps of farmers communities and comparing this view with other exploitation patterns made for the researchers in the 90's.

# B22 Premonetary currency systems in past societies

## 1. SOME THOUGHTS ON THE ROLE AND FORMAT OF PREMONETARY CURRENCY SYSTEMS IN PREHISTORIC SOCIETIES.

*Brandherm, Dirk (Queen's University Belfast) d.brandherm@qub.ac.uk*

Premonetary currencies come in a wide range of different forms, from livestock and perishable materials to inorganic matter. Their value, however, is invariably measured according to one of only two different underlying models. On the one hand we are dealing with systems based on fixed nominals, on the other we find systems in which value is determined more flexibly, e.g. on a weight-based scale. Most of today's familiar fixed-nominal systems to some extent try to integrate elements of a weight-based approach, usually by employing weight as one of the defining criteria for metal currency units. It is far from clear, however, if the same universally applies also to pre-monetary currency systems of the past.

Based on a number of case studies, this paper will attempt to explore to what extent an integration of these two basic approaches was already attempted at different stages in the European Bronze Age. The focus will be on ingot torques for the Early Bronze Age, on sickles for the Middle Bronze Age, on socketed axes for the Late Bronze Age, and on the question to what degree any of these employ weight to define the value of individual currency units.

Work on this project is still ongoing at this stage, but preliminary results seem to indicate that exact unit weight in premonetary currency systems which employed fixed nominals during the European Bronze Age was not a primary criterion for defining the 'value' of individual currency units.

As an important overall conclusion from our study it emerges that previous attempts to identify premonetary currency systems based mainly on weight standardization may have been crucially flawed, in that they presuppose a degree of integration between fixed-nominal and weight-based systems that is not generally reached prior to the 1st millennium BC.

## 2. EQUALIZATION OF TRADABLE QUANTITIES AND WEIGHT STANDARDS IN PREHISTORIC EUROPE

*Lalongo, Nicola ("Sapienza" University of Rome) nialongo@hotmail.com*

*Vacca, Agnese ("Sapienza" University of Rome) agnese.vacca@gmail.com*

*Vanzetti, Alessandro ("Sapienza" University of Rome) alessandro.vanzetti@uniroma1.it*

Traditional research on proto-money transactions generally assumes that the widespread use of metal as "commodity currency" should have resulted in the normalization of shared, widespread scales of measurement. Hence, many studies aimed at the identification of recurrent weight values as multiples/submultiples of certain (often theorized) standard units. Setting apart several important results gained, such an approach faces a critical proper methodological limitation, and a historical-comparative pitfall: 1) the absence of written references and the rarity of statistically sound samples makes it impossible to either validate or reject any reconstruction of normalized prehistoric scales of measurement; 2) in the Ancient World, unit standards unification across distinct polities is never actually fully achieved, while it is known that several, more or less different local systems co-existed.

The question will be empirically addressed through the analysis of Italian Bronze Age case studies. An *ad-hoc* mathematical methodology, based upon frequency distribution and multi-peak curve fitting, is used to analyze weighed metal records, in order to identify recurrent values across time and space.

The results of the quantitative analysis show that several significant concentrations of weight values find correspondences across many, very distant regional contexts. Furthermore, the variance of such significant quantities tends to narrow as mass values grow.

An alternative approach to the study of recurrent weight values in Bronze Age Europe can be envisaged. The identification of recurrent weight quantities (both as single objects and as total assemblage/i.e. hoard weights) can define "standard average quantities". Instead of looking for a "fractional" logic of given standards, one can observe that constant exchange activities produced a normalization towards widespread "tradable quantities": this can happen without necessarily implying a unification of the local scales of measure. This model is

loosely akin (with necessary adaptations) to the “factor price equalization” theory (Samuelson 1948), stating that commodity prices of two free-trading countries tend to equalize. A theoretical framework is also outlined.

---

ORAL

### 3. THE SET OF TEN WEIGHTS FROM THE TOMB 200 AT EL CIGARRALEJO (SPAIN, MURCIA)

*Poigt, Thibaud (Laboratoire TRACES, universit  Toulouse 2-Jean Jaur s) thibaud.poigt@gmail.com*

On the Iberian peninsula, the majority of data belonging to the practice of weighing appears in the *Alicante-Murcia-Valencia* area, between the 6<sup>th</sup> and the 1<sup>st</sup> centuries BC, therefore before coins were used for trade. Weighing and monetization involve the same process: to provide an exchange-value expressed in counting units. For this reason, many authors tried to determine relations between the masses used on Iberian metrology and the Mediterranean standards generally closely linked with current money (shekel, drachma...).

By studying the set of ten weights for weighing-scales, from the tomb 200 in the El Cigarralejo necropolis (late 5<sup>th</sup> or early 4<sup>th</sup> century BC, *Mula, Murcia*), we can propose a metrological system different from the foreign models. The existence of a local weighing system from the 4<sup>th</sup> century BC raises questions about the Iberian standards and the use of weighing.

The interest of the set from El Cigarralejo, by its homogeneity and its find in a closed context, is that it can be used as a basis for the analysis of the metrological system from which it stems. It is made of ten tronconical perforated weights, in copper-alloy, whose masses were between 1,98 g and 208,45 g, numbered in this work from I to X, from lightest to heaviest. The chosen method does not involve the application of known weighing standards to the El Cigarralejo’s weights, but proving the most probable system used for that set, and subsequently comparing it with the foreign metrological systems.

Observing the arithmetical relationship between each weight and the entire set, we noticed that the weight VI (20,48 g) offers a particular internal logic, with a ratio 1/10 : 1/6 : 1/4 : 1/3 : 3/4 : 1 : 2 : 4 : 6 : 10 and a low percentage of average error (1,13%). Assuming the establishment of the system on this unit (20,765 g for a minimal average error), the set permits, by combining the weights

among them, to produce an uninterrupted sequence of multiples up to 24 times the standard (498,36 g for the theoretical value). This system is not known in the Classical World within the same period, nevertheless few fractions and multiples could permit easy exchange transactions.

This set shows the existence of indigenous weighing systems, which, after comparison, seem to be used with high precision in restrictive circles. We have noted that the precision differs according to the observation scale: it is generally higher inside the set (like tomb 200) than inside the series or between settlements. Regarding the morphology and size of the weighing instruments, they were probably used to give a numeral value for a small quantity of material, whether a form of collection and redistribution of resources or whether for the normalization of a raw material, to give it an intermediary value. In such case, the weighing seems to be linked to forms of pre-monetary payment.

---

ORAL

### 4. HEADS OR TAILS: METAL HOARDS FROM THE EASTERN MEDITERRANEAN IRON AGE

*Heymans, Elon (Tel Aviv University) elonheyman@gmail.com*

This paper deals with the use of precious metal in monetary exchanges, based on the hoards from Israel and Greece. The introduction of coinage in the Greek world from the late 7<sup>th</sup> century BCE onwards, has often been equated with the introduction of money altogether. Needless to say, coinage is only a specific form of money, and certainly not all money is coinage. The misconception that money in the ancient Mediterranean starts with coinage, results in part from the notion that only when minted as coin precious metal becomes a symbol of value, a token issued by the state, and not only a commodity, a metal desired for its intrinsic value.

However, Hart (1986) pointed out that money is always a token and a commodity at the same time, referring to the ‘heads or tails’ combined on our coin. Following his approach, this paper proposes the study of the metal hoards as a way of understanding the monetary character of the precoinage economy.

A case study will be presented of the 8<sup>th</sup> century BCE silver hoard from Tel Arad, Israel. With reference to a corpus of 33 metal hoards from the southern Levant,

dating between ca. 1200 and 600 BCE, the material characteristics of the hoard will be discussed and placed in the context of a wider material practice. This will concern the differentiation in weight and a categorisation in shape of the pieces of silver that comprise the hoard. The hoard will be shown to contain a variety of objects, ranging from indiscriminate pieces of scrap to jewellery. The consistent cutting up of finished objects, attested in the hoards, will be discussed in the context of literary sources referring to this practice, and compared to a similar material phenomenon known from Viking Age silver hoards. This discussion will serve to interpret the hoard content as reflecting a dynamic practice, indicating the use and appreciation of metal as intrinsically transitive, with objects moving back and forth between categories.

Echoing Hart's conception of money, the hoards should be understood as neither bullion, appreciated for the metal's intrinsic value, nor collections of objects without monetary use or meaning. Rather the dynamic use of the metal as transitive between finished object and money, indicate that its qualities as token and commodity were closely interwoven.

---

ORAL

## 5. BEYOND THE USUAL FUNCTIONS ? THE CONSUMPTION OF A PREMONETARY CURRENCY.

*Hensler, Martin (Goethe Universität-Frankfurt) hensler@em.uni-frankfurt.de*

The Early Bronze Age ring ingots with looped ends (Ösenringe) have been generally seen as a typical premonetary currency in prehistoric Middle Europe. In particular M. Lenerz-de Wilde (1995, 2002, 2011) corroborated this interpretation in her publications. In line with basic economic theory, she ascribed different functions to currencies in general: standard of value, medium of exchange, storage of value and means of payment in social contexts. According to her works, ring ingots with looped ends functioned mainly as value storage, thus resulting in their deposition. As hoards are the typical archaeological sources in which these rings are discovered it has been argued that they were deposited in secret, hidden from the eyes of others.

However, the starting point for this study of the Ösenringe is the assumption that they had not been hidden secretly, but instead could have been buried publicly and under enormous efforts for everyone to

see. It is possible to interpret the deposition and the use of the Ösenringe as consumption in an anthropological meaning. Consumption is not only a combination of the acquisition and the technical use of goods. In addition, activities connected with the decision making before the acquisition itself, the definition of the necessary criteria and the function of the goods as well as their usage in the social space have to be considered. The physical properties of the Ösenringe were analyzed to determine criteria helping to discern their potential use and determination of their value. Different attributes such as weight, diameter and chemical composition among others were considered.

In this context it can also be shown, that the standardization of their weight is not an isolated phenomenon. Other formal properties were regulated in a similar way.

The results have further been used trying to reconstruct the needs underlying their consumption. The collective data show that the Ösenringe and their respective consumption had a strong communicative component extending their capacity as premonetary currencies previously described in the literature.

ORAL

## 6. WEIGHT UNITS AND THE TRANSFORMATION OF VALUE IN THE NORDIC BRONZE AGE: APPROACHING PREMONETARY CURRENCY SYSTEMS?

*Melheim, Lene (University of Gothenburg) a.l.melheim@iakh.uio.no*

Different yet interacting economies existed in Eurasia in the 2<sup>nd</sup> millennium BC, some practicing true commerce based on the mass-production of goods while others were ranked systems of exchange. The anthropological distinction between gifts and commodities and the strong emphasis on gift-exchange in the archaeologies of the 1990s nearly abolished trade from the Scandinavian Bronze Age discourse. That there is seldom an absolute division between gifts and commodities is, however, well-known. Often, a change from gift to commodity is seen when objects move across a cultural boundary. At the same time, following Frederik Barth, the up-keeping of cultural boundaries may be said to rely on a constant flow of goods across them.

In an article from 1993 Mats Malmer identified a local Nordic weight unit of 107,7 g. Arguably, this weight

unit ties in with a wider monetary system convertible with weight units used in the Mediterranean region. This paper discusses material from the Nordic metal workshops in light of Malmer's theory of a weight unit. In focus of the analysis are the clay refractories; crucibles and moulds. A strong indication of the existence of a common weight standard is found in, among other things, the standardized size of the crucibles. Another significant trait that will be discussed is the occurrence of unalloyed copper and tin.

Different strands of evidence discussed in this paper suggest that there was an ongoing process of commodification in the Nordic realm in the second millennium BC. Objects and raw materials gained through long-distance exchange were increasingly treated as socially neutral commercial products. Despite this, no urban centers or ports of trade have yet been identified and little is therefore known about how the transformation of value happened in practice. It is here argued that the centralized metal workshop sites in Scandinavia were early ports of trade, where metal was recast to meet local demands, and from there distributed further as preforms. The sites discussed in the paper are situated at locations easily accessible by boat, with abundant evidence of specialized craft production as well as long-distance imports.

It seems that in the Nordic Bronze Age, metal played central stage in the maintenance of cultural boundaries as a convertible store of value that could be endlessly transformed.

## 1. EXAMPLES OF TECHNO-FUNCTIONAL ANALYSIS OF LITHIC TOOLS : THE LEVALLOIS TOOL VS THE MICOQUIAN TOOL

*Bonilauri, Stéphanie (UMR 7041 ArScan, AnTET) stephanie.bonilauri@gmail.com*

The techno-functional approach proposed here is based on a perception of the tool "in action", structured by several functional parts including at least a part in contact with the material being processed and a part directly held by hand or indirectly using a haft. Each of these parts is structured by a number of technical traits which have a functional role in the material processed and for prehension of the tool. These technical traits that structure the tool can be completely obtained from the phase of production (débitage or shaping) or be partially obtained involving, in that case, a phase of retouch more or less important (phase of restructuring of the blank, total or partial). The techno-functional analysis thus allows to evaluate the difference between the techno-functional intentions established by the phase of production and the techno-functional traits required for the action and established during the phase of retouch.

Based on this techno-functional approach, we suggest to compare two different types of tools based on two production systems radically different: the Levallois tools (predetermined blank) and the micoquian tools (shaped blank). This comparison will be established from the study of Levallois tools from the Near east selected in the sequence of Umm el Tlel (central Syria) and from the study of micoquian tools from the site of Antonovka (Ukraine).

We will see that if these tools have differences (where the causes can be numerous: environment, functional etc.) they also present numerous similarities like their volumetric structure and some techno-functional traits.

ORAL

## 2. FROM THE FLAKE TO THE BLADE IN MIDDLE PALEOLITHIC. CO-EXISTENCE, INTERACTION AND ALTERNATION OF TWO CONCEPTS OF TOOLS. THE CASE STUDY OF RIPARO TAGLIENTE (VERONA, ITALY).

*Carmignani, Leonardo (Universitat Rovira I Virgili) leonardocarmignani76@gmail.com*

Simplifying what is produced through the lithic production, we can identify three categories of possible products: flakes and blades, produced by knapping operations (débitage), and hand axes - choppers (*lato sensu*) by shaping operations (façonnage). If the shaping operations contain a conceptual structure of modelling a morphology from a block of raw material, the dichotomy flake-blade, is, at a macroscopic scale, a double variant of the same theme, which is a separation of a piece from a volume. Evidence of blade technology is confirmed in Northern Europe (France, Belgium and South England), at least from the last part of the Middle Pleistocene (OIS 7-6). Later on, in stage OIS 5 these productions cover a larger area, which includes the North-Western Germany, central France, and occasionally the South of France. A third moment (OIS 4-3) shows us the reappearance of laminar productions in Southern Europe and more particularly in the South of France and the Italian peninsula. At the present state of research these three phases appear as on-and-off events without a clear evolutionary continuity. These productions can show an exclusive blade's production or can be associated with flakes productions mostly represented by the Levallois reduction system.

The Riparo Tagliente's lithic assemblages have been analysed across two different approaches: a productional one and a techno-functional one. The production analysis was focused on the identification of the producing intentions through the identification of techniques, methods and concepts that underlie the entire *chaîne opératoire*. The techno-functional approach was applied to identify the potentials transformative and maintenance parts of tools linked to the grade of predetermination of the systems production.

The Riparo Tagliente site shows two macrophases. The first one with an exclusive flake production and the second one with a volumetric blade production associated with others kind of flake productions. Preliminary results of this study are focused on evaluating the impact of the introduction of a new concept of tool (blade) on the production systems previously dominated by a "classical" flake production.

In the Italian peninsula laminar production doesn't have clearly evidence dating back to earlier period of isotopic stage 4. In Italy the sites holding a laminar component seem to be concentrated in the latter phases of the Middle Palaeolithic and especially in the first part of

isotopic stage 3. The geographical distribution of these products does not seem confined to a territory or a specific environment. In parallel to the emergence of the laminar volumetric systems, the Levallois concept seems to be redirected towards the production of elongated blanks at the expense of the flake modules. More generally we can observe that at the end of the Mousterian cycle the operational patterns shows a strong differentiation and the laminar production is one of the most evident expressions. The origin of this fragmentation is questionable.

ORAL

### 3. SIMPLE TECHNOLOGY, COMPLEX BEHAVIOR IN THE FINAL LOWER PALEOLITHIC OF THE RIBEIRA DA PONTE DA PEDRA SITE.

*Cura, Sara (Museu de Arte Pré-Histórica) saracura@gmail.com*  
*Grimaldi, Stefano (Università di Trento) stefano.grimaldi@lett.unitn.it.*

*Cura, Pedro (Museu de Arte Pré-Histórica de Mação)pedro-cura@gmail.com*

*Rosina, Pierluigi (IPT) prosina@ipt.pt*

The lithic assemblage of the Ribeira da Ponte da Pedra site ( OIS8-9) was produced, almost exclusively over the exploitation of quartzite fluvial pebbles of good quality and is characterized by the application of two main reduction sequences that result in abundant worked pebbles, retouched pebbles, cortical and half cortical flakes, few cores and rare bifacial artifacts. Some artifacts present irregular and variable edge modifications described as «informal» retouch that can be the result of the utilization of these blanks. From a strict technical point of view the assemblage can be described as quite simple, however we can envisage an inherent complexity starting in an accurate selection of the quartzite pebbles, with regular morphology allows a «predetermined» production of blanks with simple gestures.

ORAL

### 4. APPLICATION OF THE TECHNO-FUNCTIONAL ANALYSIS ON EARLIEST STONE AGE / MODE 1 ASSEMBLAGES: FROM MIGRATION WAVES TO LOCAL INVENTION.

*De Weyer, Louis (UMR 7041 ArScAn - AnTET) louis.deweyer@gmail.com*

The European earliest assemblages are often compared with those from the Oldowan period in East Africa, older of 500 ka, because of their archaic aspect. They are classified in the Mode 1 technology, distinguished from Mode 2 by the absence of handaxes. The African origin of the first European assemblages is an issue often used to illustrate the paradigm of migration waves. One considers that each hominid species went out of Africa with specific technical skills similar to those recognized in Africa.

However, this pattern is not so clear when archaeological data are taken into account. Indeed, very few skeletons were discovered to prove that theory, thus anthropological data are weak. Moreover, the classification of the first lithic assemblages was made in a very global way, and numerous differences could be hidden by that superficial homogeneity.

In East Africa, Oldowan is also a term that hides the variability of the first human productions. That variability has always been explained by contextual issues. Indeed, according to a site occupation context (butchery, knapping workplace, habitat), we will obviously find different remains; if the quality of the raw material is bad, the production will appear less complex. Thus, it limits the interpretations about the goals, abilities and knapping skills of the first knappers.

Contextual data cannot be the unique criterion used to define the first hominids' knapping skills. It is necessary to look at the artifacts with issues about their meaning for the ancient knappers. What did they want to do? How did they manage to realize their objectives with such a raw material? Are there similarities between tools on poor raw material and well-made tools on good raw material that we found in some other sites?

In this presentation, we use the examples of Koobi Fora FxJj-1, 3, 10 (Kenya), Fejej FJ-1 (Ethiopia), Pirro Nord (Italy) and Orce (Spain) to balance the Out of Africa I model with a local invention hypothesis, implying a convergence of ideas, based on the techno-functional analysis of the assemblages.

Developed with the combination of different disciplines, this approach aims to find the structure of the artifacts, divided in techno-functional units. That leads us to understand how the combination of the different structural areas constitutes the tool.

Regarding such issues as the variability of the first human productions, this methodology allows us to go further in the research of the first human activities and their

diversity. Each site reveals specific skills, and universals as flakes with a natural back. We propose new tool types and a combination of skills for each assemblage, leading to new comparison criterion.

According to the techno-functional analysis of the earliest technical phenomenon, the migration waves model is no longer satisfying to explain the development of stone knapping, and new hypothesis have to be stated.

ORAL

## 5. THE EARLIEST PROTOAURIGNACIAN IN ITALY: THE RIPARO MOCHI.

*Grimaldi, Stefano (Università di Trento) stefano.grimaldi@unitn.it*

*Santaniello, Fabio (Università di Trento) fabio.santaniello@unitn.it*

Based on the current evidence, the base of the Unit G of Riparo Mochi (Balzi Rossi, Italy), dating to around 37-36.5 ka BP (41.5 cal BP), is the oldest directly-dated Aurignacian assemblage in Italy.

In this paper, the lithic assemblage coming from this layer have been techno-functionally analyzed.

From a technological perspective, the assemblage is mainly represented by a bladelet production made from non-local raw materials and by an elongated-flake production made from local flint. Regardless this technological difference, the lithics have been used for tasks linked to the treatment of animal materials. In particular, besides retouched tools showing traces of hard materials (bone or antler), unretouched tools show traces related to butchering or cutting soft/medium material such as meat and hide.

According to the type and distribution of the macro and micro wears, a possible reconstruction of the hafting technique is also suggested.

---

ORAL

## 6. THE FINAL MOUSTERIAN IN WESTERN ITALY.

*Santaniello, Fabio (Università degli studi di Trento) fabio.santaniello@unitn.it*

*Grimaldi, Stefano (Università degli studi di Trento) stefano.grimaldi@unitn.it*

Late Mousterian lithic technology remains poorly known in Italy. The traditional typological approach still permeates the literature, and most technological analyses focus on the "transition" to the Upper Palaeolithic. In this paper, we provide new data about the behavior of the last Neandertals who inhabited Tyrrhenian western Italy. Lithic assemblages from two well-known sites e Riparo Mochi (Grimaldi caves, Balzi Rossi area, Liguria) and Grotta Breuil (Monte Circeo, Lazio) have been technologically and functionally analyzed.

The results are discussed and compared to other data such as fauna, chronology, and palaeoenvironmental reconstructions.

The data reveals a highly dynamic world where behavioral changes were rapid in time and characterized by strong differences in territorial exploitation.

---

ORAL

## 7. THE TECHNOLOGICAL AND BEHAVIORAL TRANSFORMATION IN THE MIDDLE UPPER PALEOLITHIC OF HOKKAIDO, NORTHERN JAPAN: INTERPRETING THE EMERGENCE OF PRESSURE MICROBLADE PRODUCTION AND ITS SIGNIFICANCE

*Takakura, Jun (Hokkaido University) jun-ta@let.hokudai.ac.jp*

In the past decades, much attention has been focused on the search for the earliest archaeological records relating to the pressure microblade production of the Late Pleistocene in Northeastern Asia. The archaeological evidence of the middle Upper Paleolithic assemblages in Hokkaido, Northern Japan, has seen a transformation in our understanding of the emergence and dispersion of the pressure microblade production in a vast range of geographical area. These assemblages, consisting of microblade and non-microblade technologies, mostly date to during and immediately before the Last Glacial Maximum (LGM) cold period, 30,000-24,000 calendar years ago.

The aim of this paper is to examine how the emergence and adoption of the pressure microblade production in Northern Japan were related to the behavioral transformation, such as composition and maintenance of tool kits, mobility, domestic activities, technological transmission, and regional interaction. To accomplish it, this paper presents the current knowledge on technological and behavioral variability and dating of

the lithic assemblages, and discusses interpretations of technological and behavioral variability in the middle Upper Paleolithic in Hokkaido, in particular based on the chaîne opératoire approach for the lithic reduction sequences as well as the use-wear analysis of stone tools. In Hokkaido, Northern Japan, the pressure microblade production suddenly appeared around 25,000 calendar years ago. Several evidences show that these were associated with the emergence of the use of organic hammers for detaching blades and the use of stone graters for fabricating bones and antlers systematically.

The adoption of the pressure microblade production in Hokkaido was apparently related to not only the emergence of newly lithic reduction sequences but also the technological and behavioral transformation of the prehistoric hunter-gatherers.

POSTER

**8. TECHNO-TYOLOGICAL ANALYSIS OF THE LITHIC ASSEMBLAGE AT CUEVA BLANCA SITE (HELLÍN, ALBACETE, SPAIN): A CONTRIBUTION TO DETERMINE THE LITHIC REDUCTION SEQUENCES IN THE LATE MESOLITHIC OF THE SOUTHEASTERN IBERIA.**

Mingo Álvarez, Alberto (UNED) [amingo@geo.uned.es](mailto:amingo@geo.uned.es)  
Barba Rey, Jesús (UNED) [jbarba@pausanasias.com](mailto:jbarba@pausanasias.com)

Cueva Blanca is situated in the northernmost sector of the Betic mountains. The geographic corridor Jumilla-Yecla-Hellín, where the site of Cueva Blanca is placed, has not shown stratigraphic references belonging to Late Mesolithic period. Its discovery provides a reference of settlement and information concerning the Late Mesolithic at the Campos de Hellín.

The archaeological layer of the mesolithic occupation is called 1B and is composed by fine detritus material that occasionally might contain some sharp clasts reaching 15cm of size. The thicknesses vary from 7 to 20cm.

The analysis is based on the Fortea's work (1973) on lithic industry of the last hunters-gatherers in Iberia. The description of the retouching has been done following the study of Laplace (1974), while the cores analysis is based on Pelegrin (1995). Finally, the alterations has been described following Bernaldo de Quirós *et al.* (1981).

The laminar lithic industry was carried out largely using local sources of siliceous rocks. However, the cores of these laminar products registered in the site are scarce (N = 4), formless and made of small size quartzite nodules. The characteristics of various *debitage* elements (all in flint), the finding of abrasion traces in several bladelets and the presence of a good number of pieces showing platform angles above 90° are aspects that help to recognize an exploitation system based in unipolar reduction, preparation of flaking and striking platforms, and abandonment by exhaustion. Two different types of laminar supports are obtained: 1) displaying parallel negatives in their dorsal face 2) with convergent and / or little regular negatives.

The flake production is done either in flint and quartzite, seeking small and medium size supports.

We have identified 3 *debitage* schemes linked to diverse strategies of raw materials procurement and exploitation. The obtainment of blades/bladelets and some short flakes of quartzite could respond to an expeditive strategy carried out on flattened small nodules present near the site. In contrast, the production of blade/bladelets in flint seems to respond to a curated strategy. We think the decortication phase of nodules didn't occur at the site, although the extraction of supports, revivals and preparations of cores is openly observed. A third and last lithic reduction system seems to be documented when generating medium size flakes of fine-grained quartzite.

For the tools, we can remark their almost exclusively abrupt, marginal and direct retouching and the use of flint to make most of them. In general, the types fit well into the classification proposed by J. Fortea (1973). The tools assemblage as a whole, especially those made on blade and bladelets, has a geometrical nature which is clearly testified through the presence of trapezoids.

The Late Mesolithic deposits in the closest regions to Cueva Blanca hold up lithic assemblages attributed to facies Cocina. Unfortunately, the limited lithic analysis carried out for these sites, except Casa de Lara, don't allow further comparison with our results.

The techno-typological analysis of Cueva Blanca lithic industry has contributed to a better knowledge of lithic reduction systems of the last hunters-gatherers in the hinterland of southeastern Iberia.

**1. ROD PRODUCTION BY EXTRACTION («DÉBITAGE» BY EXTRACTION): AN OVERVIEW OF DIFFERENT CASES IDENTIFIED FOR THE UPPER PALAEO-LITHIC AND THE MESOLITHIC IN EUROPE**

*Averbouh, Aline (Archéozoologie, Archéobotanique : sociétés, pratiques et environnements, Museum National d'Histoire Naturelle, Paris, France) aline.averbouh@mnhn.fr*  
*Goutas, Nejma (Equipe d'Ethnologie préhistorique, Maison René Ginouvès, Nanterre cedex, France) nejma.goutas@mae.cnrs.fr*

*Marquebielle, Benjamin (Maison de la recherche, Campus de l'Université du Mirail-Jean Jaurès, 5 allées A. Machado, Toulouse, France), Et membres du Groupement de Recherche International PREHISTOS.) benjamin.marquebielle@yahoo.fr*

One of the objectives of the GDRE PREHISTOS, created in 2007, is to look for cases of "debitage by extraction" on the European continent from the Paleolithic to the First Iron Age. We will thus be able to fill the gaps in our knowledge by first describing each case in technical and economic terms and by identifying new variants of this method. This debitage consists of selectively extracting a defined portion from a piece of raw material in order to obtain blanks with standardized forms and dimensions. It is a major invention in the working of osseous materials and it is conceptually similar to the laminar debitage procedure (Averbouh 2000 p. 154; Goutas 2009) in stone working in that it allows blanks of a similar shape, artificial and standardized, to be produced. The "baguette", whose shape is close to that of blades, is the best known of these blanks. This capacity to produce series of blanks with sometimes exactly similar morphology and then finished objects lead to the standardized mass productions that characterize the evolution of some categories of objects, such as projectile points. This debitage by extraction appears globally during the first half of the Upper Paleolithic (being present in the Early Gravettian of western Europe, Goutas 2004). The aim of our presentation is to give an overview of different cases identified those last years for the Upper Paleolithic to the Mesolithic, especially in Europe.

ORAL

**2. POSSIBLE EVIDENCES OF DÉBITAGE PAR EXTRACTION IN THE WORKED OSSEOUS ASSEMBLAGE OF THE HUNGARIAN PALEOLITHIC**

*Tóth, Zsuzsanna (Eötvös Loránd Science University, Budapest) zsuzsanna.toth11@gmail.com*

The worked osseous material originating from the Palaeolithic period of Hungary is not very numerous, and often rather poorly preserved. That is why research based on the reconstruction of the *chaîne opératoire* of these tools has not carried out yet.

Aim of this study was to investigate the most numerous and best preserved Late Palaeolithic tool assemblage, discovered in the Lovas ochre mine in the fifties, in order to identify different manufacturing techniques, with a main interest to the *débitage par extraction*. This is widespread in Western Europe and around the Carpathian Basin, but counted as an unknown technique in our country.

Optical investigation with low magnification was used during the study, which proved as first, that the worked osseous assemblage was relatively well preserved for the identification of the different manufacturing techniques. Some worked elk ribs and antler pieces suggested the evidence of the extraction technique, based on the grooving still visible on the pieces. Some other tools were based on a baguette preform, which suggests the use of the same technique, though the edges were completely modified during shaping, only the contours of the finished objects suggesting the existence of former grooving.

Statement of clear evidence of the knowledge and use of the extraction technique in the Hungarian Late Palaeolithic would go too far, but we may say, that our studies, based on the observation of the manufacturing stigmas on the tools and waste material suggest, that the knowledge and use of the extraction technique is plausible.

ORAL

**3. HARD ANIMAL TISSUE EXPLOITATION IN THE UPPER PALAEO-LITHIC SEQUENCE OF PAGLICCI CAVE (SOUTHERN ITALY)**

*Borgia, Valentina (University of Cambridge - UK) vb330@cam.ac.uk*

*Boschin, Francesco (Università di Siena- Italy) fboschin@*

hotmail.com

Ronchitelli, Annamaria (Università di Siena - Italy)  
annamaria.ronchitelli@unisi.it

In this paper we present evidence of the hard animal tissue exploitation at Paglicci Cave (Rignano Garganico, Foggia, Southern Italy).

Recent studies on faunal remains and on the 100 bone and antler tools found in the Upper Paleolithic sequence of the cave have allowed us to reconstruct the choices made by Paleolithic hunters both in terms of prey and the exploitation of hard animal materials for tool fabrication. Regarding the archaeozoological data, most of the sequence is characterized by the abundance of remains of species related to open or steppe environments, such as goats (especially ibex), horses and aurochs.

Only starting from layer 6 (6c, Final Epigravettian, about 17,000 cal. BP) the presence of these taxa decrease in favour of deer, wild boar and ass, reflecting an important climatic change leading to more humid and temperate conditions.

Only the bones of some hunted animals were chosen for the preparation of the tools: deer, horse, aurochs and wild boar.

In total, we identified three manufacturing techniques:  
1) the exploitation of naturally pointed bones for the construction of awls;  
2) the intensive shaping of long bones, particularly the metatarsals of deer: with the reconstruction of some waisted products it has been possible to recreate this process;  
3) the *rainurage* of antlers for the construction of spear points.

The exclusive presence of these last tools in one level of the cave (layer 17, Ancient Epigravettian, about 20,000 cal. BP) together with the total absence of waisting products and the general scarcity of remains attributable to deer, suggests interesting points for reflection on the different phases of attendance of the cave and a possible allochthonous origin of these tools.

#### 4. DEBITAGE BY FRACTURATION IN THE OSSEOUS INDUSTRY OF COVA DEL PARPALLÓ (GANDÍA-VALENCIA, SPAIN)

Borao, María (Universidad de Valencia) m.isabel.borao@uv.es

Villaverde, Valentín (Universidad de Valencia) valentin.villaverde@uv.es

Aura, Emili (Universidad de Valencia) emili.aura@uv.es

The excavations carried out by L. Pericot from 1928 to 1931 in the Cova del Parpalló allowed to document the Gravetian in the base, a potent Solutrean layers and a Magdalenian. All this sequence comprise an excepcional assemblage of portable art because their number of plaquets/objects and the great cronological amplitude. With all this information, Parpalló was included in the reduced list of reference sites to organize the european Upper Paleolithic sequence in the first half of the XX century.

The Magdalenian layers were organized in four phases, following H. Breuil's (1937) proposal. Changes in bases morfology and decorative topics on osseous points permitted this correlation, identifying by the first time the oldest Magdalenian in the south of Europe (Pericot, 1942).

With this precedent, we show in this presentation a preliminar technological and tipological study of the Ancient Magdalenian or Badegulian Parpalló's type osseous industry. The main objective is to identify the operational schemes that define the osseous material working. We analyze the different artifact categories which belongs to the production operational sequence. On the other hand we study the tipological composition of finished objects of an assemblage composed by spear points, *baguettes demi-rondes*, awls, neddles, hammers and harpoons.

The first aproach reveals us that in Parpalló, one of the operational schemes employed was fracturation. Extraction is documented as well. Both of them were used to obtain flat blanks to make objects like simple bevel points, double points or simple based points.

We make a valuation between techno- tipological transformations in lithic industries and the radiocarbon dating obtained for the beginning of this technocomplex.

All this is put in relation to the transformations produced in the SW of Europe in the LGM.

ORAL

## 5. OF HORSE METAPODIALS DEBITAGE DURING THE UPPER MAGDALENIAN IN EUROPE: AN OVERVIEW OF TECHNIQUES, METHODS AND OPERATIVE SEQUENCES.

*Bignon-Lau, Olivier (CNRS-UMR7041-ArScAn) olivier.bignon-lau@mae.u-paris10.fr*

Horse hunting strategies have been observed in a great number of Upper Magdalenian regional groups across Europe. Besides the obvious subsistence interest of these hunts, the technological exploitation of numerous raw materials leads us to a more complex understanding of Magdalenians' economical choices. In this direction, this contribution aims more particularly to point out some common techniques and methods used in the debitage of metapodials diaphysis, from Occidental to Central Europe. Surprisingly, a regular breakage pattern of these skeleton elements emerges from observations and our study tends to understand why so distant regional groups show a common operative sequence. More than this, bone fragments from this operative sequence have been used in many ways, but also, alternative operative sequence of metapodial diaphysis has been recognized in some sites. Finally, several lessons is brought to us by the study of these skeletal elements a priori of low importance, of the great similarity of the operative sequences to the diversity of the "chaînes opératoires", of its technological versatility to its economic output.

ORAL

## 6. CONTEXTUAL TAPHONOMY OF WORKED BONES IN THE NATUFIAN OF EL-WAD TERRACE (ISRAEL)

*Yeshurun, Reuven (University of Haifa) ryeshuru@research.haifa.ac.il*

*Weinstein-Evron, Mina (University of Haifa) evron@research.haifa.ac.il*

The integration of the contextual, zooarchaeological and taphonomic data with the worked osseous assemblage may enrich our knowledge of provisioning, use and especially discard of hard animal materials. Here we present a contextual taphonomy case-study from the major Early Natufian hamlet of el-Wad Terrace (EWT), in Mount Carmel, Israel, focusing on intra-site variability in

relation to architectural features and the general faunal assemblage.

The archaeofaunal sample from Early Natufian EWT (ca. 15.0-13.7/13.0 ka) is large and well-preserved. The good architectural preservation of the lower layers allows the intra-site comparison among four kinds of Early Natufian deposits: Inside and Outside Structure II, interpreted as a domestic area with consumption refuse in primary deposition; Locus 67, a stone pile showing evidence for thermal and other activities and probably resulting from a combination of primary and secondary depositions; and Locus 25, interpreted as an occasional toss-zone outside the living compound. Evidence for bone-working was recorded systematically, as part of a comprehensive taphonomic analysis of the vertebrate remains. The working procedure ensures quantitative comparisons among the worked and unworked samples.

The inclusion of worked items in the taphonomic study of EWT sheds light on an aspect that contributed to the formation and modification of the faunal assemblage, and is informative for studying the production, use and discard of the osseous artifacts. The tools and ornaments were fabricated on-site, using the available game animals that were transported to the site, mainly gazelle and occasionally partridge and tortoise elements. For gazelle at least, it can be suggested that bone-working followed butchery and consumption, and was an extension of these activities. Subsequently, the worked items were discarded with the other faunal refuse, often perhaps as a result of breakage and wear, although many beads were discarded when still usable – apparently not in any special contexts. Fragmentation and burning patterns indicate that these items underwent a similar taphonomic history to the total faunal assemblage in each context. The frequency of worked items and the diversity of types display several significant differences among the sampled contexts. Given the deposition of primary refuse in most contexts at the site, these patterns may be interpreted functionally to show where bone items were manufactured, used and discarded.

*Hershkovitz, Israel (Tel-Aviv University (Israel) anatom2@post.tau.ac.il*

*Yeshurun, Reuven (Zinman Institute of Archaeology, University of Haifa, Mount Carmel. Haifa (Israel) ryeshuru@research.haifa.ac.il*

*Schenell-Pels, Nehora (Zinman Institute of Archaeology, University of Haifa, Mount Carmel. Haifa (Israel) nehora512@gmail.com*

*Bar-Oz, Guy (Zinman Institute of Archaeology, University of Haifa, Mount Carmel. Haifa (Israel) guybar@research.haifa.ac.il*

Nowadays Levantine Upper Palaeolithic archaeology is of great importance in understanding the emergence, dispersal, and adaptations of the first Anatomically Modern Humans (AMH) populations. Nevertheless, research on this period in the studied region has been limited to specific data, for instance osseous industry suffers from a dearth of data. Thus, exploitation of osseous raw material (mainly bone and deer antler) is one of the major innovations that appears at the beginning of the Early Upper Palaeolithic (EUP) both in Levant and Europe (innovation documented since the Middle Stone Age in the African context). With this in mind, the characterisation of technical concepts chosen by the first Levantine AMH is of great interest. Until now the Levantine rich collections of bone and antler objects are mostly known from a typological point of view.

The discovery of the important site of Manot Cave (Galilee. Israel) in 2010, preserving Mousterian, Ahmarian and Aurignacian levels, has initiated a multidisciplinary and international project. The main objective of this project is to reassess the variability of the chronological sequence of the Levantine EUP confronted with data from others archaeological sites of the Region.

Within the framework of this project, we present the first results of the technological and traceological analysis of the bone and antler industry of Aurignacian levels of Manot Cave (C Area). This assemblage is until now composed by more than half a hundred pieces including objects as well as blanks and wastes. The

excavation is on-going so the data is provisional, but we already have some interesting results. The Manot Cave bone and antler industry shows both similarities with the European osseous industry: such as the choice of bone for "domestic" tools (recurrent morpho-types like awls and retouchers) and that of antler for the cinegetic equipment (spear points). Differences are present within the hunting equipment with only simple-based points and not split-based points as known in Europe and some Levantine sites. Added to these characteristics the absence of polishers and the, probably, common exploitation of fallow deer antler, among others. These features support some particularities already stated from the Levantine Aurignacian by for some authors.

The presented preliminary data from technological analysis of Manot Cave osseous industry is a part of a larger final goal. Our aim is to reconstitute and understand the operational sequences of bone and antler exploitation at the Early Upper Palaeolithic in Levant (through the enlarged study of other important Levantine collections like Ksar Akil or Hayonim D). The obtained techno-economical data, compared to European ones, will not only contribute to refine the chrono-cultural EUP sequence of the Levant but also to give a better understanding of the adaptation mechanisms of the first Anatomically Modern Humans in Eurasia.

## 8. BOIS DE RENNE ET DE CERF DANS L'AURIGNACIEN ANCIEN DE GARGAS (HAUTES-PYRÉNÉES, FRANCE): APPROCHE PRÉLIMINAIRE DES SCHÉMAS TECHNIQUES D'EXPLOITATION

*San Juan-Foucher Cristina (S.R.A. D.R.A.C. Midi-Pyrénées et UMR 5608 TRACES, Université de Toulouse-Le Mirail) cristina.san-juan@culture.gouv.fr*

*Vercoutere, Carole (Département de Préhistoire du Muséum national d'Histoire naturelle / CNRS UMR 7194 « Histoire Naturelle de l'Homme Préhistorique ») cvercout@mnhn.fr*

*Foucher, Pascal (S.R.A. D.R.A.C. Midi-Pyrénées et UMR 5608 TRACES, Université de Toulouse-Le Mirail) pascal.foucher@culture.gouv.fr*

Surtout connue par son habitat et son art pariétal gravettiens, la grotte de Gargas a livré aussi des vestiges d'une occupation aurignacienne. Mise en évidence par les travaux d'Emile Cartailhac et d'Henri Breuil (1911-1913), elle avait été attribuée à l'Aurignacien « inférieur » en raison de la présence de pointes de sagaie à base fendue dans l'assemblage.

Le projet de recherche en cours et les nouvelles fouilles sur le site (2004-2013) ont permis de mieux situer ce niveau dans la séquence stratigraphique, de le dater et d'obtenir des données complémentaires concernant les industries lithiques et celles en matières dures d'origine animale. Nous présenterons ici les premiers résultats de l'analyse des schémas techniques d'exploitation des bois de cervidés, en particulier ceux relatifs à la fabrication d'armatures de projectiles, à partir de l'étude croisée des séries ancienne et récente, dans un cadre radio-chronologique et un contexte faunique actualisés.

ORAL

### 9. L'INCIDENCE DE L'UTILISATION ET DU RÉAFFÛTAGE SUR LA TYPOLOGIE DES POINTES DE PROJECTILE AURIGNACIENNES EN BOIS DE CERVIDÉ

*Doyon, Luc (Université de Montréal, Département d'anthropologie, C.P. 6128 succursale Centre-ville, Montréal, Québec, Canada, H3C 3J7) luc.doyon@umontreal.ca*

Malgré des similitudes morphométriques qualitativement appréciables, les pointes de projectile aurignaciennes en bois de cervidé présentent un large éventail de formes et de dimensions qui mérite d'être expliqué. Dans la présente communication, la contribution de l'utilisation et du réaffûtage à cette variabilité est examinée en détail. Les résultats démontrent que ces deux processus convergents et producteurs de variabilité affectent principalement la morphométrie distale des armatures. L'analyse et la discussion offrent une perspective de recherches jusqu'à maintenant inexplorée, soit la révision des critères de classification typologique de ces pointes de projectile. Pour ce faire, un cadre d'analyse artefactuelle est avancé; celui-ci tient compte (1) des contraintes fonctionnelles auxquelles sont soumises les pointes de même que (2) leurs propriétés structurales et mécaniques dans une perspective globale de la transmission sociale du savoir technique. Finalement, une nouvelle mesure est introduite, le ratio proximo-distal, qui permet d'apprécier l'étendue des dimensions relatives des armatures considérées idoines par les chasseurs aurignaciens pour l'exécution des activités cynégétiques.

ORAL

### 10. THE INCISED BONE POINTS FROM THE EARLY AURIGNACIAN OF POTO-KA ZIJALKA, HAFTING SYSTEM OR ORNAMENT?

*Jéquier, Camille (Università degli Studi di Ferrara) jqrcll@unife.it*

From a technological point of view, the hard osseous spear points have been ever more studied during the last 20 years. The peculiarity of this kind of artefact is linked to the different raw materials, techniques and hafting systems used throughout the Upper Palaeolithic. The case study of Poto-ka zijalka, located in the Carnic Alps at 1700 m a.s.l. in northern Slovenia has yielded a conspicuous amount of fauna from its 8 main layers. The faunal spectrum is mainly composed by *Ursus speleus*, although some rare ungulates such as *Cervus elaphus* and *Bos/Bison* have been identified. The lithic industry is very poor and only one Dufour point was discovered. In layer 7 at the front of the cave, seven combustion structures were identified.

The cave also contained 125 hard osseous artefacts, mainly made of bone (only three elements were identified as antler and the raw material of two of them is unidentified). Typologically, the corpus is composed of 12 points, two roughout of spear points and 111 elements of spear points. It is probable that most of them are made out of *Ursus sp.* shafts, as is also partially confirmed by the DNA analysis previously conducted.

The finishing of the spear points is not systematic. Three types of incisions were identified, whose morphology and localisation vary. The first one, which is the most frequent (n : 15), is systematically located on the sides of the spear points. They are parallel and are often regularly disposed, mainly on the mesio-distal part of the point or on the whole length of the element. The second type of incision is much rarer, since it was only identified on three artefacts. Its morphology consists in narrow and superficial stria that turn around the point circumference. They are rarely entirely continuous and never extend to the distal extremity of the point. Finally, the third type of traces consists more in a very deep grooving than in a proper incision. They are always located proximally, over the groovings that shaped the diaphysis and, when they are present, over the first type of incisions.

If an esthetic aim can be proposed for the first two kinds of stigmata, it is difficult to say the same for the third. In particular, the morphology and the position of the stigmata seem to indicate clearly some implement in order to facilitate the hafting of the spear point to the wooden support.

## 11. BONE, DECORATIVE AND ORNAMENTAL ASSEMBLAGES OF THE GOROTSOVIAN? PARTICULAR CULTURAL UNITY OF THE EAST EUROPEAN UPPER PALAEO-LITHIC /GI-6 - GS-5/.

*Sinitsyn, Andrei (Inst. for the History of Material Culture. RAS)  
andrei.sinitsyn@gmail.com*

Bone, decorative and ornamental assemblages of the Gorotsovian – particular cultural unity of the East European Upper Palaeolithic /GI-6 – GS-5/.

As a separate cultural unity Gorodtsovian was identified by P.P. Efimenko in 50-th of the last century. In 70th G.P. Grigoriev united under this title Kostenki 14 (cultural layer II), Kostenki 15, Kostenki 16, Kostenki 12 (cultural layer I). Chronological framework of the Gorodtsovian was distinguished by the chronological group II of Kostenki model: 32-28 ka (34-32 cal ka BP), which corresponds to the GI-6 - GS-5 inside MIS3.

Principal background for Gorodtsovian definition was specific features of lithic assemblage:

- high meaning of flake knapping technology and flake-based typological set;
- high content of Mousterian tool-kit, primarily side-scrapers;
- low index of burins up to total absence in the II cultural layer of Kostenki 14;
- particular bone assemblage including Gorodtsovian 'fossil director' - large spatulas with nail-like extremity of the haft.

Gorodtsovian coexists in Kostenki with Early Gravettian (Kostenki 8, cultural layer), but provides different both lithic and bone assemblages.

Gorodtsovian sites provide numerous and expressive series of bone tools, including decorated, pendants and beads at least of four types, zoomorphic volumetric objects, etc., which is a matter for discussion in the paper. Gorodtsovian bone and decorative assemblages remains to be unique without analogies in the Paleolithic of Eastern and Central Europe.

**Acknowledgement:** Presidium RAS; RFBR: 14-06-00295; RFH: 14-01-18097.

## 12. CARACTÉRISATION NON DESTRUCTIVE DES MATIÈRES PREMIÈRES OSSEUSES PRÉHISTORIQUES: APPORT DE LA MICROTOMOGRAPHIE X À L'ANALYSE DES BOIS DE CERVIDÉS

*Lefebvre, Alexandre (UMR 5199 PACEA, Université de Bordeaux, Talence, 33405, France) a.lefebvre@pacea.u-bordeaux1.fr*

*Rocheffort, Gaël (EA 2496 Pathologie, Imagerie et Biothérapies orofaciales, UFR Odontologie, Université Paris Descartes, PRES Sorbonne Paris Cité, Montrouge, F-92120 France; Plateforme d'Imagerie du Petit Animal Paris Descartes, Paris, F-75015 France) gael.rocheffort@parisdescartes.fr*

*Salmon, Benjamin (EA 2496 Pathologie, Imagerie et Biothérapies orofaciales, UFR Odontologie, Université Paris Descartes, PRES Sorbonne Paris Cité, Montrouge, F-92120 France; Plateforme d'Imagerie du Petit Animal Paris Descartes, Paris, F-75015 France) Département d'Odontologie (Bretonneau et Charles Foix), AP-HP, Paris, France benjamin.salmon@parisdescartes.fr*

L'imagerie 3D biomédicale est aujourd'hui détournée de son domaine d'application initial pour alimenter la recherche sur la caractérisation des matières premières osseuses préhistoriques. Si les principaux biomatériaux minéralisés que compte l'industrie osseuse préhistorique (os, bois de cervidés, dentine/ivoire), ont fait l'objet des premiers essais de caractérisation concluants, la détermination taxinomique des vestiges reste, en revanche, un domaine d'étude en cours d'exploration. Dans le cas particulier des pièces archéologiques réalisées en bois de cervidés, la distinction entre le bois de cerf et le bois de renne peut s'avérer, dans certains cas, délicate (modification anthropique des vestiges et/ou action d'agents taphonomiques). En complément des techniques d'identification physico-chimiques destructives classiques (spectrométrie de masse, étude des ratios isotopiques, analyses ADN), la microtomographie par rayons X s'avère être un outil d'analyse non destructif pertinent. En collaboration avec la plateforme d'imagerie bio-médicale de l'Université Paris Descartes, cet article présente la méthodologie expérimentale (scan des échantillons, analyse d'images et statistiques descriptives) ayant conduit au développement d'une méthode de caractérisation visant à distinguer les bois de cervidés à partir de l'étude de la microarchitecture osseuse d'une collection de référence de bois actuels et archéologiques. Les limites de spécificité et de sensibilité statistiques de cette méthode de discrimination relative sont notamment discutées en fonction des différentes portions anatomiques étudiées

**(3. MICRO-PIXE/PIGE ANALYSIS OF AURIGNACIAN IVORIES: ADVANCES AND LIMITATIONS IN THE STUDY OF PALEOLITHIC OSSEOUS MATERIALS**

*Heckel, Claire (Center for the Study of Human Origins, New York University, USA) claire.heckel@nyu.edu*

*Müller, Katharina (Laboratoire d'Archéologie Structurale et Moléculaire, CNRS UMR 8220, Paris, France)*

*White, Randall (Center for the Study of Human Origins, New York University, USA)*

*Floss, Harald (Institut für Ur- und Frühgeschichte und Quartärökologie, Universität Tübingen, Germany)*

*Conard, Nicholas (Institut für Ur- und Frühgeschichte und Quartärökologie, Universität Tübingen, Germany)*

*Reiche, Ina (Rathgen Forschungslabor Staatliche Museen zu Berlin Stiftung Preußischer Kulturbesitz, Berlin, Germany)*

Non-destructive methods for the chemical analysis of osseous materials have expanded the range of archaeological artifacts that can be analyzed for their chemical composition. The results of micro-PIXE/PIGE analysis performed at the AGLAE facility at the C2RMF in Paris of ivory artifacts from Early Aurignacian deposits at Abri Castanet, Grotte de la Verpillière I, and HohleFels Cave are presented, with specimens of Middle Paleolithic origin from the Grotte de la Verpillière II for comparison. Some bone and tooth samples were likewise analyzed for comparison. This study had three primary goals: precise determination of the diagenetic alterations to mammoth ivory of Aurignacian age; the assessment of F-content as a method for establishing relative chronology within individual sites; the determination of the potential of trace element analysis as an indication of mammoth ivory provenience at the regional level.

While diagenetic alterations do impose certain limitations on the conclusions that can be drawn from chemical analyses of ancient materials, we have been able to obtain results that are significant to understanding patterns of raw material procurement and use in the Early Upper Paleolithic. The results of these studies are presented, and their implications for the study of ivory and other osseous materials from Paleolithic contexts are discussed. The indications of the potentials and limitations of these analyses will be of interest to specialists engaged in the study

DISCUSSION ET CONCLUSION

POSTER

**LITHIC-OSSEOUS INTERFACE: HOW PROTOAURIGNACIAN (EUP) LITHIC TOOLS WORKED OSSEOUS MATERIALS IN PROTOAURIGNACIAN SITES**

*Pasquini, Amaranta (LAMPEA (Laboratoire Méditerranéen de Préhistoire Europe Afrique) - UMR 7269, France) amerasi@gmail.com*

The beginning of the Upper Palaeolithic in Western Europe (ca. 40-30 ka BP) is characterized by the presence of different cultural techno-complexes in southern Mediterranean areas (Uluzzian, Protoaurignacian) and continental Europe (Chatelperronian, Early Aurignacian). Traditionally, Chatelperronian and Uluzzian lithic traditions are associated with Neanderthal fossils, while the Protoaurignacian and Early Aurignacian are considered as a Sapiens (AMH) production.

Chronologically the Protoaurignacian is considered the first techno-complex attributed to AMH in Western Europe.

Compared with the profusion and the variety of Early Aurignacian osseous production, Protoaurignacian sites show a very scarce presence of this industry (except for few rich deposits).

The usewear analysis carried out on the lithic assemblages from four French Protoaurignacian sites (Observatoire, Esquicho Grapaou, Laouza, Cottés) shows that the archaeological reality is more complicated than appears. Even in the absence of organic remains on site, a great number of analyzed lithic tools worked osseous materials (almost exclusively antler) at the different production stages of the osseous reduction sequence.

The implications and importance of these results (observed gap between "osseous" and "lithic" traces) are discussed.

POSTER

**BONE TOOLS USED IN PREHISTORIC ENGRAVINGS OF PATAGONIA (ARGENTINA)**

*Pérez, Alberto J. (Fundación Azara. Universidad Maimónides) arqueo.meliquina@gmail.com*

*Díez, J. Carlos (Universidad de Burgos) clomana@ubu.es*

We analysed skeletal remains from the Cueva-Paredon Loncomán site (Río Negro, Patagonia), dated around 2000 BP. The walls of this metamorphic rock shelter contain "Pisadas" (Menguin, 1957) zoomorphs, a style found in much of the southern tip of the American continent. Archaeological analysis identified a set of bone tools (Lama guanicoe and Pterocnemia pennata /long bones) on the Upper level with taphonomic features used in scrapings and incisions on walls. Given the novelty of this proposal, we conducted an experiment involving the manufacture and use of bones (guanaco and choique) in engraving work. The bones proved well suited for the production of similar archaeological motifs. The microscopic features seem to show that guanaco and choique long bone tools could have been manufactured and used by Patagonian hunter gatherer societies in prehistoric engravings.

**1. WHAT INFLUENCE DID CLIMATE CHANGES HAVE ON STYLES? METAMORPHOSIS IN EUROPEAN MESOLITHIC AESTHETICS.**

*Bouvry, Florence ((ARSCAN UMR 7041), Maison de l'Archéologie et de l'Ethnologie, Nanterre (92) florence.bouvry@gmail.com*

Nine to ten thousand years ago, Mesolithic era was marked by a great number of economical and social changes partially due to forest development in Europe. It's ending takes place (is to be seen) between the eight and fourth millennium B.C., with the rising of the Neolithic era.

With each new period, culture re-evaluates it's past (puts it's past back into perspective) and defines what seems contemporary, thus being the time being's preoccupations. With the transitional phase to Mesolithic, transformations are to be observed in representation styles. Those change (evolve) from Paleolithic's realistic figuration to Neolithic's symbolic figuration. As reflections of the ecological environment, these style metamorphoses match with Lithic's technological three "mutation-revolutions". (Marchand G. 1997).

As such (Being so), those different styles refer to society's mutations-or as P.Francastel (1970) would name them-"figurative systems".

P. Francastel writing : "Though we have tried to explain art by society, it is art that -partly- explains society's challenges (radical changes). We have always considered art as an ornament or an accessory, a social superstructure instead of analyzing it and questioning it as being a fundamental function. (...)"

Throughout this communication, I intend to analyze how climate changes are to be considered as the beginning of styles' metamorphosis in European Mesolithic aesthetics.

This research was performed within the AGRIVESTMED project that studies the agriculture expansion in the western Mediterranean area. Various areas surrounding main Neolithic sites in Iberia and northern Morocco were sampled (cored), including the Lake Banyoles (Girona, Spain) in which eastern margin is located a Neolithic settlement called La Draga. In this site, an archaeological project is being developed for the last 24 years in the frame of consortium composed by the UAB, CSIC and the Archaeological Museums from Catalonia and Banyoles. This work analyzes and interprets one of the cores (named SB2) retrieved from the margins of the lake, showing interesting information concerning the palaeoenvironmental evolution and human impact during the Neolithic period.

The study is carried out over 4 m long sedimentary record. The research includes: sedimentological interpretation (sedimentary facies and stratigraphic description of the core), high-resolution geochemical analysis (XRF) measured at 1cm intervals, statistical multivariate analysis of the data (PCA), mineralogical analysis by X-ray diffraction (XRD), particle size analysis and the radiocarbon dating by AMS of eight sediment samples.

To construct the chronological model of the SB2 core, 7 out of the 9 radiocarbon dates were used. The obtained ages covers nearly the whole Holocene.

Four sedimentary facies have been defined and correlated within the core according to the macroscopical and microscopical observations and compositional analyses: i) carbonate sands, ii) carbonate muds, iii) mineral-rich peat and iiiii) edaphized carbonate mud. Based on these facies we can infer four different depositional environments. Accordingly, the SB2 sequence has been divided into four stratigraphic units and furthermore in ten sub-units.

The granulometry measures the grain size and provides also four intervals according to the different sedimentation rates.

The mineralogy has been characterized by X-ray diffractation and the main minerals found have been calcite, gypsum, quartz and clay minerals.

Geochemical core logging was undertaken by XRF analysis. The core scanner measured 24 chemical elements: Al, Si, P, S, Cl, Ar, K, Ca, Ti, Rh, Ni, Cu, Zn, Ga, Ge, As, Br, Rb, Sr, Y, Zr, Nb and Pb.

A multivariate statistical analysis (PCA) was applied to the XRF results. Two main components were extracted indicated by PCA analysis: PC1 shows an opposite connection between siliciclastic elements and carbonates; while PC2, is controlled by organic content in opposite to carbonates.

The study of the SB2 core from Lake Banyoles have allowed us to define four stratigraphic units composed of four lacustrine sedimentary facies controlled by the water depth variation. The pattern is indicative of the trend and evolution of carbonate lake margin depositional environments from humid to relatively more arid environments. The decline of the water level could be due to a lower rate of precipitation in the recharge zone.

Coinciding with La Draga Neolithic settlement, some anomalies are detected in the sedimentary record probably related to deforestation.

### **3. MESOLITHIC TO BRONZE AGE LANDSCAPE SIGNATURES DURING PERIODS OF ABRUPT CLIMATE CHANGE: CURRENT WORK FROM THE UPPER VINALOPÓ VALLEY (SE SPAIN) LAKE DEPOSITS**

*Elsie Jones, Samantha (IPHES) sjones@iphes.cat*  
*Burjachs Casas, Francesc (IPHES) fburjachs@iphes.cat*  
*Fernandez Lopez de Pablo, Javier (IPHES) jfernandez@iphes.cat*

Within the last few years, different studies undertaken in southern France and the Iberian Peninsula suggest that the Middle Holocene climatic crisis had drastic impacts on Late Mesolithic foragers, causing the abandonment of previously settled areas, changes on human mobility strategies and possible population decreases illustrated by migrations and cultural gaps. There are many cultural gaps recorded at archaeological cave in-fillings between 8500-8000 cal BP. These cultural and stratigraphic gaps make it quite difficult to analyse the potential relationship between environmental factors and population dynamics during the Mesolithic-Neolithic transition.

In March 2014 a two year IEF Marie Curie project was established, entitled 'Prehistoric Transitions in the Mediterranean: Cultural and economic responses to climate change during the Mesolithic-Bronze age' (PRETM). The project was established to gain a more precise understanding of the effects of climatic-events on prehistoric economies and culture in the Mediterranean. The key objectives are to examine the effects of environmental stress on prehistoric communities, the palaeo-environmental context of the Mesolithic-Neolithic transition and the anthropogenic impact on the first agricultural and husbandry systems on landscape between 7500-4000 cal BP. Two cores were extracted, from Casa Corona and the Villena lagoon in the upper Vinalopo valley of Eastern Spain, for multi-proxy, high resolution analysis. This included analysis for pollen, phytoliths, Loss on Ignition, Magnetic susceptibility, DXR-XRF and C14 dating. The study area was selected because it provides a unique opportunity to analyse, at a local scale, a rich and very sensitive record of Holocene vegetation dynamics from natural deposits and to compare this record with completely new archaeological data from Mesolithic and Neolithic sites.

### **4. CLIMATE CHANGES, ADAPTIVE TRANSFORMATIONS AND SOCIO-ECONOMIC EVOLUTION DURING THE MESOLITHIC IN THE EBRO VALLEY**

*García-Martínez de Lagrán, Íñigo (Postdoctoral Programme of the DEUI of the Basque Government, Spain - University of the Basque Country, U.P.V./E.H.U. - IT622-13 Research Group in Prehistory, Basque System of Research, Spain -*

*Laboratoire TRACES UMR5608, Université de Toulouse Le Mirail 2) igmtzl@gmail.com*

The studies on the Mesolithic in the Ebro Valley have focused primarily on defining the evolution of lithic tools, on the characterization of the settlement and livelihoods, and on obtaining a detailed chronological framework. In the lithic industries a marked distinction between the so-called Mesolithic of Notches and Denticulates (MND) and Geometric Mesolithic (GM) is detected. Also, recently some studies have focused on certain aspects of the socio-economic development of these groups and possible paleoclimatic events (especially the 8.2 ka event) that may affect them. In this paper a compilation of the latest data on these topics will be showed and a hypothesis of the historical evolution of hunter-gatherer communities of the Ebro valley will be proposed.

In this paper the following aspects will be discussed in detail:

- 1) The chronological framework: we will analyze the available dates of MND and GM and its temporal relation to the 8.2 ka climate event.
- 2) The internal evolution of each site will be analyzed with respect to the number of faunal remains and their management, the number of lithic remains, and the number and type of lithic tools.
- 3) An approximation to the latest interpretations of the traceological studies was performed.
- 4) Data on climate and landscape and the potential visibility and impact of these events on the paleoclimatic record of the archaeological sites were listed.

The study of all these variables allow us to define the evolution of these communities of hunter-gatherers between, grosso modo, 8000 and 5500 cal BC. Subsequently, we will analyze all data in relation with the climate event 8.2 and will try to establish possible relationships between them. Also, if this relationship is finally confirmed, we will try to define the evidence of the archaeological record to show us the influence of these climatic changes in the historical evolution of these groups.

In principle, the chronological evidence could relate the development of the Mesolithic in the Ebro Valley with the 8.2 ka climate event, as already highlighted other studies, for example in Lower Aragon. Certain paleobotanic data and technological change detected between the MND and the GM would be the main evidences of this fact. However, in this paper we intend that our conclusions

have greater both chronological and socioeconomic perspective. We will analyze the evolution of these societies since the beginning of MND until the beginning of the Neolithisation and study different aspects of these societies. A priori, one could argue that this climatic event did have an influence on the evolution of these groups although the data available are insufficient and inconclusive.

ORAL

## **5. HUMAN-ENVIRONMENT RELATIONSHIPS AROUND THE TELL OF DIKILI TASH (NORTHERN GREECE): ANTHROPOGENIC IMPACTS AND CLIMATIC CHANGES FOR THE EARLY HOLOCENE.**

*Glais, Arthur (Université Caen Basse-Normandie) arthur.glais@unicaen.fr*

*Lopez-Saez, José-Antonio (CSIC) joseantonio.lopez@cchs.csic.es*

*Lespez, Laurent (UPEC) laurent.lespez@u-pec.fr*

The investigations carried out around the tell of Dikili Tash, one of the oldest Neolithic settlement site in balkanic region, improve our understanding of the evolution of the palaeoenvironment from the beginning of the Early Neolithic (6 500 cal BC) to the Bronze Age, the periods during which the site was occupied. While global climate reconstructions researches based on the study of the Tenaghi-Philippon marsh, located 7 km from the tell, have focused on forces that drive the environment at the regional or continental scales, we attempt to use the local sediment archives to identify periods of changes around the closer inhabited areas. In order to investigate the human and the climatic impacts, mainly Rapid Climatic Change events, the small-scale alluvial sedimentary archives are valuable sources of palaeoenvironmental and geomorphological information.

The reconstruction of environmental changes is based on field work and more than 20 cores located in the wetland and alluvial areas near the archaeological site. Two sources of palaeoecological investigations have been conducted: geomorphological and sedimentological investigations and pollen and non-pollen palynomorphs analyses. Palaeobotanical proxy data give an overview of an "initial environment" before the neolithisation process and thereafter a comprehensive view of anthropogenic impact on the vegetation cover which can be compared to the sedimentological changes undertaken in lowland areas. Combined with archaeological data, this

information allows reconstruction of interactions and/or adaptation of the past local societies to global changes. The chronology is based on the radiocarbon dating of 25 samples (organic sediment or charcoal) obtained by "AMS" method.

This paper presents geoarchaeological investigation conducted in order to understand the magnitude of the climatic and human perturbations. The first results covering the Neolithic period give evidence on the role of the climatic oscillations in local environmental changes. Furthermore, the implications of these events seem to have probably favored or coincided at least with a process defined such as a Neolithic settlement pattern. The Human-Environment relationships complexity is illustrated at Dikili Tash by a settlement discontinuity which no follows only climatic events. So, the cultural changes caused by environmental changes are more often inferred from the co-occurrence of the different changes than proved by the observation of the environmental change and their real consequences for the society at the local scale.

The significant contradictions between climatic regional data set and archaeological data available locally (site of Dikili Tash), that attest a setting out of an early anthropogenic system persuade to develop multiscale approach about Early Holocene dynamics. In fact, human populations can react at local to regional scales in order to assess environmental changes from inhabited areas to then broader cultural group scale.

*Peña-Chocarro, Leonor (CSIC-Escuela Española de Historia y Arqueología en Roma (Italia) leonor.chocarro@cchs.csic.es.*

Prehistoric lakeside settlements have been studied extensively in many regions of Europe. The study of lacustrine sediments, lake level changes and related palaeoenvironmental/climatic evolution has been the main concerns of such studies. However, few studies have attempted to understand the detailed interactions between the cultural and natural processes involved in site formation in such contexts.

*La Draga* is a lakeside Neolithic settlement by the Banyoles karstic lake (Girona). The study of 12 sedimentary cores obtained along the site and the facies analysis of the sediments, supported by a suite of environmental and geochemical indices, has provided detailed palaeoenvironmental data and elucidated the main processes involved in the formation of the site and its history of occupation.

We study 200 to 300 cm long 12 sedimentary cores from *La Draga* site study area (cf. 1 ha).

The research includes: sedimentological study (stratigraphy and sedimentary facies description), high-resolution geochemical analysis (XRF core scanner), organic matter determination (L.O.I.), statistical multivariate analysis (PCA), mineralogical analysis by X-ray diffraction (XRD), particle size analysis and the radiocarbon dating by AMS.

The recovered sedimentary records were lithostratigraphically correlated and 3 main pre-site, syn-site and post-site stratigraphic units were defined. Different stratigraphic subunits and sedimentary facies were described in detail in each main unit.

The geochemical analysis of the sediments was undertaken using an Avaatech XRF core scanner. 28 chemical elements were measured: Al, Si, P, S, Cl, Ar, K, Ca, Ti, V, Cr, Mn, Fe, Rh, Ag, Ni, Cu, Zn, Ga, Ge, As, Br, Rb, Sr, Y, Zr, Nb and U. A multivariate statistical analysis, Principal Component Analysis, was applied to the XRF results.

The principal components were extracted and explain the main variations in organic matter content, charcoal content or autochthonous vs. allochthonous sediment input in the studied records.

The obtained preliminary data suggest that the onset of *La Draga* site in the shoreline of the Lake Banyoles coincided with a lowstand of the lake level. The littoral sedimentary processes conditioned the formation and the characteristics of the geoarchaeological record that is being excavated in the site. The main sedimentary control in the formation, evolution and preservation of the archaeological site is the formation of local accumulation-space during Neolithic due to the subsidence of a doline present below the archaeological area.

The joint interpretation of the results obtained from the archaeological and the preliminary stratigraphic, sedimentological, geochronological and geochemical study of 12 lacustrine sedimentary sequences cored in the Neolithic archaeological site of *La Draga* allowed the recognition of the main geological controls involved in the onset, evolution and conservation of this archaeological site.

The onset of *La Draga* site coincided with a lowstand of the Lake Banyoles level possibly reflecting less humid palaeoenvironmental conditions. The main sedimentary control in the formation and preservation of the archaeological site was the differential accumulation-space formation during the Neolithic due to the subsidence of a doline. The different subsidence pulses conditioned the environmental characteristics and the anthropic use of the archaeological area during the Neolithic.

## ORAL

### 7. LATEGLACIAL-HOLOCENE TRANSITION IN NW IBERIA: A PALAEOECOLOGICAL APPROACH

*Iriarte-Chiapusso, María-José (IKERASQUE - Universidad del País Vasco) mariajose.iriarte@ehu.es*

*Muñoz-Sobrino, Castor (Universidade de Vigo) bvcastor@uvigo.es*

*Gómez-Orellana, Luis (Universidade de Santiago de Compostela) luis.gomez-orellana@usc.es*

*Hernandez-Beloqui, Begoña (Universidad del País Vasco) begona.hernandez@ehu.es*

*García-Moreiras, Iria (Universidade de Vigo) bvcastor@uvigo.es*

*Fernández-Rodríguez, Carlos (Universidad de León) cferr@unileon.es*

*Ramil-Rego, Pablo (Universidade de Santiago de Compostela) ramil.rego@usc.es*

Palaeoenvironmental reconstructions in NW Iberia may be taken into account that this is a transition area between typically Atlantic or Mediterranean territories, with continental tendencies appearing in the inner slopes and depressions. The abrupt orography also introduces local variants. The systematic recognition of a series of climate events may be a functional way to correlate pollen sequences in a large and dissimilar area such as this. Furthermore, this method allows that intra-regional migrations or un-coupled vegetation changes were detected. The existence of this spatial component might assist in better explaining the palaeoenvironmental characteristics of each territory and the unequal human influence on the landscape.

NW Iberia may be divided in four main biogeographical units, largely based on geographical characteristics, climatic parameters and present day biogeography. High quality pollen sequences from each unit were selected to obtain reconstructions of local dynamics at each site, and also approximations of the regional tendencies in each unit. The correlation between the different regional tendencies and their coherence in relation to the climatic models performed for NW Iberia and the North Atlantic are discussed.

Low summer temperatures have been reconstructed in NW Iberia for the Oldest Dryas (8 °C) and the Younger Dryas (10° C), but increasing during the Lateglacial interstadial (ca. <13 °C) and Early Holocene (>13 °C). These changes notably affected the tree-line. Several other short-lived climatic shifts occurred, with summer temperatures dropping about 0.5-1°C, that may be linked to a series of isotopic sub-stages occurring during the GI-1 (GI-1d, GI-1c2 and GI-1b) and the early Holocene (11.2 k, 9.3 k and 8.2 k events). Steppes expanded in the inland drier basins during the coldest periods, but *Pinus* woodlands persisted in mid-slope situations at highlands, especially in areas affected by rain-shadows. Postglacial tree colonization generally follows the sequence: *Betula-Pinus-Quercus*. The representation of pine is much reduced in many oceanic areas, so no *Pinus* expansion has been recorded at the sub-coastal area, and a final *Corylus* expansion is also commonly recorded in the Cantabrian coastal mountains. The tree succession in northwest Iberia may have been postponed in some landward localities compared with other seaward sites. Pollen data denote a new ascension of the tree-line at the beginning of the Holocene Climatic Optimum, when also deciduous forest colonized the lowlands.

The sequence of temperature changes might be similar to that found in Greenland and in the Alps. Nevertheless, the regional impact of most of the less intense Lateglacial/early Holocene cold events was limited in NW Iberia, where only minor vegetation changes were recorded in very sensitive sites that were very close to ecotonal situations. The vegetation successions in the studied area were strongly influenced by the steep orography and other associated factors: e.g. the rain-shadow effect; the availability (or the lack) of appropriate migration routes for the arrival of certain species; or the overrepresentation of the regional pollen sources when the local vegetation is scarce.

POSTER

**8. A PALAEOENVIRONMENTAL PERSPECTIVE OF THE MESOLITHIC-NEOLITHIC TRANSITION: THE CASE OF MARTES SPP. IN EASTERN IBERIAN PENINSULA**

*Llorente-Rodríguez, Laura (Laboratorio de Arqueozoología-Universidad Autónoma de Madrid) laura.llorente@uam.es*

*López-Sáez, José Antonio (Instituto de Historia-CCHS-CSIC) joseantonio.lopez@cchs.csic.es*

*Nores-Quesada, Carlos (Universidad de Oviedo) c.nores@uniovi.es*

*Morales-Muñiz, Arturo (Laboratorio de Arqueozoología-Universidad Autónoma de Madrid) arturo.morales@uam.es*

Current data in sympatry areas suggest little competition between pine marten (*Martes martes* Linnaeus, 1758) and the beech marten (*Martes foina* Erxleben, 1777) despite the similarities in their biology. This is probably due to niche segregation on the basis of different ecomorphologies and behavior, the pine marten being the only of the two species being strongly associated with dense forests. The beech marten is an invasive species that colonized Europe during the Holocene from its Middle Eastern quarters, apparently benefiting from the opening of the landscape that the Neolithic expansion brought about. In this presentation, the paleo - biogeography of both mustelids in the Iberian Peninsula is addressed through pollen data. The aim is to determine whether the displacement of the pine marten towards the northern Euro-Siberian regions, documented since the Mesolithic period, was somehow coupled to the retreat of the forest during the Boreal-Atlantic transition, coincident with the transition from the Mesolithic to Neolithic, or if this could instead be due to a competitive displacement caused by the beech marten being better able to cope with the newly open landscapes that the development

of farmland fostered. Within such context, the site of Cova Fosca (Castellon, Spain), with a chrono-stratigraphic sequence that includes the Mesolithic-Neolithic transition and ample data about the coexistence of both species in the area, has proved of particular relevance.

*Arsuaga, Juan Luis (Departamento de paleontología, facultad de ciencias geológicas, universidad complutense de Madrid y Centro mixto UCM-ISCI) jlarsuaga@isciii.es*

The start of the Holocene is characterized by an important warming whose pronounced optimum, called the Hypsithermal Climatic Optimum, ranged from 8300 to 5000 yr BP, at the height of the Mesolithic development. Although the Holocene is considered as an epoch of relatively stable climate, some fluctuations, likely with a cyclicity of 1500 years, have been found in marine and terrestrial records. However, the timing of these events and the response on land is not yet well established.

The speleothems are one of the main archives to reconstruct paleoenvironmental and paleoclimatic sequences during the Quaternary period. Their chronological analyses, together with the study of stable isotopes and trace elements, allow knowing the paleoenvironmental evolution delimiting climatic events of short or long duration.

A 43 cm long stalagmite named *Moreno* was used for that purpose. It was collected in the Goikoetxe cave (Busturia, Bizkaia) in the Urdaibai Biosphere Reserve.

First studies were conducted in hand-sample under binocular microscope and photography with ultraviolet light, followed by a petrographic study for determining the carbonate crystals growth and the different crystal fabrics.

C and O isotope analyses have been also conformed in 160 samples taken along the growth axis, with a spacing of 2 mm.

For the speleothem chronology, U/Th dating was performed in 6 samples. Afterwards, an age model based on the StalAge algorithm for R program was carried out extrapolating a timeline for each isotope value obtained.

The obtained dates range from ~6800 yr BP to ~4900 yr BP.

The petrographic study reveals a homogeneous crystal fabric along de whole growth, without diagenetic features.

The UV image shows an alternance of *light* and *dark* bands which may be related to changes in the content of organic matter. Cyclicities of distinct range can be distinguished, including decadal and centennial oscillations.

A very good match is observed between the UV-bands and the stable isotope data presenting relatively low  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  values within the dark bands in contrast to the light ones.

From the homogeneity of the crystal fabric, a relatively constant growth rate under constant carbonate saturation conditions can be deduced.

The high resolution obtained for the dating and the isotopic analyses as well as the UV photography allow us to establish climatic cyclicities that might be pointing variations in the rain precipitation rate and the amount of organic matter in the soils. As a preliminary hypothesis, we can associate humid conditions during the *dark* bands, rich in organic matter, and relatively drier events with the *light* bands, with less presence of organic matter.

The studied period shows a very strong cyclicity at multidecadal time scale, particularly clear for the central part of the speleothem (Unit II) which cover about 1200 yr (from 6.4 to 5.2 ka BP), suggesting the occurrence of wetter periods with more developed soils (enriched organic matter) followed by dryer periods with less developed soils. This strong cyclicity could be associated

to the operation of some mode of climate variability at multidecadal time-scale such as the NAO.

## 10. ENVIRONMENTAL CHANGES AND PERSISTENCE OF THE POPULATION AT THE ARBA DE BIEL (ZARAGOZA, SPAIN)

*Montes Ramírez, Lourdes (Universidad Zaragoza) lmontes@unizar.es*

*Domingo Martínez, Rafael (Universidad Zaragoza) rdomingo@unizar.es*

*González-Sampérez, Penélope (Inst. Pirenaico de Ecología-CSIC) pgonzal@ipe.csic.es*

*Laborda Lorente, Rafael (Universidad Zaragoza) laborda@unizar.es*

*Alcolea Gracia, Marta (Universidad Zaragoza) malcolea@unizar.es*

The Arba de Biel is a short affluent of the Ebro that forms a small basin located in the central Pre-Pyrenees. Its geographical features (high humidity in the heart of a semi-arid region, smooth relief, abundance of sandstone rockshelters, local outcrops of good-quality flint) were profited by groups of prehistoric people that frequented the area for more than 10 millennia. This paper aims to relate the archaeological sequences and the climate fluctuations, in order to explain some singularities in the human occupations.

In this area our team has discovered five sites: Legunova, Peña-14, Valcervera, Rambla de Legunova and Paco-Pons. All the sites except Paco-Pons are found in the lower areas of the valley, next to the river and oriented to rising sun. The other one is at a high-altitude location (more than 1000 m) and we relate it to the exploitation of the copper veins that can be found in its neighbourhood. The prehistoric settlements spread from the Upper Magdalenian at Legunova to the Chalcolithic funerary employment of the site of Paco-Pons

The main part of the occupation levels belong to the Mesolithic and the Neolithic periods, in a process that seems unrelated to the climate fluctuations registered in this stage by palynological and anthracological analysis: a remarkable lack of human presence for around 1000 years between the Sauveterrian and the Notches and Denticulates Mesolithic phases can't be explained from the climate register; In the other hand, it seems that the well known 8.2 event was not apparently important in this basin.

In the second half of the 8th millennium cal BP, the establishment of first farming societies in northeastern Iberian Peninsula significantly changed the relationship established between society and nature, supposing the onset of an increasing process of landscape disturbance. In that context, the study of the several geosystem changes that occurred at the onset of the Holocene takes a decisive role.

In this work we focus on a Mid-Holocene pollen record extracted in the margin of Lake Banyoles (Banyoles, Spain), located in northeastern Iberian Peninsula, 35 km from the Mediterranean Sea, 50 km south of the Pyrenees and 173 m asl.

The study area is remarkable for containing evidences of early farming communities of Iberian Peninsula, and for providing the possibility to relate archaeological sites with palaeoecological records obtained in lacustrine and peat deposits. In that sense, the main objectives of the work are 1) to assess the impact on the landscape by first farming societies; 2) to comprehend vegetation change patterns and their causes.

A 370 cm core (SB2 core) was extracted in the western shore of the lake, but only 102 cm of dark silty clay provided a good preservation of pollen remains, in terms of variability and concentration. Contiguous samples were retrieved at every 1 cm of this part of the core, and pollen, non-pollen palynomorphs (NPP) and sedimentary charcoal were analysed in a period comprised between c.9000-3000 cal BP.

Pollen analysis describes a mid-Holocene vegetation succession, reacting to both climatic and anthropic

causes. The main change in vegetation evolution is recorded in c.7250 cal BP, when is documented the impact of the settlement of early Neolithic communities in the lakeshore of Lake Banyoles. In that sense, the prevailing broadleaf deciduous trees forests are affected by human management of vegetal resources, causing a decrease in deciduous *Quercus* values and the colonization by herbs, shrubs and secondary trees.

From c.5500 cal BP an increasing aridity is recorded, with the appearance of fire episodes, water level regression, and the increase of sclerophilous evergreen trees, all of them consistent with other works in western Mediterranean at the same dates.

The analysis of pollen, NPP and sedimentary charcoal of one core from the surroundings of Lake Banyoles provides relevant data to understand the causes and consequences of different changes recorded in Mid-Holocene vegetation history. Several hypotheses were considered in order to explain the results, considering both climatic and anthropic factors and, thus, achieving the objective of understanding the relevant role that played first farming societies in landscape evolution.

## 12. RADIOCARBON DATES, CLIMATIC EVENTS AND SOCIAL DYNAMICS AT THE TIME OF NEOLITHIC TRANSITION IN IBERIA

*Bernabeu Aubán, Joan (Departament de Prehistòria i Arqueologia. Universitat de València) juan.bernabeu@uv.es*

*García Puchol, Oreto (Departament de Prehistòria i Arqueologia. Universitat de València) oreto.garcia@uv.es*

*Pardo Gordó, Salvador (Departament de Prehistòria i Arqueologia. Universitat de València) salvador.pardo@uv.es*

*Barton, C. Michael (Center for Social Dynamics & Complexity, Arizona State University) michael.barton@asu.edu*

*McClure, Sarah B. (Department of Anthropology, Pennsylvania State University) sbm19@psu.edu*

The transformation of subsistence systems from hunting and gathering to farming involved a crucial change to the relationship between humans and the environment, and affected all levels of human society. Perhaps for this reason, the issue of the origin and expansion of Neolithic economies remains a major topic in the archaeological and anthropological literature. Some consensus exists regarding the origin of Cardium-Imprinted pottery

wares in southern Italy, but the debate surrounding its process of expansion to the west remains open, most particularly in Iberia.

Lefocus in this poster on temporal and spatial distributions of human occupation in the Iberian peninsula spanning the Neolithic transition, from last hunters-gatherers groups (c. 8500 cal. BP) to the end of Early Neolithic (c. 7100-6900 cal. BP). Special attention is paid to the role of climatic events in social and economic change, using for this our database which contains information about: a) sites and their locations; and b) radiocarbon dates with indication of dated samples and the contexts with which they are associated. The method is the summed radiocarbon probability distributions (*sumprob*).

Our goals are to evaluate the rich archaeological and paleoenvironmental database produced by recent decades of research in this area in order to address issues related to the Neolithic Transition.

#### POSTER

### 13. EVOLUTION OF THE VEGETATION, DURING THE HOLOCENE IN THE SIERRA DE URBIÓN AND NEILA (SISTEMA IBÉRICO, SPAIN)

Gil García, María José (UAH) [mjose.gil@uah.es](mailto:mjose.gil@uah.es)  
Ruiz Zapata, M<sup>a</sup> Blanca (UAH) [blanca.ruiz@uah.es](mailto:blanca.ruiz@uah.es)  
Vegas, Juana (IGME) [j.vegas@igme.es](mailto:j.vegas@igme.es)  
Pérez-González, Alfredo (CENIEH) [alfredo.perez@cenieh.es](mailto:alfredo.perez@cenieh.es)

Pollen data from two lacustrine sequences are presented: LHN-H (Soria) and QS2-H (Burgos), located in the Iberian system in order to establish the behavior of the vegetation during the Holocene, as well as to detect some of the most significant events of this period from the climatic point of view (8,200, 2,800 and 4,100 cal BP). The formation of both sequences is related to the withdrawal of the ice of the last glacial period, due to overpasses or proglacial character, respectively. In both cases, it's one of the most sensitive files in the registry of climatic events.

Radiometric dating, have identified the power of sediment accumulated during the Holocene. For the extraction of pollen grains, the samples were attacked chemically with acids and alkalis; then the residue, was concentrated through the use of dense liquor of Thoulet. The graphical representation of the data was conducted with the software package TILIA<sup>®</sup>, expressing the relative percentages of all taxa identified in each of the samples,

as well as the relationship between all of the no tree, and arboreal pollens as an expression of the structure of the vegetation. In order to facilitate the reading of data has been built a synthetic diagram, based on the selection of taxa and grouping of taxa according to ecological demands, most significant, from the climatic point of view.

The vegetation composition defines the installation conditions of warm-humid are characterized by the development of the deciduous forests, consisting basically of *Betula* and *Corylus* and to a lesser extent by *Quercus* type deciduous and *Fagus*, among others. The development of perennial forest (*Quercus* type evergreen), takes place is more late, and uncompetitive rates. Climatic events, as mentioned above, are defined through development of the taxa and xeric and sub-continental steppic grasslands, fundamentally Poaceae and *Artemisia* (8,200), by the increase of Cupressaceae (4,100) or both (2,800), as well as the general loss of the rate of moisture, which leads to the reverse of the deciduous forest and the increase of the mediterranean forest and Ericaceae. In this context of high mountain is very dampened anthropic activity, centered primarily in the increase of nitrophile plants.

It is important to point out how the development the forest mass, which characterizes the entire Holocene, presents some peculiarities, for each profile, marked by the altitude and orientation of each of the deposits.

The most relevant data is summarized in:

1- Identification both of the Younger Dryas, through the development of the taxa and sub-continental steppic grasslands and xeric.

2- Characterization of the events of the 8,200, 4,100 and 2,800, through the expansion of Cupressaceae and to a lesser extent of the taxa xeric-and sub-continental steppic grasslands.

3- Pinus, next to *Betula* and *Corylus*, defined the majority composition of the forest, as a response to the installation of temperate conditions-wet.

4-The behavior of the vegetation, to roof of both sequences is very similar. After a major pine forest, expands Ericaceae, and later again pine forest.

## 1. THE CONCEPT OF CULTURAL VARIABILITY DURING THE GRAVETTIAN IN THE CANTABRIAN REGION

*Calvo, Aitor (University of the Basque Country) aitor\_calvo@ehu.es*

*Foulloubey, Christophe (INRAP Grand Sud-Ouest) christophe.foulloubey@inrap.fr*

*Martínez, Lucía (University of Oviedo) lucia\_satis@hotmail.com*

*Arrizabalaga, Alvaro (University of the Basque Country) alvaro.arrizabalaga@ehu.es*

*Bradtmoeller, Marcel (University of the Basque Country) marcel.bradtmoeller@ehu.es*

To investigate the Gravettian occupation of the Cantabrian region means to deal with different datasets of high internal variability; the mosaic topography and a regional and diachronic changing environment, as well as the heterogeneous archaeological legacy of the Pleistocene hunter-gatherers. To connect these variables is the mayor aim of this paper.

Being one small part of this legacy, we focus thereby on the reconstruction of the local lithic chaîne opératoire and the study of possible external (e.g. raw material availability) or internal spheres of influence (e.g. site function).

What impact does these factors have had on flint knapping and procurement, like reduction techniques, intensity of reduction, pattern of blank selection for tool modification or different compositions of tool types? To address this questions, scientific results from several sites between Asturias and the French Basque Country were used for this study to draw a more enhanced picture of cultural variability during the Gravettian period.

## 2. THE GRAVETTIAN LEVEL AT THE FOZ DO MEDAL SITE (SABOR VALLEY, NORTHEAST PORTUGAL)

*Gaspar, Rita (Baixo Sabor ACE) ritantunesgaspar@gmail.com*

*Ferreira, João (Baixo Sabor ACE) ritantunesgaspar@gmail.com*

*García-Vadillo, Francisco (Baixo Sabor ACE, EPPEX) ritantunesgaspar@gmail.com*

*Carrondo, Joana (Baixo Sabor ACE) ritantunesgaspar@gmail.com*

*Silva, Maria João (Baixo Sabor ACE) ritantunesgaspar@gmail.com*

The Sabor valley is located in the Douro River basin, in northeastern Portugal. This interior region was viewed as a marginal territory in the context of the upper Paleolithic settlement of Iberia, until the discovery of the nearby Côa valley engravings and sites in the 1990's. The recent archaeological works developed in an adjacent area, north of Douro river, revealed an important Upper Pleistocene occupation sequence. One of the occupations presents characteristics that can be included in the Gravettian complex. However the lithic assemblage is still under study.

The goal of this communication is to discuss the significance of lithic variability between sites with "typical" Gravettian characteristics, like those in the Portuguese Estremadura, and others with "atypical" characteristics, like Foz do Medal, and the role played by the available local raw materials and culture in technological choices. The Terraço da Foz do Medal presents a very complex stratigraphic sequence with an intensive Upper Pleistocene to Early Holocene occupation. In the 1085 layer, interpreted as the remains of a Gravettian occupation, we found a lithic assemblage that counts over 50 000 pieces, distributed by an area of approximately 120 square meters.

The vast majority of cores are directed to the production of flakes, thus the most represented blanks in this assemblage are flakes, followed by bladelets, being the amount of blades residual. The greater part of tools is also made on flakes. There is a bigger ratio of bladelets and blades among retouched tools when compared to non-retouched blanks, some used in the production of backed projectile points.

Due to the regional geological formation, chert in this territory has a high procurement cost. On the contrary a great diversity of other lithologies can be found, including at the fluvial deposits alongside the Sabor River.

The low availability of flint resulting from the regional geology led Paleolithic populations to search for alternative raw materials thus developing of lithic reduction strategies "uncharacteristic" of the Gravettian. These local adaptations resulted in an important macrolithic component of the lithic assemblage. Despite this there is a shared ground with other "more

typical" Gravettian collections, mainly concerning stone projectile elements typology but also at a technological level.

ORAL

### 3. DYNAMISM IN THE ORGANIZATION OF TECHNOLOGY IN EASTERN CENTRAL EUROPE IN THE LAST STAGE OF THE PLEISTOCENE (MIS2)

*Lengyel, György (University of Miskolc) bolengyu@uni-miskolc.hu*

Lithic assemblages related with the Gravettian lineage cover a long period in Hungary, between 28 and 12 k years BP. This period can be divided into three stages, pre Last Glacial Maximum (LGM) with Gravettian, LGM with Ságvárian, and post LGM with Epigravettian. According to lithic raw material provenience studies pre LGM assemblages have a moderate presence of distant materials, those dated to LGM have almost none, and post LGM assemblages are highly dominated by flints from Prut valley and Upper Silesia. This raw material variability may have caused variability in the lithic technologies. Present paper provides information on the dynamism of technological organization of 16 thousand years in the Pannonian basin in relation to the Eastern Central European archaeological record.

*Usik, Vitaly (Museum of Archaeology, Institute of Archaeology, Ukrainian Academy of Sciences, Kiev, Ukraine)*

*Pirson, Stephane (Royal Belgian Institute of Natural Sciences, Vautier street 29, 1000 Brussels, Belgium, & Service Public de Wallonie DG04, Namur, Belgium)*

*Nigst, Philip R (Division of Archaeology, Department of Archaeology and Anthropology, University of Cambridge,*

*Cambridge, UK, & Department of Human Evolution, Max-Planck Institute for Evolutionary Anthropology, Leipzig, Germany) prn25@cam.ac.uk*

In Central and Eastern Europe the chronostratigraphic record for the period between ca. 33,000 and 10,000 uncal BP was based during the last decades on the pedo-sedimentary signatures of long loess-palaeosol records related to pluristratified Upper Palaeolithic sites: mainly Willendorf II and Dolni Vestonice in the Middle Danube Region, Mitoc-Malu Galben, Molodova V and Cosautsi in the East Carpathian Area. In this time-span more than 15 positive climatic events marked by humic horizons grading from para-rendzina type to incipient humic soils, were recorded and chronologically positioned on the ground of long series of consistent radiocarbon dates from Groningen and Oxford laboratories. Within this system, on both sides of the Carpathians, the full development of the Gravettian techno-complexes has been recorded between 27,500 and 23,000 uncal BP, with some evidence of Early Gravettian around 30,000 BP. Here we will discuss complementary datasets gained recently in the Middle Dniester valley (Ukraine), which provide new insights on these topics. The first one deals with the Dorochivtsi III loess-palaeosol sequence recorded along the Dniester, north of Chernivtsi. Excavated since 2007, the site has given access to a 10 m thick loess body preserved on top of the first terrace. The lower part of this record contains six Gravettian cultural layers dated between 22,300 and 20,500 uncal BP; it is overlaid by a set of five loess layers alternating with humic horizons related to short interstadial episodes, capped by a 3 m thick homogeneous loess cover. The Dorochivtsi III sequence fits in with the renewed loess-palaeosol successions recorded recently at Molodova V, Korman 9 and Mitoc-Malu Galben, making the link between the Late Gravettian and the Epigravettian occurrences of the East Carpathian Area. The Dorochivtsi III sequence further provides a high-resolution palynological record complementing the pollen sequence established at Molodova V. Both pollen sequences provide a unique vegetation record, which demonstrates the persistence of a forest-steppe along the Dniester valley during the short interstadial episodes between 32,000 to 17,000 uncal BP. This record allows a direct comparison between the East Carpathian loess-palaeosol sequence and the well-dated lacustrine pollen sequence of Tenaghi Philippon (Greece) and further reinforces the proxy-correlation with the Greenland ice record.

ORAL

## 5. KOSTENKIAN STONE INDUSTRY.

*Lev, Sergey (Institute of Archaeology RAS) zaraysk@yandex.ru*

Kostenkian lithic technocomplex was discovered more than 100 years ago. The main majority types of tools were detected and well described from typological point of view. Some definitions were corrected in the middle and 2-nd part of XX century when Avdeev site was discovered and wide area excavations in Kostenki took place. A new rich material appeared in 1990-th and later after start of Zaraysk site regular excavations. Blade production analysis was made also in late 1990-th and actual till nowadays. What can be added to the type-list that exists for such a long time?

After the analysis of about 100 000 stone artefacts from Zaraysk with a detailed description and statistical analysis of the assemblage some new ideas and types of tools appeared. Zaraysk now represented as a complex of closely related inter-stratified sites. One of them Zaraysk B contains single homogenous habitation level with clear zones of knapping, technological sequences. Using the refitting method it was possible to find the spatial links between various features of cultural layer. Some of them reflected the tools production and further rejuvenation. Some showed blade production stages. It gave a possibility to add one more technological aspect to material seemed to be well-known for a long time. As far as Zaraysk site inhabitants had no need in economy of flint, they didn't use all possibilities of volume of flint tool to make numerous rejuvenations as it was in Kostenki I and Avdeev. So we have many examples of tools on different stages of utilization which is helpful for proses of reconstructions. Only few very typical for other sites reduced tools of shortened proportions were found. As well Zaraysk contains cores that represent all stages of reduction (while the other sites contain much higher percentages of heavily reduced cores).

The lithic artefact assemblage from Zaraysk (excluding small debris) contains a relatively high percentage of tools: 10.46% of the total. Such a high percentage (10-12%) is typical for major settlements of the culture. The complex of Kostenki knife, shouldered point, leaf-shaped point and backed bladelets is typical for Kostenki-Avdeev culture and wider for the sites of the "Eastern Gravettian" tradition of the Central and Eastern Europe. But in fact other categories and their percentage in collection can also be informative for cultural definition. Kostenki knife technology has been studied in detail that gave an opportunity for valid comparison with other European materials.

All of the diagnostic stone tool types of the Kostenki-Avdeev culture are present at Zaraysk. Some differences may be accounted for by the close proximity of Zaraysk to the sources of lithic raw material, reflected by the primary production that took place at the site. Among cultural layers of Zaraysk site there is no difference in technology of flint knapping, blades and tools production except one category – backed bladelets. It shows a high stability of cultural traditions in stone industry over a long period from 23 000 up to 16 000 years B.P.

ORAL

## 6. LITHIC TECHNOLOGY VARIABILITY AND HUMAN ECOLOGICAL ECODYNAMICS DURING THE GRAVETTIAN IN SW IBERIAN PENINSULA.

*Marreiros, Joao (FCHS. Universidade do Algarve) jmmarreiros@ualg.pt*

*Bicho, Nuno (FCHS. Universidade do Algarve) nbicho@ualg.pt*

*Gibaja, Juan (IMF. CSIC) jfgibaja@gmail.com*

The origin of Gravettian industries in Eurasia is associated with climatic oscillations that had a major impact on hunter-gatherer ecodynamics, reflected on technological variability. Such variability is undoubtedly portrayed by the development of a techno-cultural polymorphism, from which, different morph-types have been associated with distinct chronological phases and ecological/regional territories where such Gravettian regionalisms are recognized.

In SW Iberia, the Gravettian industries are associated with one of the oldest evidences for Anatomically modern humans c. 33 ky calBP, and is seen as an important step for the regional Upper Paleolithic cultural tradition setting. Traditionally the expansion of Gravettian industries

in Southwestern Iberian Peninsula has been seen as a uniform process, characterized by minor regional differences and no diachronic technological changes. However during the last decade, new data show that this idea is probably unlikely due to new lithic technological data.

This paper reviews lithic technology, tool design variability, settlement patterns and chronology during the Gravettian in SW Iberia. A new model show that the H3 climatic crisis was responsible for the human expansion that led to new environmental adaptations, reflected on new subsistence strategies, cultural and stylistic regional boundaries from a diachronic and regional scale, likely related to local and regional ecological human ecodynamics.

## 7. LE NIVEAU GRAVETTIAN DU SITE STRATIFIÉ DE CANOLLE FERME (CREYSSE, DORDOGNE)

*Ortega, Iluminada (Inrap) iluminada.ortega@inrap.fr*  
*Bourguignon, Laurence (Inrap) laurence.bourguignon@inrap.fr*

Le secteur de Barbas/Canaule sur la commune de Creysse est connu depuis de nombreuses années pour sa concentration en sites archéologiques. Sur un rayon de 300m une mosaïque d'occupations stratifiées tel les Barbas (I, II, III et V), les Rigoux et Canaule II, auxquels s'en ajoutent d'autres de localisations plus incertaines ayant seulement fait l'objet d'investigations ponctuelles (Canaule locus 3, 4 et 5, Canaule I, Canolle 2 et Barbas IV). Le gisement de Canolle la Ferme se situe dans ce secteur, en bordure du plateau de Pécharmant surplombant la vallée de la Dordogne situé à plus de 30 m contre bas. Le site comporte six niveaux archéologiques de période, densité et extension différentes : deux niveaux moustériens, un niveau châtelperronien, un niveau gravettien et deux niveaux Paléolithique supérieur final.

Le niveau Gravettien a livré trois concentrations de vestiges. Une des concentrations est composée principalement de nucléus de grand gabarit (dépassant parfois les 45 cm). Un des nucléus présente toutes les caractéristiques décrites pour les nucléus Canauliens (Guichard et al. 1989) issus des sites de Canaule I et de Troche sur la commune de Creysse. Il s'agit de nucléus qui présentent une construction volumétrique proche de celle définie pour le Levallois : la surface la plus large du nucléus est préparée par des enlèvements « partant des bords, convergeant vers l'axe longitudinal

du nucléus et développant une crête axiale basse... » à l'aide d'un percuteur de pierre. Cette surface de débitage est opposée à une surface de plan de frappe, aménagée au percuteur dur, beaucoup plus oblique donnant un profil global « naviforme » au nucléus (pour reprendre le terme des auteurs précités). Des lames unipolaires régulières sont ainsi obtenues de part et d'autres d'une première lame dite à « crête basse » très proche tant d'un point de vue morphologique que technologique d'une lame Levallois I. L'association de ce type de nucléus Canaulien avec des nucléus classiques du Paléolithique Supérieur et de nombreuses lames avait incité les auteurs à proposer son attribution à la transition entre la fin du Paléolithique moyen et un « Aurignacien débutant » ou un « Périgordien naissant ». Les fouilles récentes (2012) permettent de recadrer plus précisément cette chronologie. Ainsi, le remontage d'un éclat de préparation de plan de frappe compris dans une des deux autres concentrations avec le nucléus Canaulien permet de rattacher ce schéma au Gravettien.

Les deux autres concentrations se composent essentiellement des déchets de production des grands nucléus laminaires, et des outils contiennent également des 2 nucléus lamellaires de type burin de Raysse.

En conséquence, le site de Canolle Ferme constitue un nouvel exemple régional de succession chronostratigraphique s'échelonnant de la fin du Paléolithique Moyen au Paléolithique supérieur. De plus, le rattachement du Canaulien de Canaule I et de Troche au Gravettien, sur la base des données acquises sur Canolle Ferme, permet d'augmenter les occurrences de ce faciès gravettien pour l'heure particulier au Bergeracois.

## 8. LITHIC VARIATION IN THE GRAVETTIAN OF RUSSIA: RESULTS FROM A STUDY OF FIVE BACKED PIECE ASSEMBLAGES

*Reynolds, Natasha (University of Oxford) natasha.reynolds@arch.ox.ac.uk*

The Gravettian lithic assemblages of European Russia form an important and interesting part of the overall European Mid Upper Palaeolithic record. Due to various reasons of history and specific features of the Russian record, it has been difficult to integrate our knowledge of these collections into our understanding of the European Gravettian as a whole. This research seeks to redress some of these problems.

This presentation is based on a typological and basic technological study of backed lithics (including backed bladelets, Gravette points, shouldered points, etc.) from five sites: Kostenki 8 Layer 2, Kostenki 4, Kostenki 21 Layer 3, Kostenki 9 and Khotylevo-2. These backed collections have then been compared with each other and with published collections from Russia and elsewhere. Chronological information forms an important part of the comparisons made here.

Although certain similarities and differences between Russian and other European assemblages have long been recognised, this research brings a new perspective to the collections and connections between them. In particular, this research is re-evaluating certain key lithic type-fossils. Furthermore, a new perspective is given on historically stressed similarities and differences between assemblages.

### 9. THE NOAILLES GRAVETTIAN OF THE RIPARO MOCHI (BALZI ROSSI, ITALY): A TECHNOFUNCTIONAL APPROACH.

*Santaniello, Fabio (Università degli studi di Trento) fabio.santaniello@unitn.it*  
*Grimaldi, Stefano (Università degli studi di Trento) stefano.grimaldi@unitn.it*

The well-known Italian site of Riparo Mochi (Balzi Rossi, Grimaldi caves) provides a complete stratigraphic sequence of the Upper Palaeolithic. In this paper, we present the lithic assemblage coming from the Noailles Gravettian (Unit D). The location of the site is fundamental to analyze the diffusion of the Gravettian in the Italian peninsula.

The Balzi Rossi area is in a narrow corridor, named as the Liguro-Provençal Arc, that should have been a natural axis channelling the circulations of both humans and animals between central Italy and Southern France. Lithics (layer f3, dated to 24600 ±100 14C) have been analyzed in order to reconstruct raw material procurement strategy, reduction sequence, and the function of the artifacts. Results show that the local raw material is the most exploited one but French and central Italy flints were also imported in the site; technologically, the assemblage is characterized by a blade production and it is typologically represented by the presence of Noailles burins; finally, from a functional perspective, a mixture of opportunistic and curated behavior may be seen.

ORAL

### 10. TECHNICAL VARIABILITY INTO THE GRAVETTIAN WITH TANGED TOOLS: NEW RESULTS FROM BELGIUM

*Touzé, Olivier (University of Paris 1 / UMR 7041 ArScAn ; University of Liege) otouze@hotmail.com*  
*Flas, Damien (FNRS / University of Liege) damienflas@yahoo.com*  
*Pesesse, Damien (University of Rennes 2 / UMR 6566 CReAAH) damien.pesesse@univ-rennes2.fr*

Located at the interface between the Paris and the Rhine basins and the more northern territories of Europe, Belgium yield several gravettian occupations, all of which are located in the southern half of the country. The work of M. Otte in the second part of the seventies permitted to inventory eight deposits attributable to the Gravettian, and more than twice sites delivering clues that also evoke this period (Otte, 1979). But the quality of the documentation doesn't always respond to its quantity. Indeed, the analysis of the data is frequently complicated by the antiquity of the excavations conducted in most gravettian sites. The stratified records in karst context are particularly affected by this situation, thus restraining studies on the gravettian chronology in Belgium. This overview is however partly counterbalanced by two open air deposits excavated during the second half of the XXth century, and which benefited of good condition of preservation as well as more modern excavation methods: Maisieres-Canal (de Heinzelin, 1973; Haesaerts & de Heinzelin, 1979) and Station de l'Hermitage (Straus et al., 2000).

These two deposits have often been the object of comparisons highlighting their similarities, both in term of spatial establishment and in term of lithic industry. In fact, their lithic industries stand out by the presence of tanged tools, a typological marker usually associated with the early Gravettian of Western Europe, and also encountered in other Belgian sites, particularly in the Betche-aux-Roches cave in Spy recently studied by two of us (Pesesse & Flas, 2013). If Maisieres-Canal and Station de l'Hermitage might have been described as "sisters-sites" (Straus & Otte, 2000), the recent reappraisal of their lithic industries, henceforth lead us to nuance this proposal.

Our communication will therefore be the opportunity to shed a crossed look on two of the main gravettian sites of Belgium in the light of renewed data on their lithic assemblages, data that we will furthermore compare to the last results obtained on the Gravettian of Spy. New

elements of reflection will in particular be proposed on the variability of technical behaviours within the Belgian Gravettian with tanged tools, as well as on the causes that may be responsible for this variability.

camp, raw materials used, tool-making technologies, and the lithic typology and morphology. It's difficult to say if these differences reflect seasonal, cultural or even genetic differences, but we hope that future research will help us understand these observable dissimilarities.

### 11. VARIABILITY OF THE LATE GRAVETTIAN LITHIC INDUSTRIES AT SOUTHERN POLAND

*Wilczynski, Jaroslaw (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska 17, 31-016 Kraków, Poland) wilczynski@isez.pan.krakow.pl*

Kraków Spadzista is one of the most recognisable Upper Palaeolithic site from Poland. Lithic inventory is visibly dominated by local Jurassic flint and includes a large number of double-platform blade cores. There is a significant number of backed blades, shouldered points and Kostienki knives (Kozłowski et al., 1974; Kozłowski and Sobczyk 1987; Sobczyk 1996). The proportions of shouldered points varies in different zones of Kraków Spadzista—the highest number of that tool class is observed in the trench with a mammoth bone accumulation (Wilczyński et al., 2012). The long history of research which has resulted in numerous studies concentrated on technology and typology of lithic artefacts, taphonomy of Pleistocene fauna, and chronology of the Gravettian settlement, allowed until recently considered this locality as “benchmarks” for Polish Gravettian.

This situation was changed after discoveries of Jaksice II site (Wilczyński et al., 2014). On this site raw material, brought to the site in the form of small nodules of erratic flint, were worked in the camp. Blanks were obtained mainly from single-platform blade cores, characterised by a careful preparation of the striking platforms and regularization of the flaking edge. Retouched tools produced mostly on blades account for more than a fifth of the whole inventory. Another characteristic feature of this tool assemblage is the absence of shouldered points (except for a single atypical specimen) and Kostienki knives, and the high percentage of endscrapers. The presence in the backed tool group of distinctive rectangles which have both their ends modified by semi-abrupt or flat retouch, always on the ventral side (Late Gravettian rectangles), is also worth noting.

Now, on the basis of the both inventories we can assume that in the period between 24,000-20,000 yrs BP at the southern Poland various human groups operated. The comparison of Jaksice II site with Kraków Spadzista reveals evident differences, especially in the siting of the

**1. PUNCTUATED STAGES OF MEGALITHIC CONSTRUCTION: FROM BARROWS CHRONOLOGIES TO SEDIMENTS**

*Mañana-Borrazás, Patricia (Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), Spain) patricia.manana-borrazas@incipit.csic.es*

*Criado-Boado, Felipe (Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), Spain) felipe.criado-boado@incipit.csic.es*

*Martínez Cortizas, Antonio (Departamento de Edafología y Química Agrícola, Facultad de Biología, Universidad de Santiago de Compostela) antonio.martinez.cortizas@usc.es*

Archaeological excavations carried out in Galicia (NW of Iberia) during the last 15 years, have shown that megalithic barrows had a complex and long-standing life. Not only in terms of later uses and reuses (something that has been already acknowledged in bibliography since many years) but also in terms of construction and 'megalithic' use. Today, we can assume that barrows life was not so simple as: construction, use and abandonment. Rather, barrows could be easily compared, for instance, to Christian churches, that once build up were permanently used and rebuild, their 'form' becoming either the expression or the result of a permanent negotiation between social and materialization processes.

In this contribution, we review the empirical data from different well characterized barrows, such as Romea (with recognizable phases of rebuilding or use dating to 5920 – 5660calBP, 5320 – 5030calBP and 4970 – 4790calBP) and Forno dos Mouros (with a long time-span punctuated in 6510-6300calBP and 5070-4850calBP). From these data, we propose a hypothetical sequence of specific periods of building, use and rebuilding which we relate to social processes occurring on increasingly complex and progressively more unequal communities, even with changing individual identities.

This hypothesis is contrasted with a large collection of C14 dates of Galician megaliths. Based on this, we propose that the traditional assumption of a continuous monumental activity from ca. 6,500 to 4,500 cal. BP should be revised since a discontinuous series of building activity

and use is a more likely explanation for the chronologies. Activity seems to have been circumscribed to particular periods of monumental building, interspersed with long periods of inactivity, perhaps not shorter than a few centuries (200-300 years).

We suggest that this interpretation may also apply to other megalithic European regions. Therefore, the research agenda on Megalithism should incorporate this topic in future investigations as it may demand a change in excavation strategies. In order to reconstruct the formation processes, we propose a methodological approach aiming to implement the techniques of stratigraphic excavation and the chemical and pedological characterization of the sediments in megalithic archaeological contexts. Ultimately, our proposal is to treat barrows as paleoenvironmental archives.

ORAL

**2. MEGALITHIC MOUNDS AND BUILDING SOCIAL PRACTICES OF IDENTITARIAN NATURE IN NORTHERN PORTUGAL**

*Sanches, Maria de Jesus (Research Center in Archaeology, Arts and Cultural Heritage (CEAACP) and Faculty of Arts- Porto University-Portugal (FL-UP Portugal) mjsanches77@gmail.com*

In this communication we will discuss the process of building-use-condemnation of "the building" mound in the context of social practices of Neolithic societies.

Such procedures promote community cohesion but at the same time legitimize social differences. And, thereby, every monument has a specific biography because it responds, in space and time, to the social and political purposes or functions with which it was created (and not infrequently reworked during later times).

The paradigm that guides us is that the construction-use-their condemnation of the tumuli and its megalithic component (if any) should be interpreted as a practice of "use" tout court.

Since this analysis finds support in case studies, some examples of monuments excavated during recent decades in the North of Portugal are focused.

ORAL

### 3. APPLICATION OF THE BUILDING ARCHAEOLOGY ON THE MONUMENT OF CARN (PLOUDALMEZEAU, FINISTÈRE, FRANCE): UPDATING OF ITS BIOGRAPHY

*Cousseau, Florian (Phd student, Université de Rennes 1 - UMR 6566) florian.cousseau@gmail.com*

Without methodology to study them, the conserved elevations of the megalithic monuments are usually underused to define the biography of these architectures. By the time of its discovery, a tumulus is only visible in its final state, yet the study of the elevations could allow to apprehend its construction's chronology and reconstitute its different states. The biography of a megalithic monument is punctuated by two cycles of construction that must be defined: the phases and sequences.

Studying the elevations can be done only with an appropriate methodology which is the building archaeology, currently most often used for the historical periods. The first attempts of application on the megalithic architectures have been made on the tumulus C of Péré at Prissé-la-Charrière (France) under the direction of Luc Laporte and with the collaboration of Isabelle Parron. The results being conclusive, these attempts are now expanded at other monuments in Brittany within the framework of a PhD called: *The neolithic tumulus with chamber covered by corbelling in West of France*. The works carried out as part of this PhD and applied to the monument of Carn are presented here.

The tumulus of Carn, known since the beginning of the XX<sup>th</sup> century, has been half excavated and restored by Pierre-Roland Giot during the 60's-70's. An architectural chronology with several monuments has been revealed to the excavators thanks to the significant conservation of the elevations. The monograph published in 1987 states a three phases chronology which has essentially been based on the material found in the chambers. For the past 30 years, the knowledge of the different kinds of architectural modifications on the megaliths in western France have progressed a lot, allowing Roger Joussaume and Luc Laporte to update this chronology for the colloquium of Bougon. Three phases are kept with a circular cairn of 6 m diameter for the first, a quadrangular intermediate monument and another circular cairn of 30 m diameter for the final state. Consequently, a study of the elevations with the use of the building archeology has been engaged to precise the modalities of this phasing, to add its sequences of construction and to

reconstitute virtually the states of the monument at each phase. Those new data give us an updated view on the tumulus concerning its construction, its implantation in the landscape and its aim for each neolithic phase. They also enlighten us about the quality of the builders, their organization and about the choices of restoration applied to the monument.

Studying the elevations applies as well on monuments during excavations as already excavated and restored. Thanks to an appropriate methodology, both cases allow us to acquire new knowledge on the biography of the megalithic architectures and especially on its different cycles and their modalities.

ORAL

### 4. "MEGALITHIC BIOGRAPHIES": A PROPOSAL FOR THE STUDY OF THE CYCLES OF USE ON THE MEGALITHIC RECORD

*Tejedor, Cristina (Arcadia-Fundación General de la Universidad de Valladolid (FGUVA) tejedor.cristina@gmail.com*

Traditionally, studies of the megalithic phenomenon have focused on its foundational phase and the primary use of the monuments by the original builders of these big monuments, interpreting them as the result of a single event, without considering the successive phases of construction that may have occurred. Modifications made after the construction of a monument were read in terms of deterioration or later intrusions. However, the archaeological record shows that such acts are not occasional but recurrent, and also that the events of abandonment and destruction of the megaliths are unusual.

The "biography" of the megaliths is a complex superimposition of various reconstructions, removals and reuses accompanied by changes in both function and meaning. These 'post-foundational uses' can be documented by a wide range of archaeological events, such as destruction by fire, increase of the size of the mound, dumping of stone or soil to close down access, adding new architectural elements or reordering of the burial area, among others. However, archaeological documentation of these processes is often difficult or even impossible to attain because, in many cases, the modification or reconstruction of the monument entailed the destruction of older structures. With an appropriate archaeological methodology for studying

and classifying these practices from a diachronic approach, it is possible to define the "life-histories" of megalithic monuments and to obtain a global view of its constructional and/or destructive development.

Therefore, the traditional concept of the megaliths as constructions constrained to the Neolithic period is outdated, and now we see them as places which have played an important role in each of the societies that have coexisted with them in their environment. The changes in its internal and external space are "physical" evidences of all reinterpretations and reinventions of the megalithic monuments along time, whose study is fundamental to unravel the "history" of these places and of the people who used them. Then, these constructions are the final result of a long sequence of "cycles of use" and interventions by different users.

This presentation aims to approach this phenomenon from a specific theoretical and methodological framework, and present some characteristic examples of megalithic monuments in the Douro valley, in which different structural changes with a chronology between the 4th and 2nd millennia BC have been documented. The main goal is to discuss the interpretative implications of this type of archaeological events, whose presence and/or absence could establish different uses and meanings in the life of a monument, reflecting various social, economic and ideological transformations within the wider society that used them.

## 5. PATTERNS OF MONUMENTALIZATION IN THE MEGALITHIC TOMBS OF NORTH-WESTERN IBERIA

*Vilaseco Vázquez, Xosé Ignacio (Grupo de Estudos para a Prehistoria do NW Ibérico. Departamento de Historia I. Universidade de Santiago de Compostela) ignacio.vilaseco@usc.es*

Not too long ago it was upheld that megaliths in the north-west of the Iberian Peninsula (Galicia and Northern Portugal) had not undergone processes of monumentalization, namely an enlargement of the monument in successive stages throughout time. Instead of this, as certain places kept their funeral use for centuries, new tombs were built next to the previous ones, building up cemeteries.

That conception had several reasons, not the less important the archaeological record itself: North-

western monuments are all round-barrows with the funeral chamber in the center, so it is almost impossible to appreciate without excavation processes of transformation that can be glimpsed in other places where monuments of different forms existed together. Moreover, mounds cluster in cemeteries of apparently similar monuments that, once excavated, display chambers with an important polymorphism, even when they are coeval.

Scholars' attitude was relevant too: On the one hand, there was not a reflection on the way mounds were used in prehistory or the need of maintenance of an architecture done with earth and dry stone, the more so in tombs employed for more than 1.000 years. On the other hand, open-area excavations were scarce until the last decade of the 20th century, and the trench system used previously made it difficult to identify structural modifications.

The situation has completely changed in the last 25 years and today we have examples of North-western mounds that underwent processes of transformation in his architecture. Although there are many unpublished excavations, we can distinguish by now two main monumentalization patterns, one eccentric and another more or less concentric.

The eccentric pattern seems to be restricted to passage graves, as some of them were built next to a smaller mound with a polygonal chamber, as in Dombate. This is in fact a superimposition of different structures, in which the later megalithic chamber is placed beside a pre-existing mound, that is covered by the barrow of the new construction. Sometimes the older chamber seems to be emptied or even destroyed.

Concentric modifications seem to take place in different other kind of mounds, with no examples known yet in passage graves. Three models can be recognized:

Increasing the diameter and/or height of a mound that continues active, with the interpretative problem that it could be also a phase not distant in time of the same constructive process.

Raising the mound to seal definitely a tomb.

Building of a mound to seal an originally open-air architecture in stone or wood.

In view of these recent discoveries, we can point out that the building of many North-western mounds is far from

a feat frozen in time but rather a, sometimes, complex an protracted process. Also, we recognize the mound as much more than just part of the tomb, having in fact a polysemic meaning.

## 7. MEGALITHIC NARRATIVES: SEQUENCES, RATIONALITIES AND REGULARITIES IN THE NW IBERIAN PENINSULA

*Vázquez-Liz, Pablo (Universidad de Santiago de Compostela) pvliz@hotmail.com*

*Prieto Martínez, M. Pilar (Universidad de Santiago de Compostela) mpilarprietom@hotmail.com*

Since the early 20<sup>th</sup> century a large number of tumuli have been excavated in Galicia, mainly with megalithic chambers, only a small number of them have been fully excavated and published in any detail, making it difficult to reconstruct the cycles of use of these types of sites from a diachronic perspective. Despite the limited amount of data it is nevertheless possible to propose a summary of the ways in which these sites were re-used over a long period of time, since the last third of the fifth millennium cal BC until modern times, when they began to be systematically plundered. Obviously it is not possible to refer to a continuous use over this lengthy period of time, but instead to a series of moments in

which we find evidence activity of the communities who frequented and interacted with these highly symbolic spaces, which increased over the millennia.

The information provided by the 9 well-documented examples, some of which are still unpublished and unfortunately quite scarce, make it possible to verify a series of events ranging from the sealing of previously existing tumuli by more monumental structures, or the enlargement of the tumulus, apparently without affecting the funerary chambers, through to the opening of pits that provided access to the megalithic chambers and passages made by Bell Beaker communities to deposit their materials, without any architectural remodelling, and which have only been archaeologically documented in a small number of cases but which could possibly be extended to the monuments where fragments of *bell beakers* have been found, in which the degree of deterioration has destroyed any signs of the presence of these negative structures, or the cuts or openings made around the edges of a large number of Megalithic tumuli, by the communities who were bearers of *wide horizontal rim vessels*, and deposited them in the second half of the second millennium cal BC.

It possible to introduce wider concepts which are complementary but still imprecisely defined, such as conversion into *necropoli*, both internally, by making use of a previously existing funerary space to create another, larger structure, and externally, by spatially associating a monument with a previously existing one, or *monumentalisation* by increasing the size of a previously existing tumulus (internally), or, building a similar structure next to an existing tumulus, with very similar proportions, resulting in them being perceived as a single unit (externally). Although there are only a few examples of this rationality, which still lack datings, they do represent an important new development in Galician megalithic tombs.

The limited number of absolute datings means that in most cases the identification of the construction episodes and uses are based on the ceramic materials they contain, as a fundamental source of information about the use and abandonment of these types of sites. As a result, our aim is to characterise how this megalithic space was used over time, based on a small number of well-documented examples, and supported by other samples from northern Portugal.

ORAL

**8. MEGALITHIC (RE) USES IN THE MEGALITHIC TIMES. ARCHAEOLOGICAL EVIDENCES OF LATE NEOLITHIC NON FUNERARY ACTIVITIES IN THE SPANISH NORTHERN MESETA**

*Villalobos García, Rodrigo (Universidad de Valladolid) rodrigo.villalobosgarcia@gmail.com*

Since one century ago the scientific interest devoted to the megalithic monuments began to materialise in archaeological excavations in the Spanish Northern Meseta. It is curious that by nowadays the number of excavations of these monuments comes about to circa one hundred. The ancient scripts wrote by César Morán and other scholars of these times together with the abundant new archaeological reports offer a good empirical information pack for analysing this prehistoric phenomenon on this area.

Logically, we find that in these megalithic monuments the remains of Late Neolithic people were present, but there are also a lot of evidences that show us the celebration of other activities. There are cases of ossuary manipulations and relic circulation, accumulations of vessels that suggest feast-type ceremonies with (possibly) drug consumption, great fire events and architectural closures. These activities make some of the megaliths an important ideological centre and, also, the focal point of social gathering and labour investment of the Late Neolithic times.

During the last decades many prehistorians have proposed different explanations concerning this phenomenon, in which the symbolic role of these monuments has been always emphasised. They range from viewing the megalithic issue as a way of claiming territories or resources under stress conditions (Renfrew, Chapman) to as the expression of ideological strategy of social control or religious struggle (Shanks-Tilley, Sherratt), and there are even who argues that these stone buildings are the symbolic expression of the collective force of harmonious egalitarian social formations (Lull et al.).

Our aim is to test these hypotheses with the observations made on the previously referred data, as a way to inquire in the social aspects of the very first monumentality process developed in Southwest Europe.

ORAL

**9. THE REUSE OF MEGALITHIC TOMBS IN FALBYGDEN, SOUTHWESTERN SWEDEN.**

*Blank, Malou (departement of historical studies, university of Gothenburg) malou.blank.backlund@gu.se*

This paper will discuss the different types of reuse of the megalithic tombs in Falbygden. Based on new radiocarbon analyses and re-examinations of previously excavated megaliths a multitude of modifications can be seen and various later activities can be traced.

Falbygden, in the inland of Southwestern Sweden, is an important area for the research on Neolithic megalithic graves in Scandinavia. The area has one of Northern Europe's largest concentrations of megalithic tombs. Based on typological studies of chamber forms and pottery, three different types of megaliths have been distinguished: dolmens, passage graves and gallery graves. The calcareous soils of Falbygden have resulted in a large amount of preserved bone material. In this area a high frequency of radiometric dates has been implemented which has improved our knowledge about funeral practices of passage graves. The increasing availability and precision of radiocarbon dates offers new possibilities to study the use and reuse of the different graves. The main focus of research has been the construction and use of the earlier types of megalithic tombs in the middle Neolithic. In Falbygden, as in other parts of Sweden and Europe, the reuse of megalithic graves is a common phenomenon which occurred during numerous periods of prehistory.

This paper aims to highlight the diversity of reuse emphasizing later burials and various types of structural modifications.

The focus in the paper will be on the biography of two different megalithic tombs. This in order to present the diversity of reused megalithic tombs in prehistoric times. The intention of the case studies is also to show the spatial focus of activity within the monuments during different periods. Documentation from already excavated graves combined with spatial and isotope analysis will be used to show that the megalithic tombs were periodically in change and part of the prehistoric present. I will show the distribution of reused graves by applying ArcGIS. The different parts of the grave will be problematized when discussing modifications and later burials. The updated compilation of artefacts combined

with new radiocarbon analyses on human remains enables new information about later burials.

The results show that various types of megaliths have been reused in the whole area and it seems like the graves are used and adapted to fit the prevalent cultural norm. The reuse of megalithic tombs occurs more often than previously thought, with an increased intensity in the Scandinavian Late Neolithic period.

---

ORAL

### **10. DECONSTRUCTING CHOUSA NOVA 1: TOTAL EXCAVATION OF A MEGALITHIC MOUND IN CENTRAL GALICIA (NORTH-WESTERN SPAIN)**

*Bóveda Fernández, María José (Gabinete de Arqueoloxía e Xestión do Patrimonio, S. L.) majogabinete@mun-do-r.com*  
*Vilaseco Vázquez, Xosé Ignacio (Grupo de Estudos para a Prehistoria do NW Ibérico. Departamento de Historia I. Universidade de Santiago de Compostela) ignacio.vilaseco@usc.es*

The recent history of Chousa Nova 1 mound (Silleda council, Pontevedra province) was a succession of misfortunes that had seriously damaged the site. That is why its total excavation, in the context of a high-speed railway line construction project, could be considered like a worthy death to end nearly three decades of unstoppable deterioration. Surprisingly, an intact megalithic chamber was found in the battered barrow, together with evidences of a great structural complexity, with different phases both in the constructive activity and the use of the monument.

Nevertheless, the documentation of these phases, achieved mainly thanks to total excavation and removal of the site, also revealed methodological shortcomings with which usually we undertake excavations of burial mounds in North-western Iberia.

At the beginning of the excavation, the existence of a section of the mound, caused by a track, allowed the early detection of a raising of the barrow. This situation clearly directed our efforts in distinguishing the different phases of construction of the monument.

Moreover, total removal of the construction exposed the fitting-out work and ritual use of the site prior to the construction of the monument. Later on, with the control of the removal of the earth in the vicinity of the site, the preparation process of the area and a round ditch surrounding it were detected.

Due to the complete disassembling of the chamber it was also located its big pit foundation, unique for all the slabs. This helped us to understand the constructive technique and the dynamic forces that caused the collapse of the megalithic structure in prehistoric times. Possibly, Chousa Nova 1 offered so much information because it was going to vanish completely. But we believe that it is necessary to reflect on the creation of new strategies and methods that allow us to achieve greater structural information of a megalithic site without leading its complete destruction. Knowledge obtained in rescue archaeology, which normally involves the disappearance of the site, must be applicable to smaller or punctual little impact diggings, seeking the research or the enhancement of burial mounds.

### **11. IN THE SAME PLACE, BUT IS NOT THE SAME THING. "CYCLES OF USE" IN THE DOLMEN OF ARROYAL I**

*Carmona Ballestero, Eduardo (Universidad de Burgos) educarmonaball@gmail.com*

During October 2011 to April 2012 a research team at The University of Burgos conducted an excavation on the dolmen of Arroyal I (Arroyal, Spain). We were looking for information about segmentary societies of river Arlanzón basin. We choose Arroyal I as a case of study because there was a lack of data related to monumental graves in this area. The monumental grave was well preserved and we could document a significant funerary record.

The excavation procedure has followed the stratigraphic principles enunciated by Harris and developed by Carandini. In our opinion this is the right methodology to identify and to understand properly the formation process of archaeological record. This method provides a well-defined sequence of events that have formed the site. The archaeological recording was also accompanied by an absolute dating program that has provided a high resolution data of formation process.

As a result of this study, we documented a sequence of events. Between them it is remarkable an intensive and complex cycle of use during III millennium cal BC. On this regard, stratigraphy and absolute dating have offered a high resolution framework that it allows to argue about cycles of use. According to that, we have identified 3 main phases of use:

Building of the dolmen and first funerary cycle during recent Neolithic (3360-2900 cal BC). There is not too much of original funerary deposits because following modifications almost emptied Neolithic strata. But we have some certain data. Dolmen had a collective and a prolonged (over 400 years) funerary use. Besides, structural elements are well preserved (chamber, corridor and original mound).

Modification of Internal structure and second funerary cycle during Chalcolithic (2500-2400 cal BC): monumental grave probably had consecutive isolated burials in a remodeled chamber. The corridor was filled by rocks and sediment and some of the stones of the chamber were laid down on floor.

Third funerary cycle and modification of external structure during Chalcolithic (2400-2200 cal BC). It was made an isolate pit grave and also the tumulus was increased.

In consequence, the excavation has provided a diachronic relate of events well-fixed in time. This sequence tells us the biography of the grave. First, it was a dolmen, with a collective and long-term use. After that, it suffered a deep transformation not only in its internal architecture also in its funerary ceremonial. Arroyal I turned into a different kind of grave: monumental but non-open, and maybe non-collective. Therefore, data allow discussing the interpretative implications of this different uses. The explanation lies in segmentary social framework and its changes during III millennium cal BC.

ORAL

## **12. FROM THE TOMB TO A MONUMENT: THE EXCEPTIONAL PROCESS OF TRANSFORMATION OF THE MEGALITHIC GRAVE OF LA MINA (ALCUBILLA DE LAS PEÑAS, SORIA)**

*Rojo Guerra, Manuel Ángel (Universidad de Valladolid) marojo@fyl.uva.es*

*Tejedor Rodriguez, Cristina (Arcadia-Fundación General de la Universidad de Valladolid) tejedor.cristina@gmail.com*

*Garrido Pena, Rafael (Universidad Autónoma de Madrid) r.garridopena@gmail.com*

*García Martínez-de-Lagrán, Íñigo (Universidad del País Vasco (UPV/EHU) igmtzl@gmail.com*

The La Mina megalithic tomb is an exceptional site with no parallel in the whole Iberian Peninsula. It is an authentic ceremonial centre, intentionally placed in

the middle of a plain surrounded by small hills and soft slopes, which formed not only a natural scenario but also were integrated with the monument in a "cultural landscape" for those prehistoric populations in whose mythological world natural elements were crucial.

Since 2008, and financed by the "Dirección General de Patrimonio de la Junta de Castilla y León", the site was excavated during four consecutive archaeological seasons. The systematic and detailed documentation has yielded very interesting data about its constructive sequence and complex architectonic transformations. The bioanthropological analyses (ancient DNA included), which were studied by the Institute of Anthropology of University of Mainz (Germany) under the direction of Professor K.W. Alt, the radiocarbon dates and the magnetic survey also complemented the information about this site.

It is a megalithic monument with two big constructive phases: During the first one (first half of the 4th millennium cal BC) a passage grave was erected, where the chamber (around 4 m of diameter) had a collective ossuary with several grave goods. During the 2<sup>nd</sup> phase the whole stone structure of the tomb was dismantled and the ossuary covered by a small stone mound. An atypical corridor was built inside the previous tomb stone mound, using part of the stones removed from the structure of the first grave, and the whole size (height and diameter) of the stone barrow surrounding the structure increased (an oval barrow of 31 x 22 m.) and small stone wall was built around all of it, enclosing a huge ritual area. A big stone decorated menhir (2 m high) was also erected. Finally around the mid 3<sup>rd</sup> millennium cal BC the tomb was reused by Copper Age populations (Bell Beaker pottery).

The La Mina Barrow is one of the clearest examples of the transformation of a collective grave into a huge funerary monument, through a complex closure process converting this burial structure in a big Neolithic ceremonial centre dedicated to the memory of the ancestors.

ORAL

## **13. FERMETURES COMPLÈTES, FERMETURES PARTIELLES, CONDAMNATIONS**

*Masset, Claude (Université Paris 10) clmasset@orange.fr*  
*Jagu, Dominique (Comité Archéologique d'Eure-et-Loir) dominique.jagu@wanadoo.fr*

Nous présentons l'évolution de quatre monuments mégalithiques

La Chaussée-Tirancourt, Méréaucourt, Changé, Yermenonville.

Complet and partial closures ; and putting out of use. We submit our conclusions about four megalithic monuments (from middle and late Neolithic) : to the north of the Paris Basin, La Chaussée-Tirancourt et Méréaucourt ; to the south, Changé et Yermenonville. We have identified discreet periods, each one underscored by sterile fillings (i.e. almost without bones) which are more or less thick.

1) Complete but temporary closures, which are onerous operations connected with rearrangements of the monument; those can possibly go all the way to orthostat extractions. Their associated anthropic filling occupies the whole monument, including its annexes (entrance, peripheral couloir, « muche » should the case arise).

2) More inconspicuous but no less important closures, every one being associated with a change in the funerary practices (for instance, a transition from primary to secondary burials). With each one appears a thin anthropic filling, which does not go all the way to the limits of the layer.

3) Two kinds of final closures, or « putting out of use ».

The first one covers the dead and marks the end of the sepulchral use of the monument. It may go with spectacular works, going as far as moving orthostats, and putting heavy covering slabs into position. Notwithstanding the loss of their use as graves, they were afterwards visited through a long period of time.

After several centuries (ca. 2000 BC) a second closure stepped in; it affected no more the dead but the monument. It is final and always goes with a partial destruction. One observes violent fires with orthostat breakings, or the toppling of covering slabs ; a barrow may be put into place.

In those days the monument took the appearance with which we found it.

#### **14. FILES DE MENHIRS, DOLMENS ET PAROIS CONSTRUITES EN PIERRE SÈCHE : L'EXEMPLE DE LA FAÇADE OCCIDENTALE DU MONUMENT DE BARNENEZ EN PLOUZOC'H (FINISTÈRE, FRANCE)**

---

*Laporte, Luc (CNRS - UMR 6566 - Rennes) luc.laporte@univ-rennes1.fr*

*Cousseau, Florian (UMR 6566 - Université Rennes1) florian.cousseau@gmail.com*

Pour mieux appréhender ce qu'est le mégalithisme atlantique de l'Europe néolithique nous avons d'abord été amenés à redéfinir les méthodes d'étude des masses tumulaires construites en pierre sèche. Nous avons également insisté sur l'existence d'un véritable projet architectural soigneusement élaboré qui intègre de nombreux éléments d'une géométrie intuitive, avec par exemple différentes formes de correction optique. Nous avons alors insisté sur le fait qu'il s'agit d'une forme nouvelle, et sans doute un peu illusoire, de domestication du temps et de l'espace. Enfin, il nous avait paru utile de mieux définir les termes de dolmens et menhirs, redonnant alors un peu d'unité à ce qui est désormais traité le plus souvent comme deux champs d'étude distincts.

Au travers de cette contribution, nous nous proposons d'appliquer l'ensemble de ce raisonnement à la façade occidentale du long tumulus de Barnenez. Celle-ci intègre de nombreuses dalles dressées qui renforcent, sur le plan architectural, le pied d'une paroi implantée perpendiculairement à la pente. Les photos d'archives prises au moment de la fouille par l'équipe de P.R. Giot permettent de valider la disposition de chaque bloc au sein d'une façade qui fut restaurée. Alignées sur un même axe, ces mêmes pierres dressées prennent également la forme d'un alignement. Plus étonnant encore, elles se répartissent de façon symétrique de part et d'autres de ce qui, ailleurs, aurait été identifié comme une dalle de chevet.

Il s'agit en réalité du déroulé des dalles présentes les longs des parois de la chambre et du couloir d'un dolmen similaire aux dolmens A et B inclus dans la masse tumulaire de ce même monument. Huit dalles sont ici disposées de part et d'autres de la dalle de chevet, comme à l'intérieur d'une chambre mégalithique. Huit autres pierres au nord, et huit autres au sud, correspondent à celles qui, ailleurs, sont dressées le long du couloir. La disposition comme la morphologie ou la nature géologique de chacune de ces pierres dressées trouve d'étroites correspondances avec celles présentes à un emplacement similaire au sein des dolmens A et B du monument de Barnenez. Des dalles de couverture, qui pourraient correspondre à celles du couloir, ont été disposées au pied de cette façade, formant partie de l'assise de base d'une banquette latérale adjacente. Plusieurs éléments plaident en faveur du emploi des éléments mégalithiques d'un dolmen démantelé.

De tels emplois de dispositifs architecturaux construits précédemment, qu'ils aient été composés initialement des grosses pierres dressées isolément à l'aire libre d'un Menhir, ou de celles assemblées d'un Dolmen, fait partie intégrante du processus de monumentalisation.

*Lorenzo Cueva, Covadonga (CEU San Pablo de Madrid), clorenzo@ceu.es*

*Lorenzo Cueva, Epifanio (CEU San Pablo de Madrid), elorenzo@ceu.es*

In this paper I would like to take the opportunity to present the preliminary results of the research about the megalithic site Quillusara (Celica, South Ecuador). This is a project of the Universidad Técnica Particular de Loja (UTPL) in the Northern Andean. Our first aim is to contribute an interpretation about megalithic site of Quillusara and his context in Ecuador and northern Peru. Quillusara is a megalithic site at 730-650 m. snm, on a hill and near to Quillusara river, this is located at the entrance to Northern Andean. In Quillusara there are alignments, cromlech and "married orthostates" and five stones with rock art with different figures (shaman, geometric, condor and feline mask). The chronology of monument is dark because there isn't excavation and absolute dating, but the Rock Art and his iconography show a chronology from Regional Period (500 a.C-500d.C) to Inca Period (until 1532).

For this project we work with an interdisciplinary method: archaeological, architectural, botanical and artistic. The method of working commences in the collecting published about archaeological site,

paleobotanical and religion pre-Columbus in South Ecuador and North Peru.

We don't make the excavation but our work is about territorial study, landscapes, megalithic architecture and iconography.

Our preliminary results are: we have seen more alignment, one cromlech and new architectural elements: the married-orthostates.

Until today, Quillusara hasn't been studied as architectonic built into the Environment and the Landscape, but our research show than Quillusara is a megalithic monument with architectural harmony and it was an active figure in the formation of the pre-Columbian landscape.

ORAL

### 16. CYCLES OF USE AND CLOSURE IN THE PASSAGE GRAVE OF EL TERIÑUELO (ALDEAVIEJA DE TORMES, SALAMANCA)

*Rojo Guerra, Manuel Ángel (Universidad de Valladolid) marojo@fyl.uva.es*

*Tejedor Rodriguez, Cristina (Arcadia-Fundación General de la Universidad de Valladolid (FGUVA) tejedor.cristina@gmail.com*

*Garrido Pena, Rafael (Universidad Autónoma de Madrid) r.garridopena@gmail.com*

*García Martínez-de-Lagrán, Íñigo (Universidad del País Vasco (UPV/EHU) igmtzl@gmail.com*

The passage grave of El Teriñuelo is located on the first terrace of the left side of the Tormes River, on top of a small elevation, in one of the most important and well documented megalithic areas of the interior of Iberia (Salamanca Province). The passage grave has a circular chamber (around 4 m. of diameter), a corridor of 7 m. long, oriented to the southeast, all of them surrounded by a stone barrow of around 25 m. of diameter and 2.5 m high.

This passage grave has been extensively excavated first before 1930 by the Padre Morán, then by researchers from the Salamanca Museum in the 80's, mainly on the corridor. Our excavation extensively cleaned and documented the whole tomb, and ended the excavation in the last part of the passage, just to the limit with the end of the barrow.

With our excavation it was possible to document not just the internal and external structure of the stone mound but also to discover several aspects of the complex sequence of use of this burial monument. We could document how the corridor of this Neolithic tomb (4<sup>th</sup> millennium cal BC) was finally sealed during the pre-Beaker Copper Age (first half of the 3<sup>rd</sup> millennium cal BC) with a spectacular deposition of stone blocks, and how during this event pottery offerings were carefully introduced between the stones (accumulations of potsherds intentionally crushed and placed there). This will probably belong to an intentional closure of this collective tomb, clearly a big importance ritual and social event.

We have documented the archaeological remains of a single ritual ceremony where the access to the tomb was closed, a very important social event in the "life" of the megalith, since the current aspect of these monumental graves is always the result of several successive ritual practices along its time of use, ones superposing and hiding the others.

POSTER

POSTER

### **17. THE BIRTH, MATURATION AND DEATH OF SKULL BUILDING FROM THE PRE-POTTERY NEOLITHIC SITE ÇAYÖNÜ TEPEİ IN SE ANATOLIA**

*Bartkowiak, Marta (Institute of Prahistory, Adam Mickiewicz University in Pozna) martabartkowiak86@wp.pl*

The tradition of erecting the ceremonial constructions was a widespread phenomena in the Near East and SE Anatolia which began in PPNA period and existed continuously through all PPNB to disappear suddenly at the end of this period. These structures differed significantly from the domestic architecture and characterized a monumental architectural form, occurrence of various interior installations and decorations (such as bucrania, stone banks, relief decorations and pillars), and presence of human and animal burials. Considering the long-term use of these buildings and their numerous modifications (rebuilding, abandonment, intentionally destructions etc.), there is assumed that their function and role must have been modified through time and those processes must have also reflected a cultural transformation of the first farming communities. Therefore, this paper aims to scrutinize a life- history of one selected structure known as Skull

Building from the Pre-Pottery Neolithic site Cayonu Tepesi in SE Anatolia and offers a new interpretation of their use within the context the phenomena of Near Eastern ceremonial buildings.

The Skull Building was re-analyses from a perspective of the cultural biography of architecture inspired by papers of Igor Kopytoff and Ruth Tringham. This ceremonial structure has been seen as a dynamic and active medium that not only was in a process of transforming itself but might have also shaped social relations and meanings. Thus, the analysis was focused on two aspects: the human activities which modelled this structure (both their form, interior arrangements, and ritual practices undertaken inside it) and the impact of this cult building on its surroundings. Hence, the detailed examination of different phase of usage this structure and spatial arrangements of both the Building and its settlement context were undertaken in order to establish the life history corresponding to distinct social transformations of Çayönü community.

As a result of this analysis, there was possible to distinguish three major stages in life history of Skull Building, which includes Building birth and emergence of its ritual significance, maturation marked by its dominant ritual position and death associated with decline of its eminent role. The birth of the structure as a "funeral home" was inaugurated by the first burial indoors. During the stage of maturation the elaborated cult of ancestors and distinct ceremonial sector of village with Plaza was settled. The death was associated with deliberated burning of the structure and abandonment of this village sector as a consequences of reorganization of social life and rapid cultural and economic transformations

There was proved that the Skull Building was not a result of single event but rather a long chain of various activities and processes. Its social role and meaning was transformed through time in order to respond to the current social needs and its life- history reflected the various processes of this community consolidation, building identity, gradual increase of ancestors cult, tightening of interregional contacts and finally disintegration of the community and possible appearance of some kind of social stratification.

*Molist Montaña, Miquel (Universidad Autónoma de Barcelona) miquel.molist@uab.cat*

The cardial pottery decorative world represents, in the Iberian Peninsula, the first example of a Neolithic symbolic system. In this paper we aim to analyze the decorative structure of different cardial assemblages located in the northeast of the Iberian Peninsula (Caserna de Sant Pau del Camp, in Barcelona; Can Banús and Can Soldevila in Santa Perpètua de Mogoda), all along with a technical gesture exhaustive study

Whereas it has been proposed that pottery in the early Neolithic would have been produced domestically, phenomena in a macro scale like the decorative cardial style seem to indicate the existence of some shared and widely extended ideologies. Our goal is to clear up if any relationship at all would have existed between the characteristic cardial decorative patterns and the technical gestures used to produce it (which indicate different ways of doing, or technical "schools"). We will work with the hypothesis that different technical gestures used for the same decorative motives would indicate distinct potters decorating under a shared interterritorial decorative scheme, while a direct correlation between the technical gesture and the decorative patterns would indicate the contrary, distinct potters using decorative patterns created locally or much more regionally.

In this sense, we will present an analysis focused on the assemblages of two distinct territories. The first one, the Barcelona plain, close to the sea and therefore with good access to the cardial decoration tool source (shells), would be represented by Caserna de Sant Pau del Camp. The second one, the Vallès valley, an interior area separated from the Barcelona basin by the litoral chain and, therefore, with a less easy access to tool

source, would be represented by the Santa Perpetua de Mogoda sites and assemblages.

**2. AMAZON GUARANI AND POLYCHROME POTTERY TRADITION: PRODUCTION PROCESSES AND TECHNO-FUNCTIONAL STUDIES.**

*Cerezer, Jedson (Instituto Terra e Memória) jcpithi@gmail.com*

The present work aims to address the issues related to the study and analysis of archaeological ceramic vessels from Southern Brazil related to the archaeological studies of Amazon Guarani and Polychrome Tradition.

In this line of work we will present results of analyses of archaeological collections, archaeological and experimental techno-functional studies of all stages of production, decoration, use of the ceramic vessels and about the abandonment process.

ORAL

**3. THE RITUAL DECORATION OF CERAMIC VASES IN THE CHALCOLITHIC SOUTH EASTERN EUROPE SOCIETIES.**

*Gheorghiu, Dragos (National University of Arts Bucharest) gheorghiu\_dragos@yahoo.com*

In South Eastern Europe the 5<sup>th</sup> millennium B.C. is characterized by a unique flourishing of the ceramic technology. This phenomenon can be explained by the use of new principles of production determined by the social transformations occurring during this period. The ceramic production of this geographical area is characterized by a standardized production of shapes and applied patterns ("decoration"), as well as by a serial production due to the advanced pyro-technology used, which led to the emergence of the sunken up-draught kilns at the end of the millennium. Such a phenomenon could be explained by the rise of a new view on production, which becomes serialized, and therefore creating a new axiological attitude towards ceramics, issued from the ritual character of the technologies implied. For example, the "decoration" of the ceramic vases reveals the use of certain standardized techniques of incision or painting with the help of templates that could be assimilated to ritual operations, due to their immutable character.

To understand the complexity of these technologies, as well as their ritual aspects, the method employed was experimental archaeology. One example would be the description of the ritual functioning of the sunken up-draught kilns as resulting from experiments; another one would be the reproduction of the ritual methods of tracing the patterns on the vases' surface with the help of templates. The paper will present some of the transcultural methods of patterns' tracing, as demonstrated by experiments. The paper will also discuss the mathematical implications of some of the patterns experimented.

All the physical and mathematical results support the idea of a standardized, i.e. ritual, production of the South Eastern Chalcolithic societies, to cite only the use of Bézier curves, mathematical functions with a well-determined structure.

The paper intends to focus the attention on a new dimension of the ceramic production in the Chalcolithic, i.e. the ritual one (as well as "industrial"), trying to illustrate the complexity of prehistoric technologies.

ORAL

#### 4. "TECHNOLOGICAL STYLE" IN CONTEXT: CERAMIC TRADITION IN NEOLITHIC SARDINIA.

*Gradoli, Maria Giuseppina (PhD researcher in Pottery Technology, University of Leicester) ggradoli@yahoo.it*

In Sardinia since now, local practices of prehistoric ceramic production and consumption have largely remained understudied, or have only focused on stylistic attributes and their use in assessing a chronological typology. Drawing upon the ceramics characterization study of some Final Neolithic burials, ritual sites and a settlement context, the concept of 'technological style' - a sequence composed of a series of choices and actions essential to the definition of the artefact type, and variants arising from choices that have equally valuable outcomes (Lemonnier 1986) - and its implications are used in defining the role of technology as part of the cultural and social environment within which the manufacture process was learned and practised. Alternatives selected by potters, indeed, reflect internalized understanding of traditions generally passed on and preserved from one generation to the next (Gosselain 1992).

Adopting a broad theoretical context, based on both the physical and the social sciences, the process of

pottery manufacturing was studied as follows: 1) under the petrographic microscope considering the '*pottery fabric*' or the arrangement, size, shape, frequency and composition of clay, minerals, and other materials added intentionally to improve the workability and firing performances of ceramic pastes; 2) using the concept of '*chaîne opératoire*' and its individual steps to reconstruct part or the whole sequence of technical, physical and mental actions performed by potters, starting from the way natural resources (clays, sands, rocks, water) were acquired in the area, mixed together in different proportions, fashioned and then physically transformed by the process of firing; 3) the '*raw material provenance analysis*', using analytical and geological approaches, to establish whether the sampled vessels were produced using clays and other naturally or intentionally added materials obtained from the investigated area or far away from it; 4) the '*experimental archaeology*', that provides the opportunity to confirm potential hypothesis and conclusions with multiple trials and repeatable tests in a chemical/mineralogical laboratory and has been used for the reproduction of the ceramic pastes (according with the different proportion of mineral/rock inclusions and clays estimated under the microscope and their comparison with the archaeological ones under study).

The methodology adopted in the present study is starting to shed new light, in the Neolithic sites under study, on the role of technology as part of the cultural and social environment within which the manufacture process was learned and practised. Moreover, social groups whose presence was, up to now, largely invisible can be detected by distinctive patterns in pottery technology, and recognised within the wider landscape. The experimental archaeology too, due to the fact that ethnographic traditions are rarely present in the Island, proved of great help in reconstructing the ancient manufacturing processes.

In Sardinia since now, ceramic studies have mainly focused on stylistic attributes and their use in assessing a chronological typology. The application of the concept of technological style, supported by the 'experimental archaeology', informed on the communities of practise of Neolithic Sardinia and their role in shaping social structures and ritual behaviour.

## 5. NEOLITHIC POTTERY FROM THE LJUBI-EVA CAVE (ISTRIA, CROATIA).

*Percan, Tihomir (Croatian Conservation Institute)  
tpercan@h-r-z.hr*

Due to exceptional geographical position on the crossroads of ancient paths, the Istrian peninsula was an important link between east, west, north and south ever since the prehistoric times. The Ljubi-eva cave is situated in southern Istria (Croatia) near the village Marana and only 15 kilometers east of Pula, the peninsula's largest city. The cave itself is positioned on the bottom of a large sinkhole, making itself almost unnoticeable in the peaceful landscape. Sinkholes are very common in a karst region such as Istria. In the area around the Ljubi-eva cave there are many other recorded caves and pits. One of the most important Late Paleolithic sites in the northern Adriatic, the Šandalja cave, is also situated nearby. Since 2008 to 2011 archaeological excavations were carried out in cooperation between Musée d'Anthropologie préhistorique de Monaco (Principality of Monaco) and The Croatian Conservation Institute (Croatia).

Four trenches were excavated: two in the deepest part of the cave, one in the largest hall and another one in a smaller room. The trench in which we found the most significant number of finds and other archaeological data was the one in the smaller room. The entire excavated sediment was carried to a secondary location where the water sieving and flotation were carried out. The large and small fractions were later analysed in a laboratory. The reason for this rather complicated chain of actions was very moist and wet sediment and the lack of daylight, making it very difficult to notice all the findings. Using these methods, we collected and analysed a large number of valuable data related to nutrition, husbandry and lifestyle.

By collecting all the scientific research, we were able to reconstruct that the cave was continuously in use from the Epigravettian until the Bronze age. This thesis was confirmed with radiocarbon dates (C14) and the archaeological material that can typologically be placed in the mentioned periods. Recorded findings, specially ones from the Neolithic period, implied that the cave was intensively in use during this period. A large number of pottery fragments were nicely decorated with different motives and ornaments characteristic for the cultural phenomena from Early, Middle and Late Neolithic making it the period of the most intense usage of the cave.

With this oral presentation we will put the focus on the Middle Neolithic (Danilo culture) pottery and its ornaments (S shaped decoration, different spiral motifs, incrustation). We will try to compare this material with the similar ones from the Mediterranean. Furthermore, laboratory analyzed pottery and ornaments are showing the significance of this multidisciplinary kind of approach to archaeology and pottery. With this kind of experiments, interesting results were collected. It wouldn't be possible without good cooperation of archaeologists and the laboratory where the analysis was held (*Metris*, Pula, Croatia). We also emphasize the significance of the modern technology and methods to improve and advance knowledge connected to technology and production of pottery during the archaeological periods.

ORAL

## 6. GUARANI INDIANS: WOULD IT BE ARCHAEOLOGIC DIVERSITY IN CERAMIC POTTERY AN ETHNIC PARAMETER?

*Ramos Soares, André Luis (UFMS) alrsoaressan@gmail.com*

Guarani Indians are the most well studied tribe in South America. They had occupied a territory that goes from the country currently called Paraguai down to Argentina, spreading themselves through the Brazilian States of Mato Grosso, Mato Grosso do Sul, Sao Paulo, Paraná, Santa Catarina and Rio Grande do Sul, totalizing an area of more than 2.000 km from north to south and even more 1000 from east to west. Many tribes called Guarani shared common language, culture and a mythological corpus in such a vast territory. The aim of this paper is to analyze the painting patterns on pottery so the regional variations can be observed and contrasted with historical and ethnographical, searching for elements that aid a construction of knowledge from different Guarani partialities in pre-historical periods.

To observe painting patterns, the area and the form of the vessels from the analysis of ceramic paintings of archaeological vessels assigned to Guarani. Further, to relate the archaeological sites to the Brazilian regions where there is historical information about Guarani Tribes. Comparing the paintings, the patterns and their location, to observe the over position and the exclusion of graphics of spatial features, aiming consequently the determination of specific uses to their ethnical territory.

It has been observed that there are repetitive painting patterns all over the publishing related to Guarani

ceramic paintings. The circle motifs, Greek, scrolls and parallel winding or diagonal lines are recurrent in all known vessels. From one's perspective, in many records there is no relationship between the painting and the place that it occupies in the vessel, preventing a deeper understanding of the study, given that certain subjects may be associated with the location of the vessel as "shoulders", "waist" lip or bulge or inside. The absence of this areas determination where the graphics are located might become a limiter of interpretative hypothesis regarding the search of the spatiality occupied by these ethnics, once these graphics are mostly recurring. From another's perspective, we observe some samples exclusive to area, what might indicate that there are, indeed, painting motifs more recurring than others according to each group territory.

Painting over archeological ceramic from horticulturist Guaranis groups is far from being finished. The creation of subsistence models (Noelli, 1993) and their social organization (Soares, 1997) have dealt with the reconstruction of a generic Guarani Indians, in whom various information are valid and relevant, however without realizing that distinct existing biases in the past. Tochetto (1996) and Lima (2008) recent studies suggest that this topic is not exhausted. Punctual sites analysis either helped to clarify the these territories limits, posting that ceramic painting might add elements which may contribute to the determination of spatial limits of past indigenous territory.

---

ORAL

## 7. LIFE, DEATH AND RESURRECTION: RECYCLING MATERIALS IN POTTERY-MAKING

Vidal, Aixa (UCM) [aixavidal@gmail.com](mailto:aixavidal@gmail.com)

Padilla Fernández, Juan Jesús (UCM) [juanjpada@ucm.es](mailto:juanjpada@ucm.es)

When considering the manufacture of any kind of vessel, we imply not only the material elements and the techniques used, but also a complex symbolic universe intimately connected with it. The conceptual tool of the *chaîne opératoire* offers the appropriate background to discuss this close connection. However, it has traditionally been defined as a straight process, always moving forward, incorporating new elements to the sequence which are merely considered as raw materials. Regardless of their nature, we noticed that several of these materials had already been used and discarded in daily activities to be later incorporated in the pottery-making process. In this way, they are embodied with

new meanings which trespass the simple idea of raw material. Due to the recycling process they are involved in, these two seemingly opposed concepts, waste and new pottery, are redefined as a unique entity defined by their material correlates inasmuch their social value.

Three different and complementary methodologies were followed to record recycling in pottery-making: on the one hand, the analysis of archaeological pottery from different cultural periods reported the use of several materials (ashes, crashed bones, pottery sherds, animal by-products) which had certainly been active in different domestic and productive process to end up as waste.

Complementary, some experiments were carried out incorporating these elements in the modelling clay and/or using them for pottery-making so as to test their properties and visualisation. Finally, the direct observation of traditional potters' work as well as the revision of ethnoarchaeological literature revealed the actual use of these materials along the *chaîne opératoire*.

The experiments showed distinctive compositions which were similar to the ones found in archaeological specimens. Moreover, the observation of the potters' environment highlighted that a series of related activities take place together with the potter-making process, some of them with material correlates which may be traced in fabric composition.

We discuss the concept of "waste" as a final stage in the biography of any object. In the case of the pottery-making process, as probably happens in most of everyday activities, it is clear that not only what is conventionally called waste participates in the manufacture but it is also assigned new meanings. As exemplified in the case of pottery-making, it is necessary to change the traditional view which considers any production as a linear sequence to evidence the several back and forward movements present in the process which ultimately define the wider interconnected context of social life.

## 8. ARCHAOMETRIC INVESTIGATIONS ON GUMELNI A CERAMIC PIGMENTS

Bugoi, Roxana (Horia Hulubei National Institute For Nuclear Physics And Engineering, Magurele, Romania) [bugoi@nipne.ro](mailto:bugoi@nipne.ro)

*Haita, Constantin (Muzeul National De Istorie A Romaniei, Bucuresti, Romania) costel\_haita@yahoo.com*  
*Popovici, Dragomir (Muzeul National De Istorie A Romaniei, Bucuresti, Romania) mirel\_d\_n\_p@yahoo.com*  
*Sciau, Philippe (Cemes, Toulouse, France) sciau@cemes.fr*  
*Bouquillon, Anne (C2rmf, Paris, France) anne.bouquillon@culture.gouv.fr*

During the Copper Age the South-Eastern region of Europe was the cradle of several remarkable cultures – Petreti, Gumelnita, Slcua, Cucuteni – that produced remarkable painted ceramic potteries. Until now, Gumelnita ceramic paste and pigments has been just occasionally the subject of archaeometric investigations, contrary to Cucuteni culture pottery, which, in the last decades was extensively studied from scientific point of view.

To fill in the gap the nowadays knowledge about Gumelni a painted wares, a set of ceramic shards excavated at Bordu ani-Popin (Ialomi a County, Romania) and attributed to phase A2 of Gumelni a culture were subjected to some scientific investigations aiming at the characterization of the ceramic paste and the identification of the mineral pigments used for the decoration.

Optical Microscopy (OM) observations were focused on the fabric and mineralogy of the ceramic paste, Particle-Induced X-ray Emission (PIXE) was used to determine the chemical composition of both paste and painted zones, while micro-Raman spectrometry and X-ray Diffraction (XRD) led to the un-ambiguous determination of the compounds present in the decorated layers present on some shards.

The pottery paste shows a remarkable variety induced not only by the matrix mineralogy, but also by the inclusion characteristics (nature, texture, frequency and dimensions). The micro-mass includes very fine silty grains of quartz, feldspars, muscovite and some opaque phase grains. The overall texture of the paste was divided into three main groups: very fine (silty clay), medium (silt) and coarse/ medium-coarse grained sand. Inclusions consist mainly in fragments of crushed pottery (grog) and rare quartz sand grains. Occasionally, carbonaceous inclusions, such as shells or limestone fragments and vegetal debris were observed, too.

The analytical results showed that the white color was produced through the application of a calcite - based compound ( $\text{CaCO}_3$ ), while the black colored regions feature high amounts of graphite (C).

This archaeometric study led to some conclusions about the manufacturing techniques and raw materials employed by the potters who crafted these painted ceramic.

## 9. ANALYSIS OF INCRUSTATION OF LASINJA CULTURE POTTERY FROM THREE SITES IN CROATIA

*Cataj, Lea (Croatian Conservation Institute) lcataj@h-r-z.hr*  
*Posilovic, Hrvoje (Croatian Geological Survey) hrvoje.posilovic@hgi-cgs.hr*  
*Kos, Katarina kos\_katarina@yahoo.com*

White incrustation is one of the decorating techniques used on middle Eneolithic Lasinja culture pottery. The aim of this presentation is to show the composition and technology of the white incrustation paste.

From three sites in central Croatia seven samples of incrustated pottery were analyzed. Old town Barilovi and Crkviše-Bukovlje are only few kilometers away from each other, south to the town of Karlovac. The site Brekinjova kosa is placed close to the town of Glina, about 50 km to the southeast of the above mentioned sites.

Five of the analyzed pottery samples belong to the Eneolithic Lasinja culture, absolutely dated from 4300 to 3900 cal BC: three of them are from the site of Crkviše-Bukovlje, one from the Old Town Barilovi and one from the site Brekinjova kosa.

For comparison two samples from Brekinjova kosa were analyzed. One of them dates to the late Eneolithic Vu edol culture (cca 3000 - 2400 cal BC) and the other one to the Early Bronze Age Vinkovci culture (cca 2500 - 2000 cal BC).

The composition and technology of the white incrustation paste on prehistoric pottery was analyzed and described. Deep field optical microscopy was used for structural investigations. Chemical composition of incrustation paste was determined by chemical tests. Scanning Electron Microscopy (SEM) coupled with an Energy Dispersive Spectrometer (EDS) was used for additional particle analysis.

The paste was applied in incisions or flutes, up to 1,5 mm deep and up to 2 mm wide. Pottery ornaments were incised before firing, using a sharp tool in the still

fresh material. Incrustation paste was applied in incisions or flutes previously impregnated with organic resin. The incrustation material is of excellent whiteness and powdery texture. The material was mixed with organic binder and applied in the incisions or flutes. At the end of process the whole surface was resin coated which resulted in a shiny thin layer. The chemical tests and EDS analysis showed calcium-phosphate composition. The elements stoichiometric ratio closely matches the composition of hydroxyapatite. The incrustation particle shape and structure is in accordance with mammal bone material structure. It is possible that the material was obtained by deer antler burning. In resin remains plant material particles could be found; the tissue structure is similar to birch-tree.

Although from different time periods, all of the samples display similar composition of the incrustation paste. It is interesting to mention that the results of incrustation analysis from eastern Croatia belonging to the late Eneolithic Kostolac and Vu edol, as well as to the middle Bronze Age Transdanubian Encrusted Pottery showed almost the same composition of the white paste.

# B30 A diachronic perspective of human behavioural adaptations to interglacial lakeshore environments during the European Pleistocene to early Holocene

*Gaudzinski-Windheuser, Sabine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) gaudzinski@rgzm.de*

During the course of human evolution, we have successfully adapted to various environments. Changing climates and landscapes often required new behavioural strategies for survival: human societies indeed came into being against the background of this challenge. Although the casual connection between the development of human behaviour and environmental change is well acknowledged, the processes involved are still not fully understood. To what extent, how rapidly and at what scale climate and environmental change led to modifications in human behaviour are issues which are only just beginning to be intensively addressed. A fundamental problem is the complexity and interdependence of human behaviour and environmental conditions, necessitating the identification of relevant levels of comparability in order to provide a solid foundation on which to base the archaeological record as a product of behavioural adaptation.

A major prerequisite of this research are sites with high resolution archives. In our session we consider human

behavioural adaptations to European interglacial environments, beginning in the Middle Pleistocene, some 500,000 year ago, through to the beginning of our own interglacial, the Holocene, just over 10,000 years ago. Interglacial sites offer favourable conditions for the preservation of archaeological remains and high-resolution ecological records. Frequently, these records have been recovered near to freshwater sources (lakes, springs, rivers, etc.), which provided attractive, well-known locations for the procurement and butchering of animals, lithic provisioning and occasionally more permanent visits.

Collating evidence from sites of different character, from ephemeral sites to extensive, multi-occupation localities to the highly detailed information preserved at early Mesolithic sites, we aim to understand the importance and attractiveness of freshwater localities as focal points for human behaviour during interglacials.

In this session, we evaluate freshwater sites during interglacials in order to understand the interplay between hominin/human behaviour against the context of availability and distribution of local resources. Our ultimate goal is to evaluate how survival strategies in similar environmental situations evolved throughout the course of our history.

ORAL

## 2. A RE-EVALUATION OF AN INTERGLACIAL SITE IN THE CENTRAL RHINELAND OF GERMANY: THE LOWER PALAEO-LITHIC SITE OF MIESENHEIM I

*Turner, Elaine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) turner@rgzm.de*

The Lower Palaeolithic site of Miesenheim I, located at the edge of the Neuwied Basin, was investigated in a series of campaigns at the end of the 1980's and beginning of the 1990's. The site produced an interglacial fauna in association with a small assemblage of lithic artefacts. The deposits date to approximately 500,000 years ago. Several lines of evidence suggest find-deposition took place in the back-waters of the Rhine Valley, close to a flood-plain pond. When the site was analysed in the mid 1990's, the role of hominins in the accumulation of the faunal assemblage was difficult to decipher and the character of the site could not be clearly defined. At that time, the evidence from Miesenheim I was compared with that of "home base" sites, "foraging" sites and "short-

stay" sites and failed to meet the predictions for each of these different types of localities. A fundamental problem appeared to be the site itself with complex, superimposed sequences of deposition and faunal remains subject to varying degrees of modification by different agents. Here the results of a critical re-appraisal of the evidence are presented.

The aim is to redefine the earlier results by re-assessing the archaeozoological, taphonomical and spatial, in particular refitting, analyses. In this way, processes of site formation can be reconsidered from a state of the art perspective and patterns pertaining to hominin activities can be more easily identified.

Just over 1,100 faunal remains could be identified to several species of smaller and larger mammals, birds and fish. Including species typical of warm phases, such as wild boar, the faunal assemblage is representative of the type of vertebrate community which would have been living in and around the Rhine Valley during an interglacial.

Although lithic artefacts were recovered and refitting showed that some of these had been produced at the site, the assemblage is relatively small ( $n = 113$ ). Strong evidence of human interaction with the faunal remains is lacking. A conchoidal flake scar, similar in form to notches produced by humans when opening bone shafts to obtain marrow, was observed on a fragment of a long bone of horse or large bovid. Fine linear incisions on three bones, superficially resembling cut marks, are probably of natural origin.

Currently, the evidence from Miesenheim I hints at a transient use of the site by hominins. This is in strong contrast to the evidence from large interglacial sites such as Schöningen and Neumark-Nord, where masses of faunal remains and abundant traces of hominin interaction indicate repeated visits along lake-shore margins. Despite this, sites such as Miesenheim I are important, since they provide not only additional information on hominin movement and land-use, but present another, ephemeral, facet of human behavioural adaptations in interglacials.

*Gaudzinski-Windheuser, Sabine (MONREPOS Archaeological research Centre and Museum for Human Behavioural Evolution, RGZM) gaudzinski@rgzm.de*

The Schöningen archaeological site, located in Lower Saxony, Germany, has received much attention over the past twenty years for the remarkable discovery of well-preserved wooden spears in association with a large assemblage of Middle Pleistocene faunal remains. Geological and palaeoenvironmental contexts indicate an accumulation during an interglacial phase (MIS 9), roughly 300.000 years ago. Here we present preliminary interpretations of the faunal assemblage from the "Spear Horizon".

Through a combination of archaeozoological, taphonomic and spatial analyses, we aim to reconstruct the processes of the site formation and to identify patterns in the faunal assemblage that relate directly to Middle Pleistocene hominin subsistence behaviours.

The assemblage is clearly representative of an interglacial lake-shore environment, dominated overwhelmingly by horses (*Equus mosbachensis*), but also includes bovids (*Bos primigenius*, *Bison priscus*), cervids (*Megaloceros giganteus*, *Cervus elaphus* and *Capreolus capreolus*), smaller mammals, waterfowls and fish.

Preliminary results suggest the use of the site as a location of repeated ambush hunting along the lake-shore margin during the Middle Pleistocene. Age and sex profiles of the horse population indicate the presence of multiple herds and multiple hunting episodes. Evidence of systematic butchery (filleting, disarticulation and marrow extraction) indicates that the entire sequence of carcasses exploitation occurred at the hunting site. Secondly, medium-sized carnivore activity is present, but subsequent to abandonment by Middle Pleistocene hominins. The excellent preservation at the site allows for the study of other modifications produced by the use of different bone pieces as retouchers, soft hammers and anvils.

While the circumstances for preservation and discovery of the Schöningen 13II-4 "Spear Horizon" assemblage was quite fortuitous, the accumulation of the site was not a matter of chance. The warm interglacial environment provided the hominids groups with a variety of vegetal and animal resources to exploit. The site, situated along the margins of a large lake close to the foot of Elm hill range, represented a well-known location on the landscape for Middle Pleistocene hunter groups to ambush large ungulate, especially horses. This unique archaeological record provides an exceptional assemblage to analyse the functional organization of hominid behaviour during the Middle Pleistocene.

#### 4. WHAT WERE THEY UP AGAINST? MIDDLE PLEISTOCENE CARNIVORES AND HOMININS AT SCHÖNINGEN (GERMANY)

Starkovich, Britt (University of Tübingen) [britt.starkovich@uni-tuebingen.de](mailto:britt.starkovich@uni-tuebingen.de)

Conard, Nicholas (University of Tübingen) [nicholas.conard@uni-tuebingen.de](mailto:nicholas.conard@uni-tuebingen.de)

The Lower Paleolithic site of Schöningen in north-central Germany preserves a unique set of archaeological materials, including multiple wooden spears and a large number of Pleistocene horse remains. The site is situated on the shores of a paleolake that attracted a range of herbivores as well as hominin and carnivore predators. The role of hominins as part of the carnivore guild at this time is significant in understanding the evolution of hominin subsistence strategies and cultural adaptations. This paper presents the results of an analysis of the faunal remains from the "Spear horizon south," a southern extension of the main excavation area that yielded the famous Schöningen spears (13II-4). In particular, we evaluate taphonomic modifications on the bones that were caused by carnivores, and highlight specific carnivore taxa recovered from the site, mostly two *Homotherium latidens* individuals. This large saber-toothed cat occupied Europe during much of the Pleistocene and, along with other large and small carnivore species, directly competed with hominins for meat resources. Carnivore remains were identified using standard zooarchaeological techniques and the length and breadth of gnaw marks on the faunal materials were measured using digital calipers. The resulting bite sizes were compared to experimental data presented by Dominguez-Rodrigo and Piqueras (2003) to determine the size and behavioral categories of

carnivores that impacted the faunas. Consistently large bites on both spongy and compact bone indicate that large-bodied taxa such as wolves, lions, or saber-toothed cats impacted the assemblage. In rare cases where cut marks and bites are both present on bones, bites tend to overlie cuts, indicating that hominins had primary access to the carcasses. This reinforces the idea that hominins were successful carnivores in their ecosystem as early as the late Lower Paleolithic in north-central Europe. The position of hominins toward the top of the Middle Pleistocene carnivore guild was undoubtedly the result of foraging strategies that included opportunistic scavenging alongside increasingly complex and cooperative hunting strategies. This flexibility in food procurement, facilitated by an organic and inorganic toolkit, set the stage for the long-term success of the human species.

ORAL

#### 5. MIDDLE PLEISTOCENE LAKE SHORE ENVIRONMENTS AND ARCHAEOLOGICAL SITES OF SCHÖNINGEN, LOWER SAXONY, GERMANY

Urban, Brigitte (Leuphana University) [b.urban@leuphana.de](mailto:b.urban@leuphana.de)

Kolfshoten van, Thijs (Leiden University) [T.van.Kolfschoten@arch.leidenuniv.nl](mailto:T.van.Kolfschoten@arch.leidenuniv.nl)

Serangeli, Jordi (Tübingen University) [jordi.serangeli@uni-tuebingen.de](mailto:jordi.serangeli@uni-tuebingen.de)

The long Quaternary terrestrial record of Open Mine Schöningen comprises glacial sediments as well as interglacial lake and fluvial deposits which serve as outstanding archives for reconstructing Western European climatic and environmental evolution since the Late Middle Pleistocene. Five interglacials including the Holocene have been identified succeeding the Elsterian glaciation and have been correlated with MIS 11, 9, 7, 5e and 1. More than 30 archaeological/paleontological sites have been examined in Schöningen, whereof the the hunting spear-bearing lake shore site Schöningen 13 II-4 of the Middle Pleistocene Reinsdorf sequence is the most prominent.

Our contribution focusses on the oldest archaeological site Schöningen 13 I and the Reinsdorf Interglacial lake succession at archaeological sites Schöningen 13 II and 12 II. Environmental reconstruction is mainly based on botanical data supported by faunal and sedimentological investigations.

From high resolution palynological and faunal investigations we can conclude that the deposits of the oldest archaeological find horizon Schöningen 13 I, which stratigraphically underlies the Reinsdorf sequence, most probably developed during a late boreal-steppe phase of an interglacial. As classical Holsteinian interglacial pollen assemblages described in the northern mining field differ significantly from the Reinsdorf vegetational succession, the Schöningen 13 I layers might relate to late Holsteinian (*sensu stricto*) phases. Sedimentation of Reinsdorf interglacial deposits was initiated on an eroded gleyic surface only during the interglacial thermal optimum indicative of a rising groundwater table (Schö 13 II-1). Subsequent layer 13 II(-2c5) has been U/Th dated and tentatively correlated with MIS 9. Based on palynological findings it correlates with archaeological find horizon Schöningen 12B, which is characteristic the late interglacial *Carpinus-Abies-Pinus-Picea* pollen zone. Several lake fluctuations were identified, succeeding the full interglacial phases, during a deteriorating and oscillating climate. During level 13 II-4, lake marls were deposited under a high ground water table that transitioned into an organic muddy/peaty horizon containing the hunting spears. Dry steppe-forest environmental conditions deduced from the pollen evidence, was supported by the macrofaunal remains that included some 20 carcasses of *Equus mosbachensis*, excavated from that horizon (Schö 12 II-4(c/b/a)).

The long term multidisciplinary research project has enabled reconstruction of the local and regional environmental conditions providing a required background for the interpretation of human behavior particularly during the late Middle Pleistocene of Western Europe.

With high resolution botanical, faunistic and sedimentological studies and the dating of the entire Schöningen sequence with multiple chronometric techniques, we will continue to contribute to the debate on the correlation of Western and Central European terrestrial records with the marine stratigraphy.

*Smith, Geoff (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) smith@rgzm.de*

*García-Moreno, Alejandro (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) garcia@rgzm.de*

“Being constantly on the move” seems to be among the various aspects that characterise Middle Palaeolithic hominins’ lifeways. These hominins exploited habitats which they controlled by continuous roaming. Against this background, the majority of our archaeological sites ideally provide us with only a static snapshot that we use to reconstruct a basically dynamic way of life. It is therefore of utmost importance to understand the whole repertoire of activities carried out in the wider landscape) as they actually represent Middle Palaeolithic hominins “homes”. However, the characterisation of these habitats provides us with some difficulties as Middle Palaeolithic open air sites often grant only very limited and blurred insights. Various factors are responsible. Among them are the small scale of our excavated areas, the variable quality of organic preservation at these sites and the fact that their palimpsest character can only rarely be unravelled. The exposure at Neumark-Nord (Germany) offers the unique opportunity to challenge our restricted knowledge on Middle Palaeolithic habitats.

The archive at Neumark-Nord (Germany) is exposed in an abandoned open cast lignite mine. It represents a large last interglacial Eemian lakescape. The preservation of organic material is outstanding. Two archaeological sites, Neumark-Nord 1 and Neumark-Nord 2 have been discovered. The Neumark-Nord 1 exposures were studied in the 1980’s and the 1990’s, over a period of 11 years by Dietrich Mania and colleagues. New studies are currently underway. Neumark-Nord 2 was excavated from 2004 until 2008 by our working group. A geological, palaeoenvironmental and palaeoecological framework for the analysis of Neumark-Nord was established as well as detailed analysis of fauna and lithics.

According to the pollen, sedimentary, AAR and other data, the archaeology of the two archaeological sites Neumark-Nord 1 and 2 is contemporaneous on a scale of resolution rarely achievable in Palaeolithic studies. Hence both sites represent a more than 25ha large part

of an Eemian Interglacial lakescape in which hominins were repeatedly present within an earlier stage of the Interglacial. Neumark-Nord 2 represents a small "puddle" at the margins of the larger Neumark-Nord 1 lake. Especially the role of hominins in the exploitation of the lakescape is a key issue which can be addressed by detailed analysis of the faunal remains in both assemblages.

The large scale of the exposure and the quality and quantity of the faunal remains, micro- and macrobotanical finds and the associated archaeology make the lakescape Neumark-Nord into one of the key sites of the European Palaeolithic. Neumark-Nord yields the potential to open a new chapter in understanding Middle Palaeolithic lifeways by moving away from a site perspective to a habitat perspective.

---

ORAL

## 7. THE MIDDLE PALAEOOLITHIC SITE OF NEUMARK NORD 2: NEANDERTHAL ADAPTATION AND BEHAVIOUR WITHIN AN EEMIAN LAKE LAND ENVIRONMENT.

*Smith, Geoff (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) smith@rgzm.de*

*García-Moreno, Alejandro (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) garcia@rgzm.de*

*Kindler, Lutz (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) kindler@rgzm.de*

*Gaudzinski-Windheuser, Sabine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) gaudzinski@rgzm.de*

During excavations of the large lake basin (c.24ha) of Neumark Nord 1 (NN1; Geiseltalsee, eastern Germany) an additional, smaller basin (1.6ha) was identified (Neumark Nord 2 [NN2]). Excavations of the sedimentary infill of NN2 were undertaken over an area of approximately 500m<sup>2</sup> and yielded c.20,000 flint artefacts and more than 120,000 faunal remains. Application of palaeomagnetism, combined with an extensive pollen and micromorphology record, position the main find bearing units to the first half of the Last Interglacial period, the Eemian (MIS 5e). Sedimentological studies suggest that the basin was infilled over a narrow time interval (c.500 years). Continuing research is investigating the specific site formation processes and taphonomic agents

operating at NN2 in order to contextualise Neanderthal behaviour at the site and provide a unique window into their subsistence behaviour during interglacials.

Detailed zooarchaeological analysis, combined with both experimental procedures and GIS analysis, has allowed for a more comprehensive understanding of both site formation and Neanderthal behaviour at NN2. To date, c.20,000 bones have been analysed, representing an almost complete north-south transect that encompasses both the margins and the deeper regions of the basin. Holistic taphonomic analysis has been used to identify and disentangle evidence for both natural and cultural modifications. GIS-based spatial analyses are being used to identify taphonomic process and Neanderthal use of space.

A variety of warm-stage fauna were identified including elephant, rhino, bovid, equid, cervids alongside carnivores such as bear and lion. Skeletal representation highlights both denser and more friable bone portions are preserved suggesting limited post-depositional destruction. Detailed bone surface studies have identified a predominance of human modifications, with a surprising absence of carnivore and other natural modifications (e.g. fluvial). This suggests a primary role for Neanderthals in faunal accumulation at NN2, supported by GIS analysis that illustrates no statistical correlation between bone remains and hydraulic flow. Further spatial analysis illustrates more fragmented remains in the northern areas of NN2 contrasting with larger, more complete remains, often in anatomical alignment, in the south. Thus, the highly fragmented nature of the assemblage in the north of the NN2 basin could be, largely, the result of Neanderthal butchery and marrow processing activities.

Because of its large excavated area and high resolution archive, NN2 provides a unique opportunity to identify, document and analyse taphonomic processes and provide a clearer understanding of Neanderthal exploitation in a lakeland environment during and interglacial. Multidisciplinary analyses suggest that the site was repeatedly used by Neanderthal populations for butchery and carcass processing. At NN2 natural accumulation agents appear to have had a reduced role in site formation. Instead, the site appears to represent a focal point to which Neanderthals both transported material and potentially exploited animals that had died naturally. Similar behavioural signatures were also noted around the nearby NN1 basin, illustrating that NN2 was only one focal point within this broader lakeland environment.

ORAL

**8. THE EEMIAN INTERGLACIAL (OIS5E) LAKE BASIN NEUMARK-NORD 2: VEGETATION OPENNESS AND HOMININ ACTIVITY AS A RESULT OF LARGE HERBIVORE PRESENCE?**

*Pop, Eduard (Leiden University, Faculty of Archaeology)  
e.a.l.pop@arch.leidenuniv.nl*

Were Neanderthals able to maintain themselves in forested interglacial conditions? Several sites provide conclusive evidence of their presence during the Eemian Interglacial, but how forested were the environments exactly? Interpretations regarding the character of Eemian interglacial landscapes range from fully forested environments ("high forests") to mosaic-like park landscapes ("wood pastures"), the latter being maintained by large herbivores. Others take a more intermediate position by suggesting a dominance of closed forests, but with local openings due to soil conditions or disturbances by grazing or fire. Grazing would especially occur near wetland areas where water and a diverse vegetation would attract (large) herbivores, as documented by Eemian floodplain localities in the UK. Known Eemian sites from the continent that also provide evidence for hominin presence show conditions ranging from closed forests to mixed environments. The basin site Neumark-Nord 2 yielded a detailed environmental record that covers the complete Eemian Interglacial, as well as the largest archaeological record known from this timeframe. This paper discusses these datasets in order to reconstruct the character of the vegetation during phases of hominin activity and study the interrelationship between water availability, large herbivore presence and vegetation openness.

The extensive sampling strategy employed at Neumark-Nord 2 provided a substantial environmental dataset covering the complete basin infill. The pollen record and more specifically the ratio between arboreal and non-arboreal pollen were used to reconstruct the (openness of the) vegetation surrounding the basin. Aquatic molluscs, water plants and ostracods were used to identify phases of increased and decreased water within the basin. These datasets have been correlated to the position of the archaeological find levels located at the margin of the basin.

The pollen data suggest relatively open environmental conditions during the Early Eemian, which covers all exposed find levels. Indications for vegetation openness however fluctuate and seem to correspond to fluctuating

water levels within the basin: phases of increased water within the basin are correlated to more open environmental conditions, while decreased presence of water correlates to a more closed vegetation. Although winnowing by overland flow led to a certain amount of "enrichment" of finds during wetter intervals, the lack or very low amount of archaeological material deposited during drier phases suggests that hominin activity is focused on phases of wetter basin conditions and more open environmental conditions.

The strong link between water availability within the Neumark-Nord 2 basin and vegetation openness is suggestive of being mediated by large herbivore activity, whose presence is well documented by the faunal assemblages of Neumark-Nord 2 and of the neighbouring basin Neumark-Nord 1. This scenario can also explain the focus of hominin activity on the same specific phases, as they would provide increased subsistence opportunities in the form of (large) game and possibly edible plants as well. This study suggests that small basins like Neumark-Nord 2 and other wetland localities played an important role in hominin survival within Eemian Interglacial environments.

ORAL

**9. METHODOICAL SUB-AQUATIC DISPOSAL OF BUTCHERING WASTE AT AN EARLY HOLOCENE MESOLITHIC CAMPSITE**

*Street, Martin (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM)  
street@rgzm.de*

The early Mesolithic site of Bedburg-Königshoven was found at the end of the 1980s in the open-cast lignite mine of Garzweiler (German Lower Rhineland). The presence of well preserved faunal remains and the recognition of an intentionally modified antler frontlet broadly similar to those from the English site of Star Carr underlined the importance of the discovery and the necessity of carrying out an investigation. A rapidly carried out pollen analysis and radiocarbon dating already confirmed the Preboreal age of the site during excavation.

At the time of discovery the Bedburg site had already been severely truncated in all dimensions by earlier earth-moving activities. What remained of the site was investigated over just a few winter months by a salvage excavation which was nevertheless able to identify and

excavate the find-bearing horizon over most of the surviving site recording the 3D-location of all identified finds within a grid system set up to run parallel to the palaeotopography. The bulk of the excavated sediment was subsequently wet-sieved, ensuring a contextual recovery of even smaller material overlooked during excavation.

It became clear at an early stage of excavation that the find-bearing horizon consisted of a calcareous and organic limnic deposit (gyttja) formed under sub-aquatic conditions, probably in the still or very slow moving water of a palaeochannel of the River Erft. The surviving stratigraphy and topography and subsequent analyses confirmed that these deposits had been truncated vertically almost exactly at their transition to the original shoreline. In view of the loss of the originally present (semi-)terrestrial sediments it was not expected that the distribution of recovered finds would reveal any meaningful spatial patterning. In fact, in combination with the zooarchaeological analysis of the mainly large mammal fauna, it was possible to show a certain spatial sorting of material which even extended to the recognition of repetitive processes of butchery and disposal for specific elements of the carcass.

Since terrestrial surfaces upon which prehistoric butchery was primarily carried out will generally preserve faunal material poorly or not at all, it is self-evident that discard of waste into adjacent bodies of water will provide otherwise unavailable insights into butchery operations in the form of cut and impact marks which can show in detail how an animal carcass was processed. The analysis of a faunal assemblage from the early Mesolithic site Bedburg-Königshoven showed that an additional level of interpretation for butchering processes may be provided by meaningful spatial patterning which can in some cases be identified even when elements of the discarded carcass have been discarded into a sub-aquatic environment.

## 10. RE-THINKING THE FUNCTION OF THE EARLY MESOLITHIC SITE OF BEDBURG-KÖNIGSHOVEN

Wild, Markus (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM)  
wild@rgzm.de

The Early Mesolithic lake site of Bedburg-Königshoven was discovered in 1987 within Erft valley during lignite

mining. Excavations exposed calcareous gyttja sediments of Early Holocene age that contained archaeological material. The common interpretation of the site is that of an off-bank discard zone showing a palimpsest, created by repeated visits of hunter-gatherers undertaking secondary butchery activities at the site (Street 1989; Street and Wild *in press*).

The faunal remains – dominated by *Bos primigenius* – indicate the systematic exploitation of typical large ungulates of the Central European Early Mesolithic. Some bird and fish remains represent background fauna and they cannot be linked directly to the human presence at the site.

The small lithic assemblage consists of a handful of cores, some scrapers, microliths, unretouched flakes and blades and a heavy pic. The assemblage suggests the deliberate discard of butchery tools used in animal butchery (Street 1998; Street and Wild *in press*).

During the re-analysis of *Hirschgeweihkappen* [deer antler caps] from Early Mesolithic sites the spatial character and function of Bedburg-Königshoven compared to other Early Mesolithic sites with antler frontlets (Friesack 4, Hohen Viecheln (Germany), Star Carr (UK)) was re-assessed. This was combined with experimental procedures that attempted to understand the production and function of a *Hirschgeweihkappe*.

Some features of the assemblage do not fit with the interpretation of Bedburg-Königshoven solely as a secondary butchering site. The close association of the only two bone tools from the site (a chisel and a point) suggests a more complex site function, as do the two perforated deer skulls. Indeed, the *Hirschgeweihkappen* seem to be half-finished and deliberately stored underwater, perhaps either to protect them from carnivore gnawing or as part of the manufacturing process. Together, these two lines of evidence suggest a more complex and longer-term use of the site that fits with the finds of other *Hirschgeweihkappen* underwater at sites like Star Carr.

Lyman (1992, 247–248) points to the fact that secondary butchering sites are often situated in the direct vicinity of camp sites. This might be supported by the fact that there is barely any evidence of further processing of meat at Bedburg-Königshoven, although the bones are completely defleshed. The off-bank discard zone may therefore reflect a highly specialised part of a camp, which could be compared with large Preboreal sites like Star Carr.

ORAL

## 11. MANAGEMENT AND EXPLOITATION OF ANIMAL RESOURCES IN LAKESHORE ENVIRONMENTS IN THE EARLY NEOLITHIC IN THE NORTH-EAST OF THE IBERIAN PENINSULA

*Verdún Castelló, Ester (Departament de Prehistòria, Universitat Autònoma de Barcelona) estercv@gmail.com*

*Navarrete, Vanessa - vanessa.navarrete@uab.cat (Departament de Prehistòria, Universitat Autònoma de Barcelona), Blanco, Àngel (Institut Català de Paleoecologia Humana i Evolució Social, Universitat Rovira i Virgili; 1Departament de Prehistòria, Universitat Autònoma de Barcelona) angel.blanco.geoterna@gmail.com*

*Garcia, Lluís (UMR 5140, Centre National de la Recherche Scientifique) lgp@pangea.org*

*Saña, Maria (Departament de Prehistòria, Universitat Autònoma de Barcelona) maria.sana@uab.cat*

La Draga site is located on the eastern shore of the Lake of Banyoles (Girona, Spain). Chronologically it corresponds to the early Neolithic. Two occupation phases have been distinguished: one corresponding to 5430-5000 cal BC and another one corresponding to 5210-4796 cal BC. The site has an extension of 8000m<sup>2</sup> and only 10% of it has been excavated. It is partially underwater, a characteristic that permitted the excellent conservation of the remains.

In La Draga, the presence of several kind of domestic and wild animals (mammals, fishes, birds, molluscs, reptiles...) (more than 50 species), has been documented and shows the exploitation of different environments. The exploitation of areas with different characteristics requires the combination of different techniques and economic practices (herding, hunting, fishing and collecting) and the implementation of a system of social organization to exploit and to manage the resources of these diverse environments.

A detailed analysis of each type of archaeofaunal remains has been carried out (taxonomic analyses, MNI quantification, biometrics...). All the obtained data have been integrated in order to offer a general explanation about the exploitation and management of the faunal resources.

Remains of birds, fishes, domestic and wild mammals, molluscs and turtles have been documented. This wide variety of animal resources shows: a) the exploitation of different environments (high mountain areas, forest, lakeshore, coastal areas, grazing areas; and b) the

implementation of adequate techniques of managing, obtaining and processing of each type of animal.

Chronologically La Draga site corresponds to the first moments of the implementation of agriculture and herding in the Iberian Peninsula. This characteristic together with the excellent conservation of the remains, makes La Draga an exceptional site to study the transition of an economy based on hunting and gathering to agriculture and herding and the social implications of this change. The study of the role of animal resources in La Draga and the interrelation among the different resources in a moment of economic change between two economic systems, could afford new data to reconstruct the social activities and the social organization system of the first agricultural and herding societies.

The analyses of the animal remains recovered in La Draga show a combination of different productive activities (herding, hunting, fishing and collecting of molluscs). All these activities, permitted the inhabitants of the settlement to exploit all the available resources. However it seems that the consumption of domestic animals would be more important than the other. Although the presence of different types of species denotes the consumption of resources from different environments, lake environment and forest areas surrounding the site were the most exploited.

ORAL

## 12. MESOLITHIC ANIMAL EXPLOITATION AND PAL-AEOECONOMY: DISCUSSION OF A NEW METHODOLOGICAL APPROACH

*Noack, Elisabeth (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution) noack@rgzm.de*

During the Holocene two economic systems pursued: "Neolithic" agriculture and stock breeding and "Mesolithic" exploitative hunting, gathering and fishing. To understand the relationship between these economic concepts, detailed study of economic practices applied during the Mesolithic is necessary. Against this background a new economically focussed methodology will be discussed.

Studies of economic systems consider basic questions related not only to subsistence but to a wide spectrum of physical and social requirements. Therefore economic behaviour encompasses all activity necessary to gain

sustenance and is manifested in various aspects of the archaeological record. One way to characterize these complex systems is the application of a methodology which is based on an economic concept currently used for discussion on Neolithic economy.

In a pilot study, the approach of "total" animal exploitation (see Fontana et al. 2009) is combined with an economic model. In this model the components of the entire economic system are defined and related to each other. To illustrate the potential of this methodological approach, one aspect of Mesolithic economic behaviour, the exploitation of hunted animals, is considered. Therefore big game species such as red deer, roe deer, elk, aurochs and boar are analysed in regard to different aspects of their exploitation. The faunal material originates from lakeshore sites including Hohen Viecheln and Rothenklempenow (Germany).

The pilot study demonstrates that human exploitation of various animal species is not solely based on nutritional requirements. To understand the contribution of each animal species within the economic system, the different aspects of their utility use have to be considered and related to each other.

Studies on the Mesolithic based on a holistic point of view gain new insights into past human behaviour. Based on this study, diachronic analysis of preceding and succeeding archaeological periods could improve our understanding of economic evolution during the Holocene.

#### ORAL

### 13. ISLANDS IN THE SWAMP - MESOLITHIC SITES IN THE RHINLUCH AREA (GERMANY).

*Groß, Daniel (Centre for Baltic and Scandinavian Archaeology) daniel.gross@schloss-gottorf.de*

The Rhinluch in Brandenburg in eastern Germany is a valuable area for analyzing the function and use of a micro-region in the early Mesolithic in Europe. Near the modern town Friesack three sites are known of which one is thoroughly excavated (Friesack 4). Another site, Friesack 27a, is only known by small scale trenches and the third, Friesack 27b, just by surface finds. Nevertheless, this area bears great potential to analyse the taskscape of early Holocene hunter-gatherer-fishers, due to detailed excavation techniques and (archaeological) contemporaneity. Providing high potential for preservation of organic material, these sites also gave excellent results

for environmental reconstructions, too, which are supported by modern remote sensing techniques.

The excavations followed standard procedures for wet-land-sites. To reduce the pressure of groundwater pumps were used and the trenches were divided into sectors. During the excavations it became obvious that the use of sieves and shovels would destroy fragile finds like nets and strings. Due to this the use of spatulae and toothpicks became common practice and thus also tiny finds (e.g. fish scales and beetle elytra) were recovered. During the excavation campaigns a considerably large probing program was conducted between the sites to reconstruct the Pleistocene surface. Furthermore palynological, archaeozoological and macrobotanical investigations provided information on the palaeo-environment and for socio-economic analyses.

In the beginning of the Holocene the micro region around the sites of Friesack 4, 27a and 27b was characterized by large lakes and fens in the lower and forests on the higher and dryer areas. Humans were settling on rather small islands in the lakes and based their subsistence strategy mainly on hunting and fishing. There are only a few indications for plant gathering for nutritional purposes. The reconstruction of palaeo-riverbeds enabled us to embed the sites within their environment. It was proven that a connection to open waters was one of the relevant criteria for choosing a place as settlement area. The importance of infrastructural aspects was not only proven by finds like dugout-canoes but also by the point in time when a site was abandoned, as this coincided with specific environmental conditions.

The excavations in the Friesack area showed intrinsically how important careful and thorough excavations of wet-land-sites are for archaeological research. The potential of organic preservation expands our knowledge of the past far more comprehensively than dry-land-sites ever will. The former sites usually provide far more data than solely archaeological remains, for instance, extensive proxy data for environmental reconstructions and developments. By understanding the developments in the past, we are enabled to give prognosis for future developments with respect to environmental changes.

Apart from this, the investigations have shown that modern ways of agriculture are an enormous threat to archaeological material. The drainage of many wetlands results in an accelerated loss of organic soils and the attendant destruction of non-lithic artefacts. Therefore excavations on such sites have rather to be seen as salvage excavations.

**UNE RÉÉVALUATION DES DONNÉES YABROUDIENNES : ÉTUDE DU SITE DE YABROUD (SYRIE).**

*Al Qadi, Amjad (Université de Genève) amjad.alqadi@unige.ch*  
*Besse, Marie (Université de Genève) marie.besse@unige.ch*  
*Bourguignon, Laurence (INRAP) laurence.bourguignon@inrap.fr*

Dated around 350,000 years ago, the Yabroudian is a Paleolithic Levantine culture Stratigraphically and chronologically situated between the Acheulean and Mousterian periods. Its characteristic industry was defined by Alfred Rust during his excavations between 1930 and 1933 in a rock shelter in Yabroud, located 80 km north of Damascus, Syria (Rust 1950). The Yabroudien phase is distinguished primarily by scrapers, usually shaped from thick flakes and retouched with a scalarform technique (Bordes 1958 1984 Garrod, 1956, Bourguignon 1997 The Tensorer 2005 Al Qadi, 2011). The yabroudian industries have technological and typological similarities to the European industries of the Middle Paleolithic of south-west France, such as the Quina Mousterian and the Micoquian types (of Micoque) (Bordes, 1955, Bourguignon 1997). The yabroudian industries of these two collections, one from the excavations held in the 1930s (material of A. Rust's excavation, stored at the Institute of Prehistory, University of Cologne, Germany), and that from the 1960's excavations (the excavated material of R. Solecki, the museum of Deir Atieh near Damascus, Syria), were analyzed.

A technological approach was adopted that classified the artifacts by category and studied all known material concerning the processes carried out during knapping. This methodology involves a reconstruction of the steps taken from the initial processing block of raw material until the finished products (Tixier 1991 Pelegrin 1995).

The Yabroudian phase of Yabroud is oriented towards the production of thick yet short flakes with a wide and smooth butt demonstrating an alternation of recurring fabrication techniques on the two surfaces of the block. Scrapers are the most common tool found, with the more simple types being the most abundant. The resharpening flakes is seen in several variations, each presenting several stages of fabrication for these Yabroudian scrapers.

Bifacial tools also appear alongside the scrapers. In several layers of the Yabroud site, the Yabroudian industry has several similarities to those found in Quina, France (Bour-

guignon 1997). The cores have a different morphology (sub - triangular , sub- circular , sub- quadrangular ). The controlled shaping of the surfaces shows an alternation in the exploitation of several different core surfaces. At this site the industrial patterns coexists with others that tend towards the Levallois techniques.

Analyses of the yabroudian industries found at Yabroud help establish the systematic patterns of the yabroudian tool-shaping industry. The smooth and wide butt demonstrate the use of a hard hammer. Soft-hammer technique was used during the operations of retouching and resharpening the scrapers. The yabroudian bifacial tools detach from Acheulean handaxes, and while remaining the techno-complex that surmount it chrono-stratigraphically such as in several Levantine sites (Hummal, The Tensorer 2005 and Tabun, Garrod 1956). Typical scalariform/yabroudian retouch dominates. The Yabroudian and Quina Mousterian type have a technological resemblance as a specific debitage mode with the coexistence of Levallois scheme. The Yabroudian could be classified as belonging to the early Middle Paleolithic or archaic Middle Paleolithic.

ORAL

**LA SEQUENCE PLEISTOCENE DU SITE D'UMM EL TLEL, SYRIE.**

*Boeda, Eric (université Paris X) boeda.eric@gmail.com*  
*Griggo, Christophe (université Grenoble 1) christophe.griggo@ujf-grenoble.fr*  
*AlSakhel, Heba (Conservateur Musées de Syrie) christophe.griggo@ujf-grenoble.fr*  
*Bonilauri, Stephanie (UMR7041) stephanie.bonilauri@gmail.com*  
*Pagli, Marina (UMR 7041) marina.pagli@gmail.com*

Le site d'Umm el Tlel présente une séquence archéologique s'échelonnant de l'Acheuléen au début du Néolithique, sans discontinuité culturelle, sur plus de 20 mètres d'épaisseur. Les dépôts sédimentaires successifs : alluviaux, lacustres et éoliens, ont permis un enregistrement de près d'une centaine de niveaux archéologiques, comprenant des artefacts lithiques, bitumineux, osseux et végétaux particulièrement bien conservés. Ces vestiges permettent de restituer une évolution diachronique des comportements techniques liés aux matières minérales, animales et végétales. Si la technologie lithique indique, pour chacune des grandes périodes chronologiques, une grande variabilité de faciès corrélable aux changements sédimentaires, les analyses archéozoologiques et climatiques tempèrent cette cor-

relation. En effet, la zone steppique est extrêmement sensible au moindre changement climatique. Cela se marque très facilement par des enregistrements sédimentaires très variés, dont l'importance n'est pas liée à des changements climatiques d'ampleur générale. L'enregistrement est micro-régional, ce que confirme l'analyse archéozoologique qui montre que les comportements d'acquisition de matières animales transcendent ces changements.

The site of Umm el Tlel presents an archaeological sequence ranging between Acheulean and early Neolithic culture, without interruption, for more than 20 meters thick. Successive sedimentary deposits: alluvial, lacustrine and eolian, allowed a record of almost one hundred archaeological levels, including lithic artefacts, bitumen, bones and plants, particularly well preserved. These remains enable us to reconstruct a diachronic evolution of technical behaviors based on mineral, animal and vegetable material. If lithic technology shows for each major chronological periods of high variability of facies correlated with sedimentary changes, the archaeozoological and climate analyzes temper this corrélation. Indeed, the steppe area is extremely sensitive to any climate change. This is easily marked by very diverse sedimentary records, the importance of which is not linked to climate change in overall magnitude. Registration is micro-regional, which confirms the archaeozoological analysis that shows that the behavior acquisition of animal matters transcend these changes.

### **HOMININS THROUGH GLACIALS AND INTERGLACIALS IN THE AZRAQ OASIS, JORDAN: THE CONCEPT OF PALEOLITHIC DESERT REFUGIA.**

*Cordova, Carlos (Oklahoma State University) carlos.cordova@okstate.edu*

*Nowell, April (University of Victoria) anowell@uvic.ca*

*Ames, Christopher (University of California at Berkeley) cjhames@gmail.com*

*Pokines, James (University of Boston) jamespokines@gmail.com*

A geoarchaeological study of sediments in the Azraq Oasis, in the Eastern Desert of Jordan, provides information on the fluctuations of the geomorphic and hydrologic systems in this region in relation to prehistoric occupations spanning the late Lower Paleolithic, Middle Paleolithic, Upper Paleolithic and Epipaleolithic. The study shows that local geomorphic and hydrological environments fluctuated between marsh, lake and playa

(dry lake bed with eolian activity and/or carbonate accumulation). In some instances, local wet conditions correlate with those registered in other regional paleoclimatic records, as is the case of the period comprising MIS 5c and probably early MIS 5a (Cordova et al. 2013; Ames et al. 2014). In other cases, paleoecological data obtained from the sedimentary sequences indicate local wet conditions and regional desert environment, which in turn suggests that the Azraq oases may have acted as desert refugia at times of regional adverse climatic conditions (Cordova et al. 2013). The fact that Azraq represents a potential desert refugium has important consequences for understanding major issues in the Middle Paleolithic of Southwest Asia, namely the arrival, survival, and extinction of populations of both Neanderthals and early modern humans. The location of Azraq at crossroads between the Levant, the Arabian Peninsula, and other regions of the Middle East, is also an important geographic aspect of desert refugia during the critical period of hominin dispersal in Southwest Asia. This study is part of the Azraq Marshes Archaeological and Paleoecological Project (AMAPP) aims at reconstructing the ancient environment and settlement patterns of hominins around the Azraq oases and the immediate desert areas around (Fig. 1). AMAPP is sponsored by the Social Sciences and Humanities Research Council of Canada and the team is composed of several specialists from Canada, the United States, Europe, and Jordan.

*Muhsen, Sultan (Damascus University) smuhsen@hotmail.com*

*Al Sakhel, Eba (Musée des Antiquités Nationales. Damas) alsakhel@mail.com*

*Wegmueller, Fabio (IPAS, Univ. Basel) fabio.wegmueller@unibas.ch*

The Syrian desert offers a unique potential to study effects of climate variability on hunter-gatherer communities throughout the Quaternary period. Its central position between Eastern continental, Western Mediterranean and Southern desertic influences provide a sensitive system to climate changes. Its endoreic configura-

ration and epithermal artesian springs have favoured sedimentation by hydric/aeolian processes, resulting into long finely stratified depositional sequences with interstratified paleosols. The aridity has favoured the recurrent fossilisation of paleosurfaces with traces left by hunter-gatherer communities and animal flocks. We present here a field/multi-analytical study of the ones showing a finely stratified organomineral facies which provide a high resolution record of human occupation and environmental changes.

The Paleolithic sites of Hummal and Umm El Tlel form prominent mounds at artesian springs, resulting from recurrent episodes of lacustrine, limnic and aeolian sedimentation in pseudo-karstic depressions. The 20 m thick sequence at Hummal provides a succession of archaeological levels from the Oldest Paleolithic (Oldowan) to the Upper Paleolithic. We focus on the black organogenic facies (layer 17) sealing the Oldowan occupation (layer 18) dating back far before the Brunhes-Matuyama boundary. The 10 m thick sequence at Umm el Tlel sequence displays 70 thin occupation stratum that are interstratified with aeolian, lacustrine and palustrine deposits. We focus here on the series of black organomineral facies that contains Middle Palaeolithic microstratified occupation floors. In addition to the field and micromorphological study of the organomineral facies, sampling by individual microstra was performed for tracing relevant components with respect to sediment sources and depositional conditions. They have been characterized by ESEM; MEB-EDA, XRD and Raman spectrometry.

The organomineral facies identified in the Hummal and Umm El Tlel sequences display a similar microstratification formed of authigenic lacustrine calcareous silty clay interlayered with dark brown organic rich clay and dull orange silty clay. The later display the characteristics of peat-like weakly decomposed organic matter finely mixed with exogenic aerosols that consist of distinctive carbonaceous (polymer filaments, graphitic charcoal, vesicular vitrous char, carbon fibres) and mineral components (breccia, quartz, fine quartzite, zircon, monazite, lime) with ribbon-shaped incrustations of Fe-Ni, Fe-Cr-Ni, Cu-Zn, Ag, Au. These components bear the diagnostic signatures of atmospheric aerosols that have been recycled by hypervelocity plasma processes linked to cosmic events, have suffered long distance transport and have accumulated at high rate during rainy episodes in regions marked by a strong climate contrast. When present in the other pedo-sedimentary facies, rounding of the singular aerosols and mixing with the local aeolian materials suggest a secondary position due to reworking by surface runoff and violent winds.

The peat-like organomineral facies with their singular aerosol assemblage are concluded to trace the recurrence of a particular climate configuration on the Syrian desert in response to a global increase of atmospheric dust loading and occurrence of cosmic events. These events marked by high rainfall due to cloud condensation nuclei effects, reduced albedo and weak winds have created throughout the Quaternary favourable conditions to the settlement of humans and flocks in the heart of the el Kowm basin.

ORAL

### **THE LARGE MAMMAL FOSSIL RECORD OF THE SITE OF HUMMAL (EL KOWM, CENTRAL SYRIA) AND ITS PALEOENVIRONMENTAL INDICATIONS (FIRST RESULTS).**

*Elsuede, Hani (Institut for Prehistory and Archaeological Science (IPAS) University of Basel Switzerland) hani.elsuede@unibas.ch*

The region of El Kowm, located in the desert area of the Levant (central Syria) is considered as a key area for the studies of the prehistory of the Middle East. The presence of natural resources in an arid area has attracted humans and animals to the area. The undertaken researches in this region have produced evidence of a very dense human occupation. This steppe territory has served as a passing zone during the ancient Paleolithic, along with the natural route of the "Levantine corridor", one of the main hominin routes out of Africa, situated at the meeting point of Africa and Eurasia, the Arabian deserts and the Mediterranean Sea, making it ideal for tracing climate variability. Climate change is frequently considered an important driver of hominin evolution and dispersal patterns. Palaeoecological investigations based on fossil assemblages are a useful tool to reconstruct key environmental changes. Studies of mammal fossils can contribute to our knowledge of how palaeoenvironmental circumstances affected the spread of hominins. In many cases, mammals shared their habitats with hominins and/or formed key resources for human subsistence.

The sites of Aïn Fil, Hummal, Nadaouiye Aïn Askar and Umm el Tlel, all situated and excavated in the region of El Kowm, possess an extraordinary richness of archaeological and palaeontological material. They therefore can allow us to reconstruct the evolution of cultures, to identify the key aspects of the occupation and to reconstruct the environmental changes of this region.

The present paper has the aim to shine light on the faunal assemblage of the site of Hummal, to compare it with

other sites in the region and to interpret its paleoenvironmental indications.

ORAL

### **EL KOWM OASIS, HUMAN SETTLEMENT IN THE SYRIAN DESERT DURING THE PLEISTOCENE.**

*Jagher, Reto (Institute of Prehistory and Archaeological Science - University of Basel) reto.jagher@unibas.ch*

The El Kowm area in the geographic centre of modern Syria is well known for its abundance of Palaeolithic sites covering more than one and a half million years of human history. Imbedded between two major mountain ranges, the area occupies an important transit route between the Euphrates River in the North and the vast expanses of the Arabian Desert in the South. The attraction for game and humans since the Lower Pleistocene is due to the presence of several dozens of natural springs within an area of less than 15 km across. The artesian groundwater is supplied by a geological reservoir independent of coeval precipitations hence these springs have been reliably running also under extreme dry climatic conditions. At any times water was available at a substantial number of places permitting a save subsistence for hunters and gatherers in this area. Secure supplies of water at the surface are scarce throughout Syria's interior. A further point of interest for Palaeolithic man is the unlimited availability of a first grade flint in nodules up of several decimetres in diameter in infinite quantities, within 5 to 20 km from the natural wells. Despite varied geologic conditions at the different spring sites, usually an intermittent but rapid sedimentation, provided an excellent preservation of Palaeolithic sites; tracing a steady human presence since at least 1.5 million years. The history of El Kowm Oasis clearly demonstrates that early humans did not depend on perfect environments alone, but easily adapted to different conditions. Since the first surges Out of Africa, humans regularly ventured far into the harsh environments of the desert and semi-desert of the Levant, revealing their capacities to adapt to the specific conditions and their independence of favourable environments alone. The particular situation, with the availability of water attracting game from afar and the presence of a first grade raw material for stone tools, made El Kowm Oasis a kind of early Paradise for Pleistocene humans despite its unfavourable setting.

### **THE OLDOWAN SITE AÏN AL FIL (EL KOWM, SYRIA) AND THE FIRST HUMANS OF THE SYRIAN DESERT.**

*Le Tensorer, Jean-Marie (University of Basel IPNA) jean-marie.letensorer@unibas.ch*

*Le Tensorer, H  l  ne (University of Basel IPNA) hletensorer@wanadoo.fr*

*Martini, Pietro (University of Basel IPNA) pitemart@hotmail.com*

*Vallalain, Juan Jos   (University of Burgos) villa@ubu.es*

Nowadays, the oldest traces of human cultures are found in Eastern Africa. New discoveries set anew the questions about human and animal dispersal into Eurasia. Issuing from Africa, the first humans migrated at different periods. During these dispersal phases, the Near and Middle East played a leading role as a crossroads between the three continents.

In fact, for over 1.8 million years, humans have been present in the Levant. Alongside the corridor stretching from the River Jordan to the Orontes Valley, early Palaeolithic groups already found favourable places for settlements and a natural route towards new horizons. An extensive program of surveys and excavations in the Syrian Desert have been carried out over 30 years by the Institute for Prehistory and Archaeological Science of the Basel University, together with the General Directorate of Syrian Antiquities; these studies showed that this part of the world was also a very ancient land of settlement. In Central Syria, the oldest site, A  n al Fil was discovered in 2008 in the region of El Kowm, between the Euphrates basin and the desert steppe stretching from Palmyra to Deir-ez-Zor. The lithic industry in the lowest layer can be characterized by numerous unretouched flakes, pebble-tools and core-like artifacts. This assemblage is typical in a broad sense of archaic Palaeolithic the debitage of which corresponds to mode 1. From a techno-typological point of view, this industry tallies quite well with the so-called Oldowan stage. It shows remarkable similarities with the oldest African assemblages. From a chronologic point of view, these levels occur before two positive events in the Matuyama paleomagnetic sequence. According to the preliminary studies of faunal assemblage of large mammals they should be older than 1.5 million years at least. Together with those of the neighbouring site Hummal, these levels would be the oldest traces of human presence ever found in Syria.

In the Syrian Desert, the archaeological record from 1.8 to 0.8 million years points to at least three major waves of early migrations probably out of Africa. The earliest

dispersal involved core and flake industries (Oldowan) around or before 1.8 Ma. The second wave related to early handaxes producers possibly around 1.4 Ma. The third wave occurred around 1 - 0.8 Ma, and is represented by Acheulean groups who manufactured numerous elongated bifaces and sometimes large flake cleavers.

Since the very beginnings of human presence in the Levant, i.e. more than 1.8 million years ago, first humans not only occupied favourable zones but regularly ventured deep into less welcoming environments suggesting an astonishing flexibility in their behavioural and survival skills.

*Le Tensorer, Jean-Marie (Universität Basel - IPNA) [jean-marie.letensorer@unibas.ch](mailto:jean-marie.letensorer@unibas.ch)*

*Schmid, Peter (University of Witwatersrand - ESI) [smidi@aim.uzh.ch](mailto:smidi@aim.uzh.ch)*

The family Camelidae (Artiodactyla) originated in North America during the middle Eocene (~45 Ma). In the Miocene they became very successful, and diversified into many species and at least 20 genera. The first genus to reach the Old World was *Paracamelus*, which is recorded since the latest Miocene (MN13, ~7 Ma) and is considered ancestral to the Pleistocene and Recent genus *Camelus*. However, the evolution of Eurasian camelids is poorly known. Several species are recognized, but most of them are based on scarce material or have been described only superficially.

A good opportunity to study the diversity and evolutionary trends of Eurasian camelids is provided by the faunal record of the El Kowm Basin (central Syria). The many Palaeolithic archaeological sites of this region have provided with abundant mammalian fossils, among which camelid remains are the most frequent faunal element over all layers. We present the first results from the analysis of this camelid succession, which spans the early to late Pleistocene, from more than 1.5Ma to 50 ka. The material studied was excavated in three sites (Ain al Fil, Hummal and Nadaouiyeh Ain Askar) within few km from each other.

The oldest remains from Ain al Fil (Early Palaeolithic, Early Pleistocene, between 1.8 and 1.5 Ma) suggest the coexistence of two species, one dromedary-sized and the other much larger. Later forms from the lower section of Hummal are also larger than modern camels, with long limbs and small heads. A size reduction is seen from the Early to the Late Pleistocene. A rare Middle Pleistocene skull from the rich sample of Nadaouiyeh Ain Askar (Acheulean layers, 450 Ka) has a unique morphology, with many characteristic details. Fossils that are similar and somehow intermediate between the two modern species are frequent only in the Late Pleistocene of Hummal (Mousterian layers, 150 to 50 Ka). During this period they coexisted with a highly distinctive giant species, which is the most recent example of the formerly common giant camels.

The richness and uniqueness of the El Kowm camelid fauna make the study of this region fundamental to understand the evolution of these important domestic animals.

### THE MIDDLE PALAEOOLITHIC CULTURAL OCCURRENCES IN THE PALMYRA BASIN, SYRIA

*Nishiaki, Yoshihiro (The University of Tokyo) [nishiaki@umutokyo.ac.jp](mailto:nishiaki@umutokyo.ac.jp)*

*Akazawa, Takeru (Kochi University of Technology) [akazawa.takenu@kochi-tech.ac.jp](mailto:akazawa.takenu@kochi-tech.ac.jp)*

The Palmyra basin, central Syrian, was one of the major prehistoric research fields of the University Tokyo between 1967 and 1984. Along with the excavations of the Middle and Epi-Palaeolithic site of Douara Cave, a series of prehistoric surveys was conducted in its vicinity, which produced rich archaeological and palaeo-environmental data especially of the Middle Palaeolithic period. In this paper, we attempt to re-evaluate those records in the light of recent developments of the Middle Palaeolithic research in the arid environments of the Levant.

### CROSS-ZAGROS RELATIONS DURING UPPER PALEOLITHIC.

*Otte, Marcel (Université de Liège) [marcel.otte@ulg.ac.be](mailto:marcel.otte@ulg.ac.be)*

All the datas coming from Rust excavation in Near East

present close relationship with our own excavation in the Zagros mountain, in Iran.

There seems to be an east-west axis for the diffusion of early Aurignacian, which has been poorly known until now.

This reinforces the close land origin in this part of the world, leading to European Aurignacian.

### **TECHNO-CULTURAL VARIABILITY AND SETTLEMENT PATTERNS IN THE SYRIAN DESERT DURING LATE MIDDLE PALAEO-LITHIC: A CASE FROM UMM EL TLEL (CENTRAL SYRIA).**

*Pagli, Marina (UMR 7041 archéologie et sciences de l'antiquité (ArScAn) - équipe "Anthropologie des Techniques, des Espaces et des Territoires au Pliocène et au Pléistocène (AnTET) marina.pagli@gmail.com*

*Bourguignon, Laurence (Institut national de recherches archéologiques préventives (INRAP) laurence.bourguignon@inrap.fr*

We propose a reconstitution of settlement dynamics in a semi-arid context considering the Mousterian sequence of Umm el Tlel. This open air site is located in the semi-arid steppe zone of Central Syria, in an area where aridity is attenuated by the presence of artesian springs. The Late Middle Palaeolithic sequence yielded a succession of occupations around a lake or backwaters, attributed to the Mousterian with Levallois reduction.

We present a double analysis of one part of this sequence, represented by the occupation levels of complex V2.

On one side technological analyses show the operative schemes variability for each level of this complex, suggesting a strong techno-cultural diversity of the human groups which occupied the site. On the other side, a comparison with experimental analyses shows the circulation of blanks, the introduction onto the site of some of the lithic artefacts, or their production in situ, and highlights the mobility patterns of each occupation, suggesting that the site was integrated in a complex network of places occupied by the human groups.

The integration of these components of lithic analysis contributes to show the settlement modalities of this semi-arid region and the techno-cultural identity of the populations who occupied the area.

ORAL

### **AN EARLY HOMININE IN AN ACHEULEAN CONTEXT.**

*Schmid, Peter smidi@aim.unizh.ch*

The Middle East is apparently the most important passage for the dispersal of early hominines. Numerous archaeological sites prove the existence of hominine populations in this region. Despite these rich cultural remains, hominine fossils are very rare. In 1997 a hominine left parietal was found in an Acheulean context. In addition, the faunal remains show a steppe environment. What does this single cranial fragment tell us? Based on new publications and especially on recent finds the value of isolated elements will be discussed.

ORAL

### **CONTEXTUALISING THE MOUSTERIAN OF HUMMAL (EL KOWM, SYRIA): LOCAL AND REGIONAL PATTERNS OF HUMAN ADAPTATION IN THE LEVANTINE MIDDLE PALAEO-LITHIC**

*Thomas Hauck - Thomas.Hauck@uni-koeln.de (Institute for Prehistoric Archaeology, University of Cologne)*

The well-site of Hummal in the arid steppe region of El Kowm (Central Syria) is scientifically important because of its long archaeological sequence. Beginning probably over a million years ago, humans visited the spring during a range of environmental conditions, and their remains can be found in more than 60 archaeological levels.

This paper focuses on the Mousterian deposits, which comprise the uppermost and longest section of the Hummal sequence. Over 30 archaeological levels display evidence of intermittent site frequentation by Mousterian hominids. The 5m sequence of littoral deposits mirrors a steady shift between water transgressions and regressions, which caused the development of a broad ecological spectrum ranging from extended, oxygen-rich lake systems to marshy ponds or water-depleted depressions. In this paper, we integrate the Mousterian of Hummal in the Levantine MP record by reviewing different levels of analytical scale.

ORAL

### **THE LOWER PALAEO-LITHIC OF HUMMAL**

*Wegmüller, Fabio (Institute of Prehistory and Archaeology)*

*cal Science (IPAS) University of Basel, Switzerland) fabio.wegmueller@unibas.ch*

The site of Hummal is situated in the region of El Kowm in central Syria. The site shows an archaeological sequence over the entire Pleistocene epoch which encompasses all major Palaeolithic complexes currently known in the Middle East. At the bottom of the site, 14 m below the actual surface several layers with lithic assemblage attributed to the Lower Palaeolithic were excavated during the last years. Today a lithic assemblage of 450 stone artefacts and more than 3000 bone fragments is available from this part of Hummal.

The lithic assemblage is characterized by a simple flaking technique and the presence of different pebble tools, such as choppers, hammerstones and sphaeroids. Additionally four handaxes were found which have a symmetric form and are rather flat and clearly bifacial, therefore these objects correspond rather with Upper Acheulean handaxes than with the Early Acheulean found in other archaic sites in the Levant (e.g. Ubeidiya)

The stratigraphic position in the sequence of Hummal as well as biostratigraphic indications of the microfauna and large vertebrate remains indicates an age of this assemblage surely older than 500 Ka, preliminary palaeomagnetic results suggest a chronological position below the Matuyama-Brunhes boundary and therefore older than 780 Ka.

In large part the lithic assemblage from the lowermost layers in Hummal resembles an Archaic Lower Palaeolithic and belongs to the so-called Oldowan or Mode 1 stage, but the presence of well-shaped and symmetric Handaxes questions the attribution to Mode 1, Oldowan or early Acheulean Stage and raises the question if these common classifications lithic industries are adequate to describe the archaeological record from this period in the Middle East.

: ORAL

### **NOT ONLY BLADES; THE PRODUCTION OF SMALL IMPLEMENTS IN HUMMALIAN.**

*Wojtczak, Dorota (Basel University) dorota.wojtczak@unibas.ch*

The Hummalian industry is known for the systematic production of large blades. Although blade reduction was certainly dominant in the Hummalian primary flaking processes, two additional reductions, directed towards production of different small-sized debitage

items are also clearly identifiable. There was a separate production of bladelets from burin-cores, and bladelet cores and small flakes from cores on flake. Additionally, recently undertaken refitting shows the targeted production of Janus small debitage pieces. These elements combined indicate an outstanding level of complexity in blank production.

The phenomenon of blade and bladelet production within Middle Palaeolithic context is widely recognized. Very small flakes have also been described in Lower and Middle Palaeolithic sites worldwide. But the eventual purpose of their production remained in more cases obscure with two exceptions Qesem Cave and Umm El Tlel. The former shows that tiny flakes were removed from the ventral face of cores-on-flake having two ventral, flat and smooth, faces (Janus flakes). Use-wear analyses have shown they were employed for precise meat-cutting activities. The production of tiny bladelets was recognised in Mousterian levels on the second site of Umm El Tlel. The bladelets were detached from the proximal part of elongated Levallois points. The micro-wear analysis displayed that they were used for working meat, bone and vegetal matter and they show hafting traces. These results change our view on the behaviour of early hominids and draw attention to importance of small specimens such as bladelets and small flakes found on other Palaeolithic sites within Hummal.

The aim here is to present and discuss the presence of the small implements discovered in Hummalian layers and if their existence is significant for this cultural horizon and possibly related to the site-function and specific task activities.

POSTER

### **PALAEOECOLOGY OF THE SPRING OF NADAOUYEH AÏN ASKAR. - INFERENCES FROM OSTRACOD ANALYSIS OF A SEDIMENTARY SEQUENCE OF A PALAEOOLITHIC OASIS IN THE SYRIAN DESERT.**

*Kalbe, Johannes (Universität Potsdam, Institut für Erd- und Umweltwissenschaften, Karl-Liebknecht-Str. 24-25, D-14476 Potsdam-Golm) johanneskalbe@gmx.de*

*Jagher, Reto (Universität Basel, Integrative prähistorische und naturwissenschaftliche Archäologie (IPNA), Spalenring 145, CH-4055 Basel) reto.jagher@unibas.ch*

The site of Nadaouiyeh Aïn Askar with its main human

occupation from about 550 to 35 ka is located in the region of El Kowm, in the arid interior of Syria, 90 km north-east of Palmyra. This area is known for its rich archaeological legacy from the Lower to Upper Pleistocene (Jagher & Le Tensorer, 2011).

We present new sediment geochemical and first micro-paleontological data for limnic sediments of the artesian spring of Nadaouiyeh Ain Askar, which belongs to an important cluster of natural springs in the Syrian desert. This section is characterized by a lithic assemblage assigned to the Acheulean techno-complex (Nad-C: ~ 450 ka; Jagher, 2011).

The timing and regional significance of water availability and its environmental influence on local wetland and spring systems during the Pleistocene of this region is still poorly known. Studies on Quaternary ostracod faunas, which can be used to infer past environmental settings are scanty for the eastern Mediterranean region in general and missing for central Syria.

The studied sediments of Nadaouiyeh Ain Askar consists of carbonate rich silts, with particularly high amounts of ostracod carapaces. Ostracod abundances are higher in the upper section. *Heterocypris salina*, *Darwinula stevensoni*, *Plesiocypridopsis* sp., *Pseudocandona* sp. and *Ilyocypris* sp. are the common ostracods in these sediments. *Cyprideis torosa* is a frequent ostracod in some of the samples. Numerous charophyte gyrogonites are preserved in the topmost zone of the studied section.

The ostracods common in the sediments of the studied section are characteristic for a permanent and stagnant water body. *Cyprideis torosa* and *H. salina* suggests an influence of a higher degree of salinity in some ranges of the section. The charophyta found in the upper part of the section indicate a shallow oligohaline and probably permanent small water body.

Ostracod fauna of the site of Nadaouiyeh Ain Askar allows to reconstruct an environment of an oasis with a permanent and sometimes brackish water body during the deposition of the studied section, when the site was occupied by Lower Palaeolithic humans. Our study provides the first detailed ostracod record for the Pleistocene of central Syria.

#### POSTER

### **BIOSTRATIGRAPHICAL AND PALAEOECOLOGICAL IMPLICATIONS OF THE MICROVERTEBRATES FROM UNIT G/LAYER 17 OF THE ARCHAEOLOGICAL SITE OF HUMMAL (EL KOWM, CENTRAL SYRIA).**

*Maul, Lutz Christian (Senckenberg Research Station of Quaternary Palaeontology, Weimar, Germany) lmaul@senckenberg.de*

*Smith, K.T. (Senckenberg Research Institute and Natural History Museum Frankfurt, Germany)*

*Wegmüller, Fabio (Institute for Prehistory and Archaeological Science (IPAS), University of Basel, Switzerland) fabio.wegmueller@unibas.ch*

*Le Tensorer, Jean-Marie (Institute for Prehistory and Archaeological Science (IPAS), University of Basel, Switzerland) jean-marie.letensorer@unibas.ch*

A total of c. 2,000 microvertebrates (1,800 small mammals, 230 reptiles) was found in unit G/layer 17 of Hummal by screen washing sediments from an area of 4 square metres. The mammals are referred to: *Crocodyridae* indet., cf. *Suncus etruscus*, *Chiroptera* indet., *Lepus* cf. *capensis*, *Ellobius* ex gr. *fuscocapillus-lutescens-pedorychus*, *Microtus* cf. *guentheri*, *Meriones* ex gr. *tristramilibycus-persicus-crassus*, *Gerbillus* cf. *dasyurus*, *Mus* cf. *macedonicus*, and *Bandicota indica*. The reptile remains belong to *Gekkonidae* indet., cf. *Trapelus* sp., *Lacertidae* indet. (2-3 species), *Eryx* cf. *jaculus*, *Natricinae* indet., and *Testudinidae* indet.

The recorded arvicolids provide the first biostratigraphic information for layer 17 at Hummal. The presence of *Ellobius* indicates a minimum age of 200 ka as in the Near East, this species ranges from late Acheulean (Oumm Qatafa) to Early Mousterian (Tabun D and Hayonim E). The maximum age is given by the m1 of *Microtus* cf. *guentheri*, which displays (although based on a single fragment) significant features of a more advanced evolutionary level than the corresponding *Microtus* species from the Gesher Benot Ya'aqov locality in Israel, dated to 700 ka. However, detailed studies of the *Ellobius* finds will provide further refinement of the biostratigraphic age of this assemblage, although the preliminary result is broadly consistent with the fact that layer 17 is situated beneath Yabrudian, Hummalian and Mousterian horizons.

The ecological requirements of the recorded taxa indicate different, mainly open habitats, but also the presence of vegetation and wet condition, at least close to the site. *Lepus capensis*, *Ellobius*, *Meriones*, *Gerbillus*, *Trapelus* and *Eryx jaculus* live to various extents in open grasslands; in steppes, semi-deserts, and deserts respectively. *Bandicota* requires streams or other water bodies and occupies a variety of wooded habitats, grassland and savannah, but is recorded also from desert margins, provided that some water is available.

From the biogeographic point of view, *Ellobius* and *Bandidocota* are of special interest, since these taxa do not occur in Syria today. Their nearest populations are now in Transcaucasia and in westernmost India respectively, so that the region between Syria and India must have experienced much more humid conditions than now.

The fragmentary preservation of the microvertebrates suggests that they were accumulated as prey remains. The question of whether they were accumulated by owls, diurnal raptors or mammalian carnivores is the subject of ongoing investigations.

**PALAEOMAGNETISM IN EL KOWM ARCHAEOLOGICAL SITES (SYRIA)**

*Villalain Santamaría, Juan José (Universidad de Burgos · Department of Physics) villa@ubu.es*

*Wegmüller, Fabio (Institute of Prehistory and Archaeological Science (IPAS) University of Basel) fabio.wegmueller@unibas.ch*

*Le Tensorer, Jean-Marie (Institute of Prehistory and Archaeological Science (IPAS) University of Basel) jean-marie.letensorer@unibas.ch*

The El Kowm Region is well known for its archaeological record over the whole Pleistocene period. Since more than 20 years a research team from the University of Basel under the directorate of Jean-Marie le Tensorer excavates different sites in the El Kowm region. In two of these sites several layers were found bearing an archaeological and faunal material which most probably dates back to the Early Pleistocene.

In order to proof the age of this layers and to get a more detailed view on the paleomagnetism of the stratigraphy in 2009 Juan José Villalain from the „Grupo de Paleomagnetismo de la Universidad de Burgos“ carried out an extensive sampling in the sites of Hummal and Ain al Fil.

This poster presents the first results of the analysis of these samples and their implications for the dating of the oldest archaeological sites in Syria.

**1. PASSAGE OF TECHNOLOGIES - AN ARCHAEO-METRIC CASE STUDY OF IRON ARTIFACTS OF A SCYTHIAN AGE GRAVE FROM THE CARPATHIAN BASIN.**

*Török, Béla (University of Miskolc) bela.torok@uni-miskolc.hu*

*Gyucha, Attila (Hungarian National Museum) bureau@eu-far.net*

*Kovács, Árpád (University of Miskolc) femkov@uni-miskolc.hu*

*Barkóczy, Péter (University of Miskolc) fembarki@uni-miskolc.hu*

*Gulyás, Gyöngyi (Ásatárs Cultural, Archaeological Servicing and Commercial Ltd) gyongyi.gulyas@bcehok.hu*

During the Middle Iron Age the southern part of the Carpathian Basin was the contact zone for several major cultural groups of fundamentally different origins and traditions. The Great Hungarian Plain was characterized by the westernmost occurrence of the Scythian style material culture, while the easternmost Hallstatt groups occupied Northern Transdanubia. Moreover, southern Transdanubia and the Drava–Sava Interfluvium likely were inhabited by Illyrian and Venetic tribes. Examining the nature and direction of contacts between these contemporary cultural units in the aforementioned regions, this paper presents the results of typological and archaeometric analyses on Middle Iron Age iron artifacts from a grave excavated in the southern part of the Danube–Tisza Interfluvium (Bátmonostor–Szurdok) on the eastern bank of the Danube as a case study. The area is considered to be part of the Alföld group of the Great Hungarian Plain during the period however the site is located ca. 100 km apart from the nearest Alföld group sites.

The members of the ARGUM carried out a complex archaeometric investigation on six iron weapons (an adze-axe, a probable long axe, a shaft-hole axe, a trunnion axe, a larger spearhead and a sheath) using computer-operated optical microscopy, scanning electron microscopy with energy dispersive x-ray spectrometry (SEM-EDX), and micro-hardness testing (HV1). The analyses are unique in the Carpathian Basin with regards to the period.

Based on material structure and compositions of slag inclusions, the artifacts can be classified into two distinct

groups in terms of quality of material and supposed manufacturing technology. The trunnion axe, the shaft-hole axe and the long axe were produced by forging by means of multiple reheating, as evidenced by layers containing different amounts of carbon. The artifacts of the other group were individually made from a piece of single bloom. The blades of the adze-axe may be considered to be the hardest material among the relatively soft ferritic-perlitic structures of the samples. Grouping of the examined artifacts is also supported by the compositions of slag inclusions with special regard to different phosphorus contents.

The various analyses conducted on the artifacts imply that the burial assemblage may reflect shared cultural traditions between different regions. While the grave construction and the vast majority of ceramic, antler, bronze and iron findings revealed from the burial fit well in the Scythian Period of the Great Hungarian Plain and indicate that the individual was a member of the community of Alföld group, the quantity of grave-goods and several iron weapon types (long axe, shaft-hole axe and trunnion axe) bear resemblance to the Transdanubian Hallstatt Culture. The archaeometric investigations clearly indicate technological choices that might also have derived from different practices. The individual with whom the Bátmonostor–Szurdok feature is associated was a high-ranked person with significant economic and political power. The isolated position of the burial might be related to commercial activities between the communities of the southern part of the Carpathian Basin, and may be associated with a trading outpost that controlled the flow of commodities across the Danube during the 6-5<sup>th</sup> centuries BC.

**2. MIDDLE BRONZE AGE METALWORKING IN THE SOUTH-WEST SARDINIA (ITALY)**

*Paglietti, Giacomo (Dipartimento di Storia, Beni Culturali e Territorio, Cagliari University (Italy) gpaglietti@unica.it*

*Serra, Marco (Dipartimento di Scienze dell'Antichità, University of Rome "La Sapienza" (Italy) marco.serra@unica.it*

*Naitza, Stefano (Dipartimento di Ingegneria Civile, Ambientale e Architettura, Cagliari University (Italy) snaitza@unica.it*

*Tanda, Giuseppa (Dipartimento di Storia, Beni Culturali e Territorio, Cagliari University (Italy) gtanda@unica.it*

A metal work station and two metal artefacts of middle bronze age were founded in 2012 by the department of history, cultural heritage and territory of Cagliari university (Sardinia, Italy), during the excavation of the karst cave of Monte Meana-Santadi (south-west Sardinia, Italy). The metalwork station was composed of a digged fire place (probably a *bowl furnace*) with a number of charcoal fragments, smelting slags and pottery vessel sherds with vitrified inner surface, which confirm the metallurgical activity on the site. Two metal artifacts were founded in a crevice of the cave. They consist to a dagger with a simple base and two rivets, and an awl. Similar objects are known from the S. Iroxi phase (middle bronze age of Sardinia).

A radiocarbon measurement made on charcoals, dated the smelting furnace between 1920 and 1660 BC (cal.). The archaeometric investigations were carried out on two archaeological artefacts, five smelting slags and three vitrified remains of the furnace. The analysis was extended to certain portions of metalliferous ore sampled near the archaeological site.

A preliminary macroscopic analytical approach was aimed to define the visible "hand samples" characters: colour, presence of alterations such as oxides, porosity and blistering.

Subsequently, slags and artefacts were subjected to chemical analysis with non-destructive energy dispersive x-ray fluorescence spectrometry (ED-XRF). Micro-destructive inductively coupled plasma optical emission spectrometry (ICP-OES) and crystallographic x-ray diffraction tests (XRD) were run on powders of slags. Finally, several slags were observed by metallographic microscope.

The aim of this study is the definition of the qualitative and quantitative chemical characters and the mineralogical composition of the materials analyzed, for the reconstruction of ancient technological aspects of metallurgy, as the use of alloys, and definition of the raw materials used by local Nuragic people.

The investigations have shown that artefacts and slags are made primarily by copper, with significant amounts of iron (in the form of fayalite), zinc and traces of arsenic and manganese. All samples had calcium but only slags displayed small quantities of sulfur.

The minerals sampled and analyzed in this study, revealed the presence of arsenopyrite, chalcopyrite and malachite local ores.

Artefacts and slags are evidently composed of copper. The substantial presence of iron in both categories of samples, can be linked to the presence of this element in added blast furnace burdens or, most probably, in the mineral charge.

Arsenic identified in metal products and slags, is contained also in close metalliferous outcrops. This fact indicates the possible use of a local natural blend of copper and arsenic, with other impurities (zinc and manganese).

The presence of calcium suggests the ancient exploitation of malachite or the effect of karst activity on archaeological remains.

Sulfur, only included into the slags, indicates the absence of roasting before the smelting phase and shows the choice of sulphates or carbonates (chalcopyrite and malachite) for metallurgical activity.

### 3. COPPER METALLURGY IN THE SOUTHWEST OF THE IBERIAN PENINSULA IN THE III MILLENNIUM B.C.E.: TOWARDS A NEW MODEL OF INTERPRETATION FROM THE ANALYSIS OF PRODUCTION TECHNOLOGY BY METALLOGRAPHICS TECHNIQUES.

*Bayona, Moisés (Universidad de Huelva) moises.rodriguez@dhis1.uhu.es*

*Nocete, Francisco (Universidad de Huelva) nocete@dhis1.uhu.es*

*Inácio, Nuno (Universidad de Huelva) nuno.inacio@dhis1.uhu.es*

The metallurgy of copper, whose production, distribution and accumulation materialize the emergence of class relations among past societies, remains one of the central themes of prehistoric archaeology. Copper metallurgy defines an activity with one of the most historical projection and possibility of creating a regional scale of archaeological tracers, whose technological indicators are essential to the understanding of prehistoric societies.

Since the establishment and delimitation of one of the spatial frames associated with the oldest metallurgy throughout Europe, the Southwest of the Iberian Peninsula, we have selected two major casuistries for empirical evaluation: Cabezo Juré (Huelva) and Valencina de la Concepción (Sevilla). Their archaeological record

defines the first intensive and specialized metallurgical production of the Iberian Peninsula (ca. 3100 B.C.E.).

This paper\* presents the definition of technological process used in the manufacture of copper products of Cabezo Juré and Valencina de la Concepción, performed by the application of an archaeometric methodology based on traceological analysis, textural and compositional characterization and the study of the internal structure and mechanical properties of selected samples. The analysis included the study of the elemental chemical composition by Electron Microprobe (EPMA), the determination of the phases, inclusions and alteration products by Scanning Electron Microscope (SEM), microstructural analysis by metallographic microscopy and evaluation of mechanical properties by optical microhardness tester.

The characterization of the manufacturing process of copper products from Cabezo Juré and Valencina de la Concepción allowed us to define a "specific" technological model for the southwest Iberian Peninsula.

This study shows communities with an efficient knowledge of technology and metallurgical techniques, where the preferred implementation of complex manufacturing processes, by applying cycles of thermal and mechanical treatments and the determination of positive trends and statistical correlations, allow us to infer a intentionality control of production techniques and / or the characteristics and qualities of the resulting products. This model refutes the traditional interpretation of the technological levels metallurgy defined as rudimentary, primitive and domestic.

In that sense, this study of Cabezo Juré and Valencina de la Concepción, not only fills an important void in the knowledge of Archaeometallurgy discipline and established the validity of a model of technological competence for southwest peninsula (also discriminate in its means of production, archaeological contexts, circulation of raw materials and products, etc.) but substantially expands the boundaries of scientific debate, completing and changing concepts and perception of prehistoric metallurgy and its chronological, technological and social development.

**Agnowledgements:**The analysis developed in this work has been funded mainly by the *Atlantic Copper Foundation* (Huelva).

#### 4. PREHISTORIC GOLD METALLURGY IN TRANSYLVANIA ? AN ARCHAEOMETRICAL STUDY

*Cristea-Stan, Daniela (National Institute for Nuclear Physics and Engineering, Bucharest, Romania) daniela@nipne.ro*  
*Constantinescu, Bogdan (National Institute for Nuclear Physics and Engineering, Bucharest, Romania) bconst@nipne.ro*

Transylvania is one of the richest in gold European region. Consequently, many gold artifacts were discovered here, dated from Late Neolithic, Bronze Age and Iron Age periods - see "Ancient gold and silver of Romania", National History Museum of Romania (Exhibition Catalogue), 2013. To clarify the metallurgical techniques used by our ancestors a compositional study on relevant gold artifacts from each period was realized.

We used X-Ray Fluorescence, a non-destructive elemental analysis method performed "in situ", directly on artifacts exposed in some representative Romanian Archaeological Museums.

For Late Neolithic period we analyzed some small beads found in the site of Pestera Ungureasca (Cheile Turzii), identifying the use of small alluvial gold nuggets, some of them cold hammered and others partially heated and hammered. The mean gold composition - Au=91.4%, Ag=7.7%, Cu=0.2%, Fe=0.8% - is practically identical with present alluvial gold composition from neighbor Aries river.

For Bronze Age period we analyzed artifacts from Smig, Cauas, Sacuieni, Pecica, Cacova and Valea Pianului. A very interesting case is a 3 cm diameter gold hair-ring, where XRF analysis showed four regions of very different composition: (1) Au=33.5%, Ag=64.9%, Cu=0.1%; (2) Au=40.4%, Ag=57%, Cu=0.1%; (3) Au=57.4%, Ag=42.5%, Cu=0.3% and (4) Au=60.3%, Ag=37.9%, Cu=0.7%, probably four different nuggets soldered together by local heating and hammering in one final object.

For Iron Age period a spectacular example is a bracelet found at Boarta, near Valea Pianului - the best known ancient area of gold placers from Transylvania. In the visual inspection of this bracelet, we noticed two different types of gold (one white and the other yellow), XRF results showing different elemental compositional patterns: Au=55%, Ag=44%, Cu=2.6% (white aspect) and Au=79%, Ag=19%, Cu=1%, Sn=traces (yellow aspect).

Most probably, different nuggets were put together, hammered and partially heated to obtain their "welding". A similar primitive metallurgy was also used in the case of 13 Dacian gold spiraled bracelets (1<sup>st</sup> Century BC) found in Sarmizegetusa, Dacian capital situated in Central Transylvania. The relative in-homogeneity of the ingots used for the manufacture of the Dacian bracelets could be caused by the fact that the technique implied incomplete melting of a mixture of gold dust and nuggets (not reaching the high melting point of gold), without perfect homogenization. The primitive sintering of the gold concentrates (simultaneous hammering and non-uniform or insufficient heating) into ingots is expected to preserve impurities like isolated mineral grains and micro-inclusions. Using micro-PIXE (Proton Induced X-ray Emission) we identified tin (from cassiterite), copper and iron (from chalcopyrite) micro-inclusions, proving the above mentioned primitive metallurgical procedure.

In conclusion, in Transylvania rich in gold, from Late Neolithic to Dacian period, during more than 2000 years practically the same relatively primitive metallurgy of alluvial gold was used to produce the spectacular artifacts exhibited now in Romanian Museums.

#### ORAL

### 5. BRONZE AGE SILVER ARTIFACTS FROM ROMANIA? AN ARCHAEO-METALLURGICAL STUDY

*Constantinescu, Bogdan - (National Institute for Nuclear Physics and Engineering - Bucharest) bconst@nipne.ro*  
*Cristea Stan, Daniela (National Institute for Nuclear Physics and Engineering - Bucharest) daniela@nipne.ro*  
*Popescu, Anca Diana (Institute of Archaeology Vasile Parvan - Bucharest) anca\_diana\_popescu@yahoo.com*

Bronze Age silver artifacts were found only in Extra-Carpathian region of Romania, despite Inter-Carpathian region (Transylvania) is famous for its rich in silver (until 30%) native gold. The most spectacular aspect of these Bronze Age artifacts is the predominant presence of "exotic" alloys as auriferous silver and high-content copper silver alloy. Are these alloys natural (geologically) or anthropic (man made)? - this is the fundamental question.

To try to clarify it we performed an archaeo-metallurgical study using X-Ray Fluorescence (XRF) non-destructive elemental analysis technique.

The first case is the silver axes from Persinari hoard - see Al. Vulpe in "Prehistoire du Bas Danube/Prehistory

of the Lower Danube", XV, 1997. Their composition varies around Ag = 80%, Au = 17%, Cu = 3%. Because the axes are broken it was possible to investigate their bulk structure. The microscope examination revealed a mixture of silver alloys nuggets also including few gold nuggets, suggesting an incomplete melting.

Auriferous silver was also identified in a metallic disc of Vulchitrun type- see Dorel Bondoc, Bogdan Constantinescu "A Vulchitrun-type disc discovered at Calarasi", SCIVA, 54-56, 2003-2005. Its diameter is 30.4 cm, with a prominence in the centre - an umbo or omphalos with a middle of bronze, plated with silver and gold - with the diameter of the base of 11.3 cm and the height of 11.9 cm. The XRF analysis results are: Ag = 72%, Au = 24.5%, Cu = 3.5% for the silver foil, Au = 86.4%, Ag = 13%, Cu = 0.5%, Sn traces for the gold foil and Cu = 75%, Sn = 21%, Ag = 3%, As = 1%, Pb traces for the bronze part.

A strange silver-copper alloy was identified in a dagger found at Poduri, central Moldavia - see Bogdan Constantinescu et al "Considerations on the provenance of Poduri dagger as resulted from compositional analysis", SCIVA, 61, 2010: Ag = 70%, Cu = 30%, Pb traces.

A comparison with other Bronze Age artifacts realized from similar "exotic" alloys is discussed based on the papers:

- A. Hauptmann, A. Palmieri "Metal production in the Eastern Mediterranean at the transition of the 4th/3rd Millenium: case studies from Arslantepe", in Der Anschnitt Zeitschrift fuer Kunst und Kultur im Bergbau, 13, 2000

- M. Primas "Gold and silver during the 3rd Millenium B.C." in Prehistoric Gold in Europe. Mines, metallurgy and manufacture, G. Morteani and P. Northover editors, Dordrecht, 1995

- H. Born, S. Hansen "Helme und Waffen Alteuropas", Sammlung Axel Guttman, Berlin, 2001

The similarities with artifacts found in Eastern Mediterranean area (auriferous silver) and with Kozarac-type axes found in former Yugoslavia, now in Axel Guttman collection (high-content copper silver) are evident. Despite it is not possible to distinguish between natural and anthropic alloys, the provenance of our artifacts from Eastern Mediterranean area - including Anatolia and possibly Caucasus - is a credible hypothesis.

ORAL

## 6. EARLY IRON AGE POTTERY IN SOUTH-WESTERN IBERIA: ARCHAEOOMETRY AND CHRONOLOGY

*Krueger, Michal (Uniwersytet im. Adama Mickiewicza w Poznaniu) krueger@amu.edu.pl*

*Brandherm, Dirk (Queen's University Belfast) d.brandherm@qub.ac.uk*

The purpose of this paper is to present the first results of an ongoing project on the beginnings of the Early Iron Age in the south-western part of the Iberian Peninsula. Our current knowledge of many relevant aspects remains rather insufficient. Despite a long tradition of research on cultural contact in Iberia's Early Iron Age, basic problems still remain unsolved: the chronology and the nature of the first contacts between the Phoenicians and the native inhabitants of Andalusia, the Tartessians. The colonial impact on Tartessian society is often perceived as a unidirectional process in which the locals are mute consumers of imported goods. Such simplistic models go hand in hand with a lack of knowledge about patterns of long distance trade between the Phoenicians and the locals. Currently, the origin of foreign artefacts found in local contexts in most cases remains uncertain.

This paper argues that through systematic spectrographic analysis of pottery specimens from Tartessian sites (Setefilla and eleven other sites) it is possible to overcome these problems. The methodology is based on both destructive and non-destructive analysis of ceramic samples. For the latter a highly sensitive portable X-ray fluorescence device is employed. The proposed paper is also concerned with the strong need for a reliable C14-based chronology for the development of Tartessian material culture. Therefore, a new approach to refine our chronological framework for this period will be proposed that aims at providing us with a better grasp of the development of interdependences between the Phoenicians and the Tartessians over time.

As the purpose of this paper is to present the research design and objectives of a project still in its initial stage, no results are available at this time.

The ongoing investigations will have important consequences for our understanding of the development of the region during the transitional period between the Late Bronze Age and Early Iron Age, when for the first time indigenous communities were exposed to new social and economic models originating from the Eastern Mediterranean. Provenancing suspected imports

and establishing a reliable chronological framework will further our understanding of historical transformations in south-western Iberia during this crucial period.

ORAL

## 7. AN INDIGENOUS POTTERY PRODUCTION STRATEGY IN THE LATER EARLY BRONZE AGE SITE OF MURSIA, PANTELLERIA, ITALY. PERSPECTIVES ON SOCIAL COMPLEXITY AND INDIGENOUS INTERACTION PATTERNS

*Cantisani, Matteo (UTAD) matteo.cantisani@gmail.com*

A first analysis on the pottery production from Mursia was carried on in the 60s by tozzi (1968), followed by other typological studies aimed to understand both the settlement dynamics chronology and *rodindari-vallelunga* (RTV) morpho-stylistic patterns (tozzi 1978; ardesia et alii 2005; ardesia and cattani 2011). Archaeometric analyses on some samples have been carried on only recently (secondo et alii 2011), to infer differences in technology in between RTV and castelluccio productions. It is worth to note the absence of specific studies addressed to the comprehension of social organization of production first, as preliminary step towards a better understanding of material patterns of technological changes in between different communities. The preliminary results presented in this communication show first the existence of well-defined "islander" pottery production. It seems to own specific technological features and, as spatial analysis results show, it is related to a dynamic and articulated social context development.

Petrographic analyses and textural analyses by polarized optical microscope were first carried on 30 samples from the multiphase household B3. The potsherd samples were chosen according to specific criteria.

Spatial analysis using ArchGis platform (trial version) were subsequently led, to infer connectedness among production patterns and social organization of space.

The fabric characterization of the samples, as well observations on shape's vessel, permitted to identify two production patterns related to diversified raw material sources exploitation and pottery functionality. The presence of exploitation strategies and diversified fabrics preparation, according to the final purposes, as well as the relatedness between artifacts distributions, functionality and use of inner space, allowed to infer an

articulated household production. Evidences related to a possible kiln within the settlement appear to suggest a more specialized craft in the later period. At the same time the settlement development patterns support the hypothesis of a demographic growth.

The results enable to assess first the importance of technological knowledge for affecting, and be affected by, the context of transmission (eerkens 2007). Moreover, these partial results allow to define technological patterns of a specific pottery production. The importance of such a study to infer socio-cultural dynamics and connectedness between population size is evident. In this perspective, articulated comparisons both among different patterns of pottery productions and organization of inner/outer space in between multiphase sites well dated, shall permit to find out material patterns of technological changes and interpret innovations. As innovation rates, population size and interactions can be related (henrich 2004; kylene and boyd 2010), material patterns of technological changes in pottery production shall be useful to deduce indigenous exchange networks as potential means to explain local social development patterns.

### 8. BRONZE AGE CERAMICS FROM SARDINIA (ITALY): A TECHNOLOGICAL STUDY

*Gradoli, Maria Giuseppina (PhD researcher, School of Archaeology, University of Leicester (UK) ggradoli@yahoo.it*

The present work is based on my current PhD research *'Dynamic Social Changes and Identity. A petrological study of Bronze Age ceramics in Nuragic Sardinia'* carried out with the aim of investigating the pattern of pottery production, consumption and exchange at an inter-site level on the one hand, and the complex sequence of social changes accompanying the appearance of megalithic towers (nuraghi) during the Middle Bronze Age (1600 BC) and their later complexity during the Recent and Final Bronze Age (around 900 BC), on the other hand. Major phases of growing settlement complexity in a case-study area are studied in relation to 450 sherds of domestic pottery, looking deeper beneath their apparent 'static cultural homogeneity' through continuity and change in technology with the help, when possible, of the historical data and the anthropological and ethnographic approaches.

In Sardinia since now, local practices of prehistoric ceramic production and consumption have largely remained understudied, or have only focused on stylistic attributes and their use in assessing a chronological typology. The methodology here used - analysing ceramic fabric variability among selected common vessel forms and domestic architectures - represents thus an innovation. After the adoption of a broad theoretical context, based on both the physical and the social sciences, the process of pottery manufacturing is studied under the petrographic microscope considering: 1) *'pottery fabric'* or the arrangement, size, shape, frequency and composition of clay, minerals, and other materials added intentionally to improve the workability and firing performances of ceramic pastes; 2) the concept of *'chaîne opératoire'* and its individual steps to reconstruct part or the whole sequence of technical, physical and mental actions performed by potters, starting from the way natural resources (clays, sands, rocks, water) were acquired in the area, mixed together in different proportions, fashioned and then physically transformed by the process of firing; 3) the *'raw material provenance analysis'*, using analytical and geological approaches, to establish whether the sampled vessels were produced using clays and other naturally or intentionally added materials obtained from the investigated area or far away from it; 4) the *'experimental archaeology'*, that provides the opportunity to confirm potential hypothesis and conclusions with multiple trials and repeatable tests in a chemical/mineralogical laboratory and will be used for the reproduction of the ceramic pastes (according with the different proportion of mineral/rock inclusions and clays estimated under the microscope and their comparison with the archaeological ones under study).

The petrological study, supported by the clay chemical/mineralogical analyses, is shedding new light on the potters' cultural affiliation, drawing important comparative data about community practices, type of human activities and how nuragic ceramic production and culinary practices were organized at the scale of the micro-region.

In Sardinia since now, ceramic studies have mainly focused on stylistic attributes and their use in assessing a chronological typology. Analysing ceramic fabric variability among selected common vessel forms and domestic architectures inform on the way mundane pottery were manufactured, used, exchanged or circulated across the wide landscape through social networks of local groups.

**9. ARCHAEOLOGICAL STUDY OF THE AENEOLITHIC ANTHROPOMORPHIC STATUES FROM NURALLAO (CENTRAL SARDINIA, ITALY)**

*Serra, Marco (Dipartimento di Scienze dell'Antichità, University of Rome "La Sapienza" (Italy) marco.serra@unica.it*

*Cannas, Carla (Dipartimento di Scienze Chimiche e Geologiche, Cagliari University (Italy) ccannas@unica.it*

*Tanda, Giuseppa (Dipartimento di Storia, Beni Culturale e Territorio, Cagliari University (Italy) gtanda@unica.it*

In the 70s of twentieth century, the bronze age burial of aiodda-nurallao (sardinia, Italy) was investigated by the archaeologists of Cagliari University. During the excavations, a number of limestone's anthropomorphic sculptures ("menhir statues") were founded in the walls of the grave. They are probably from a local sanctuary of aeneolithic period (III millennium BC), and they were re-used as building material by nuragic people in the II millennium BC. Some of these megaliths were removed from the burial site, and were exposed at the national museum of Sassari.

Near the tomb of aiodda, in the perda tellada's area, an ancient quarry of limestone blocks probably used in prehistoric times, was discovered also.

A multi-technique instrumental and autoptic approach was carried out on 10 geological samples collected from the local fossiliferous limestone of "villagrecia unit", and on 14 statues from aiodda.

For the geological material we used geochemical and mineralogical analytical techniques such as ED-XRF, ICP-AES, ICP-MS, XRD and macroscopic survey. In agreement to conservative requirements, on sculptures we have achieved only non destructive ED-XRF measurements and autoptic observations.

This approach has allowed us to determine the characterization, the geochemical intra-source variability and the technological properties of local limestone. Through the comparison between artifacts and lithological outcrop's analytical data, we were able to define the sourcing phenomena about prehistoric megaliths and to establish spatial relationships between stone sources and the founding places of sculptures.

The macroscopic observation of the villagrecia lithology, manifests its fine structure with fossiliferous inclusions. All instrumental tests show that the calcium and its minerals are predominant in this rock. The ED-XRF qualitative data of geological material present a compositional set formed by K, Ca, Ti, Mn, Fe, Sr. The discriminant intensity ratios of these analytes, reveal a clear segregation between the samples taken from perda tellada and the other lithic fragments of Villagrecia limestone. It demonstrates the existence of two geochemical sub-groups. This intra-source variability was confirmed by ICP-AES and ICP-MS. These instrumental techniques also show a very low percentage of silica with a consequently good working properties of this rock. The XRD survey reveals a main mineralogical phases of calcite (Mohs 3) and subordinate quartz, in agreement that the villagrecia's limestone is a "soft-stone".

The fluorescence and the autoptic analysis achieved on anthropomorphic sculptures, reveal many geochemical, structural and mineralogical common characters between archaeological and geological materials. The main affinities are between statues and the limestone of perda tellada's quarry, located near the nuragic tomb. All analyzes show the calcareous nature of the micritic organogenic outcrop of villagrecia. Instrumental approach expose the geochemical differences within the geological unit, and its high workability by ancient technologies.

The comparison between geological and archaeological analytical data confirms the use of local limestone, especially from perda tellada's quarry, for the production of the aeneolithic statues of nurallao, according to the optimization of economic resources. In agreement with these criteria, is also the installation and the re-use of the sculptures near the area of the likely megalithic quarry of perda tellada.

**10. INVESTIGATING WOOL TRADE AND NETWORKS DURING SCANDINAVIAN BRONZE AND IRON AGES BY THE STRONTIUM ISOTOPE TRACING SYSTEM**

*Frei, Karin Margarita (National Museum of Denmark) Karin.M.Frei@natmus.dk*

*Bergerbrant, Sophie (Gothenburg University; Sweden) sophie.bergerbrant@gu.se*

*Kristiansen, Kristian (Gothenburg University; Sweden) kris-*

*tian.kristiansen@archaeology.gu.se*  
*Mannering, Ulla (National Museum of Denmark) Ulla.Mannering@natmus.dk*

New developments in the field of the strontium isotope tracing system have provided new means to investigate the provenance of ancient textiles raw materials. This presentation aims at giving a brief overview of the methodology as well as discussing key-case studies from the exceptional well-preserved Bronze and Iron Age wool textile collections from Scandinavia.

Archaeological textile research is today a growing field, proving to be an important source of information for prehistoric societies at the social as well as the economical level. As Scandinavia and in particular Denmark, possesses one of the best textile collections from Bronze and Iron Ages they provide a unique window to investigate the textiles raw materials provenance. Hence, we applied the strontium isotope tracing method ( $^{87}\text{Sr}/^{86}\text{Sr}$ ) to wool and plant fibers textile threads samples from these collections.

Our investigations -which are still ongoing- reveal a high complexity behind textile production and trade. For example, single large textile pieces could be made of wool coming from a large variety of geographical areas including non-local areas, as in the example of the pre-Roman Iron Age Huldremose garment. However, other contemporaneous garments could be made of only local wool. Similarly, we also show that textiles made of plant fibers were sometimes made of non-local raw materials, even though the plant fibers they were made of were locally available, as in the example of the Bronze Age Lusehøj nettle textile. Therefore, we will explore trade networks based on textile's raw material provenance as well as discuss technological issues behind wool production in prehistory.

## **11. ORNAMENTS EXCHANGE, MANUFACTURE AND USE AMONG HUNTER-GATHERERS FROM CENTRAL-EASTERN SECTOR OF PAMPEAN REGION (ARGENTINA)**

*Acosta, Alejandro (INAPL-CONICET) acosta@retina.ar*  
*Buc, Natacha (INAPL-CONICET) natchabuc@gmail.com*  
*Davireux, M. Natalia (INAPL) mnataliadavireux@gmail.com*

Archaeological ornaments were object of several studies among hunter-gatherers and/or societies with emerging systems for food production. Focus is usually on manufacture techniques, raw material acquisition and their "non-utilitarian" functions (related to symbolic or identity behaviors). The aim of this communication is to test different aspects related to exchange, manufacture and use of items found in different archaeological sites from central-eastern sector of Pampean Region (Argentina) dated in the last 2000 radiocarbon years (Late Holocene). In this regional study we consider sites from different ecological units, including Low Riverine floodplains, Delta sectors and sites from High Plains of Pampa sector. Most of them are hunter-gatherer campsites, although we also include one assemblage made after horticulturalist groups.

For this purpose we identify different items that can be considered as ornaments, and classify them according to raw materials used. It includes teeth, bones, shells, clays, rocks and metals. Each one is analyzed according to their own properties. For example, to test provenance local macro comparison with actual databases were used for most cases; however, X diffraction was needed in metals materials to state the chemical composition. Metrical and microscopic structures are considered in all assemblages to discuss homogeneous and/or heterogeneous manufacture centers.

Results show that different materials behave through different paths. For example, we can state a local production for teeth pendants and malacological items (beads and *tembetás*) which appear in high proportions in sites from Low Riverine floodplains. In general terms, assemblages show inter-site homogeneous properties which suggest similar behaviors with these raw materials. On the other hand, beads made from specific lithic materials (such as malachite), items made after marine shells, and metals, are coming from distant sources of production or availability.

On that basis and considering environmental local aspects, including ecological and social particularities of societies under study, we propose different provision and exchange networks for interpreting these materials. These include distant areas such as the northwest region of Argentina, the area of Central Ranges in Córdoba province, and the marine coast of the Atlantic Ocean. At this regard, variability in ornament's use and distribution enhanced cultural complexity among local societies during Late Holocene.

Barranc de la Boella integrates several outdoor archaeological sites dating to the Lower-Middle Pleistocene transition whose formation is related to a deltaic sedimentary environment. Its age makes it a key-site for studying the behavior of early hominins groups of the Iberian Peninsula.

Scheduled excavation began in the gully in 2007 and now is carried out in three different archaeological sites (Centre de Convencions, la Mina and el Forn). Work at the la Mina site started in 2008. Three archaeostratigraphic levels have been identified, being the level two the richest in faunal, coprolite and stone tools remains recovered.

Cervids (*Cervus* sp., *Dama* cf. *vallonetensis*, and *Megaloceros savini*) and equids (*Equus* cf. *stenonis*) are the most represented taxa. Elements of *Hippopotamus antiquus*, Bovidae, *Mammuthus meridionalis* and *Macaca sylvanus* were also recovered. Among the carnivores, few fossils of *Ursus* sp., *Panthera* cf. *gombaszoegensis*, *Canis*

*mosbachensis* and coprolites belonging to a hyaenid have been found.

The different correlation index of the mineral density indicates no relationship among the elements recovered. Carnivore activity is notably documented. Tooth marks have been recognized in 7.4% of the bones, mostly in the shaft of the long bones as a result of the pronounced lack of epiphyses (the epiphysis-diaphysis ratio is 0,46). Tooth marks affect all weight categories and all skeletal elements, although long bones of medium-sized carcasses are the most affected. Were also documented other modifications caused by carnivores as digested bones, pitting, lacking or some diaphyseal cylinder. Some features related to carnivore activity suggest the presence at least of a bone-cracking carnivore above the assemblage.

Anthropic activities above the remains are scarce and prevent realize inferences above the carcass acquisition mode. Chemical alteration of the bones, usually caused by rinsing soluble sediments, prevents the identification of cut marks, although stone tools are abundant and fresh. However, percussion impacts are documented in some large bones. Different ratios of anatomical profiles analysis suggest high levels of competition among predators during the assemblage formation context.

The palaeoecological context inferred at the Barranc de la Boella site was an optimal spot for hominins to visit in order to acquire resources. The taxonomical diversity is indicative of an open landscape at the edge of a pond where animals came to drink and predators came to hunt their prey.

ORAL

**2. THE IMPORTANCE OF DEFINING AND NORMALIZING THE FUNCTION OF THE SITE. AN EXAMPLE IN THE CUEVA DEL ANGEL (LUCENA, CÓRDOBA).**

*García-Solano, José - jgsolano@outlook.com (Universidad de Granada)*

*Moigne, Anne Marie - moigne@mnhn.fr (European Centre for Prehistoric Research at Tautavel)*

*Celiberti, Vincenzo - vceliberti@hotmail.com (European Centre for Prehistoric Research at Tautavel)*

*Barroso Ruiz, Cecilio - ceciliobarroso1@hotmail.com (Foundation prehistoric and human evolution research institute)*

In the research work on the Paleolithic homotaxiality criteria based on lithic technology and absolute and/

or relative chronologies as an indispensable way to establishing periodization, regional sequences, changes in lifestyles or making comparisons and parallels between different sites are used. Great importance is given to contemporaneity in order to make generalizations between archaeological records. This is obviously significant; however, many regional interpretations and systematization are made without regard to the type of occupation or site functionality, which causes confusion or misleading conclusions. The lower frequency of information on sites of former periods, conservation issues/problems or taphonomic biases, has a definite influence on this work, in which it's possible to use, for example, data from a non-defined stop-hunting place and a residential place in order to create, for instance, a model of dynamics of livelihood or settlement similar to regional scale (contemporary or evolutionary). Thus, the importance of defining, standardizing and systematizing the function and form of the anthropic occupation of establishments is raised.

In the scientific literature there is a wide and scattered variety of terms used to review or nominate the types of establishments or anthropogenic occupations. However, the criteria used in the nomenclature are not always the same, as it is possible to find similar sites with a different name and the same function and vice versa. From a literature review on the functional scheme of the deposits and some examples of European sites, standardization is proposed on the possible functions that can be developed in different sites of intervention.

ORAL

### 3. ZOOARCHAEOLOGICAL STUDY OF JARAMA VI (UPPER PLEISTOCENE, SPAIN)

Díez, J. Carlos (Universidad de Burgos) [clomana@ubu.es](mailto:clomana@ubu.es)  
Romero, Antonio (UPV/EHU) [romeroalonsoaj@hotmail.es](mailto:romeroalonsoaj@hotmail.es)  
García-Solano, José (IGME) [jg.solano@igme.es](mailto:jg.solano@igme.es)  
Arceredillo, Diego (Universidad de Burgos) [diego.arceredillo@hotmail.com](mailto:diego.arceredillo@hotmail.com)  
Jordá, Jesús F. (UNED) [jjorda@geo.uned.es](mailto:jjorda@geo.uned.es)

The latest datings and studies of the Jarama VI site (Valdesotos, Guadalajara) support the attribution of the archaeological levels to Neanderthal occupations. The upper (JVI.1) and lower (JVI.3) units are markedly clastic and were formed in cold conditions. The middle unit (JVI.2) corresponds to fluvial deposits. At the top of this level, a floodplain developed where a hearth was detected (JVI.2.1). The environment was very moist

with a high rate of sedimentation. All units contain lithic Middle Palaeolithic technology.

We conducted a taphonomic study of the remains from units JVI.1 and JVI.2, along with an anatomical and species determination and an analysis of the differential representation. We studied all fractures and marks made by humans and the action of other agents in the pre- or post-burial phases. We took into account the differences between levels in order to ascertain whether the bone assemblage was determined by climate, sedimentary patterns or taphonomical conditions.

The similarity between the remains of the two levels suggests that the behavior of the Neanderthals was equivalent in both periods, independently of the climatic and environmental factors and without postdepositional features determining the final composition.

Rodríguez-Hidalgo, Antonio (IPHES, Institut Català de Paleoeologia Humana i Evolució Social, C. Marcel·lí Domingo s/n, Campus Sescelades URV (Edifici W3), 43007 Tarragona, Spain./Àrea de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Sp) [arodriguez@iphes.cat](mailto:arodriguez@iphes.cat)

The characterization of the faunal assemblages present on Neanderthals deposits has been performed mainly based on the anatomical representation patterns and the application of different utility indexes. Through them have been established recruitment strategies and transportation which define a large part of economic skills that might have got the Neanderthals groups.

Our object of study is faunal assemblage of level M of Abric Romani (51-55 ka BP). We have applied a taphonomic and zooarchaeological analysis over whole remains bigger than 2cm. We have reconstructed the original anatomical representation through MNI, MNE and MAU, in addition we have also analyzed the bone surface to identified pre/postdepositional alterations. With the aim of identify potential transport strategies have been applied SFUI and Shannon diversity index on the elements of high survival.

The faunal assemblage of level M of Abric Romani is a fully anthropic accumulation. Neanderthals carried out a transport strategy Unconstrained, where the anatomical elements were introduced based on their abundance in a complete skeleton. We observed a similar anatomical representation in all animal sizes, so transportation was not differentially performed according to the animal weight. With the aim of understand the behavioral implications of this type of transport strategy we have applied the same statistical model sets generated by Hadza groups. We know that they have at least six different transport strategies conditioned by various causes. However, the application of SFUI and Shannon diversity index pointing to unconstrained transport strategy, with similar results to those found in the level M.

The principal characteristic of the M level of Abric Romani, as well as the Hadzas assemblages analyzed are the overlapping hunting and transportation events. The successive occupations and depositions hide each specific event. This apparently results in a homogeneous assemblage, but that is a result of a behavior characterized by variability. The transport of the different elements is not determined exclusively by the animal size or nutritional value of the elements. The main characteristic of transport is the high diversity of elements that can be transported in each hunting event. This behavior requires highly organizational capacity, resulting from a high sociocultural complexity which characterized the Neanderthal groups.

### **5. ABRIGO DE LA QUEBRADA (CHELVA, VALENCIA, SPAIN): ARCHAEOZOOLOGICAL STUDY OF A NEANDERTHAL HUNTING GROUND IN CENTRAL MEDITERRANEAN IBERIA**

*Real Margalef, Cristina (Universitat de València) cristina.real@uv.es*

*Sanchis Serra, Alfred (Museu de Prehistòria de València) alfred.sanchis@dival.es*

*Morales Pérez, Juan Vicente (Universitat de València) juan.morales@uv.es*

*Eixea Vilanova, Aleix (Universitat de València) alejo.eixea@uv.es*

*Zilhao, Joao (Universitat de Barcelona) joao.zilhao@ub.edu*

*Villaverde, Valentín (Universitat de València) valentin.villaverde@uv.es*

Abrigo de la Quebrada (Chelva, Valencia) is an archaeological site with various levels of Neanderthal occupation. Human presence in the shelter has been favoured by its location in a narrowing ravine, giving rise to a kind of natural trap where hunting animals would be feasible. Moreover, the immediate environment is varied (abrupt and plain zones), allowing the presence of a wide range of preys.

The seven excavation seasons conducted (24 m<sup>2</sup>) have determined eight sedimentary levels. It has been obtained three AMS radiocarbon datings, one in level III of 40 500 ± 530 BP (Beta-244003); and two at level IV of 43 930 ± 750 BP (Beta-244002) and >50.8 ka BP (OxA-24855).

The materials presented in this work are from level IV, whose formation reflects a slower rate of sedimentation, favoured the typical structure of palimpsest, with a high density of lithic and bone elements and a large number of combustion structural remains.

The faunal sample (103 510 remains) has a high level of fragmentation, which represent a low rate of determination. A large number of bones are affected by fire and post-depositional processes that have complicated the characterization of prey processing and consumption. This problem has led to the application of a specific methodology for small indeterminate fragments. The species and anatomical elements identification has been done using reference collections. It has been established the age structure of the preys, the fragmentation level of the remains, the origin of fractures and it has been described the bone surface modifications to determine the origin of the accumulations.

It has been taxonomically identified only the 1.3% of the sample, including different families: Bovidae, Equidae, Cervidae, Leporidae, Testudinidae, Suidae, Rhinocerotidae, Felidae and Canidae, where Spanish ibex, horse and red deer are the predominant species. Among the indeterminate remains highlights small fragments of long bones, sometimes with fire modifications,

corresponding mostly to the Spanish ibex and red deer sizes. The anatomical representation data show that medium size preys carcasses have been transported complete; while the large size ones indicate a certain parts selection processes. The age structure of the three main species is characterized by the predominance of adult individuals.

Percussion impacts and cut marks have been identified on some remains that confirm the human character of the sample. The modifications related to the action of other non-human predators, as carnivores or bird of prey, are very scarce. The remains also show high frequencies of calcareous deposits.

The faunal accumulations are the result of repeated occupation of the shelter by Neanderthals groups.

The shelter has functioned as a hunting ground, where it has been transported and processed hunted animals in the immediate environment. With this study we obtained more extended information on the subsistence of Neanderthals groups in central Mediterranean Iberia.

ORAL

## 6. NEANDERTHAL-MAMMOTH INTERACTIONS: RE-EVALUATING EVIDENCE FOR REPEATED "MAMMOTH DRIVES" AT LA COTTE DE ST BRELADE (JERSEY).

*Smith, Geoff (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) smith@rgzm.de*

La Cotte de St Brelade is one of the most prolific Middle Palaeolithic localities in Western Europe (ca. 96,000 lithic and 1,500 faunal remains). Two distinct "bone heap" levels (Layers 3 and 6), composed almost entirely of megafaunal remains, have been suggested as the remnants of Neanderthal game drives. Since final publication the interpretation of the site as a mammoth drive locality has remained a unique, if untested, hypothesis. Presently, such structured and repetitive subsistence behaviour has been suggested, but never concisely argued, for any other European Middle Palaeolithic site, calling for a re-evaluation of the CSB fauna.

This paper presents new faunal analysis of material from the McBurney excavations (1961-78). 1,494 faunal remains were recorded from all horizons, placing the two "bone heaps" within context. Species and body

part were allied with a range of attributes (weathering, abrasion and root-etching) to fully understand the site formation processes. Furthermore, an oblique light source and hand lens (20x magnification) allowed for a detailed assessment of bone surface modifications.

Results confirm the dominance of mammoth and woolly rhino with smaller quantities of horse, wolf and bear. Overall, per layer, Minimum Number of Individuals (MNI) are very low, usually 1 or 2. Only within the "bone heaps" of Units 3 and 6 do mammoths dominate with MNIs of 7 and 11, respectively. Further data, however, indicates complex site formation and preservation. Bone weathering throughout all horizons suggests more prolonged exposure, repeated input of faunal material and differential preservation, potentially related to shelter from the granite walls.

Neanderthal presence was identified within all deposits through either burnt bone or butchery modifications suggesting the exploitation of these individuals, throughout all contexts. Newly identified carnivore modifications were only recorded on faunal material from the "bone heap" horizons. Detailed analysis of the quantity and distribution of these modifications suggests a more complex Neanderthal subsistence pattern than previously acknowledged, and questions the interpretation of CSB as game drive locality.

Contextualising this new data at a broader European scale provides more detail about the importance of megafauna in Middle Palaeolithic diet. Whilst regular megafaunal exploitation by Neanderthals has been suggested, there is no evidence for the systematic hunting of these species and hence their dietary contribution appears limited. Whilst CSB remains exceptional, being unique in the recurrent presence of mammoth remains and Neanderthal stone tools, a more intricate behavioural and site formation scenario presents itself. Rather than Neanderthal occupation, punctuated by large-scale game drives, the site is similar to other cave faunas from Europe, with an accumulative role for both hominins and carnivores. Over a long duration, Neanderthals regularly utilised the CSB landscape, exploiting various species, including mammoth. The CSB ravine system could have provided the perfect location to track and hunt animals, whilst the enclosed site structure provided protection and shelter for butchery and processing. The CSB locality would have proved similarly attractive to carnivores, meaning that faunal accumulation was a composite mix of Neanderthal hunts, carnivore kills and natural deaths, and not merely the results of mammoth drives.

ORAL

**7. NEANDERTHALS AND THEIR FELLOW TRAVELERS ON THE "MAMMOTH STEPPE": A HORSE-DOMINATED FAUNAL ASSEMBLAGE FROM THE 50 KY BP MIDDLE PALAEOLOGIC WFL-SITE AT VELDWEZELT-HEZERWATER, BELGIUM**

*Bringmans, Patrick M.M.A. (The 'Veldwezelt-Hezerwater' Neanderthal Research Centre - Belgium) Patrick.Bringmans@hotmail.com*

*de Warrimont, Jean-Pierre (Archeologische Vereniging Limburg - The Netherlands) Patrick.Bringmans@hotmail.com*

*Cordy, Jean-Marie (Université de Liège - Belgium) JM.Cordy@ulg.ac.be*

The lithic artefacts (N=133) and the animal bones (N=225) from the WFL-Site at Veldwezelt-Hezerwater were excavated in a sealed lithostratigraphical unit. The WFL soil formation phase seems to represent an important phase of Middle Weichselian pedogenesis, which could be dated around 50 ky BP. It is known that the interstadials of Marine Isotope Stage (MIS) 3 were characterised by high-frequency and high-amplitude oscillations of the order of 1,000–2,000 years duration. It is likely that Neanderthal occupation of North-West Europe was sporadic and restricted to these relatively warm interstadials.

The mammalian fauna from the WFL-Site at Veldwezelt-Hezerwater has been identified as mammoth (MNI=1), woolly rhinoceros (MNI=2), horse (MNI=5), European ass (MNI=1), steppe bison (MNI=2), reindeer (MNI=1), arctic fox (MNI=1), cave lion (MNI=1), cave hyaena (MNI=2), badger (MNI=1) and hare (MNI=1). The WFL-fauna thus shows a series of cold-adapted species. There is only one warm-adapted species present and that is the badger. Overall, the character of the WFL-fauna shows the existence of continental conditions, with fairly warm summers, but harsh winters. This would result in the dominance of rich open grasslands (i.e. the 'Mammoth Steppe' of Guthrie 1990).

The WFL faunal assemblage seems to be an example of a so-called 'species-dominated' assemblage. In this case, a 'horse-dominated' faunal assemblage, could be an indication for the anthropic origin of the assemblage. On the other hand, the presence of a 'hyena den' in the immediate surroundings of the WFL-Site, is indicated by the simultaneous presence of corroded and/or partially digested bones, by the remains of a coprolite and by the presence of some bones and teeth of the hyena itself. In the latter case, it is significant to note that practically all

the excavated remains belong to very young individuals, proven by the presence of unfused long bones and milk teeth. They were probably still-born individuals. These data imply that the place of parturition (i.e., the 'hyena den') is very close. This would indicate that both Neanderthals and hyaenas were sympatric, thus existing in the same geographical area, around 50 ky BP. It is easy to envisage how Neanderthals and hyaenas might co-exist. As hyaenas are active almost entirely at night and spend the day in dens, there would be little direct competition for resources with the Neanderthals. As hyaenas consume organs and bones, little would remain.

The WFL-Site probably represents a very brief occupation by a Neanderthal task group, whose main technological activity appears to have been maintaining a heavily curated tool-kit, suggesting high mobility and planning. The WFL faunal assemblage corresponds in its composition to a typical steppe fauna. The development of large deforested spaces, characterised by the expansion of grasses during summer, allowed the development of herds of large herbivores. In such a context, the cave hyena and the Neanderthals represent the most adapted super-predators. The presence of a 'hyena den' complicates the interpretation of the bones excavated at the WFL-Site, since there obviously is a mixture between a human occupation site and a carnivore habitat.

ORAL

**8. FAUNAL ASSOCIATIONS AT THE END OF MIDDLE PALEOLITHIC IN THE SOUTH OF FRANCE FROM THE PALEOBIOLOGICAL AND ZOOARCHAEOLOGICAL STUDIES OF THE UPPER SEQUENCE OF MANDRIN**

*Brugal, Jean-Philip (CNRS) brugal@mms.univ-aix.fr*

The upper sequence of final middle Paleolithic site of Mandrin located in the Rhône valley (left bank) is dated to the beginning of isotopic stage 3 (e. 52-42 ka cal BP) and yielded four levels with six human occupation with rich and diversified bone assemblages (more of 60.000 remains). Paleobiological and zooarchaeological studies would give a synthetic overview about faunal associations with 13 herbivore species (horse and deer dominant), 9 carnivore taxa (wolf and red fox dominant) and mésofauna (leporids, large rodent). The structure and composition are similar to the animal communities known for this period in the South of France although we can notice some regional differences. Indications about anatomical representation, age structure,

taphonomy, biological marks allow to precise the origin of assemblages, essentially due to Neanderthal groups for ungulates. These data allow us to discuss about socio-economical factors and site functions. The humans occupations are dense, recurrent and pluri-seasonal demonstrating some stability through time in human hunting behavior on areas exploited during long period. However, settlements are less intense in the upper levels probably related with changes in mobility and/or group size. Those groups are the last evidence of Neanderthals in this mediterranean region, and some hypothesis on their reduction, then disappearance can be hypothesized within a more general frame.

ORAL

### 9. ARE THE TIMES CHANGING? A ZOOARCHAEOLOGICAL APERCU TO THE MIDDLE-UPPER PALEOLITHIC TRANSITION IN COVA GRAN (SOUTHEASTERN PRE-PYRENEES, IBERIA)

*Samper Carro, Sofia Cristina (Dept. Archaeology & Natural History, CAP, Australian National University; Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria (CEPAP), Universitat Autònoma de Barcelona) sofia.samper@anu.edu.au*

*Martinez Moreno, Jorge (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria (CEPAP), Universitat Autònoma de Barcelona) jorge.martinez@uab.cat*

*Mora, Rafael (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria (CEPAP), Universitat Autònoma de Barcelona; Program ICREA-Academia, Institut Català Recerca Avançada (ICREA) rafael.mora@uab.cat*

The Middle to Upper Palaeolithic (MP/UP) transition constitutes a central focus in European Paleanthropological studies. Within this research line, the study of subsistence patterns is a key element to understand Neanderthals and anatomically modern humans (AMHs) behaviour.

Zooarchaeological analyses from late Middle Palaeolithic and early Upper Palaeolithic contexts provide insights about the subsistence behaviour of last Neanderthals and first AMHs.

The material analysed comprises the zooarchaeological assemblages recovered in Cova Gran, a rock shelter located in the southeastern Pre-Pyrenees (Lleida, Iberia). We discuss the skeletal part representation, age at death, and bone modifications observed in the assemblages from two Middle Palaeolithic units and the earliest Upper Palaeolithic level documented.

The taphonomical analysis conducted attempt to identify similarities and differences in these assemblages, which could be related to changes in Neanderthals and AMHs subsistence strategies.

The taxonomic representation of species (in terms of MNI) varies from Middle to Upper Palaeolithic occupations, with a greater amount of large-size mammals from Middle Palaeolithic levels. Breakage patterns and cut marks suggest the anthropogenic origin of the accumulations, although syn/post-depositional processes have affected bone fragmentation.

The small number of individuals identified, compared to the number of bone remains and the excavated area results from intense syn/post-depositional processes affecting bone preservation. Nevertheless, these assemblages might reflect sporadic visits to the rock shelter, which could be related to human mobility.

Zooarchaeological results show remarkable changes related to Neanderthals and AMHs subsistence. Shifts observed in the taxonomic composition could be linked to environmental changes and prey availability, but also might reflect variations in prey acquisition practices.

ORAL

### 10. PALAEOLOGICAL SUBSISTENCE ACTIVITIES AND ENVIRONMENT IN QUERCY: THE FAUNAL ASSEMBLAGES FROM LES FIEUX (LOT).

*Gerbe, Magali (UMR 7269) gerbemagali@yahoo.fr*

*Brugal, Jean-Philip (CNRS UMR 7269) brugal@mmsh.univ-aix.fr*

The site of Les Fieux (Miers, Lot, France) is one of the major archeosequence for the end of Middle Palaeolithic (MP) and the early Paleolithic (late OIS 4 to OIS 2) in southwestern France. The study of bone assemblages gives us the opportunity to understand subsistence behaviours of Neanderthals and Modern human, especially about the acquisition and exploitation of faunal resources through time and in the same spot.

The taphonomical and archeozoological analysis of bone assemblages from different archaeological levels (Mousterian, Aurignacian and Gravettian) shows the predominance of bison and red deer during the Middle Palaeolithic when reindeer and horse-bison are the main hunted species during the Upper Palaeolithic (UP). This change is considered in relation with palaeoenvironment

and climate changes, marked by cooling condition starting at the beginning of Upper Palaeolithic.

The socio-economical interpretations demonstrate repeated occupations of the site by Neandertals for seasonal hunting combined with the use of the cave by carnivores for denning (hyaena, wolf and fox). During the Upper Palaeolithic, the occupations' purposes are still the exploitation of ungulates within a wider exploited territory according to the lithic raw materials; the site corresponds more to a shelter than a kill site because of the evolution of its topography. The study of the faunal association of Les Fieux constitutes an original opportunity to envision and interface data from climate, technology and subsistence during the transitional period MP-UP within a same geo-topographical context.

### **11. THE CONTRIBUTION OF DATED PALEONTOLOGICAL SITES TO THE UNDERSTANDING OF HUMAN BEHAVIOURS AND THEIR ENVIRONMENT ? THE PIT FALL OF IGUE DU GRAL AND THE UPPER PALEOLITHIC OF QUERCY**

*Castel, Jean-Christophe (Muséum de Genève) jean-christophe.castel@ville-ge.ch*

*Boudadi-Maligne, Myriam (PACEA-CNRS, Université de Bordeaux) m.boudadi-maligne@pacea.u-bordeaux1.fr*

Reconstruction of the Paleolithic paleoenvironment of Western Europe have been based since at least the 1990s on the analyses of the faunal spectrum identified from prehistoric sites. The scientific community has become more and more aware of the potential disjunction between prey spectrum and paleoenvironment, and thus to question the extent to which habitation sites represent the best proxies for such reconstructions, particularly during the Upper Paleolithic. Meanwhile, the discovery of numerous paleontological sites in the Quercy region (Southwestern France) has revealed the existence of a very varied mammal fauna in the late Pleistocene. Unfortunately, most of these sites could not be dated sufficiently accurately to allow a precise chronological comparison with human occupations.

In 2001 we commenced excavation of a natural accumulation of remains in a pit fall, the Igue du Gral close to the decorated Pech Merle cave, at the heart of a relatively densely populated region. This site is important because of a combination of three elements: rich and well conserved assemblages, a succession of

easily identifiable horizontal deposits and the possibility of obtaining a large number of radiocarbon dates.

The excavation has produced nearly 25,000 taxonomically and anatomically identified objects as well as forty dates spread among the six main levels that correspond to the Last Glacial Maximum and Late Glacial. In contrast with what is seen in the archaeological sites of the second half of the Upper Paleolithic of the eastern margin of Aquitaine, the larger species (bison, horse) are well represented in the pit fall. These are accompanied by reindeer, as expected, but also by a great variety of other taxa including a large amount of hare remains, a species that was apparently not hunted before the second part of the Magdalenian.

The diversity of the fauna thus revealed places the richness of the environment and the often very restricted choice of prey by the late Upper Paleolithic populations in stark contrast.

With the collaboration of: Jean-Philip Brugal, Hubert Camus, François-Xavier Chauvière, Delphine Kuntz, Véronique Laroulandie and Jean-Baptiste Mallye

### **12. THE RABBIT IN EARLY UPPER PALEOLITHIC HUMAN DIETS OF THE IBERIAN MEDITERRANEAN CENTRAL REGION**

*Pérez Ripoll, Manuel (Universitat de València) manuel.perez@uv.es*

*Sanchis Serra, Alfred (Museu de Prehistòria de València) alfred.sanchis@dival.es*

*Real Margalef, Cristina (Universitat de València) cristina.real@uv.es*

*Villaverde Bonilla, Valentín (Universitat de València) valentin.villaverde@uv.es*

The rabbit is a very abundant species in the archaeological sites of the Upper Pleistocene and early Holocene from the Mediterranean area of the Iberian Peninsula. In some general theoretical models, has proposed the intensive use of rabbits from the beginning of the AMH occupation in the Mediterranean Iberia. However, in most Aurignacian sites in this area, there are not concluding taphonomic studies, samples are reduced and in some cases there are conservation problems (Cova de les Malladetes, Cova Beneito, Cova Foradada, Cova de l'Arbreda). As to the Gravettian, the human origin of the samples is defined from the analysis of one site.

The present work aims to conduct a review and a taphonomic study of various rabbit accumulations of the Early Upper Paleolithic of the Iberian Mediterranean area, to determine the moment when the rabbit starts to be a predominant resource in the diets of AMH.

The rabbit assemblages studied come from the Aurignacian and Gravettian levels of Cova de les Malladetes (Barx, Valencia), that belong to the excavations of the 40s (unpublished materials) and 70s (review of Davidson work, 1989) with an area about 13m<sup>2</sup>. The Gravettian samples of Cova de les Cendres come from the study made by Pérez Ripoll in 2004 (2 m<sup>2</sup>) and new excavations (2 m<sup>2</sup>).

The remains have been identified taxonomically and anatomically using reference collections. For quantification it has been used the NISP, MNE, MNI and %R. The age structure has been estimated from degree of joint fusion. A complete taphonomic analysis has been realized: fragmentation, origin of fractures and bone surface modification (anthropogenic, other predators or post-depositional origin).

The Aurignacian samples of Malladetes show two types of accumulations: (1) a majority of non-anthropogenic remains (bones with digestive corrosion) that come mostly from the interior area; and (2) a reduced set of bones of anthropogenic origin (cut marks and fractures), located in the entrance area. The Gravettian samples are very scarce and do not provide crucial information about its origin.

The Gravettian sample of Cendres, as opposed to Malladetes, is very important in number and the remains are mainly of anthropogenic origin (marks, fractures and fire modification).

The Aurignacian anthropogenic samples (Malladetes) are very scarce and it is possibly that they can be related to sporadic human occupations (important role of carnivores). The emergence of rabbit prominently in the AMH diets of the regional Upper Paleolithic is determined from the Gravettian of Cendres but not in Malladetes.

All this results takes us away from a specific model for the Early Upper Paleolithic in this area, and suggest the fact that the role of the rabbit in human diets may vary depending on the features and functionality of human occupations and the settlements localization.

### 13. ZOOARCHAEOLOGY OF A FINAL GRAVETTIAN SITE. EXAMPLE OF THE ABRI PATAUD, LEVEL 2.

The site of abri Pataud (Dordogne, France) is one of the four French sites that provided a well defined Final Gravettian facies (historically named "Protomagdalenian"), around 22,000 years BP. Because of the rarity of evidence of this culture, the abri Pataud is a key site in order to improve our knowledge about human behaviour at the end of the Gravettian period. The Final Gravettian of level 2 of the abri Pataud was first excavated by H. L. Movius in 1958 and 1963, who discovered numerous human remains. Since 2005, a new multidisciplinary research project has been conducted, under the direction of R. Nespoulet and L. Chiotti, in order to re-examine the archaeological context and the status of these human remains, including new excavations (in connection to those of Movius), new studies of Movius' collections and analysis of Movius' archives.

The results have clarified the context of the human remains deposit as the result of funerary practices. The results also allowed us to a better understanding of the modalities of the successive occupations of this level, although the surface of excavation was voluntarily limited.

The level 2 is very rich in archaeological remains especially faunal ones: more than 8 000 bones remains inventoried since 2005.

The Reindeer (*Rangifer tarandus*) is the most numerous species. This species was not only hunted for food but also used for some non-dietary activities, providing raw material (bones, antlers and teeth) for tools, weapons and body ornaments. Then, Reindeer could be considered as the species on which the economy of people who lived at the abri Pataud was mainly founded. But, thanks to the new research project, in particular the study of osseous artefacts and the biogeochemical analyses, we could demonstrate now that the subsistence behaviour was more diversified than this initial point of view. The global study of all faunal remains (butchery wastes and osseous artefacts) for the entire collection allowed us to show that others species had a significant importance for the Final Gravettian people (Mammoth, Bovine, Red deer, Wolf...).

We present here our results of the archaeozoological, biogeochemical and osseous artefacts studies to discuss the place of the different mammals during the Final Gravettian at the abri Pataud and over a larger regional context.

Wojtal, Piotr (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska 17, 31-016 Kraków, Poland) wojtal@isez.pan.krakow.pl

Roblickova, Martina (Anthropos Institute, Moravian Museum, Zelný trh 6, 659 37 Brno, Czech Republic) mroblickova@mzm.cz

Oliva, Martin (Anthropos Institute, Moravian Museum, Zelný trh 6, 659 37 Brno, Czech Republic) moliva@mzm.cz

Dolní Vestonice I site is one of the most significant Pavlovian localities known from southern Moravia. It was excavated for the first time in 1924, by K. Absolon, and later, by B. Klima (Absolon 1945; Klíma 1963). During fieldworks different areas of the site were investigated, from where numerous lithic artefacts, bone products, human remains, and art objects with famous "Dark Venus" were discovered. Human artefacts are accompanied by a vast assemblage of animal bone, which were collected from the whole surface of the site. In the upper part of

the site (excavations carried out in 1924-28 and 1948-50) mammoth bone accumulations and dwellings where five dwelling structures, accompanied with fireplaces and mammoth bone concentrations were described (Klima 2001). Unfortunately the fully taphonomic and zooarchaeologic studies of this materials were newer done. From this site we have only short information about fauna representation is known (Musil 1959). On the basis of the recent studies we can conclude that in the area of dwelling structures remains of different mammals species were found. Bones and teeth of wolf, wolverine, reindeer and woolly mammoth are most numerous. In the contrast to the Pavlov I site the presence of mammoth bones is very high, and other game species like reindeer and hare are much less numerous (Wojtal et al., 2012). At the same time numerous bones of carnivores (especially wolf and wolverine) bear marks of cut marks. On this basis, we can conclude that the carnivores beside mammoth were an important component of the diet of Pavlovian hunters.

**Acknowledgments:** The present studies were partly supported by National Science Center (grant decisions No. DEC-2013/09/D/HS3/04470 awarded to J. Wilczynski).

ORAL

#### 15. THE EQUINES OF FAUSTIN SHELTER (CESSAC, GIRONDE): A TAPHONOMIC AND ZOOARCHEOLOGICAL STUDY OF A LATE GLACIAL SITE IN GIRONDE

Feyfant, Léa (PACEA) lea.feyf@gmail.com

Thanks to the high resolution of archaeological record, paleoenvironmental and chronological data, the Magdalenian society is one of the most documented cultures of the Upper Paleolithic. Through the last fifteen years, several sites of *Entre-deux-mers* (Gironde), in the South-west of France, were the center of zooarchaeological work. In the Paris Basin, horses provided main part of the subsistence of this society, and a new socio-economical organization model based on the concomitant exploitation of the horses and the reindeers was proposed. In this communication we attempt to compare our data through a zooarchaeological study of a new late Magdalenian site with this model.

Faustin shelter is a Late Magdalenian site in Gironde with an abundance of horses in the faunal assemblage. Lithic and bone industries (*pointes à crans*, *pointes de Laugerie-Basse*, Magdalenians harpoons) and new C14 datings provided a good setting chrono-cultural. This site also

yields engraved bones and particularly a female figure on a horse bone.

The taphonomic and zooarchaeological study of the faunal assemblage aims to understand the hunting processes, the carcass transport strategies and the butchery processes employed by hunter-gatherers on horse.

This work, carry out by the Magdatis project, focuses primarily on horse remains. The methods that were used are conventional in zooarchaeology: age determination, quantification of skeletal elements and observation and quantification of natural and anthropogenic marks. These analyses provided relevant information on seasonality, prey choices and hunting strategies.

The bone assemblage (NISP = 1393) is well preserved with numerous bone refits. This allows a good identification of butchery processes. All skeletal elements of the horses are represented. It indicates that whole carcasses of the horses were transported from the kill site to the base camp. Moreover, all the 'chaîne opératoire' of butchery is documented (from skinning to the percussion of bones to extract grease and marrow). The analyses of mortality curves show that horses were hunted throughout the year and family groups are preferentially hunted.

Preferential hunting on family groups does not preclude opportunist hunting of isolated horses or on single groups. These variations may be related to the seasonal horses' behavior. The optimal exploitation and the transport of whole carcasses are raising the question about the number of horses hunted per hunting events. Like in all base camps of south of France, the carcass exploitation is optimal with extraction of grease and marrow on all long bones. Moreover, we assume a predetermination in the fracture of metacarpal or radius in order to make needle or punch. On the account of the geographic and the topographic position of the site, results are compatible with a hypothesis about a deliberated choice of Magdalenian for horse hunting.

We conclude that Magdalenian in Gironde could have employed similar hunting and socio-economic strategies than the ones described in the Paris Basin: hunting throughout the year focused on family groups and proximity between kill site and base camp and the optimal exploitation.

*Rufí, Isaac (Universitat de Girona) u1901889@campus.udg.edu*

*Ventura, Helena (Universitat de Girona) u1904732@correu.udg.edu*

The Cau del Roure is a small cavity, with a vertical access, which is part of the Reclau Caves (Serinyà, Girona, NE Iberian Peninsula). Excavation work performed in 1972 permitted to know the site. Recently, the archaeological excavation started again with the intention to better study the human occupation during the Paleolithic at the site.

The archaeostratigraphy indicates that below a Chalcolithic level with human burials, which was totally excavated by early excavations, there is a sedimentary package belonging to the Upper Paleolithic age, according to the C14 dates. This package, about 1.40 m thick, is homogeneous from a sedimentary point of view. It contains materials of diverse nature. Continental mollusks and rabbit remains are abundant, as well as the remains of microvertebrates. Conversely, the remains of large mammal are not very abundant, but different taxa were identified: *Equus ferus*, *Cervus elaphus*, *Sus scrofa*, *Canis lupus*, *Vulpes vulpes* and Felidae. The elements of material culture are very rare; however we can highlight some elements of ornamentation - perforated marine gastropods. In addition, the anthropic presence is proven by various human skeletal fragments.

While the recent excavation is still modest and therefore the results are preliminary, the archaeozoological study is resulting to be a key to interpret the origin of the material and the functionality of the site during the Upper Paleolithic. Taxonomic richness and relative

diversity or abundance of each taxon are raising various possible scenarios, but the comprehensive study of the bone assemblage is permitting to attribute the origin of the accumulation of large mammals to the most likely agent.

### 17. THE FEARLESS ICE AGE BEAST KILLERS. THE GRAVETTIAN HUNTERS IN CENTRAL EUROPE

*Wojtal, Piotr (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska ) wojtal@isez.pan.krakow.pl*

*Wilczynski, Jaroslaw (Institute of Systematics and Evolution of Animals, Polish Academy of Sciences, Slawkowska ) jaslov@wp.pl*

The Gravettian culture emerged about thirty thousand years ago and during the next millennia spread across much of Europe. The most distinctive features of individual stages in the development of the cultures of the Gravettian technocomplex include the presence of characteristic stone tools (backed bladelets and shouldered points) and figurative art, such as zoomorphic and anthropomorphic objects. In South Moravia (Czech Republic) the Gravettian is documented by an exceptional complex system of early sites, dated to about 27-25,000 BP. They are located at the foot of the Pavlovské Hills and include such large and well known open-air long-term camp sites as Pavlov I, Dolní Vestonice I, and Dolní Vestonice II. In Poland, Slovakia and the Czech Republic the later phase of the Gravettian is documented by the presence of sites dated to about 24 – 20 ka BP.

On the evidence from the Gravettian sites of the older phase – Pavlov I and VI, Dolní Vestonice I and II (Czech Republic) - the hunters had a varied diet as documented by the presence in the osteological material of several animal species, mostly small (birds, hare, fox) and medium animals (wolf, reindeer, wolverine), but also with a smaller percentage of large mammals (bear, cave lion, horse and mammoth). All taxa are represented by more or less equal proportions, showing that the prey spectrum of hunters was wide. Osteological material recovered from sites of the younger phase of the Gravettian – Kraków Spadzista Street, Jaksice II (Poland), Moravany Lopata II (Slovakia) and Milovice I (Czech Republic) is visibly dominated by woolly mammoth and reindeer. This suggests specialisation in mammoth or reindeer hunting.

Thus it seems obvious that reindeer, woolly mammoth, horse and hare were very significant taxa in the everyday life of the Gravettian people. They provided both meat and raw materials. All parts of the body were used – the hide, the marrow, meat, bone, teeth, tusk and antler – a source of food and material in the manufacture of tools, personal ornaments and art.

Many older and younger Gravettian sites of Central Europe have yielded the remains of bears (brown bear and cave bear) and cave lions. This shows that during this age hunting large and dangerous carnivores was not accidental but intentional.

A striking feature of older sites in South Moravia is the presence of a large amount of carnivore and bird remains belonging to dozens, and sometimes, even hundred individuals (wolf, tetraonid, raven and fox, respectively). Birds were certainly a source of food but feathers also could have been an important raw material. Carnivores – two species of fox, the wolf, and the wolverine – were mainly the source of hides and raw material for the production of tools and ornaments. Probably, the meat of these carnivores was also consumed by the Gravettian hunters.

Our studies show that the Gravettian people were efficient and skilful hunters, not afraid to confront the larger and more dangerous representatives of the Pleistocene fauna. What is more, they knew how to utilise the resources of the environment in which they lived.

### 18. SELECTING, STORING AND SHARING FAUNAL RESOURCES IN THE EARLY EPIPALAEOLITHIC: A CASE STUDY FROM EASTERN JORDAN

*Allentuck, Adam (University College London) a.allentuck@ucl.ac.uk*

*Martin, Louise (University College London) louise.martin@ucl.ac.uk*

Ongoing zooarchaeological investigations of Early Epipalaeolithic deposits at Kharaneh IV in the eastern steppe of Jordan provide a rare opportunity to examine

intra-site spatial manifestations of repeated seasonal occupations. At Kharaneh IV dense accumulations of faunal remains have been excavated from hearths, middens, caches and some of the earliest and best preserved hut structures in the Near East. The combination of a high density of faunal deposits and a constrained series of radiometric dates indicates that Kharaneh IV was intensively and repeatedly occupied by large groups of people over a maximum span of twelve hundred years.

Patterned spatial distributions of faunal remains from floor and superstructure deposits from a well-preserved and systematically excavated hut structure are examined in terms of frequency and density data from taphonomic, taxonomic, anatomical, butchery, and combustion variables.

The question of how large human groups organized their food preparation activities within circumscribed spaces is of particular relevance. In this presentation, we examine architectural boundaries and contextually variable patterns of zooarchaeological remains as a means of discerning differential uses of space.

The case of Kharaneh IV indicates that Early Epipalaeolithic foragers in eastern Jordan performed different domestic tasks in spatially circumscribed locations within their dwellings. This work suggests that early seasonal sedentism entailed highly organized and innovative strategies of procuring, preparing, storing and sharing faunal resources.

### **19. THE RIGHT ITEMS FOR A NEW MENU: ENVIRONMENTAL CONSTRAINTS AND CULTURAL CHOICES IN HUNTER-GATHERER SUBSISTENCE DURING THE LATE UPPER PALAEOOLITHIC AND MESOLITHIC IN THE BALKAN PENINSULA**

*Lopicic, Milica (University of Belgrade, Faculty of Philosophy)  
milica.lopicic@f.bg.ac.rs*

Nutritional stress which provoked the inclusion of low-ranked food items in the diet of Late Upper Palaeolithic and Mesolithic communities has been observed in a number of regions. Several sites in the Balkan Peninsula exhibit the same trend, although its manifestations differed regarding chronology and environmental characteristics. The uneven timing of the shift in

subsistence was explained by a difference in the extent of the modification of the coastal geography caused by the sea-level rise, but an encompassing research is lacking. Research was done to investigate the change in the meat diet breadth as related to a number of environmental factors as well as human decisions. They include 1) territorial diminution during the Late Pleistocene and Early Holocene in coastal areas, 2) geographical position of sites, 3) site function, and 4) socio-cultural preferences.

Faunal assemblages originating from the Late Upper Palaeolithic and Mesolithic period, c. 18000-6000 cal BC were characterized by the abundance of animal taxa, their percentage and the index of diversity (Inverse of Simpson's index) based on NISP values. The analysis was done separately for large and small animals in order to determine the human behaviour regarding prey choice of high-cost and low-cost resources. The assemblages had been ascribed to several categories following chronological and environmental criteria, along with attribution of site functions and social groups based on the analyses of lithic artifacts. Their comparison enabled us to observe the interplay of diverse factors.

The general trend in broadening the spectrum of hunted species is present regarding the total of the assemblages from the Balkan Peninsula. Variations in the diet breadth are observed on regional level, as well as between sites presenting diverse geographical characteristics and human activities, although the differences in the index of diversity were not statistically significant in all situations.

### **20. THE ORIGIN OF BONE ACCUMULATIONS AND ITS CONTINUITY IN THE STRATIGRAPHIC SEQUENCE AT CUEVA DEL ANGEL (LUCENA, CORDOBA).**

*García-Solano, José (University of Granada) jgsolano@outlook.com*

*Moigne, Anne Marie (Centre Européen de Recherches Préhistoriques de Tautavel) moigne@tautavel.univ-perp.fr*

*Celiberti, Vincenzo (Centre Européen de Recherches Préhistoriques de Tautavel) celiberti@cerptautavel.com*

*Barroso, Cecilio (Foundation Institute for Research in Human Evolution and Prehistory) barroso.cecilio@gmail.com*

Cueva del Angel's stratigraphic sequence, which is about 5 m deep, has a large amount of faunal remains and lithic

artifacts in each level. There is a clear continuity of the fossil record along the entire sequence without any archaeological and paleontological record gaps during the filling process. Zooarchaeological and taphonomic analysis of the fossil record has revealed that the origin of the accumulation has a marked anthropogenic character.

Carnivores frequency within the fossil assemblage of each level is very low and there is also an extremely low damage in all the remains analyzed. However, anatomical representation and the strong presence of human-induced changes (thermal alterations, intentional breaking, cut marks) especially faunal spectrum (including carnivores) indicate that the single accumulating agent at each level was likely human. This repeated anthropogenic pattern at all stratigraphic levels suggests a human recursive occupation of the site without any registered alternations of occupation by carnivores.

ORAL

**21.A NEW OVERVIEW OF THE POITOU-CHARENTES AREA DURING LATE MIDDLE PALEOLITHIC: HUMAN SETTLEMENT DYNAMICS AND UNGULATES HANDLING.**

*Voeltzel, Bénédicte. INRAP. benedicte.voeltzel@inrap.fr*

"Population dynamics and settlements in the "Seuil du Poitou" area in France during the Middle Palaeolithic (300 000/40 000)", is a Research Program directed by Sylvain Soriano (CNRS) from 2009 to 2012. It was initiated by the drastic lack of recent data and valuable chronological frames for Late Middle Paleolithic studies in Central-western France. The area between Poitiers and Angers appears as a "no man's land" during the Mousterian period, except for the site of Roc-en-Pail (Maine-et-Loire) which did not draw any attention since Dr Gruet's last excavation in 1970. The Poitou-Charentes region (northward the Charente river) has many archeological sites of great interest so it is suggested that, due to the geographical interface between human settlements in the North and in the South-west, a complete review and update of archeological data is necessary. It is proposed that archeological collections, including faunal and lithic artefacts, as well as sites, require further investigations.

The zooarcheological research we have undertaken so far concerns faunal assemblages collected at l'Ermitage

(Vienne) and Hauteroche (Charente,) where the last excavation was carried out by A. Debenath in 1974. Exploitation of the heuristic potential of existing collections, made possible by accurate stratigraphies and previous high standard field work on both those sites, will develop knowledge of Neandertal groups' behaviors, economic choices, mobility and settlement patterns on a seasonal basis. Preliminary results already suggest patterns using reindeer toothwear analysis. Understanding ungulates herd structures and death curves for reindeer was made possible according to toothwear degrees and osteological measurements.

Both at Hauteroche and l'Ermitage, hunting and butchering strategies as well as meat consumption appear similar for large size game such as Horse and Bovids, but different for middle-size game such as reindeer. These results appear quite similar to those delivered on the nearby site of Jonzac (Charente-Maritime). Hauteroche also reveals varying butchering strategies, depending on cultural levels - Quina and Denticulate - and type and duration of sites occupation? Seasonality has been clearly identified : although covering a large temporal span, occupations took place limited either to summer or winter season. Links between faunal spectrae and species associations also deliver information on IOS 3 climate and paleoenvironmental context.

New excavations and datings to come at Hauteroche and Roc-en-Pail will provide components for a better understanding of the previous findings and their archaeological context. They will also add to the results obtained at neighbouring sites like Marillac-le-Franc-Les Pradelles and Jonzac, in order to try to decipher the functions of those sites.

SESIÓN B33 (en el último lugar de todo, al final de los posters, es decir, nº3. Ya está incluido en el programa, sólo hace falta meter el texto del resumen en el libro, que es lo que te mando)

The El Kowm Region is well known for its archaeological record over the whole Pleistocene period. Since more than 20 years a research team from the University of Basel under the directorate of Jean-Marie Le Tensorer excavates different sites in the El Kowm region. In two of these sites several layers were found bearing an archaeological and faunal material which most probably dates back to the Early Pleistocene.

In order to proof the age of this layers and to get a

more detailed view on the paleomagnetism of the stratigraphy in 2009 Juan José Villalain from the „Grupo de Paleomagnetismo de la Universidad de Burgos“ carried out an extensive sampling in the sites of Hummal and Ain al Fil.

This poster presents the first results of the analysis of these samples and their implications for the dating of the oldest archaeological sites in Syria..

POSTER

**22. BROKEN TO SPLINTERS. ROCA SAN MIGUEL (ARÉN, HUESCA) AND THE GAME MANAGEMENT IN A NEW OPEN-AIR MOUSTERIAN SITE.**

*Domingo Martínez, Rafael (Universidad Zaragoza) rdomingo@unizar.es*

*Montes Ramírez, Lourdes (Universidad Zaragoza) lmontes@unizar.es*

*Sola Almagro, Cristina (Universidad Zaragoza) csola@unizar.es*

Roca San Miguel is an open-air site recently found next to the right margin of the river Noguera Ribagorzana, in a small hill that controls the transit along the valley. Our first researches in 2013 have shown a common Mousterian industry based on the exploitation of some small nodules of flint and larger non-siliceous rocks (quartzite-type, basalts...) that can be found locally. The tools include the usual sidescrapers and denticulates as well as some points, with centripetal *débitage*.

We have detected a striking management of the faunal remains, which appear reduced to small splinters in various states of combustion (non-cremated, burnt and even calcined). These amounts of burnt bones may reflect their employment as fuel after their consumption for food purposes. A taphonomical analysis is being applied in order to explain the faunal exploitation patterns. That behaviour adds a difficulty to the identification of the bones, but we have been able to detect the presence of large herbivores and, thanks of the integrity of some teeth, horses in particular.

This site is in the heart of one of the main areas for the study of the Middle Palaeolithic in Spain, the Cinca-Segre and its tributaries. These rivers occupy a wide territory in the northeastern Ebro basin, in a crooked landscape that articulates through them. Up to ten Mousterian sites have been extensively excavated in the last years:

between them, Fuente del Trucho, Moros de Gabasa, Cova Gran or Roca dels Bous are well-known settlements that have yielded an enormous amount of information about the economics and the social behaviour of Neanderthal people. The infrequent finding of open-air sites makes us hope that Roca San Miguel will contribute to our knowledge of this period with new accurate data that will allow sketching a wider perspective of the Neanderthal people's activities.

POSTER

**23. MOUSTERIAN LEVELS OF EL CASTILLO CAVE (PUENTE VIESGO, CANTABRIA, SPAIN): AN ARCHAEOZOOLOGICAL STUDY**

*Luret, Mathieu (Section of Earth and Environmental Sciences, Forel Institute, Laboratory of Prehistoric Archaeology and Anthropology, University of Geneva, 18 Acacias, CH 1211 Geneva 4) matluret@msn.com*

*Burke, Ariane (Université de Montréal, Département d'Anthropologie, C.P. 6128, succursale Centre-Ville, Montréal, QC, Canada H3C 3J7) a.burke@umontreal.ca*

*Bernaldo De Quiros, Federico (Area de Prehistoria, Universidad de Leon, Campus de Vegazana, 26071 Leon, Spain) f.bquiros@unileon.es*

*Besse, Marie (Section of Earth and Environmental Sciences, Forel Institute, Laboratory of Prehistoric Archaeology and Anthropology, University of Geneva, 18 Acacias, CH 1211 Geneva 4) marie.besse@unige.ch*

El Castillo cave is of particular significance because human occupation of the cave spans the Middle to Upper Palaeolithic transition. Here, we present the our analysis of faunal remains attributed to the Mousterian occupation of the cave, which includes level 21, dated to 69300 ±9100 BP (average date, Rink and *al.*, 1997), and level 20, dated to 43300 ±3800 BP (GifA92506). This research was carried out in the context of our thesis project, *Paleo-environment and subsistence behaviours of the last Neanderthals and early modern humans: taphonomic fauna study of El Castillo cave (Spain)*.

The faunal remains under analysis were recovered during excavations conducted by Cabrera Valdès and Federico Bernaldo de Quiros between 1980-2004. The faunal assemblage from levels 20 and 21. A total of 6495 bones were identifiable, including N=2419 bones for level 21 and N=4076 bones for level 20. A quantitative analysis of the material was conducted in order to evaluate the role of differential conservation and transport on the proportional representation of anatomical elements.

This was followed by a taphonomic analysis; each bone fragment was subjected to a thorough macroscopic examination with the aid of a 20X magnifier hand lens and all non-anthropogenic and anthropogenic traces were catalogued. The location and morphology of the anthropogenic traces (cut-marks, percussion marks) was inventoried in order to assess the exploitation patterns of the carcasses. Bones recovered from sieve residues were classified by type of tissue (compact, spongy, rib) and by class size (0-20mm, 20-30mm, ...) and traces of burning were quantified.

Red deer (*C. elaphus*) is the dominant species in levels 20 and 21, followed by large Bovidae, horse, chamois, roe deer and rhinoceros. Carnivores are poorly represented with 9 bones remains.

The state of conservation of the bones is poor and most of the remains are highly fragmented, with the exception of podial elements. This may reflect intentional bone breakage by humans in order to exploit the marrow of long bones. The presence of impacts on shaft fragments and breakage patterns of first and second phalanges confirms this hypothesis. The absence of taphonomic traces attributable to carnivores (and the small number of carnivore remains) suggests that neither level results from carnivore activities. Skeletal part representation for deer, horse, and large Bovidae indicate that the axial skeleton is less well represented than the limbs and teeth, which occur in higher frequencies. A comparison between levels 20 and 21 revealed no significant differences in patterning.

Preliminary results indicate that the two Mousterian occupations at El Castillo cave share similar patterns of faunal exploitation. Red deer is the dominant species in both levels and bone was transported to the cave for butchering and consumption. Although butchering marks are rare, human bone-breakage is present in both levels. Future analyses will explore whether these levels are characterised by the exploitation of anatomical parts with low nutritive yields, a potential indicator of nutritive stress. The analysis of the Aurignacien occupation (level 18), which is underway, will allow us to compare the subsistence behaviours of Neanderthals and modern humans.

# B36 Analysis of the economic foundations supporting the social supremacy of the Beaker groups

## 1. GRAVES OF METALLURGISTS IN MORAVIAN BEAKER CULTURES

*Jaroslav, Peska (Archaeological Centre Olomouc, Czech Republic) peska@ac-olomouc.cz*

Despite advanced skills of the Beaker people as regards metalworking and metallurgy of all available metals (copper, gold, silver, electrum) in the 3<sup>rd</sup> millennia BC, archaeological contexts yielded only little exact evidence of these technological processes. Technological equipment is lacking and individual components of metalworking tools are most often found as parts of prestigious artefacts of grave goods in forms of symbolic packages in clearly defined deposits. It is significant that they were fixed to rich male burials (even cenotaphs!), often at a leading position within the burial ground. They were found on the vast territory between England (Amersbury) and the Carpathian Basin and they significantly accumulated on the territory of the Czech Republic, particularly in Moravia. Together with other attributes, they strengthened and emphasized the social level, position, power and identity of their owners. At the same time, they could reflect the ritualised control over important technologies through the high position within the hierarchising society, leading – in the case of the early Bell Beaker Culture – to the creation of regional élites.

Evidence of metal casting is minimum (Ludé ov - mould, Szigentszentmiklós - nozzle). The number of documented metalworking tools is higher (hammers and anvils) in Moravian Corded Ware pottery (Nechvalín, T šetice, Velešovice) as well as in the Bell Beaker Culture (Turovice, Holešov, Maršovice-Jezelany, etc. – total of about 17 graves), which is even more numerous. New microscopic analyses (using scanning electron microscope) have brought further evidence confirming the function and practical use of these tools (high presence of gold, silver and copper) prior to their deposition in graves. Examples thereof are new burial grounds in Central Moravia Hulín 1, Hulín-Pravice 2 and Opatovice). Similar analyses of a number of other tools will have to be performed. In addition, it would be interesting to conduct a multi-elementary chemical analysis of metal content in bones (teeth) of the buried metallurgists with an attempt to determine health impact in connection with their assumed regular contact and work with metals.

ORAL

## 2. BELL BEAKER HORIZON IN THE LOWER EBRO VALLEY: CULTURAL SUBSTRATE AND EXCHANGE ELEMENTS.

*Ríos Mendoza, Patricia (Universidad Autónoma de Barcelona) patricia.rios@uab.cat*

*Piera, Marc (Universidad Autónoma de Barcelona) piera-tex@hotmail.com*

*Gómez Bach, Anna (Universidad Autónoma de Barcelona) anna.gomez@uab.cat*

*Molist Montaña, Miquel (Universidad Autónoma de Barcelona) miquel.molist@uab.cat*

The Ebro valley is an important space for the development of the first settlements of farmers, over Recent Prehistory. The backbone is undoubtedly the river itself that acts as a route of communication and movement of goods and products that unite a broad and complex territory.

The Ebro valley is elected by different societies, between the third and second millennium cal BC. Through various economic and spatial strategies, these groups structure a complex pattern of settlement that today is still under study and understanding.

Traditionally in this area is considered that after a first phase, represented by international and /or corded Bell Beakers, a more recent stage represented by the regional style of Salomó is developed.

In this communication we aim to provide a critical review of Bell Beaker in the Lower Ebro valley from updated documentation, and focusing mainly the presence of elements that appear in the record as a reflection of the inclusion of this valley in exchange networks present in the rest of the Iberian Peninsula. Among these elements that must circulate within the territory are metal weapons -mainly daggers, and v perforated buttons to which should add some raw materials.

Access to these objects and surely control of exchange routes seems must have been key to the emergence of bell beaker elites of the region, which are well represented in known burial caves.

ORAL

### **3. EL PEÑÓN DE LA ZORRA (VILLENA, ALICANTE, SPAIN): CHANGE AND CONTINUITY IN SETTLEMENT PATTERN AND BURIAL PRACTICES DURING BELL BEAKER CULTURE**

*García Atiénzar, Gabriel (Universidad de Alicante) g.garcia@ua.es*

In this paper we will discuss the results of the recent excavations in the archaeological site of the Peñón de la Zorra, and the revision of the burial caves associated with this settlement. On the basis of this work we will propose a reinterpretation of the transition between the Chalcolithic and Bronze Age in the Alto Vinalopó region. Traditionally, this site had been interpreted as the first evidence of a fortified settlement in high areas. This change in the settlement pattern was linked to the first evidence of individual burials associated with small caves opened at the same elevation. However, archaeological surveys undertaken in 2011 allow us to propose a reinterpretation of the historical process developed between 2400 and 1700 cal BC in the north of the province of Alicante.

Several proposals will be made. Firstly, we would like to argue that plain settlements and settlements in height were occupied at the same time, although the first ones seem to have been abandoned earlier. Secondly, the settlements are not uniform, for, as seen at the Peñón de la Zorra, in this settlement a singular space was built next to a defensive building type tower, associated with a lot of bell-beaker pottery. This feature is not found in other similar high sites.

Furthermore, we have been able to demonstrate a long-term use of at least some settlements like the Peñón de la Zorra, for in it there is a clear stratigraphic continuity from Bell-Beaker to Bronze Age structures. The site continued to be occupied at least until 1700 cal BC, a date close in time to the abandonment of the high sites and the emergence of large settlements such as Cabezo Redondo.

Finally, the radiocarbon analysis of human remains found in burial caves in the area show the continuation of this ritual practice during the Bronze Age. We see this as an evidence of the origin of this type of funeral - burial caves are associated with settlements - in the Bell-Beaker period.

In sum, on the basis of our recent work in Chalcolithic and Bronze Age sites in the Alto Vinalopó region we argue

that many of the characteristic features of the Bronze Age originated during the Beaker period. Furthermore, this process of change was not simultaneous in the whole area, for we can see changes occurring earlier in the south than in the north extremes of the region. Similar transformations are apparent to the south of the River Segura at the beginning of the third millennium cal BC, but transformations only take place to the north of this border around 2600 cal BC and finally appear in the Alto Vinalopó around 2400 cal BC. In this sense, it can be argued that the intensification of contacts of these territories with the cultural group of Millares, at first, and later with the Argar Culture was one of the basis for the changes observed in the communities located in River Vinalopó.

ORAL

### **4. EVIDENCE OF INTERACTION BETWEEN BRITISH BEAKERS AND CIEMPOZUELOS GROUPS: THE CASE OF GOLD ORNAMENTS.**

*Delibes de Castro, Germán (Universidad de Valladolid) delibes@fyl.uva.es*

In this paper, we will examine some prestige items found in Beaker graves from Central Iberia that illustrate contacts with the British Isles. More specifically, we will focus our attention on gold ornaments. Although they are not unusual in the Ciempozuelos tombs, their designs are very simple: beads or small plaques, and less frequently diadems. The discovery of a pair of basket-shaped earrings at a non-megalithic mound in the province of Burgos (Spain), where they occur in association to Ciempozuelos pottery, is therefore quite exceptional. We find parallels for these ornaments in the Atlantic regions, mainly in Britain, where most of the finds are associated to adult male burials. They were a sign of high status, as the gold discs were in Ireland. The pieces from Burgos suggest the existence of long-distance exchange networks that connected the British Isles and Iberia.

ORAL

### **5. LA PANOPLIA SÍMBOLO DE SUPREMACÍA DE LAS ÉLITES CAMPANIFORMES**

*Blasco Bosqued, Concepcion (UAM) concepcion.blasco@uam.es*

Entre los elementos que integran el *package* campaniforme destaca la panoplia, sin duda mucho más escasa que la vajilla cerámica, en especial en su versión más completa. Entre los campaniformes peninsulares dicha panoplia está compuesta por una o varias puntas palmelas, el puñal de lengüeta y el brazal de arquero, todas las armas ofensivas funerarias están elaboradas en cobre y, de manera general, se asocian a varones de edades muy distintas.

Si bien es cierto que se ha enfatizado en que la presencia de armas en los ajuares de los líderes más destacados se justifica como instrumento y símbolo de sumisión, sin embargo, no podemos ignorar una segunda vertiente que destacamos en el trabajo: el hecho de ser, además, los primeros objetos de la Prehistoria ibérica en los que, de manera normalizada, se amortiza el metal, una materia prima todavía en estos momentos, al alcance de muy pocos, aunque hay que reconocer que la cantidad de metal utilizado en la confección de una de estas panoplias rara vez supera los 100 grs. teniendo en cuenta que el peso tanto de las puntas, como los puñales, no suele superar los 30 grs.

Teniendo en cuenta el papel desempeñado por la confección de las armas en el desarrollo de la metalurgia inicial, nuestro trabajo pone el acento, sobre todo, en que por primera vez hemos podido contrastar que a la tradicional panoplia de los campaniformes ibéricos, al menos en el Valle del Tajo Medio, se suma un elemento más: la albarda, lo que supone un considerable salto cuantitativo y cualitativo de la importancia de las armas entre las élites campaniformes, tanto por la complejidad tecnológica y las novedades funcionales que incorpora, como por la visualización que ofrece esta arma de tamaño considerablemente superior al de los puñales y, sobre todo por la cantidad de metal que se amortiza en ella, a lo que se suma un segundo avance: el haber obtenido una datación que supone subir, de manera considerable, la cronología de estas armas complejas en el panorama de la metalurgia ibérica a la par que de aumenta el grado exaltación de los líderes campaniformes mediante símbolos más visibles y costosos.

El trabajo ofrece como novedades más destacadas tres conclusiones:

a) Haber obtenido una primera contextualización funeraria de una albarda de tipo atlántico, hasta ahora aparecidas en depósitos o hallazgos aislados.

b) Contrastar que la metalurgia campaniforme es más compleja y antigua de lo que se conocía.

c) Haber obtenido una datación que supone subir, de manera considerable, la cronología de estas armas complejas en el panorama de la metalurgia ibérica.

ORAL

## 6. INDICATIVE OF PRESTIGE AND BELL-BEAKER IN VALENCINA DE LA CONCEPCIÓN (SEVILLA).

*López-Aldana, Pedro M. (Departamento de Prehistoria y Arqueología, Universidad de Sevilla) [aldanap@supercable.es](mailto:aldanap@supercable.es)  
Pajuelo Pando, Ana (Departamento de Prehistoria y Arqueología, Universidad de Sevilla) [anpando@supercable.es](mailto:anpando@supercable.es)*

The settlement of the third millennium a.n.e. Valencina de la Concepción possesses dimensions that exceed 400 ha. , and since the nineteenth century have been making countless archaeological excavations increased in number from the 80s of last century. However, the bell-ceramic waste form appeared very often limited to isolated findings. In recent years, some archaeological work conducted under the administrative form of "preventive excavations" have provided a remarkable volume of this type of ceramic products that enrich the scientific knowledge of this phenomenon in the peninsular sw.

The findings come from both residential and funerary contexts, in some cases, associated with metallic elements copper and gold. In this sense we performed various analyzes to ceramic pastes and metal elements that point, a priori, to local production and manufacturing.

Therefore, the association bell-beaker and metallurgy indicates consolidation of a social elite that sinks its emergence in the transition from IV-III millennium BC that control the production, distribution and exchange.

ORAL

## 7. EXCHANGE NETWORKS OF PRESTIGE GOODS AND BELL BEAKER TOMBS IN CENTRAL IBERIA

*Liesau von Lettow-Vorbeck, Corina (Universidad Autónoma de Madrid) [corina.liesau@uam.es](mailto:corina.liesau@uam.es)*

Throughout the latter years, new lines of research on Bell Beaker grave goods have broaden our knowledge of the burial practices in this horizon. The traditional typological and stylistic approach to the study of pottery

and copper artefacts has given way to an archaeometric approach in them, which also has become essential in order to determine the origin of other raw materials used to elaborate some of the objects accompanying the Beaker *package* itself.

By applying different non-destructive methods (FTIR, IRMS,  $\mu$ -CT), bone ornaments, such as V-perforated buttons recovered from Bell Beaker graves have been studied to determine the origin and characteristics of their raw materials. Likewise we have analyzed (DRX) some red pigments scattered over skeletal remains or on some grave goods.

The combination of different methods has led to identify several raw materials used to elaborate some of these ornaments. The key question is, if the origin of these raw materials has a local origin or reveals long distance interactions, as the results do not exclude any of both possibilities. In a similar manner, the use of red pigments in some of the burials also implies an intentional selection of certain minerals with a high symbolic meaning.

The identification of the raw materials employed for several ornaments in some Bell Beaker tombs allows us to emphasize the exclusivity of V-perforated buttons and other ornaments made of different types of so-called *ivories*. These items, in combination with other artefacts and the use of cinnabar reinforce the elitist character of several Beaker tombs and the existence of relatively standardized burial practices in Madrid region.

---

ORAL

## 8. THE ROLE OF FLINT ARROWHEADS IN BELL BEAKER GROUPS OF THE CENTRAL IBERIAN PENINSULA.

*Ríos Mendoza, Patricia (Universidad Autónoma de Barcelona) patricia.rios@uab.cat*

Among the objects of Bell Beaker package, arrowheads have been traditionally interpreted as part of archer equipment together with wristguards. But rarely their role in beaker exchange networks has been assessed. Arrowheads exchange occurred? Were they circulated as finished pieces or as raw materials? Was there control over the raw material, or the production or distribution? The frequent association of flint arrowheads and the metal weapons raises another question that researchers have been asking: Are these grave goods reflecting warriors or hunters? More recent interpretations have been about an idealized identity of warriors, especially

male. In this sense, weapons and appearance of warrior should play a central role among beakers.

Trying to approach these issues, in this paper we analyze data from various sites in the center of the Iberian Peninsula, where the record documented in recent years could shed light on the matter. The presence of Beaker cemeteries with a total absence of any type of weapons and arrowheads compared to other cemeteries where it does appear, could be talking about Beaker groups with different status or prestige symbols? Does this presence answer to a true reflection of beaker hunters or warriors? Or is it the reflection of the access and control of exchange networks of these objects? And what is even more interesting in this regard: can be related documentation of specialized areas in the production of arrowheads on these sites with Beaker burials with the monopoly of its production and distribution to Beaker elites? Was there an increased of arrowheads production in Beaker time to satisfy the demand of the exchange networks?

This latter issue allows us to raise the question of the true value that these "prestige items" had for beaker elites, allowing them distinguishable from the rest of society.

---

ORAL

## 9. SALT AND BEAKERS IN THE COPPER AGE.

*Guerra Doce, Elisa (Universidad de Valladolid) elisa.guerra@uva.es*

Salt was a commodity of great importance in prehistoric times. Apart from its use as a condiment and as a dietary supplement for livestock, it played a very important role in the preservation of foodstuffs and in a range of industries (leather tanning, cloth dyeing, among others). However, it is only in the last decade that salt has emerged as an important issue in European prehistory. An increasing number of sites confirm that salt was intensively exploited in prehistoric Europe from the Neolithic onwards. The excavations carried out at the Beaker salt-processing factory of Molino Sanchón II, in the natural reserve of Las Lagunas de Villafáfila (Zamora, Spain) confirm that Ciempozuelos elites in Central Iberia obtained salt through the method of boiling brine. Other sites in this geographical setting also suggest the importance of salt among Beaker groups. The aim of this paper is to examine the role of salt in the Beaker exchange networks.

### 1. NATURALISTIC FRACTURE MECHANICS: TECHNOLOGY, SKILL, AND DEBITAGE MORPHOLOGY

*Stout, Dietrich (Emory University) [dwstout@emory.edu](mailto:dwstout@emory.edu)*

Controlled fracture experiments have identified causal relations between platform variables (thickness, breadth, angle) and the size and shape of flakes produced. Whether they are explicitly aware of them or not, knappers must work with these underlying relations to achieve technological goals. Study of platform variables thus offers a potential window on prehistoric knapping choices and skills. However, in contrast to controlled experiments, actual knapping takes place under highly variable natural conditions. It is not well known how additional factors such as percussive technique, reduction strategy and stage, platform shape and preparation, differential fragmentation, and/or knapper skill might interact with platform size and angle to produce observed flake morphologies.

To address these questions in the case of bifacial reduction, we conducted naturalistic knapping experiments in which each blow was recorded (percussor, posture, marginal/non-marginal percussion, core face, preparation) and directly associated with the piece(s) detached. We then collected detailed morphological data (weight, dimensions, cross-sections, partial volumes) for all whole flakes using scales, calipers, 2D image analysis of digital photos, and 3D laser scans. Finally, these experimental samples were compared to debitage from the early Middle Pleistocene site of Boxgrove, UK.

Preliminary results confirm that known platform-mass relations are robust across changes in other variables, but suggest that the relative distribution of volume (i.e. flake shape) is more labile to manipulation in multiple ways.

Understanding the sources of variation in flake shape under naturalistic knapping conditions has more important implications for assessing utility and economization during tool production as well as for identifying the expression and cultural transmission of technological skill and understanding.

*Phillipps, Rebecca (University of Auckland)*

*[rphi025@aucklanduni.ac.nz](mailto:rphi025@aucklanduni.ac.nz)*

*Wendrich, Willeke (UCLA) [wendrich@humnet.ucla.edu](mailto:wendrich@humnet.ucla.edu)*

Stone artefacts dating from the period 10 000 BP through 6 000 BP are abundant in the Fayum, Egypt. In this paper we report new analyses that show changes in the way raw materials of different forms were made, used and discarded during this period.

Attributes for analysis were selected based on the results of controlled flake formation experiments. These were applied to stone artefact assemblages numbering in the thousands of items recently recorded from locations in the Fayum and associated with dated hearths.

By understanding the fundamental processes of flake formation based on the results of controlled experiments we are able to develop a firm basis from which to make inferences about the utilization of stone artefacts at a landscape scale in the Fayum. We are able to show changes in the way raw material was acquired and flaked over this period as well as changes in the way the products of flaking were moved.

When combined with information on the palaeoenvironment, site structure and fauna we are able to make inferences about changes in past socio-economies from the early to mid-Holocene.

Anglo-American and French approaches to lithic analysis have dominated technological studies but continue to remain epistemologically separate, underpinned by very different research histories. French approaches have largely emphasised qualitative analyses supported by experimental archaeology and refitting studies, a methodology refined through long-term engagement with the rich cave sequences of the French Palaeolithic. This approach highlights the conceptual and technological domains of analysis. Anglo-American approaches have instead focused on quantitative attribute-based analyses with investigations of fracture mechanics in which refitting artefacts can be lacking. This approach highlights measurable and comparative domains of analysis. Owing to their differences, the equivalence and applicability of these two approaches has been the subject of intense debate amongst lithic analysts (e.g. Bar-Yosef and Van Peer, 2009; Tostevin, 2011).

In this paper, we test the extent to which the two approaches are complementary to each other and investigate what unique information regarding lithic technology each method provides. We first conducted multivariate attribute analyses of several lithic chaînes opératoires from the Middle Palaeolithic site of Le Pucueil in France. We then compared the goodness-of-fit between the results of the attribute analysis and the known sequence of the same refitted cores.

The results permit the first comparative evaluation of these approaches and show how the different schools of analysis articulate with a range of research questions and types of data.

The analysis of Middle Palaeolithic (Mousterian) assemblages in Eurasia was initially dominated by culture history approaches based in large part on Bordes' Mousterian Facies. In more recent decades technological analysis (following the Chaîne Opératoire approach among some researchers and adaptation and settlement patterns among others) has dominated attempts to understand the nature of Middle Palaeolithic lithic variability. Here, based on data from Middle Palaeolithic sites in SW France, we attempt to return to more basic (and generally interpretation-free) characteristics of lithic assemblages in order to identify broad patterns of chronological change in Middle Palaeolithic stone tool production. These patterns can then be placed in the context of changes in climate/environment and faunal exploitation. The goal of the analysis is to attempt to identify meaningful patterns in Middle Palaeolithic lithic assemblages, that represent changes in lithic reduction/production strategies, while avoiding the interpretive pitfalls inherent in the use of interpretation-based technological classification schemes (such as 'Levallois').

According to the chaîne opératoire method reduction sequences have been defined as the result of a volumetric conception. In the last years this conception is debated in discoïd method, due to many studies that have shown an important variability within this method. This variability is usually considered an expression of mental concepts based on the alternation of predetermining and predetermined flakes during the recurrent centripetal reduction of the core: short centripetal flakes, pseudo-levallouis points and débordant flakes. This technical system had a wide geographical and chronological spread and was often associated with other knapping systems corresponding to an expedient behaviour in which the mental concept related to the volumetric structure of the core was absent and the technical aim of the core reduction was the production of flakes, without control of the morphology, in search of cutting edges.

The aim of this study is to ascertain whether the discoïd technology could also represent an expedient behaviour, going beyond the simple geometric definition of the knapping sequence and trying to find a way for interpret the technical behaviour in a social and cultural perspective. Our hypothesis is that this knapping strategy had a great flexibility to adapt the organisation of the removals to raw material morphology allowing a transition between orthogonal and bifacial conception. The "holistic" approach that we use will be very useful for the discussion of cultural traditions and differences between assemblages.

The study was based on refitting data from layer M of the Abric Romani site. This Middle Palaeolithic layer has been dated between 51 and 55 kyr BP. The lithic assemblage has been studied from a technological perspective to reconstruct the productive sequences first through a diacritical approach and then through systematic Raw Material Unit analysis and refitting of all the finds. The lithic industry is composed by more than 4,800 finds greater than 1 cm.

Discoïd cores are well represented as well as the typical product of discoïd recurrence. Refitting data show a less clear scenario, displaying a knapping strategy without rigid volumetric conception or a well structured method. Some of the most complete refits found in this assemblage will be presented as example. Our results suggest that discoïd knapping were the expression of an expedient adaptation to the morphology of raw material, therefore may have been an expedient

behaviour. The rigid criteria used so far to identify the mental concept and the volumetric structure of this knapping strategy may therefore not be really accurate to understand the technical behaviour behind "discoïd" products. Also, from a methodological standpoint, refits appear of outmost importance for a detailed comprehension of technical behaviour and for compare on large scale assemblages in order to reconstruct human behaviour.

ORAL

## 6. INDIVIDUALS, SOCIAL GROUPS, AND CULTURAL EVOLUTION? WHAT CAN WE LEARN FROM LITHIC ARTIFACTS?

*Hovers, Erella (Institute of archaeology, The Hebrew University of Jerusalem) hovers@mscc.huji.ac.il*

Being the most ubiquitous find from prehistoric records, lithic artifacts served as the basis for broad-range inferences about evolutionary changes in human behavior in relation to environmental, functional and social factors. Notably, the use lives of stone tools reflect actions based on individual decision-making in highly circumscribed temporal (i.e., historical) contexts, a framework that contrasts strongly with the one necessary for studying evolutionary processes of cultural stasis, variability, and change. To bring stone tools into the cultural evolutionary arena, it is necessary to consider lithic assemblages as the time-averaged outcome of processes of information transfer.

Despite a plethora of recent theoretical, analytical and methodological thinking along similar lines, the application of this worldview in the analysis of prehistoric lithic assemblages has been limited and often problematic. Major difficulties involve isolating elements of lithic artifacts that are most likely to reflect socially-biased transmission of technological knowledge, and may result in prolonged 'technological traditions,' rather than convergence of practices due to external factors (e.g., raw material properties or the constraints of flaking mechanics, environmental conditions or functional demands).

Here I discuss the potentials and limitations of this approach, through specific case studies from the Levantine Middle Paleolithic, using differences in stratigraphic modes (continuities vs. breaks) to formulate expectations about the intra- and inter-site patterning of transmission of technical knowledge. On a broader scale, this approach provides tools for identifying parallelisms, convergences

(analogies) and potentially, shared ancestry (homologies) in lithic (and other) technological practices.

## 7. POPULATION SIZE AS AN EXPLANATION FOR PATTERNS IN THE PALAEOLITHIC ARCHAEOLOGICAL RECORD: MORE CAUTION IS NEEDED

*Collard, Mark (Simon Fraser University and University of Aberdeen) mcollard@sfu.ca*

*Buchanan, Briggs (University of Tulsa) briggs-buchanan@utulsa.edu*

*O'Brien, Michael (University of Missouri) obrienm@missouri.edu*

It has become commonplace over the last several years to use population size to explain patterns in the Palaeolithic archaeological record. Among the patterns that have been argued to reflect the impact of population size are the “creative explosion” of the late Middle Stone Age and Upper Palaeolithic; the absence of directional technological change and the reappearance of previously existing cultural behaviors in the Middle Palaeolithic and Middle Stone Age archaeological records; and the emergence of the Bromme and Perstunian technocomplexes in Northern Europe during the Late Glacial. A number of modeling papers support the hypothesis that population size can affect cultural evolution, but the results of empirical studies are ambiguous. Here we report a study that used technological data from recent hunter–gatherers, in conjunction with correlation analysis and regression analysis, to test the population-size hypothesis.

Three samples were used: a global sample consisting of populations from several continents; a continental sample of populations from North America; and a regional sample of populations from the Pacific Northwest.

The results of the analyses do not support the population size hypothesis. Simple correlation analyses indicated that population size was correlated with two of the three toolkit variables in the global sample. However, these relationships disappeared when we used partial correlation analysis to control for two factors that have previously been found to affect the richness and complexity of hunter-gatherer toolkits—risk of resource failure and mobility. Population size was not correlated with the toolkit variables in the correlation analyses that focused on the North American and Pacific Northwest samples. Standard multiple regression analyses yielded

results that are compatible with the results of the partial correlation analyses: Population size was not a significant determinant of toolkit richness or toolkit complexity in any of the samples.

Our study challenges the use of population size to explain patterns in the Palaeolithic archaeological record. Population size may explain some of the patterns in question, but this needs to be demonstrated on a case-by-case basis through tests in which the population size hypothesis is pitted against competing hypotheses, such as adaptation to shifting ecological conditions. Simply attributing patterns in the Palaeolithic archaeological record to population size is not a defensible course of action.

## 8. EVOLUTIONARY MODELS AND LITHIC TECHNOLOGICAL VARIATION IN LATE PLEISTOCENE SOUTHERN AFRICA

*Mackay, Alex (University of Wollongong) amackay@uow.edu.au*

*Steele, Teresa E. (University of California, Davis)*

*testeele@ucdavis.edu*

Evolutionary models of technological change in southern Africa's late Pleistocene have focussed on environmental constraints or demographic pressures as key causal mechanisms. Alternative ‘non-evolutionary’ models have focussed on technology as cultural expression without consideration of the forces underlying information transmission. In this paper we review the southern African record with a particular focus on the well-known Howiesons Poort industry, a technocomplex associated with complex lithic technologies and distinctive symboling systems that flourished in southern Africa from 65-60 ka. We examine lithic and faunal data drawn from sites across the region and evaluate competing explanations for the causes underlying the appearance, form and disappearance of the industry.

Lithics from the late Pleistocene sites across southern Africa are assessed with respect to patterns of provisioning, core reduction, and tool form. These are taken to reflect adaptive constraints (provisioning), and potential extent of population interconnection (core reduction and tool form). Climate regions and faunal data are taken to reflect underlying subsistence conditions as a measure of environmental similarity between sites. Changes in the size of Angulate tortoise from the deep sequence site of Diepkloof are used as a proxy for local

human population size.

We find that: not all technological change is accounted for by adaptation to environments, increased complexity is probably not related to population increase, and cultural expression manifests in ways consistent with information transmission through variably interconnected populations.

Single cause explanations for technological change in late Pleistocene southern Africa are unsatisfying. We propose that the changes observed in the Howiesons Poort are best explained in terms of information diffusion between variably interconnected populations under differing environmental conditions. The relative complexity of the classic Howiesons Poort reflects a time in which widely spread populations were most strongly connected.

## 9. THE USE OF ECOLOGICAL NICHE MODELING METHODS IN THE INVESTIGATION OF MECHANISMS AT WORK IN CULTURE-ENVIRONMENT RELATIONSHIPS

*Banks, William (Université de Bordeaux)*

*william.banks@u-bordeaux.fr*

*d'Errico, Francesco (CNRS) f.derrico@pacea.u-bordeaux1.fr*

The examinations of numerous regional archaeological sequences have recognized the appearance and disappearance of complex cultural behaviors, many of which have been associated with the emergence of cultural modernity. The vast majority of the scenarios proposed to explain the origin of this multitude of behaviors have been based on single-caused models. Such models, however, cannot sufficiently explain the complex paths and the multitude of cultural adaptations inferred from the archaeological records associated with various hominin populations in different regions of the world. There is a need for our discipline to develop and implement approaches that focus on the identification of mechanisms that influenced the development of specific cultural adaptations as means for coping with both environmental and cultural stimuli. To this end, we have argued that one such approach is the integration of cultural, chronological, and paleoenvironmental datasets via ecological niche modeling architectures, with the goal of understanding how environmental dynamics may have influenced prehistoric human adaptations and distributions. It is in this way that one can move away from analyses

focused on documentation towards studies in which one examines cultural variability and change through time with respect to ecological dynamics. It is through such interrogations of the archaeological record that we should be able to effectively identify short- and long-term mechanisms at work in the evolution of cultural adaptations within their respective environmental frameworks. In this vein, this presentation first outlines the theoretical and methodological underpinnings of this approach and provides the results of its application to the Western European early Upper Paleolithic as a case study demonstrating its potential.

To examine culture-environment relationships between ca. 42 ka cal BP and ca. 31 ka cal BP, we use genetic algorithm (GARP) and maximum entropy (Maxent) techniques to estimate the ecological niches occupied by different archaeological cultures that were present during this period. For data inputs, GARP and Maxent require the geographic coordinates where the target population has been observed and raster GIS data layers summarizing environmental dimensions. The occurrence data consist of archaeological sites from which material culture assemblages have been recovered and identified as belonging to the temporal variants of the broader Aurignacian and Gravettian archaeological cultures. The environmental data layers are derived from high-resolution paleoclimatic simulations derived from the LMDZ3.3 Atmospheric General Circulation Model and a regional zoom, as well as the ETOPO datasets. Preliminary results for the time frame between Greenland Interstadial 8 (ca. 38 ka cal BP) and Heinrich Stadial 3 (ca. 31 ka cal BP) will be presented and interpreted in light of patterns observed for the initial Upper Paleolithic.

## 10. WHAT'S THE DIFFERENCE? COMPARATIVE ANALYSES OF COMPLEXITY IN TOOL BEHAVIOR USING COGNIGRAMS AND EFFECTIVE CHAINS.

*Haidle, Miriam Noël (Research Project The Role of Culture in Early Expansions of Humans ROCEEH, Senckenberg Research Institute and University of Tübingen, Germany)*  
*miriam.haidle@uni-tuebingen.de*

The use of tools to reach an aim represents an extension of the problem-solution distance. While zebras simply bow their neck to feed on grass, chimpanzees are able to shift their focus for some time from the target (nut) to a tool (hammerstone) in order to satisfy a need (eating). Tool behavior can open up new 'resources' via extrasomatic

faculties associated to the tool-using subject; primates are especially versatile in using tools in several contexts. In human evolution, the inhibition of direct fulfillment of basic needs is markedly increasing. The first stone tools show an expansion of the problem-solution distance by using a tool (hammerstone) to produce a tool (flake) to reach an aim (cut off meat from a carcass e.g.). Tools were increasingly used as exchangeable modules in different problem-solution settings. Since the Middle Pleistocene tools were also combined with other tools to create new tool entities with new qualities (composite tools). Since the Late Pleistocene tools were interdependently developed as parts of complementary tool sets, and finally they were plated with notional concepts. The expansion of the problem-solution distance and the increase of complexity in tool behavior can systematically be analyzed by coding the processes of tool manufacture and use in cognigrams and effective chains. The approach allows the comparison of different aspects of complexity across all types of tools from various raw materials and across different species. It has been used to set up a model of the development of cultural capacities in the course of human evolution (Tübingen model).t.

ORAL

### 11. PATTERNS IN OBJECTS OR BEHAVIORS: TECHNOLOGICAL EVOLUTION IN THE EARLY STONE AGE OF THE KOOBI FORA FORMATION

*Braun, David R. (Center for the Advanced Study of Hominin Paleobiology George Washington University) david\_braun@gwu.edu*

*Harris, J. W. K. (Rutgers University) jwharris@rci.rutgers.edu*

The archaeological record of stone artifacts in the Paleolithic provides possibly one of the best preserved records of evolutionary mechanisms on human behaviors. Unfortunately we have little understanding of how to interpret the variation in these chipped stone tools through time. Other than the relatively coarse measures of shape variation in artifacts through time, we have very little information about the evolutionary significance of the variations in artifact manufacture. Models of evolutionary change in behavior have been suggested by Bettinger (2009) to indicate the mechanism through which these patterns of behavior are transmitted. We use his model of adaptive landscapes to investigate patterns of behavior through time to indicate the different trajectories of change for different types of behavior. We suggest that some

types of behavior (transport, movement) may be more informative than others (production, manufacture) for understanding adaptive changes in through the Early Stone Age. These patterns are particularly relevant as we increase our understanding of the finer scale variation in environmental influences on hominin behavior. We investigate these models using the rich Early Stone Age archaeological record from East Turkana from 2.1 to 1.4 million years ago.

ORAL

### 12. STONE ARTIFACT MOVEMENT, CURATION AND ASSEMBLAGE FORMATION

*Douglass, Matthew (UNL) matt.j.douglass@gmail.com*

*Lin, Sam (UPenn) samlin@sas.upenn.edu*

Variation in the movement of groups and individuals represents a fundamental means by which humans have adapted to the varied conditions of the world's habitats. Differences in the nature and extent of these movement patterns are driven by environmental, ecological, and social processes that act across multiple temporal and spatial scales. Past movement patterns, however, are difficult to observe directly from the archaeological record. Here we present ongoing research into the quantification of cortical surface area in stone artifact assemblages as an approach with which to link patterns in stone artifact assemblages to past patterns of human movement. Using archaeological and simulation data, this study provides key insights into the relationships between rates of artifact production, selection, and transport onto the formation of the lithic archaeological record. A key outcome of this study are the insights it provides onto the important interrelationship between the assemblage units archaeologists employ, the behavioral patterning these units present, and their representation of the broader suite of behaviors that transpired in the past.

### 13. UNRAVELING THE INITIAL UPPER PALEOLITHIC

*Kuhn, Steven (University of Arizona) skuhn@email.arizona.edu*

*Zwyns, Nicolas (University of California, Davis) nicolas\_zwyns@eva.mpg.de*

Paleolithic "cultures" or culture complexes such as Acheulean or Aurignacian can be extraordinarily

widespread and persistent. Archaeologists have given relatively little attention to the processes that could lead to the dispersal and fixation of certain cultural traits across very large areas. Similarities in lithic technology are often presumed to track hominin dispersals. Similar outcomes could also be results of convergence in technological solutions, guided by the fracture mechanics of isotropic stone or responses to similar ecological challenges. The so-called Initial Upper Paleolithic (IUP) illustrates the methodological challenges of very broadly-distributed Paleolithic cultural phenomena.

Originally proposed to describe a small group of assemblages from the Levant, the term Initial Upper Paleolithic has subsequently been broadened to include any early Upper Paleolithic or transitional assemblage characterized by forms of blade production that combine elements of Levallois method (faceted platforms, hard hammer percussion, flat-faced cores) with features more typical of Upper Paleolithic blade technologies. Lithic assemblages conforming to this broader definition have been identified throughout most of Eurasia, from the southern Levant through central and eastern Europe to the Siberian Altai and Northwest China. Although some researchers believe the IUP tracks a major dispersal of *Homo sapiens*, we must be prepared to recognize that this global phenomenon could also be a consequence of technological convergence, with subsequent dispersal from multiple centers of origin. It is not disputed that lithic technologies from all of these areas exhibit similar features. However it is not self-evident that they represent a unified cultural phenomenon: in fact, a great deal of variability in forms of shaped tools and processes of débitage can be recognized among IUP assemblages.

Untangling the processes leading to very broad dispersal of lithic technological packages such as the IUP requires a more explicit differentiation between analogies (results of convergence) and homologies (results of common descent) in lithic assemblages.

#### 15. THE EARLY UPPER PALAEOOLITHIC OF THE MIDDLE DANUBE REGION: MODERN HUMAN DISPERSAL OR LOCAL EVOLUTION?

*Nigst, Philip R (University of Cambridge & Max-Planck-Institute for Evolutionary Anthropology) prn25@cam.ac.uk*

The Early Upper Palaeolithic (EUP) record throughout Europe is characterized by various changes in human behaviour. Different models explaining these changes

and the emergence of the EUP have been proposed over the past decades. The research presented here focuses on answering the question of whether the EUP changes in human behaviour are due to local evolution or diffusion processes. The applied approach is based on the methodology developed by Tostevin (2000, 2012) including an attribute analysis and the use of the individual steps in the knapping process as units of analysis. Building on Tostevin's work, knapping behaviours are compared between assemblages, but in an attempt to further develop Tostevin's approach the analysis is structured along the reduction sequence (Nigst 2012). Using such a methodology, the models of local evolution, diffusion, and stimulus diffusion are tested against the archaeological record of the Middle Danube region. The Middle Danube region was selected as a test case as it is located along one of the proposed dispersal routes of modern humans into Europe, shows variability of EUP technocomplexes (Bohunician, Szeletian, Aurignacian), provides a secure chronostratigraphic framework for the time period in question (appr. 45 to 30 ka BP) and a climatic context for the discussed assemblages. The results suggest the rejection of the local evolution model for the development of the Szeletian and the support of the model of early modern human dispersal into Europe as manifested by the Bohunician.

## **16. THE TRIANGULAR FLAKES FROM THE MIDDLE STONE AGE AT DIEPKLOOF (SOUTH AFRICA): INNOVATION, CONVERGENCES**

*Porraz, Guillaume (CNRS, IFAS / ESI, University of the Witwatersrand) guillaume.porraz@mae.u-paris10.fr*

Triangular flakes are one of the technological ideas that typified the Middle Paleolithic and the Middle Stone Age. They appeared and disappeared at different times and in different geographic contexts, mostly in association with Levallois reduction strategies, but not only. Here,

we present a new case study from the MSA of Diepkloof Rock Shelter (West Coast, South Africa). We identified an original and previously non-described reduction strategy dedicated toward the production of flakes of triangular morphology (called *accourcies* points). This reduction strategy documents an independent innovation and presently finds no equivalent outside of southern Africa. Though original, this technological manifestation echoes many other Stone Age contexts, and contributes to fuel discussion on innovations and convergence through time.

*Collard, Mark (Simon Fraser University) mcollard@sfu.ca*

*Buchanan, Briggs (Simon Fraser University) briggsb@sfu.ca*

*Shipton, Ceri (University of Queensland) c.shipton@uq.edu.au*

Debates over the timing and routes of modern human dispersal out of Africa have relied primarily on fossil and genetic evidence. Here we employ tool-type richness and phylogenetic analyses of stone tool assemblages to test three competing models of modern human migration out of Africa to Eurasia and Oceania: 1) early out of Africa with Middle Stone Age technology model, 2) late out of Africa with microlithic technology model, and 3) late out of Africa with Middle Stone Age technology. Results of

the richness analysis indicate that the number of tool types declines with distance from Africa, as predicted by all three models. Results of the phylogenetic analyses are only consistent with the late out of Africa with Middle Stone Age technology model. Together, the analyses support the idea that modern humans dispersed out of Africa after 75kya with a Middle Stone Age technology lacking microlithic elements, and the notion that the Indian microlithic and European Aurignacian were later offshoots of the migrants' Middle Stone Age technology.

# B38 Advances in the dating of human dispersals, interactions and extinctions in the Palaeolithic

**1. DATA FROM PLEISTOCENE OF SARDINIA (ITALY):  
THE PALEOLITHIC LANDSCAPE**

*Ginesu, Sergio (University) ginesu@uniss.it*  
*Carboni, Donatella (University) carbonid@uniss.it*

The particular condition of the Sardinia's landscape, produced by the prevailing erosive morphogenetic activity during all the Pleistocene, imposes the search of the pre-protolithic landscape a particular survey. Most geoarchaeologic researches use mainly land surface prospecting in order to identify archaeological features existing in a chosen area. These investigations will serve "natural" subjects as the territorial geography and geomorphology in attempt to reconstruct the paleoenvironment through the study of supply basins (two to five kilometers to the agricultural areas, and 10 kilometers to hunting and gathering areas). This geographic approach can be applied starting from the Neolithic into account the wide variation in the coastline that affected the whole Mediterranean sea, producing a great variation in Sardinia where the continental shelf is more extensive. The reconstruction of the paleolandscape becomes more difficult when you consider the study of the Paleolithic Age, particularly in the lower levels. It appears evident by the geomorphologic reconstructions performed in the northern Sardinia where the territory has changed faster, to become unrecognizable today.

Starting from literature data, in the island five sites attributed to the Lower Paleolithic are known, these are located in different spatial contexts. The sites were surveyed through the geomorphologic reconstruction and recognition of morpho-climatic erosion surfaces and Ar/Ar radiometric analysis on some lava flows. Among these, one has uncertain origin, another has a radiometric dating and the other ones are dated through the artefacts. The sites are located in abandoned river terraces, in the region Anglona (in northern Sardinia) as shown by the morphological reconstructions in this area where the river network still proceeds on the same Paleolithic system, although much more affected. The southern Sardinia site is located in a low terrace of the wide tectonic plain of Campidano; an important graben which has been affected by a subsidence (more than 100 meters?) during all the Pleistocene.

Two other sites are located in caves, the first, in which the presence of man is uncertain, is located in a moun-

tain area in the inner island; the second one documents the presence of man (archaic Neanderthal man?) by the presence of a bone (phalanx) and evidences of scarification in animal bones.

The geographical and geomorphologic reconstruction has allowed us to recognize, within these areas, the lower and middle Paleolithic surface referable to a period between 300,000 and 500,000 years B.P. These fossil erosion surfaces can be dated with stratigraphic precision thanks to the recent volcanic activities that affected some areas of northern and central eastern Sardinia from the end of Pliocene period (3 M.y.b.p.).

The geographical and geomorphologic method applied to the reconstruction of the background, surfaces and erosion terraces, in an area like Sardinia, allows to "follow" the traces of early human presence in the island's history through the archaeological prospecting targeted still preserved remains of the Paleolithic landscape.

Located along the western slope of the Don Valley, south of Voronezh, the Upper Palaeolithic site of Markina Gora (Kostenki 14) provides one of the best documented Middle to Late Pleniglacial pedosedimentary successions in Central Russia. The record encompasses several cultural layers, from Gravettian to early Upper Palaeolithic, as well as two independently dated markers: the Campanian Ignimbrite (Y5) ash, related to an Aurignacian assemblage, and the Laschamp event recorded in between the cultural layers IVa and IVb (Sinitsyn, 1996; Velichko et al, 2009). The chronological background of the Markina Gora sequence is based on a long series of radiocarbon dates on charcoal ranging from 23 to ca 38 ka uncal BP (Haesaerts et al., 2004; Sinitsyn, Hoffecker, 2006) reinforced by paired dates produced in the Oxford laboratory, applying ABA and ABOx-SC pretreatment methods (e.g., Douka et al., 2010). Here we show how the conjunction of this record with that of the adjacent sites of Kostenki 1, Kostenki 12 and Kostenki 17, allowing the establishment of a high-resolution regional sequence. This in turn could be used as a key for long distance correlations between the Russian Plain, the East Carpathian Area, and the Middle Danube Basin, as well as with the Greenland Ice Record. This approach also represents a major contribution to the understanding of the development of a large set of Palaeolithic occurrences (including early Upper Palaeolithic, Spitznian, Gorodsovian, Stretleskian, Early Aurignacian and Gravettian) on a global scale.

**Acknowledgments:** The loess research in Kostenki is a contribution to the Sc-09 and MO/36/021 research projects of the Belgian Science Policy, with complementary funding from the INTAS 2000-879 research project. Research has been co-funded since 2012 by the McDonald Institute for Archaeological Research (University of Cambridge), a MC-CIG grant (NEMO-ADAP Project, Grant nr. 322261), the Isaac Newton Trust (Cambridge), and the Max-Planck-Society. Additional Oxford dates were funded by a NRCF-NERC grant (NF/2009/1/19).

ORAL

### 3. RADIOCARBON DATING THE FINAL MOUSTERIAN OF EURASIA USING ADVANCED RADIOCARBON METHODS

Higham, Tom (Oxford University) [thomas.higham@rlaha.ox.ac.uk](mailto:thomas.higham@rlaha.ox.ac.uk)  
Douka, Katerina (Oxford University) [katerina.douka@rlaha.ox.ac.uk](mailto:katerina.douka@rlaha.ox.ac.uk)  
Wood, Rachel (ANU Canberra) [rachel.wood@anu.edu.au](mailto:rachel.wood@anu.edu.au)

To understand the disappearance of the Neanderthals, a reliable chronology is required. This has largely eluded

science thus far; despite many radiocarbon determinations being obtained from sites dating to the Middle to Upper Palaeolithic transition, our knowledge of the timing of this is opaque. The western European archaeological record constitutes the best evidence there is for the prehistoric replacement of one species of human by another, so deciphering the signals of this transition assumes importance in understanding what happened. For example, exploring the dates of the disappearance of Neanderthals and the arrival of modern humans might help us to understand the possibilities for overlap between the two groups, and therefore whether there was any genetic or genetic exchange between the two populations.

AMS dating material dating older than 30,000 BP is challenging, but work undertaken in Oxford over the last decade has improved the dating of material from this period. We have developed aspects of our pre-treatment chemistry, particularly the purification of bone collagen using ultrafiltration and in the dating of single amino acids from bone, as well quantifying our background limits and corrections.

We have dated over 400 samples of bone, shell and charcoal from more than 50 key Palaeolithic sites in 10 countries. The main focus has been on sites with a succession of contexts containing lithic industries attributed to the Mousterian, Châtelperronian (both seemingly associated with Neanderthals), Uluzzian (now thought to be anatomically modern humans (AMH)).

We used Bayesian age modelling to obtain robust probability distributions allowing us date Mousterian archaeological contexts. The data may be plotted spatio-temporally.

The results reveal patterns in the distribution of final Mousterian sites which may be significant in terms of examining the distribution of near contemporary AMH populations in the period 45-40 ka cal BP in Europe.

### 4. PROCESSING TECHNOLOGY OF HARD ANIMAL MATERIALS IN THE UPPER PALEOLITHIC IN EASTERN SIBERIA (BASED ON MALTA-SITE).

Lbova, Liudmila (Institute of Archaeology and Ethnography SD RAS Novosibirsk, Russia) [lbovapnr5@gmail.com](mailto:lbovapnr5@gmail.com)

Malta is a main geo archaeological site of the Upper Paleolithic in Siberia (dated near 19-23 th. BP). Collec-

tion is represented by of more than 500 wide known decorated objects of ivory, horn and bone. A detailed technical-typology study of most part of the collection stored in the State Hermitage Museum (St. Petersburg) has allowed establishing the general steps processing technology ivory, horn and bone by Siberian Gravette.

The study was based on principals of morphological, technical and typological, use-wave analyzes and experiments. The collection include a sculpture of Man, birds, fish, etc. , ornamented plates, rods , personal ornaments. Microscopic analysis allows systematizing the process of shaping techniques, processing, and ornamentation Paleolithic sculptures by Malta. Also we propose defined stable sets of tools and techniques used to work with each of the selected morphological types Paleolithic sculpture.

We identified some manufacturing technologies of Primitive Art pieces, including flaking, drilling, carving, grinding, and polishing. A number of tools were employed for the manufacture of artifacts: hammer stones, retouches, bow-shaped drills, perforators, boring, different kind of burins and knives, reamers, engravers, grinding tablets and scrapers. Basic tools that were involved in forming - planer knives, variants of scrapers. When allocating the use of decorative elements noted burins and knives. Drilling holes and ornamental elements used bow-shaped drills, perforators, boring, different kind of burins. Cases polishing abrasive for solid surface have a single character, mostly marked trail use soft abrasives (eg, skin).

The early decorative complex, along with the evidence of symbolic behavior, with different kind of drilling with boring, reamer or perforated of hole with thinning body of initial form sets the early stage of the culture formation of Siberian Last Gravette period:

### 5. COSMOGENIC NUCLIDES: DATING PALEOLITHIC SITES OVER THE QUATERNARY.

*Lebatard, Anne-Elisabeth (CEREGE-CNRS) lebatard@cerege.fr  
Bourlès, Didier L. (CEREGE-AMU) bourles@cerege.fr*

Over the last 40 years, the development and improvements of the Accelerator Mass Spectrometry technique have allowed broadening the applications of the cosmo-

genic nuclides to a growing numbers of geoscience domains such as geomorphology, tectonics or paleoclimate.

Although the application of the most famous cosmogenic nuclide,  $^{14}\text{C}$ , to archaeological purposes is well established, that of the other potentially relevant (due to their half-lives) cosmogenic nuclides such as  $^{10}\text{Be}$  ( $T_{1/2} \sim 1.4$  Ma),  $^{26}\text{Al}$  ( $T_{1/2} \sim 0.7$  Ma) and  $^{36}\text{Cl}$  ( $T_{1/2} \sim 0.3$  Ma) to archaeological and paleoanthropological problematics emerges only in the last decade.

If the use of the dating method based on the atmospherically produced  $^{10}\text{Be}$  in continental environment is still in progress after its successful application in the peculiar desertic setting characterizing the fossiliferous area containing the *Sahelanthropus tchadensis* remains (Chad), the burial dating method based on the in situ-produced  $^{26}\text{Al}/^{10}\text{Be}$  ratio has been successfully applied to major sites in South Africa, Spain, and China. Lately, another dating method based on the in situ-produced  $^{36}\text{Cl}$  has been developed and applied to dating the closure by successive rockfalls of the Chauvet cave (France), evidencing then the Chauvet cave artwork was elaborated more than 21 ka ago and corroborating thus the conclusions drawn from the  $^{14}\text{C}$  dating.

The burial dating method is based on the differential radioactive decay of the  $^{26}\text{Al}$  and  $^{10}\text{Be}$  accumulated with a known production ratio within the quartz ( $\text{SiO}_2$ ) mineral fraction (in situ-production) of rocks exposed at the Earth's surface. Once buried below a thickness of matter large enough (few meters) to efficiently attenuate the cosmic ray flux and thus stop the production due to the cosmic ray derived particles, the accumulated cosmogenic nuclide concentrations start to radioactively decay according to their respective half-lives. Due to its shorter half-life, the  $^{26}\text{Al}$  concentrations decrease roughly twice as fast as the  $^{10}\text{Be}$  concentrations, which implies that the  $^{26}\text{Al}/^{10}\text{Be}$  ratio decreases exponentially with an apparent half-life of  $1.48 \pm 0.01$  Ma. This leads to a period of applicability comprised between 100 ka and  $\sim 5$  Ma.

At CEREGE which hosts the French National AMS Facility ASTER, among other geosciences domains, the applications of the cosmogenic nuclides to archaeometry are developed. The burial dating method was notably used to absolutely date the burial of lithic assemblages or paleoanthropological remains at  $\sim 1.4$  Ma at Dungo (Benguela, Angola), at  $\sim 1.5$  Ma at Attirampakkam (India), at  $\sim 450$  ka at Mansu-Ri and Wondang-Jangnamgyo (South Korea), at  $\sim 1.2$  Ma at Kocaba? (Denizli, Turkey) and studies at la Caune de l'Arago (Tautavel, France) are currently in progress. Altogether, these results provide

absolute chronological framework for the hominid evolution and migration steps.

ORAL

## 6. DATING THE MID UPPER PALAEOOLITHIC OF RUSSIA: PROBLEMS WITH THE RADIOCARBON CHRONOLOGY AND SOME POSSIBLE SOLUTIONS

*Reynolds, Natasha (University of Oxford) natasha.reynolds@arch.ox.ac.uk*

The construction of a reliable and detailed culture history for the Mid Upper Palaeolithic (MUP, ca. 34-24,000 years ago) of European Russia poses significant challenges. Despite the existence of a large number of published radiocarbon dates, the dating of individual assemblages is generally ambiguous. Alleviating this problem by obtaining more precise and accurate dates for each assemblage would make a significant contribution to building a better culture history for this region during the MUP and hence improve our understanding of Upper Palaeolithic cultural dynamics, with ramifications for many important current debates.

This presentation, based on recent research into the chronology and lithic industries of this time period, will demonstrate the current problems with the radiocarbon chronology, and suggest ways of improving the situation.

ORAL

## 7. THE DIACHRONOUS EEMIAN (LAST INTERGLACIAL) IN EUROPE.

*Sier, Mark J. (Utrecht University) marksier@gmail.com*  
*Peeters, Jan (Utrecht University) J.Peeters1@uu.nl*  
*Cohen, Kim (Utrecht University) K.M.Cohen@uu.nl*  
*Dekkers, Mark J. (Utrecht University) M.J.Dekkers@uu.nl*  
*Pares, Josep (Cenieh) josep.pares@cenieh.es*  
*Roebroeks, Wil (Leiden University) j.w.m.roebroeks@arch.leidenuniv.nl*

The Eemian, first defined by Harting in 1874 in the Netherlands, is the term for the terrestrial Last Interglacial in Europe. Extensive research has been devoted to this period from a wide range of disciplines. Archaeologists have an interest in this period as it contains the Last Interglacial presence of *Homo neanderthalensis* in Europe. Understanding the geographic and environmental range of this species, particularly the range limits, gives

important insights in their social and/ or technological abilities. Studying the North western European (including the Eemian typelocality in the Netherlands) Eemian helps to contribute to this understanding.

Here we present the combined results of research done at three Eemian sites, Neumark Nord 2 (Germany), Caours (France) and Rutten (Netherlands). Detailed palaeomagnetic and palaeoenvironmental studies were performed at these sites. In all three sites we identified a palaeomagnetic excursion which is the Blake Event. We used this Blake Event as a chronostratigraphic marker in order to compare our records with the well dated marine core MD952042 (of the Iberian coast). When comparing our results with this core we can conclude that the onset of Eemian was delayed by 5000 years in north western Europe with respect to southern Europe. This means that the onset of the Eemian in north western Europe is placed well after the Marine Isotope Stage 5e sealevel highstand. As a result no "dry path" towards Great Britain was available during this warm period, possibly explaining the absence of *Homo neanderthalensis* during this period.

ORAL

## 8. CONTINUITIES AND DISCONTINUITIES IN THE EAST EUROPEAN UPPER PALAEOOLITHIC: REFLECTIONS BASED ON THE KOSTENKI MODEL.

*Sinitsyn, Andrei (Inst.for the History of Material Culture. RAS) andrei.sinitsyn@gmail.com*

Kostenki group of Upper Palaeolithic sites includes 26 sites: 21 in Kostenki and 5 in Borshchevo. Ten of them are multilayer sites. For the moment we deal with remains of more than 50 settlements in good stratigraphic position divided by sterile sediments.

Two events of high chronological resolution were identified at the sections: level of the volcanic ash and Lashamp palaeomagnetic excursion. According to analytical studies at 80-th last century and at first decade of our century the volcanic ash was connected with eruption CI (Campanian Ignimbrite) of the Phlegrean Fields in South Italy and horizon Y5 of the Adriatic marine cores, the age now is regarded as 39-40 ka. In 2000 the cultural layer of Aurignacian attribution directly connected with volcanic ashes was identified at Markina gora (Kostenki 14). The age of Lashamp excursion is defined at ~ 41 ka. Two cultural layers at Kostenki 14 beneath them have to have a more ancient age: with radiocarbon dates of 36-37 ka nonCal (~ 39-41 kaCal) and IRSL-OSL frame of 42-46

ka. Current model of Kostenki' palaeolithic (Middle Don basin, Central Russia) based on stratigraphic evidences and series of nearly 300 radiocarbon dates is four partial:

- Initial Upper Palaeolithic stratum (42-40 cal ka BP) as an association of the Spitsyean and the cultural tradition of cultural layer IVb at Kostenki 14;

- Early Upper Palaeolithic (40-36 cal ka BP) showing the pan-European bimodal structure with the coexistence of the Aurignacian and "transitional" Streletskian;
- Early Middle Upper Palaeolithic (34-32 cal ka BP) connected with the appearance of the Gravettian, but in association with the Gorodtsovian – a particular East European cultural unity;
- Recent Middle Upper Palaeolithic (27-25 cal ka BP) as an association of a number of Gravettian varieties in coexistence with assemblages of non-Gravettian affiliation.

Sites of LGM are absent at the area according to this model and two chronological gaps are attested: between the EUP and early MUP (~34-35 cal ka BP), and between the early and recent MUP (31-28 cal ka BP).

**Acknowledgments:** Presidium RAS; RFBR: 14-06-00295; RFH: 14-01-18097.

Dating Pleistocene occupations in the Circum-Mediterranean region plays a key role in the study of human evolution, as it is critical to establish an accurate time framework for better understanding how, when and why the first human expansions occurred outside the African continent. In Eurasia this out of Africa expansion and colonization probably occurred through the Middle East and along several pulses (Aguirre and Carbonell, 2001; Allué et al., 2013; Bermúdez de Castro and Martínón-Torres, 2012; Carbonell et al., 2008; Toro-Moyano et al., 2013) as documented by sites such as Dmanisi, with an age of 1.7 to 1.8 Ma (Ferring et al., 2011; Lordkipanidze et al., 2007) or archaeological sites presents in the Circum-Mediterranean basin such as Atapuerca, Pirro Nord, Ubeidiya, among others (Parés et al., 2011) with ages between 0.8 and 1.4 Ma.

However, the chronology of deposits in North Africa such as Ain Hanech and E-Kerbha, shows that, the dispersal from Africa of genus Homo, began earlier than previously thought, possibly since the beginning of the lower Pleistocene (Sahnouni et al., 2010; Parés et al., 2014). In this sense, the chronology of Paleolithic archaeological sites in Morocco, such as in the basin of Aïn Béni Mathar (eastern Morocco), can be crucial to contextualize old human dispersal in Northern Africa. Sediments and terraces in the Aïn Béni Mathar area, in the basin of the same name, contain remains of both Acheulean (Mode II) and Oldowan (Mode I) stone tools that have been discovered in successive campaigns since 2006.

In attempt to provide a first chronological context for these archaeological sites in Eastern Morocco, we have collected samples from two different yet related areas within the basin for paleomagnetic dating. The first succession is found near to the town of Aïn Béni Mathar, where 50 samples were obtained along a sequence of about 80 meters and the second one, near to the town of Guéfait, with a sequence of approximately 120 meters with 110 specimens. Paleomagnetic analysis was carried out at both University of Burgos, and CENIEH, and all samples were demagnetized by stepwise progressive alternating field of thermal demagnetization to determine the characteristic remanent magnetization (ChRM) directions.

The paleomagnetic analysis of both sequences have resulted in a two local magnetic magnetostratigraphies, where both normal and reverse polarities are observed. Due to the lack of biostratigraphic data, a conclusive correlation of the local magnetostratigraphy to the Geomagnetic Polarity Time Scale (GPTS) is not possible, although we will discuss possible options, which are constrained by the presence of stone tools remains.

## 1. ONE MILLION YEARS OF CULTURAL DENTAL WEAR AT ATAPUERCA SITES

Lozano Ruiz, Marina (IPHES-Tarragona, Spain) [mlozano@iphes.cat](mailto:mlozano@iphes.cat)

Bermúdez de Castro Risueño, José M<sup>a</sup> (CENIEH-Burgos, Spain) [jm.ber@cenieh.es](mailto:jm.ber@cenieh.es)

Arsuaga Ferreras, Juan Luis (Centro Mixto UCM-ISCIII de Evolución y Comportamiento Humanos-Madrid, Spain) [jlarsuaga@isciii.es](mailto:jlarsuaga@isciii.es)

Carbonell Roura, Eudald (IPHES-Tarragona, Spain) [ecarbonell@iphes.cat](mailto:ecarbonell@iphes.cat)

Cultural dental wear provides useful information about the use of teeth for non-alimentary purposes. Non-alimentary tasks are usually related to economical and cultural activities. The presence of cultural dental wear has been identified in three different *Homo* species from Sierra de Atapuerca sites.

The human remains analyzed in this study were recovered in four sites from Sierra de Atapuerca: Sima del Elefante, Gran Dolina-TD6, Sima de los Huesos and El Mirador. The chronology of these sites ranges from more than one million to 4,000 years ago. More than 500 teeth from 56 individuals belonging to three different species (*Homo antecessor*, *Homo heidelbergensis* and *Homo sapiens*) have been analyzed by means of electron scanning microscopy (SEM and ESEM). Dental wear features have been identified, measured and described to determine patterns of dental wear. These patterns can be related to specific activities.

Evidence of cultural dental wear has been documented in the three *Homo* species analyzed showing the use of teeth as a tool as far as one million years ago. However, each species shows specific typology and frequency of dental wear features. Also, the dental features are located in different dental surfaces and teeth indicating a diversity of activities carried out using teeth as a tool.

The use of teeth as a tool was a widespread habit in the genus *Homo*. However, each species carried out specific types of tasks involving the use of different dental surfaces and teeth. The diversity of dental wear patterns can be related to cultural and economical activities widening our knowledge of the behaviour of these hominins.

Carretero, José Miguel (Laboratorio de Evolución Humana, Universidad de Burgos. Centro mixto UCM-ISCIII de Investigación sobre Evolución y Comportamiento Humanos, Madrid.) [jmcarre@ubu.es](mailto:jmcarre@ubu.es)

Arsuaga, Juan Luis (Centro mixto UCM-ISCIII de Investigación sobre Evolución y Comportamiento Humanos, Madrid. Departamento de Paleontología, Universidad Complutense de Madrid) [jlarsuaga@isciii.es](mailto:jlarsuaga@isciii.es)

The morphology of the human foot is closely related with locomotion and weight transmission. The preservation of *Homo* fossil foot remains previous to modern humans and Neandertals is very scarce throughout the fossil record. Previous studies have demonstrated that modern humans and Neandertal feet are similar in overall size and proportions and are indistinguishable in the implied locomotor capabilities. However, the robusticity and some metrical and morphological traits that characterize the Neandertal foot are different from that of modern humans. Due to the evolutionary and morphological relationship between Neandertals and the Sima de los Huesos (SH) sample, important information can be extracted from SH foot remains that is relevant to the understanding of the Neandertal foot evolution.

Among more than 6500 human fossils recovered so far in SH, around 500 belong to the foot. They represent approximately the 60% of the foot remains of the *Homo* fossil record prior to Neandertals and Early *Homo*

*sapiens*. This large collection offers an unprecedented opportunity to study the morphology of the foot in a population from the Middle Pleistocene, something that was not possible until the discovery and thorough excavation of the SH site. Here, we present a detailed metrical and morphological study of the foot remains from SH. The entire collection of foot remains from SH represents a minimum number of 16 individuals.

As a whole, the morphology of the foot from SH is similar to that of Neandertals and modern humans except for the robusticity of the fossils. However, this study provides further features that allow to distinguish SH hominins from modern humans. Both the SH hominins and the Neandertals display tali with short necks and broad lateral malleolar facets, broad calcanei with long bodies and projected sustentaculum tali, stout naviculars, short intermediate cuneiforms and robust metatarsals and phalanges. In addition, the SH tali show small heads that are different from the large ones typical of the Neandertal tali.

The morphological study of the foot bones from SH confirms the evolutionary relationship between this Middle Pleistocene population and the Neandertals. Nevertheless, some traits differentiate the SH hominins and Neandertal feet. These results are also in accordance with the proposed large corporal size for the SH population and its primitive biotype.

**Acknowledgments:** We are deeply grateful to SH excavation team and our colleagues from LEH-ISCIII. We are indebted to many people who have allowed access to some important skeletal collections. The sacrum is situated in the lower part of the vertebral column and transfers the body weight from the trunk to the pelvic girdle and as such plays a key role in the sagittal balance of the body. On the other hand, the sacrum forms the back part of the pelvic cavity and its study is important to understand the birth mechanism. This skeletal element is poorly represented in the human fossil record. Most of the fossil remains are fragmentary and only few specimens preserve significant portions to investigate the sacrum as a whole. In particular, a number of studies have concluded that Neandertal sacrum is essentially similar to that of modern humans.

The Sima de los Huesos site (SH) is located within a small chamber inside the Cueva Mayor karst system in the Sierra de Atapuerca (Spain). This cavity is partially filled with a fossil-bearing clay deposit that contains more than 6500 human remains from at least 28 individuals. This collection is presently dated to an age around 430 ka. These hominins have been considered phylogenetically related to Neandertals. Here, we present a complete inventory and a preliminary morphometric description of the sacral collection coming from the SH site. This is the most extensive assemblage of non-anatomically modern human fossil sacra coming from a single site.

Original fossils from SH have been studied. In addition to this collection, comparative fossil and modern human samples have been included. Data from the literature has also been taken into account. A set of metrical measurements were taken using standard callipers.

The fossil sacral collection from SH is composed of 39 specimens. All these specimens represent a minimum number of 10 individuals (MNI=10) with immature and adult individuals equally represented. There are complete

or fragmentary portions of five sacral elements (S1-S5) within this collection.

SH adult sacra are not significantly different from modern humans regarding the straight length of the complete sacrum and the sagittal diameter of the sacro-lumbar plate. In contrast, the sacral breadth and the transverse diameter of the sacro-lumbar plate of SH are significantly greater than those of modern human sacra. On the other hand, SH and Neandertal sacrum shows partial fusion and a similar morphology ("second promontory") of the S1-S2 suture whereas SH sacra are significantly broader than those of Neandertals.

Sacrum is badly preserved in the fossil human record. SH site provides valuable material to investigate the evolution of this skeletal region. Metrical and morphological analyses reveal differences between SH collection and modern human and Neandertal samples.

Humeral morphology has the potential to provide insights in terms of both, phylogenetic relationships and functional morphology. However, some traits used

for these purposes seem to be variable within the genus *Homo*, and thus it is difficult to understand their significance, either in phylogenetic or functional terms. In this sense, an ontogenetic approach can help to solve these questions. Unfortunately, there are not studies, as far as we know, about this specific topic, probably due to the scarcity of subadult humeral remains. Thereby, in Pre-Neandertal record there are three subadult humeri: Dmanisi D2715/ D26280, KNM-WT-15000 y ATD6-121; and even among the Neandertal there are five individuals.

Since 1976 more than 6000 human fossils have been recovered from Sima de los Huesos site (SH). Among these, over 72 represent juvenile humeri, belonging to a minimum number of seven individuals. Thus, this sample can be considered the most promising source of evidence for exploring the relationship between phylogeny and ontogeny. In order to carry out this goal, we analyzed the development of robusticity, mid-shaft shape and morphology of distal end in SH sample.

Development of robusticity was established through the relative growth trajectory of mid-shaft circumference and maximum length. In the case of mid-shaft shape, we considered the relative growth of medio-lateral and antero-posterior diameters at mid-shaft. To assess the changes of morphology of humeral distal end through the ontogeny, we established three different relative growth trajectories: (1) medial pillar thickness and olecranon fossa breadth, (2) medial pillar thickness and lateral pillar thickness, and (3) olecranon fossa breadth and distal metaphyseal breadth. For comparative purposes, these traits are, also, studied in two actual human samples, fossil anatomical modern humans, Neandertals, TD6 humeri and KNM-WT-15000.

Neandertals and SH hominins differ from those of modern humans in their growth of midshaft circumference relative to their maximum length. However, there are not differences among these human groups in the relative growth of both diameters at midshaft. The wide olecranon fossa and narrow pillars characteristic of both, Neandertals and SH hominins, are due to the slower growth of the medial pillar relative to both, olecranon fossa and lateral pillar.

Therefore, some distinctiveness humeral traits appear early in the ontogeny, while others are developing through the whole growth process.

Our findings are showing how the study of the ontogeny of humeral traits can be a clue for the correct

understanding and interpretation of the morphological variation that exists in the adult specimens of different species. Moreover, analogies and differences in the ontogeny can help to explore the most plausible developmental scenario for *Homo heidelbergensis* and its phylogenetic relationship to *H. neanderthalensis* and *H. sapiens*.

## 5. PALEONEUROLOGY OF HOMO ERECTUS: ENDOCRANIAL VARIATION AND PROPORTIONS IN AFRICAN AND ASIAN SAMPLES

Bruner, Emiliano (Centro Nacional de Investigación sobre la Evolución Humana, Burgos (Spain) [emiliano.bruner@cenieh.es](mailto:emiliano.bruner@cenieh.es)

Grimaud-Hervé, Dominique (Muséum National d'Histoire Naturelle, Paris (France) [dgherve@mnhn.fr](mailto:dgherve@mnhn.fr)

Wu, Xiuji (Chinese Academy of Sciences, Beijing (China) [wuxiuji@ivpp.ac.cn](mailto:wuxiuji@ivpp.ac.cn)

Holloway, Ralph (Columbia University, New York (USA) [rlh2@columbia.edu](mailto:rlh2@columbia.edu)

There is still no agreement on the taxonomic and phylogenetic affinity between African, Chinese, and Indonesian specimens generally referred to as *Homo erectus sensu lato*. Apart from minor differences in brain size, no endocranial differences have consistently been described among these three groups. This study is aimed at evaluating differences in the endocranial proportions among these three geographical samples.

We compute a multivariate survey on a set of traditional metric variables commonly used in paleoneurology, to evaluate the degree and pattern of endocranial variation in the whole group. Principal component analysis and cluster analysis have been computed on arcs and diameters, to quantify possible differences and shared patterns of variability.

The three groups largely overlap in terms of morphological variation. The Indonesian sample displays a larger variation in terms of size, but more homogeneous proportions in terms of overall shape. However, group-specific differences cannot be tested statistically because of the small sample size. General morphometric affinity between specimens seems not influenced by geography.

Independently upon the taxonomic and phylogenetic status of these three groups, the endocranial proportions

cannot reveal patent differences in the overall brain form, at least taking into account the current available sample and the traditional endocranial diameters and curves. It remains to be evaluated whether or not discrete characters or shape analysis can reveal more localized or subtle differences between these three geographic groups.

## 6. THE BRAIN OF HOMO HEIDELBERGENSIS AND HOMO NEANDERTHALENSIS

Grimaud-Hervé, Dominique (UMR 7194 - MNHN - Paris ) [dgherve@mnhn.fr](mailto:dgherve@mnhn.fr)

Balzeau, Antoine (UMR 7194 - MNHN - Paris) [abalzeau@mnhn.fr](mailto:abalzeau@mnhn.fr)

Détroit, Florent (UMR 7194 - MNHN - Paris) [fdetroit@mnhn.fr](mailto:fdetroit@mnhn.fr)

Paleoneurology is an important field in the study of hominin evolution and diversity and particularities such as variations in size and shape of the endocast help differentiate between hominin species. The aim of this study is to compare *Homo heidelbergensis* and *Homo neanderthalensis* based on endocranial form (i.e. size and shape) and morphology including middle meningeal vascular impressions in the context of evolutionary trends observed from the earliest *Homo heidelbergensis* to the latest *Homo neanderthalensis*.

To do so, a large sample is composed of hominin including european *Homo heidelbergensis* (Arago, Swanscombe, Reilingen, Biache-Saint-Vaast 1, Ehringsdorf H), western Europe *Homo neanderthalensis* (Saccopastore 1 and 2, Steinheim, Neandertal, Le Moustier 1, La Chapelle aux Saints 1, La Ferrassie 1, La Quina H5, Spy 1 and 10, Gibraltar 1) and extant modern humans.

The estimation of cranial capacity by direct method and the morphological description of encephalic structures and vascular imprints were performed. Also recorded were traditional linear measurements for 2D metric analysis and landmarks registered with a microscribe for 3D geometric morphometric analysis.

The morphological features joined to the 2D and 3D metrical results allow to highlight differences between these two hominin species.

Although the origin and evolution of european *Homo heidelbergensis* is still debated, the main features of the earliest one, which is Arago endocast, clearly align

it with specimens frequently assigned to this extinct species of genus *Homo*. The results clearly show the differences of the morphological features between *Homo heidelbergensis* and *Homo neanderthalensis*.

ORAL

### 7. THE KOCABA? FRAGMENTARY SKULL: A HOMINID IN TURKEY IN THE MIDDLE OF EURASIA BETWEEN 1,6 AND 1,2 MY. EVOLUTIONARY INFERENCES.

Vialet, Amélie (MNHN UMR7194) [vialet@mnhn.fr](mailto:vialet@mnhn.fr)  
Alcicek, Mehmet Cihat

In 2002, a fragmentary fossil hominid was discovered by Mehmet Cihat Alcicek in the Denizli Basin (locality of Kocaba?) in the south-west of Turkey. Recently, a multidisciplinary study combining cosmogenic nuclide concentration ( $^{26}\text{Al}/^{10}\text{Be}$ ) and paleomagnetic measurements with sedimentological observations provided an absolute chronological framework, bracketed between 1,2 and 1,6 My, for the Upper fossiliferous Travertine unit where the Kocaba? hominid was discovered. This date is confirmed by the large mammal assemblage, typical of the late Villafranchian, found in the same deposit.

The Kocaba? skull comprised three fragments belonging to the same individual (a young adult): a fragment of the right part of the frontal bone, the anterior half of the right parietal bone and two left frontal and parietal fragments still connected. A 3D reconstruction re-established the anatomical connection between the three cranial remains. A morphological and metrical study was carried out comparing the Kocaba? skull with the other Pleistocene specimens from Africa, Asia and Europe, focusing on the frontal bone which is almost complete on the reconstructed Turkish fossil.

Results show that the Kocaba? hominid belongs to the *Homo erectus* s.l. group that includes Chinese and African fossils, and is different from Middle and Upper Pleistocene specimens. However, the proportions (shared with the African *Homo erectus*) of the short and large Kocaba? frontal bone (without the supraorbital torus) differentiate it from Asian *Homo erectus*, which present a longer frontal squama.

Settled outside Africa, at the crossroad of Eurasia, this Turkish fossil contributes to bridging a palaeoanthropological gap around 1,2 - 1,6 My contributing to the dis-

cussion about the origins of *Homo antecessor* to the west and *Homo erectus* s.s. to the east.

ORAL

### 8. A CLADISTIC METHODOLOGICAL PROTOCOL TO TEST EVOLUTIONARY SCENARIOS WITH APPLICATION TO HOMO HEIDELBERGENSIS

Caparros, Miguel (Muséum National d'Histoire Naturelle, Département de Préhistoire, Paris.) [capmig@aol.com](mailto:capmig@aol.com)  
Mounier, Aurélien (The Leverhulme Centre for human Evolutionary Studies, Department of Archaeology and Anthropology, University of Cambridge.) [aurelien.mounier@gmail.com](mailto:aurelien.mounier@gmail.com)

Most of the proposed evolutionary diagnostic scenarios in human evolution are based on comparative morphology analyses or phenetics.

Because of individual variation among fossils and often times confusion concerning the recognition of morphological character diagnosis, many authors who advocate taking into account overall similarity tend to disagree among themselves when it comes to defining paleospecies of the genus *Homo*.

Phenetic methods do not allow the recognition of homologies to identify taxa and are based on general numerical similarity between specimens. Although they are classification tools, they cannot handle character based phylogenetic hypotheses and thus should not be considered as phylogenetic reconstruction methods. The results of phenetic analyses summarized in a clustering dendrogram do not provide the supporting evidence related to character states at the nodes which define the morphotypes of common hypothetical ancestors of terminal taxa.

The only method for species / taxa recognition is to identify well-defined morphological assemblages on the basis of several apomorphies in a pragmatic Hennigian cladistics framework. The aims of cladistics is to find the sequential order in which morphological novelties (homologies) appear in populations and to ascertain what the hypothetical ancestors of these populations at the nodes look like. This approach is rarely used in palaeoanthropology.

Wiley (1981) recommended that the identification of homologies must be organised in two stages. The first one, primary homology based on conjecture of

similarity, deals with the identification of homologous characters by using morphological criteria (de Pinna, 1991). In a second stage these homologies are tested phylogenetically by the principle of parsimony, and discovered *a posteriori* as secondary homologues, i.e. synapomorphies (homologies *sensu stricto*) or homoplasies (non-homologies *sensu stricto*).

We present here a cladistic methodological protocol that draws on prior research (Caparros, 1997) and essentially expands the second stage by parsimony analysis conducted in three conceptual steps. The first step is a low-level analysis (discovery of the information content of characters), the second step is a high-level analysis (cladistic analysis after reweighting of characters) and the final step is the character state optimization for identification of the morphology of the hypothetical ancestors at the nodes of the cladogram. The second step, the high-level analysis (cladistic analysis after reweighting of characters), and the final step, character state optimization, are simultaneous. We illustrate this protocol by testing two different scenarios that have been proposed to explain the Middle Pleistocene fossil record (Mounier, 2009): *Homo heidelbergensis sensu stricto* and *Homo heidelbergensis sensu lato*. We show that none of these two scenarios is validated by our cladistic protocol analysis.

## 9. ELLIPTIC FOURIER ANALYSIS OF MANDIBULAR SYMPHYSEAL OUTLINE: DIFFERENCES BETWEEN MODERN HUMANS, NEANDERTHALS AND MIDDLE PLEISTOCENE HOMININS

Arnaud, Julie (Università degli Studi di Ferrara) [julie.arnaud@unife.it](mailto:julie.arnaud@unife.it)

Détroit, Florent (MNHN) [fdetroit@mnhn.fr](mailto:fdetroit@mnhn.fr)

Grimaud-Hervé, Dominique (MNHN) [dgherve@mnhn.fr](mailto:dgherve@mnhn.fr)

Peretto, Carlo (Università degli Studi di Ferrara) [carlo.peretto@unife.it](mailto:carlo.peretto@unife.it)

Morphological and morphometric study on human mandibular remains have highlighted significant inter and intra individual variability in modern humans but also in Neanderthals and Middle Pleistocene hominins. It appears necessary to develop new methodological approaches to quantify and analyse specific mandibular area in order to find accurate discriminative traits in these human groups.

In this work, we propose a study based on Elliptic Fourier

Analysis (EFA) to analyse shape variations of mandibular symphysis outlines and to distinguish specific morphotypes in the European human groups.

This general analytical framework involves 144 mandibles of adult and juvenile individuals belonging to three different taxonomic groups of the genus *Homo*.

For this particular study we focused on adult specimens only, with balanced sub-samples of 19 *Homo sapiens* and 19 *Homo neanderthalensis*, as well as the best preserved Middle Pleistocene hominin mandibles (n=6).

Symphysis outlines were digitized on 3D models of the specimens realized with a NextEngine laser scanner. Each outline includes three anatomical landmarks (*Infradentale*, intersection of the digastric fossae and *Infradentale posterior*) and 41 semi-landmarks. Raw coordinates in 3D were transformed in 2D data (through a dimensionality reduction procedure) before applying EFA. Fourier descriptors (harmonics) derived from EFA were used in multivariate analyses: Principal Component Analysis and Linear Discriminant Analysis (PCA and LDA). The efficiency of this methodological approach to discriminate the different taxonomic groups was tested with a leave-one-out cross-validation procedure for calculating the percentage of misclassified specimens in each group by the discriminant functions.

The results show a high reliability of this method, with 93% of correct classifications after cross validation. Multivariate analyses (PCA and LDA) applied on the Fourier descriptors of the mandibular symphysis outlines allowed to discriminate correctly the three taxonomic groups taking into consideration. The major shape variation corresponds to the shape and magnitude of the mental projection, which discriminates clearly modern humans from Neanderthals/Middle Pleistocene hominins. Secondary variations are although highlighted on the internal face of the symphysis, especially on the expression of structures (presence/absence of the transverse torus). Shape differences are also found between Neanderthals and Middle Pleistocene hominins, with a slightly more receding symphyseal profile in the latter group.

Martinez, Ignacio (*Departamento de Paleontología de la Universidad de Alcalá, y UCM-ISCIII Centro Mixto para el estudio de la Evolución y Comportamiento Humanos*) ignacio.martinez@uah.es

Gracia, Ana (*Departamento de Paleontología de la Universidad de Alcalá, y UCM-ISCIII Centro Mixto para el estudio de la Evolución y Comportamiento Humanos*) agracia@isciii.es

Arsuaga, Juan Luis (*Departamento de Paleontología. Universidad Complutense de Madrid y UCM-ISCIII Centro Mixto para el estudio de la Evolución y Comportamiento Humano*) jlarsuaga@isciii.es

When a mass grave is discovered there should be a big quantity of bones from different individuals which are mixed or/and without any clear anatomical position. Because the main goal in every Physical and Forensic Anthropology and Archaeological studies is to characterize the population biological profile, one of the first steps in all the cases is to try to establish a minimum number of individual (MNI) which of them are males and which females, the age at dead, and of course, and to try associate bones belonging to the same individual to be able to determine body proportions. So, the founding of mixed and isolated bones of different individuals is one of the biggest problems to be solved.

Until now, systematic search by symmetry and articular congruence was the main way to try to define an individual, but in here we will try to add a new tool for this, the diaphyseal cross-section geometric properties of the bones.

We use several modern human samples (N=150) and a Neandertal sample (N=9) to check the use of the new proposed technic to other potential populations and/or species. Correlation in joint size measurements in contiguous bones and bone length in parallel ones are

used for eliminate the most unprovable association of couple of bones, and then the correlation of geometric properties at 50% level for all bones (except in the humerus in which we use the 35% level) is used only in those most probable pairs.

Sliding caliper and osteometric board for articular and length measurements as well as computer tomography, Mimics software and Autocad are used to extract and calculate the mechanical parameters.

It can be said, that correlation coefficients between joints in the same individual are high enough to, at least, eliminate some bone couples which are unable to belong to the same individual. Geometric properties are indeed the best approach to associate bones with r values around 0.9 in most cases. In this work we are showing that Neandertals look to follow the same trend than modern humans.

This methodical combination is a powerful tool in order to associate isolated bones, and as in Neandertals is also valid, we are opening here a new way for associating bones in other hominin samples.

Lorenzo, Carlos (*Àrea de Prehistoria, Universitat Rovira i Virgili (URV), 43002, Tarragona, Spain. / IPHES, Institut Català de Paleoecologia Humana i Evolució Social (IPHES), 43007, Tarragona, Spain.*) carlos.lorenzo@urv.cat

Cova Foradà is a cave located near Oliva village (Valencia, Spain) in south-eastern of Iberian Peninsula and close

to Mediterranean coast. Inside the cave there is a site with archaeological levels from Upper Pleistocene to Holocene (including Mesolithic and Bronze Age levels). In 2000 a Neandertal maxilla and other human remains were discovered in the Mousterian levels associated to abundant lithic tools and fauna remains. The maxilla was a Neandertal maxilla covered with a hard layer of sediment which difficult to study the morphology and anatomy of the fossil, its surface and to take measures on it. In 2010 the maxilla and the other human fossils were transported to the Conservation Laboratory at Institut Català de Paleoecologia Humana i Evolució Social to clean the remains and to perform a new paleoanthropological study. In this report we describe the preservation works on the maxilla and the conservation processes carried out.

We have applied different non-destructive techniques to analyze the composition of the bone and concretions before and after the cleaning treatment to conduct a better preservation of the fossil. We have avoided the use of chemical products to prevent the contamination of the fossil. With the same objective of preserving all information of the fossil without the introduction of chemical products on the bone, we have used three dimensional technologies to record the morphology of the maxilla. First of all the maxilla was 3D scanned (with CT and with a surface scanner), we perform a reconstructed version of the maxilla by symmetry, we reproduce these virtual reconstructions with a 3D printer and finally it was casted. At last, we have designed a method to preserve the fossil in the best conditions.

## 12. ENDOCRANIAL VASCULAR TRACES AND PALEOANTHROPOLOGY

*Písová, Hana (Charles University in Prague, National Museum in Prague) hana.pisova@natur.cuni.cz*

*de la Cuetara, José Manuel (Universidad Autónoma de Madrid) jm.delacuetara@gmail.com*

*Velemínský, Petr (National Museum in Prague) petr\_veleminsky@nm.cz*

*Bruner, Emiliano (Centro Nacional de Investigación sobre la Evolución Humana) emiliano.bruner@cenieh.es*

The traces left on the endocranial surface by arteries and veins can supply evidence on physiological processes associated with brain biology in fossil hominids. Morphological differences in these networks and

consequent thermoregulation patterns can support inferences on brain evolution and metabolism. Despite the relevance of these topics, issues associated with selective brain cooling in humans remain largely elusive. Digital anatomy currently provides tools and methods to investigate these traits in modern and fossil samples, and computed modeling allows reliable methods to evaluate anatomical changes and differences according to the principles of functional craniology and integration. These same characters and methods have also relevance in forensic anthropology, archaeology, and medicine.

In this study, we used cranial samples of anatomically modern humans from different historical periods (early medieval, late medieval and modern age) to evaluate bias and limits associated with the anatomical reconstruction and evaluation of vascular traits from bone remains. In particular, we focused on those traits generally considered in paleoanthropology, like middle meningeal vessel imprints, foramina/tunnels of emissary veins, traces of venous sinuses and other structures which can be scored and measured from bone and computed tomography. Vascular features were visually assessed from the semiautomatic backface projected CT reconstructions, and then compared with physical specimens when available. The endocranial area of physical specimens was also approached with digital endoscope.

The digital analyses were able to show intrasosseous connections of various venous channels that cannot be inferred by exclusive inspection of the ecto- and endocranial surfaces. Besides reconstructions of multiple mastoid emissary foramina, the mastoid tunnel transferring occipital artery and vein in the close proximity of mastoid emissary foramen was frequently present. This passage for occipital artery was easily confused with mastoid foramen and in several cases the tunnel was reconnected with mastoid emissary foramen and/or sigmoid sinus groove. Other traits such as imprints of middle meningeal vessels showed frequent presence of tunnels above lesser sphenoid wing hardly traceable with endoscopic examination. Moreover, middle meningeal vessels in the area of sphenoparietal sinus produced numerous reconstructions with diploic system.

This preliminary survey showed a complex intrinsic vascular network, especially in the area above mastoids, where digital anatomy proved to be necessary to make any further interpretation of the external vascular

characters. The analysis of the inner vascular network is then mandatory when dealing with paleoanthropological hypothesis, for which the study of the ectocranial traits alone is not sufficient and can be even misleading.

---

POSTER

**13. COMPUTED TOMOGRAPHY, DIPLOIC VESSELS, AND HUMAN EVOLUTION: A PRELIMINARY COMPARISON IN PHYSICAL AND DIGITAL SPECIMENS.**

*Rangel de Lázaro, Gizéh (Universitat Rovira i Virgili) gizrandel@gmail.com*

*de la Cuétara, José Manuel (Universidad Autónoma de Madrid) jm.delacuetara@gmail.com*

*Lorenzo Merino, Carlos (Universitat Rovira i Virgili. Institut Català de Paleoecologia Humana i Evolució Social.) carlos.lorenzo@urv.cat*

*Bruner, Emiliano (Centro Nacional de Investigación sobre la Evolución Humana) emiliano.bruner@cenieh.es*

The diploic channels were identified in mammals over 200 years ago, and subsequently described in humans by Gilbert Breschet in 1829. However, diploic veins are scarcely considered in current anatomical studies. This vascular network appears to be more developed in humans than in non-human primates, which suggests this topic may be relevant in evolutionary biology. Diploic vessels grow in the spongy tissue between the cranial tables (internal and external), mostly within frontal and parietal bones, with large veins connected through a complex network of microscopic channels. The vessels are valvesless. Quantitative studies on diploic channels in extinct human species can supply information on vascular evolution and endocranial thermoregulation, specifically brain cooling. The aim of this study is to determine the application of computed tomography (CT) in digital analysis of diploic vascular system in human anatomy and paleoanthropology.

We analyze potentiality and limits of CT to evidence and reconstruct diploic channels in modern and fossil specimens. A first modern sample included 10 physical skulls CT scanned at high resolution (pixel size and slice thickness 0.25 mm). Physical specimens were checked by transillumination and their digital replica by computed imaging. Transillumination equipment was performed with two Cool-White LEDs, of 1500 lumens each. Predominant wavelengths were 450 nm and 600 nm, with a minimum peak at 490 nm and correlated color temperature was in the range of 5000-8300 K. A second modern sample included 10 digital skulls

scanned at medium resolution (pixel size and slice thickness between 0.30 and 0.40 mm). We considered CT scans from three Neanderthal skulls: Saccopastore 1, Spy 1, and Spy 2. Digital imaging was computed by using Mimics 10.01 and Image JA 1.45b. One skulls of each sample was analyzed in high, medium and low resolution, to evaluate the effect of different degree of resolution on diploic channels visualization.

In the current physical sample (mean vault thickness =  $5.2 \pm 1.1$  mm) transillumination is not able to reveal the presence or patterns of diploic network, giving only minor information on the imprints of middle meningeal vessels.

To achieve 3D reconstruction of diploic veins without the diploe noise interference we created a specific protocol to filter the original CT images. Most channels are observed with pixel size and slice thickness at 0.25 mm, at this resolution 3D reconstruction is partially confused because of the noise introduced by spongy tissue. At lower resolution only the largest channels can be recognized.

Transillumination is not an informative method to investigate diploic channels in physical samples. The protocol used for treating CT images with digital software was successful for perform anatomical surveys in modern and fossil human remains, providing an important tool to investigate the evolution of cranial vascular networks in extinct human species.

**14. AN ONTOGENETIC PERSPECTIVE ON CRANIAL BASE VARIATIONS IN EXTANT HOMINOIDEA AND FOSSIL HOMININS**

*Profico, Antonio (Dipartimento di Biologia Ambientale, Sapienza University of Rome, Italy) antonio.profico@uniroma1.it*

*Di Vincenzo, Fabio (Dipartimento di Biologia Ambientale, Sapienza University of Rome, Italy) fabio.divincenzo@uniroma1.it*

*Piras, Paolo (Center for Evolutionary Ecology, Rome, Italy) paolo.piras@uniroma3.it*

*Manzi, Giorgio (Dipartimento di Biologia Ambientale, Sapienza University of Rome, Italy) giorgio.manzi@uniroma1.it*

Several studies on cranial base morphology deal with basicranial flexion, mainly in relationship with cranio/facial size and shape (Bastir et al., 2010; Bastir et al., 2011). On the opposite, our aim is to test to what extent basicranial morphology is related to functional and/or

ontogenetic patterns. In particular, we are interested in the evaluation of factors that may have influenced the cranial base morphology in Plio-Pleistocene Hominins.

We used a configuration of 17 landmarks distributed on cranial base; the sample includes 131 specimens belonging to *Homo*, *Australopithecus*, *Paranthropus*, *Pan*, *Gorilla*, and *Pongo*; the age at death was assessed by patterns of teeth eruption.

The landmark set has been transformed into shape coordinates by Generalized Procrustes Analysis (GPA) and the variance-covariance matrix was explored through Principal Component Analysis (PCA). Shape predictions for extant species were performed via separate regressions of the PC scores on centroid size (CS) in order to display the respective pattern of growth within the different OTUs. A quantification of phylogenetic signal (Adams & Otárola-Castillo, 2013) has been carried out on GPA-aligned coordinates on an adult sample.

When the first two principal components (49,41 % of total variance) are considered together, two clusters are clearly recognizable: *Pongo*, *Gorilla*, and *Pan*, share a common growth pattern of cranial base variation, while modern humans and fossil Hominins show a distinct pattern of change with analogous ontogenetic polarity. In the morpho-space Australopithecids and early-*Homo* specimens seem to be closer to *Homo* spp. than to great Apes cluster.

Shape variations accounts for relative changes in basioccipital and foramen magnum dimensions along the PC1 and for variation in the basioccipital flexion along the PC2. This different pattern appears more related to functional demand (posture/locomotion) than to phylogeny, the phylogenetic signal explaining the 21% of total shape variability (p-value = 0.00398; iterations = 1000).

The regression on CS performed on extant species shows that all trajectories are in ontogeny. The allometric trajectories of *Gorilla* and *Pan* diverge from *Homo* while are parallel each other.

For what concerns our evolutionary lineage and great Apes, these results indicate that main factors driving differences in cranial base morphology are primarily in relation to function and ontogeny. Further research will focus on other anatomical features that may have influenced morphological variation of the skull base present in the Hominoidea.

**1. REFLECTIONS ON THE CHRONOCULTURAL VARIABILITY OF THE LATE MIDDLE PALAEOLOGIC OF WESTERN EUROPE TURQ, ALAIN (MNP) ALAIN. TURQ@CULTURE.GOUV;FR**

*Ashton, Nick (British museum) nashton@thebritishmuseum.ac.uk*  
*Soressi, Marie (Leiden University) m.a.soressi@arch.leidenuniv.nl*  
*Roebroeks, Wil (Leiden University)*  
*j.w.m.roebroeks@arch.leidenuniv.nl*

The western part of Europe is a key area for the study of late Middle Palaeolithic (MIS 5-3) adaptations, as a result of a variety of factors, including its latitudinal extension (from Portugal to Wales), its diversity of ecosystems and its long research history, which has made it into a densely sampled region. Over the last three decades, our knowledge of the Late Pleistocene geomorphology of the area has increased significantly, with solid data regarding changes in land-sea distribution, the chronological and spatial distribution of permafrost phenomena and of the deposition of a wide range of aeolian sediments. Detailed archaeological studies of the chronology, technology and typology and of lithic assemblages retrieved from Pleistocene sediments have afforded us with a detailed picture of the presence and absence of Neandertals here, with a degree of resolution enabling us to reflect on the chrono-cultural variability of the last Neandertals on the basis of a large data set.

From a historical perspective, this diversity was mainly demonstrated using methods developed by Francois Bordes. As a result of its heavy typological focus, this approach was applied foremost in regions with caves and rockshelters, i.e. in karstic areas, where the numbers and percentages of retouched tools are as a rule much higher than in the open air sites of the north. There, the dominance of rescue excavations of large – and often : well-preserved - open air sites has favoured the development of studies with a strong emphasis on technological aspects of Middle Palaeolithic assemblages.

A first phase of critical reflection on the Bordes method has led to the identification of a few technocomplexes (TCL) which seem to follow each other in chronological order in the archaeological sequences of the Perigord area: TCL Levallois, TCL Quina and a TCL with denticulates. We consider it important to continue this critical revision by discussing criteria for various TCL's with colleagues working in western Europe at large. This will en-

able us to reflect on the key questions at stake in studies of the late Middle Palaeolithic such as the significance of both the autonomy and the co-existence of various ways of producing blanks in the TCLs ? What is the role of faconnage in TCLs ? Which TCL's are present in this geographical area, how are they distributed in time and space, and how to interpret the chronological relationships between the TCLs of the northwest and the southwest of Europe ? And in more general terms, is it possible to obtain data on the (cultural, environmental ?) factors which may be steering these techno-economic systems ? We will present a few case studies, taken from the area at stake here, to illustrate the relevance of these issues for studies of the late Middle Palaeolithic.

**2. LA FIN DU PALÉOLITHIQUE MOYEN EN EUROPE DU NORD-OUEST - END OF MIDDLE PALAEOLOGIC IN NW EUROPE DEPAEPE, PASCAL (INRAP) PASCAL. DEPAEPE@INRAP.FR**

*Di Modica, Kevin (Centre archéologique de la grotte Scladina) kevin\_dimodica@yahoo.fr*  
*Richter, Jürgen (Universität zu Köln ) al002@uni-koeln.de*

Ces dernières années ont vu un renouveau important dans les études sur le Paléolithique moyen dans le Nord-Ouest de l'Europe. D'une part, de nombreuses fouilles, pour une grande partie préventives, ont enrichi le corpus. D'autre part, des collections issues de fouilles anciennes ont fait l'objet de réexamens critiques fournissant de nouvelles informations. Enfin, les approches chronostratigraphiques ont été précisées et les datations radiométriques se sont multipliées, autorisant ainsi un positionnement affiné des sites dans la chronologie absolue. Ces éléments permettent un nouveau regard sur la fin du Paléolithique moyen (MIS 4-3) dans une région aux biotopes variés et très sensibles aux variations climatiques. Seront particulièrement abordés les problèmes de mouvements des populations (nord-sud, est-ouest) au travers des influences culturelles, ainsi que le statut de cette région : carrefour ou cul-de-sac.

ORAL

### 3. TIME SCALE AND CULTURAL COMPONENT IN RECENT MIDDLE PALAEO-LITHIC IN NORTHERN FRANCE GOVAL, EMILIE (UMR7194, INRAP) EMILIE.GOVAL@INRAP.FR

*Auguste, Patrick (UMR8217) Patrick.Auguste(at)univ-lille1.fr.*  
*Paris, Clément (Inrap) clement.paris@inrap.fr*

In northern France, the Upper Pleistocene is characterized by discontinuous human presence, closely linked to climatic variations. Human groups were mainly present during the Eemian interglacial and the beginning of the Weichselian (Early-glacial), as well as during the Late glacial, in close correlation with variations in large mammal populations. In addition, during the Upper Pleistocene, climatic erosion phases linked to rapid climatic events modified raw material access, which partly impacted lithic production modalities. However, the influence of cultural traditions remains important, for both lithic production and subsistence strategies.

The excavation of numerous Late Middle Palaeolithic sites over the last twenty years has provided invaluable chronological and environmental information on Upper Pleistocene human occupation contexts in northern France, mainly in loessic context. This study is based on data from 45 excavated archaeological levels, representing a total surface of about 54 000 m<sup>2</sup>, combined with a unique pedostratigraphic reference frame for European Upper Pleistocene. A total of ~ 62 000 artefacts have been unearthed in these levels.

From a chronological viewpoint, five of these levels are contemporary with the Eemian interglacial (MIS 5e), seven are attributed to MIS 5c, 10 to MIS 5a (temperate continental forest / grey forested soils) and 8 others, to the end of MIS 5a (steppe soils). Lastly, 13 others are contemporary with the end of the Lower Pleniglacial (MIS 4) or Middle Pleniglacial (~ MIS 3).

This significant database has enabled us to analyze interactions between climatic fluctuations, responsible for palaeoenvironmental modifications, and prehistoric occupations, focusing on four main themes: occupation density, raw materials, lithic industries and faunal remains.

ORAL

### 3 BIS. THE MIDDLE PALAEO-LITHIC SITES OF KESSELT-OP DE SCHANS (BELGIUM), MAASTRICHT-BELVÉDÈRE (THE NETHERLANDS) AND VELDWEZELT-HEZERWATER (BELGIUM) PROVIDE AN EXCEPTIONAL RECORD OF NEANDERTHAL OCCUPATION DURING THE LATE-MIDDLE AND THE LATE PLEISTOCENE OF NORTHWESTERN EUROPE.

*Bringmans, Patrick M.M.A. (The 'Veldwezelt-Hezerwater' Neanderthal Research Centre - Belgium) Patrick.Bringmans@hotmail.com*  
*de Warrimont, Jean-Pierre (Archeologische Vereniging Limburg - The Netherlands) warrimont@archeogeolab.nl*  
*Meijs, Erik P.M. (ArcheoGeoLab Maastricht - The Netherlands) Meijs@archeogeolab.nl*

The interstratified loess–soil sequences in the Provinces of Belgian and Dutch Limburg reveal a continuous record of palaeo-climatic variations during the late-Middle and Late Pleistocene. The most detailed stratigraphic information comes from remarkable exposures on the left side of the Meuse Valley. These impressive loess–soil sequences represent the last five glacial–interglacial cycles. The study of these loess-soil sequences yielded at least 17 different archaeological levels.

The investigation of these very detailed loess-soil sequences opens unseen possibilities to extend temporal and spatial correlations regionally and across the European loess belt.

At Kesselt-Op de Schans five archaeological levels were found (2007–2008). Level 1 could be dated to around 85 ky BP (in situ). Level 2 is reworked and probably 200 ky old. Level 3 could be dated to 280 ky BP. Level 4, which can be dated around 390 ky BP, is reworked, just as Level 5, which could be dated to around 480 ky BP. Level 5 and 4 comprised only a few non-Levallois artefacts, a retouched blade, sidescrapers with bifacial retouch and bifacial points. At Level 3, four small Levallois knapping spots (ODS 1, 2, 3 & 4) were excavated. A few centripetal Levallois cores, small flakes, larger Levallois flakes and a few side-scrapers were also excavated. At Level 1 and 2 there were also Levallois products present.

The Maastricht-Belvédère pit has been the object of archaeological investigation between 1980 and 1990. Two separate interglacial periods within MIS 7 (ca. 250 ky BP) were present. The oldest archaeological find horizon IV-B (Sites: B, C & G) is part of the interglacial MIS 7.5, while the archaeological find horizon IV-C (Sites: A, D, F, H, K, & N) is

part of the younger interglacial MIS 7.3. Most of the excavated Middle Palaeolithic artefacts belong to Levallois core reduction sequences. A large 'Micoquian' handaxe was found in a small channel, which could be dated to MIS 6.

The Veldwezelt-Hezerwater site is the most important of these three localities. There, the successive archaeological excavation campaigns (1998-2003) provided important new data of at least seven separate Middle Palaeolithic settlements. At Veldwezelt-Hezerwater, Levallois products have been found at the VLB Site (MIS 6.01), the VBLB Site (MIS 5a), the TL Site (MIS 3) and the WFL Site (MIS 3). At the VLL Site and the VLB Site (both MIS 6.01), blades and small tools were produced. Oversized tools, which are tools that are exceptionally big relative to the rest of the lithic toolkit, have been found at the TL Site (MIS 3) and the WFL Site (MIS 3). Quina tools have been excavated at the TL Site and the WFL Site at Veldwezelt-Hezerwater.

The simultaneous presence of several 'discrete' core reduction strategies (e.g., Levallois, blade, prismatic & opportunistic) and tool reduction strategies (e.g., Mousterian, Quina) shows that the Neanderthals did make use of more than one core or tool reduction strategy at a time. At Veldwezelt-Hezerwater, this phenomenon is probably a direct consequence of the flint knappers working with different sizes and qualities of lithic raw materials.

#### **4. LES TECHNO-COMPLEXES DU PALÉOLITHIQUE MOYEN RÉCENT EN FRANCE MÉDITERRANÉENNE : UN PREMIER BILAN PLUS DE QUARANTE ANS APRÈS LES DERNIÈRES SYNTHÈSES RÉGIONALES**

*Lebègue, Frédéric (UMR 7194 M.N.H.N / U.P.V.D) fred.leb-  
egue@gmail.com*

*Wengler, Luc (UMR 7194 M.N.H.N / U.P.V.D) wengler@univ-perp.fr*

Dans son ouvrage de 1971, intitulé le Paléolithique inférieur et moyen du Midi Méditerranéen dans son cadre géologique, H. de Lumley suggère l'existence d'une multiplicité de faciès typologique du Moustérien, tout en pointant certaines variantes et particularités régionales. Mais quoi de neuf depuis ?

L'apport documentaire des fouilles menées dans les années 80-90, mais aussi, et surtout, le renouvellement méthodologique dans l'étude des ensembles lithiques (archéo-pétrographie, technologie, techno-économie) rendent aujourd'hui possible une autre perception du

Paléolithique moyen dans le Sud-est de la France. Le ré-examen en cours des principales collections régionales, basé sur l'analyse des systèmes techniques et économiques ainsi que sur leur interprétation en termes de mobilité et d'entité techno-culturelles, conduit à revoir la classification chrono-culturelle proposée voici plus de 40 ans.

Les résultats obtenus ces dix dernières années en domaine méditerranéen mettent ainsi en évidence une certaine « originalité », tant dans la diversité que dans l'organisation archéo-stratigraphique des systèmes techniques, qui contraste avec les observations faites dans d'autres régions, en particulier le Sud-ouest de la France. L'importante diversification des systèmes de production et des techno-complexes (Quina, Discoïde à denticulé, MTA, Levallois), qui caractérise la phase récente du Paléolithique moyen d'Aquitaine, ne se retrouve pas en Méditerranée. Au contraire, une certaine homogénéité se dégage au niveau des « traditions techniques », avec l'emploi massif du débitage Levallois récurrent centripète au sein des ensembles lithiques des stades isotopiques 4 à 3, peu importe le contexte lithologique ou le type d'occupation. Les systèmes Discoïde et Quina, très fréquents à la même époque dans le Sud-Ouest, sont ici peu voire pas représentés. Le Moustérien de tradition acheuléenne, et plus largement le système bifacial, sont également absents.

Ces traits techniques du Midi-Méditerranéen, qui se conjuguent avec une permanence dans l'organisation du territoire (gîtes exploités, formes de circulation des matériaux, etc.), traduisent non seulement un cadre, mais aussi une dynamique culturelle propre à la zone méditerranéenne.

Dès le début du XIX<sup>ème</sup> siècle et les prémices de la Préhistoire, le Bassin aquitain a constitué un territoire privilégié pour l'étude du Paléolithique moyen, notamment en raison de la richesse et de l'abondance des gisements qui s'y rapportent. L'un des enjeux récurrents au cours du temps fut la compréhension de la variabilité des traditions techno-culturelles qui composent l'entité moustérienne, qu'il s'agisse de réelles différences profondes ou de nuances plus ténues.

Depuis plusieurs décennies, de nombreuses études ont été conduites au gré de la disponibilité des matériaux datables et des évolutions méthodologiques en géochronologie. Une première synthèse, fortement ancrée dans l'interdisciplinarité, fut établie à partir de l'examen critique des données chronologiques acquises plus ou moins anciennement et en tenant compte de la représentativité des datations effectuées par rapport aux faits archéologiques étudiés (Guibert et al. 2008). Depuis ces travaux de nombreux sites, inédits ou connus, ont été étudiés ou ré-étudiés, bénéficiant ainsi des progrès méthodologiques importants qui ont été réalisés dans le domaine des datations paléodosimétriques (Guérin et al. 2012, par exemple).

Nous proposons ici un nouveau bilan critique des données chronologiques du Paléolithique moyen aquitain, pour tenter de dépasser la vision binaire interrogeant la possibilité de « contemporanéités ou successions » des Techno-complexes moustériens, tout en questionnant la réalité des ensembles anciennement définis. Il s'agit donc avant tout d'établir une synthèse des connaissances actuelles afin de proposer une chronologie objective des grands systèmes de production lithique (Levallois, Quina, Discoïde, ...), intégrant des considérations techno-économiques plus avancées pour tendre vers une vision plus fine. Le but de cette révision est de renouveler le registre de données chronologiques rela-

tives à l'émergence, au développement et au remplacement des différentes traditions techno-culturelles moustériennes.

The Roc de Marsal is a small cave located on a cliff close to the Vézères River, in the Dordogne region of France. It is famous for the discovery of the well preserved skeleton of a Neanderthal child [1]. Recent excavations focused on the Middle Paleolithic occupation layers, and revealed very rich deposits in terms of both lithics and

fauna. Geoarchaeology shed new light on the processes of sediment deposition and allowed discussing the intentionality of the 'burial' of the Neanderthal child [2]. Combustion features were also uncovered in a very good state at the base of the sequence [3].

In a previous attempt to date the Mousterian occupations of Roc de Marsal [4], TL on heated flints and sedimentary quartz, as well as multi-grain OSL on fine grained quartz extracts from both heated and unheated sediment samples were studied. This original study revealed a systematic discrepancy between OSL and TL ages, and the authors concluded that multi-grain OSL results from fine grain quartz could not be trusted because of small scale dose rate heterogeneities and/or incomplete OSL signal resetting of fine grain quartz, possibly due to roof spall contamination.

To resolve this discrepancy and further constrain the chronology of the sequence (in particular, Quina layers at the top of the sequence remained poorly dated because of the scarcity of heated flint samples), coarse grain quartz and potassium-rich feldspar extracts have been studied using, respectively, single grain OSL and various IRSL signals.

These luminescence signals, because they provide complementary information, are expected to shed more light on the chrono-stratigraphy of Roc de Marsal. In particular, OSL and IRSL signals have different sensitivities to sunlight exposure: thus, their comparison allows identifying luminescence signals resetting problems at the time of sediment deposition, and help constrain single grain OSL analysis. The OSL from eight samples has been measured; in all cases, the OSL signal is dominated by the fast component. However, the proportion of grains emitting detectable OSL greatly varies between samples: whereas ~30-40 % of the grains sampled from combustion features (n=3) are usable for OSL dating, only ~5-10 % of the grains from unheated sediment samples (n=5) show an uncertainty on the test dose (~25 Gy) response of less than 20 %. Multi-grain post-IR IRSL signals at elevated temperature (225 °C) and IRSL signals at 50 °C have been measured and corrected for fading; they indicate that the OSL signals from all samples were fully reset before subsequent sediment deposition.

Statistical analysis of measured OSL data is performed using a newly developed Bayesian central age model [5].

New ages, both from IRSL and single grain OSL signals, will be presented and discussed, and an overall chronological scenario will be proposed.

ORAL

## 6. AN INTEGRATED APPROACH TO THE PALEOENVIRONMENTAL SETTINGS OF MOUSTERIAN HUNTERS IN SOUTHWESTERN FRANCE: COMBINING DATA FROM LARGE AND SMALL FAUNA COMMUNITIES

*Discamps, Emmanuel (University of Bergen, AHKR & Université de Bordeaux, PACEA) ediscamps@gmail.com*

*Royer, Aurélien (Université de Bordeaux, PACEA) aurelien\_royer@hotmail.com*

From MIS 5 to 3, Western Europe was subject to important climatic changes that affected the environments inhabited by past human societies. As a result, environmental changes have often been considered as a key factor in explaining the cultural and biological histories of Middle Paleolithic hunter-gatherers, as well as potentially underlying the technological variability of Mousterian lithic industries.

For the southwestern part of France, pollen analyses from deep-sea cores have well documented the evolution of floral communities and suggested that global climatic fluctuations influenced the evolution of terrestrial ecosystems. However, the exact impact of climatic changes on terrestrial ecosystems at local and regional scales is still poorly documented. Such changes certainly shaped the environments used by Neandertals, by constantly redefining the floral and faunal resources available to them.

Here, we present the first results of ongoing interdisciplinary research aimed at reconstructing the paleoenvironmental settings of Neandertal societies in southwestern France, through the exploitation of a regional GIS. This technique allows us to combine contextual information (site locations, stratigraphic sequences, cultural attributions, absolute dates), with climate and environmental data from different continental sources (archaeological and paleontological sites) and proxies (herbivore populations, small vertebrates communities and isotopic compositions). The patterns identified are then compared with pollen analyses of deep-sea cores. Chronological correlations of the different records are achieved by Bayesian modeling, a type of statistical analyses that integrates both absolute dates and stratigraphic constraints. A critical assessment of this dataset highlights the pros and cons of the different proxies.

In the end, it can be shown that global climate changes did not have the same impact on terrestrial ecosystems depending on geographical regions, even at such a small

scale. The results obtained emphasize the need of detailed, regional-scale, paleoenvironmental analyses of faunal communities in order to discuss human - environment interactions. Moreover, our integrated approach of large and small fauna communities allows estimating to what degree changes in subsistence strategies were influenced by changes in prey availability. We then discuss how much the diversity of Mousterian techno-complexes could be explained by Neandertal technological and behavioral adaptation to different types of environments.

ORAL

## 7. RÉVISION DES MODÈLES D'ORGANISATION TECHNO-ÉCONOMIQUES DES SOCIÉTÉS DU PALÉOLITHIQUE MOYEN RÉCENT DANS LE NORD-EST AQUITAIN

*Faivre, Jean-Philippe (UMR 5199 PACEA) jp.faivre@pacea.u-bordeaux1.fr*

*Bourguignon, Laurence (INRAP) laurence.bourguignon@inrap.fr*

*Turq, Alain (MNP) alain.turq@culture.gouv.fr*

*Jaubert, Jacques (UMR 5199 PACEA) jjaubert@pacea.u-bordeaux1.fr*

Le renouvellement des études sur le Paléolithique moyen récent permet, aujourd'hui, de percevoir différemment la variabilité des techno-complexes lithiques moustériens dans le nord-est du Bassin aquitain. Cette situation s'illustre notamment au travers de l'étude conjointe des savoir-faire techniques et des activités de subsistance s.l (e.g. modalités d'acquisition et / ou de gestion des ressources animales et minérales), démarche décisive dans l'appréhension des espaces parcourus et occupés par les groupes moustériens (e.g. Binford 1979 ; Kelly 1983 et 1988 ; Bamforth 1986 ; Kuhn 1992, 1995 ; Andrefsky 2009 ; Delagnes et Rendu 2011). Parallèlement aux travaux portant sur la géographie et la chronologie des systèmes de production (Levallois, Quina, Discoïde, ...), cadres majeurs et structurants des techno-complexes lithiques, il convient aujourd'hui de préciser les modèles d'organisation techno-économiques développés à partir de ses savoir-faire techniques afin, in fine, de réviser les stratégies de mobilité qu'ils sous-tendent.

ORAL

## 8. LES TECHNO-COMPLEXES LITHIQUES DU PALÉOLITHIQUE MOYEN RÉCENT (MISS5-3) DU NORD-EST AQUITAIN : ÉTAT DE LA QUESTION

*Turq, Alain (MNP) alain.turq@culture.gouv.fr*

*Bourguignon, Laurence (INRAP) laurence.bourguignon@inrap.fr*

*Faivre, Jean-Philippe (UMR 5199 PACEA) jp.faivre@pacea.u-bordeaux1.fr*

*Gravina, Brad (UMR 5199 PACEA) gravina.brad@gmail.com*

*Discamps, Emmanuel (AHKR Institute, University of Bergen) ediscamps@gmail.com*

*Soressi, Marie (Leiden University) m.a.soressi@arch.leidenuniv.nl*

*Jaubert, Jacques (UMR 5199 PACEA) jjaubert@pacea.u-bordeaux1.fr*

Le nord-est du Bassin aquitain est riche de plusieurs espaces géographiques (Charentes, Périgord, Bergeracois, Agenais, Quercy) constituant des territoires singuliers de par la densité des enregistrements archéologiques et les données lithologiques qui leurs sont propres. Pour chaque techno-complexe lithique (TCL) moustérien, ces données lithologiques mettent en relation certains territoires.

Ainsi, un ensemble cohérent s'organise autour du Périgord noir et de ses archéo-séquences, à partir desquelles ont été largement définis les faciès "bordiers" et, plus récemment, les TCL paléolithiques moyen (ACRs Aquitain et Quercy).

Dans le cadre de cette communication, nous proposons une révision des critères de définition des TCL excluant largement ceux retenus par F. Bordes dans la définition de ses faciès, et privilégiant, comme cadre structurant, les systèmes de production lithique (Levallois, Discoïde, Quina, ...). À partir de ce cadre, les données techno-économiques révéleront la dynamique relative à la mobilité des populations porteuses de ces savoir-faire. Une nouvelle grille de lecture, systémique, structurera l'ensemble de ces données.

Une approche renouvelée des archéo-séquences ainsi sélectionnées (selon un enregistrement diachronique et selon un degré d'intégrité fiable) au sein de ce territoire sera proposée à partir de cette grille de lecture.

ORAL

## 9. SOURCES OF VARIABILITY IN LATE MIDDLE PALEOLITHIC LITHIC TECHNOLOGY IN EASTERN CANTABRIAN REGION

*Rios-Garaizar, Joseba (CENIEH) joseba.rios@cenieh.es*

In the last decades the Late Middle Paleolithic (LMP) of Cantabrian Region has been thoroughly investigated from a technological perspective, resulting in a significant increase of the information available for synthetic approaches (among others: Carrión et al 2008, Maillo 2005, Sánchez-Fernández and Bernaldo de Quirós 2008, Rios-Garaizar 2008). One of the major features of this period in this region is the high degree of variability than can be observed in settlement strategies, raw material provisioning, lithic tool production and use. Precisely, in Eastern Cantabrian Region, the information available from sites like Axló, Amalda, Arrillor or Lezetxiki evidences this variability. Different technological strategies can be observed through time, for example in Axló Levallois based technologies are substituted by Quina, but also the use of different technological strategies can be observed inside the same assemblage, as happens in Amalda level VII (Rios-Garaizar 2010). We can see also subtle differences in the way the same technological strategy is applied, as has been observed between Quina technology levels in Axló (Rios-Garaizar 2005).

In this scenario the environmental transformations played an important role creating the conditions which Neanderthal populations adapted to, but the process of choosing and applying different technological solutions seems to rely more on cultural traditions and socio-economic organization. For example the process of ramified Levallois production is not a simple response to raw material scarcity, but a solution for new productive necessities (Rios-Garaizar et al. submitted). We are going to explore the possibilities of inferring changes in social organization as the source of this variability between Lithic Techno-Complexes from LMP in the Eastern Cantabrian Region.

ORAL

## 9 BIS. MESS AT THE END. THE LATE MOUSTERIAN IN NORTH AND NORTH-EAST IBERIA: CUEVA DEL ESQUILLEU (CANTABRIA, SPAIN) AND TEIXONERES CAVE (BARCELONA, SPAIN)

*Chacón, María Gema (IPHES, URV (Tarragona, Spain) gchacon@iphes.cat*

*Baena, Javier (UAM, Department of Prehistory (Madrid, Spain) javier.baena@uam.es*

*Carrión, Elena (Ministerio de Cultura (Madrid, Spain) elena.carrion@mecd.es*

*Torres, Concepción (UAM, Department of Prehistory (Madrid, Spain) conxi\_@hotmail.com*

*Rosell, Jordi (IPHES, URV (Tarragona, Spain) jordi.rosell@urv.cat*

*Blasco, Ruth (Gibraltar Museum (Gibraltar) rblascolopez@gmail.com*

*Rivals, Florent (ICREA (Barcelona, Spain) frivals@iphes.cat*

The Iberian Peninsula is an important region for the study of the final evolution of Mousterian communities on European scale. This region presents very important sites that provide a great quantity of information to address the socio-economic variability of last Neanderthal groups. Heterogeneity and complexity of Mousterian groups seems to show a variety of responses that include both adaptive processes, like other characterized for changes in the patterns of exploitation of the environment and ecological alternative occupation.

In this paper we present the data about the lithic techno-complexes from Esquilleu Cave (Santander, Spain) and Teixoneres Cave (Barcelona, Spain). These sites are located in two different geographical areas where the traditional interpretation of the Late Mousterian propose different technical behaviors between the Cantabrian and Mediterranean Neanderthals groups, and in this way different subsistence adaptive answers.

The cultural attribution of some lithic assemblages, especially when they show knapping strategies with little specializations as is the case of discoid production schemes, could be ambiguous and confusing. This is further complicated if we add the temporal coexistence with non expedite knapping methods as Levallois or Quina. The Esquilleu cave has a very well-known archaeological sequence that provides essential data to understand the Late Mousterian at the Iberian Peninsula. More than 41 stratigraphical levels with 34 with late Mousterian occupation provide a recent regional chrono-cultural sequence with particular changes. From periods with wide presence of Quina and Levallois knapping schemas to

the late and speed changes of the controverted discoid unit (levels VI-III), the whole sequence demonstrates during the MIS3 the existence of particular adaptations to the mountainous Picos de Europa context.

Teixoneres Cave (Barcelona, Spain) excavated since 2007 has also provided a significant archaeological record belonging to the Late Pleistocene (MIS 3). Level III (that focus this paper) corresponds to a palimpsest alternating human and carnivorous activities. The recent results of the techno-complexe studies show technological patterns similar to these from late Middle Paleolithic Levels from Esquilieu with a mix use of Levallois and discoidal methods, the last one essentially on quartz with production orientated to obtain pseudolevallois points.

This paper provide new information about the singular or coexisting production systems in very different geographical and ecological areas to show diachronic and synchronic trends at the south-west Europe, and at the same time scope the particularities of the late Iberian Mousterian.

## 1. EARLIEST MESOLITHIC BONE INDUSTRY FROM A PEAT BOG SITE STANOVOYE 4.

*Zhilin, Mikhail (Institute of Archaeology Russian Academy of Sciences, Moscow) mizhilin@yandex.ru*

The site Stanovoje 4 is situated at Podozerskoye peat bog between Ivanovo and Yaroslavl, Upper Volga region of Central Russia, about 250 km to the north-east from Moscow. 600 square meters were excavated there under the direction of the author in 1993-2002.

Its lower (IV) cultural layer is the earliest site of Butovo culture. The site was situated on a low lake shore at the source of a small river and was flooded by a lake transgression. Pollen spectra from the bottom layer of gyttja overlaying cultural layer IV in two cores are characteristic for the very end of the Younger Dryas. Samples of gyttja deposited during this transgression are dated to  $10.060 \pm 120 - 9850 \pm 60$  BP. Two tools made from elk bone and antler yielded  $^{14}\text{C}$  dates  $9879 \pm 50$  and  $9741 \pm 40$  BP. These data indicate habitation of this site during transition from the Younger Dryas to Preboreal period or in the very beginning of the Holocene.

54 bone and antler tools were found in the lower (IV) cultural layer of Stanovoje 4. All of them were subject for complex research including typological, technological and use-wear analyses. Experiments in making replicas of bone slotted arrowheads, shafting them into arrows and shooting with bow were carried out.

Weapons are represented by a long flat arrowhead and three similar ones with a slot along one side, one of which preserved inserts – two fragments of the same unretouched microblade still in their original position. Similar inserts, removed from one core dropped out from the second arrowhead and were found mainly within 1-5 cm from it. Two similar arrowheads have slots along both sides. Two broken lance points and a broken dagger with slots along both sides were found. Other tools include broad knives made from elk scapulae; narrow knives with rounded end; antler axe and adze blades and two sleeves for their mounting; awls made from various bones and antler; long side scrapers; burins-scrapers made from beaver mandibles; antler pressure-flakers and a punch. A wedge; a preform of a dagger made from elk tubular bone; a fragment of a harpoon preform; fragments of long splinters, removed

with “groove and splinter” technique from tubular bones; fragments of various undeterminable tools and worked bone; an antler perforated ornamented disk were also found in this layer.

Materials of the lower (IV) cultural layer of Stanovoje 4 demonstrate that already in the very beginning of the Mesolithic Upper Volga population worked out main groups of bone and antler weapons and tools needed for successful adaptation and life in the forest environment. Sites of Preboreal and Boreal periods show further development of these traditions in Butovo culture.

Acknowledgements Research was supported by RFBR, grant 12-06-00100.

ORAL

## 2. DATING FRIESACK 27A

*Groß, Daniel (Centre for Baltic and Scandinavian Archaeology) daniel.gross@schloss-gottorf.de*

The site Friesack 27a is located in the Warsaw-Berlin ice margin valley of the last Glaciation northwest of the modern town of Friesack. Nowadays it appears as a small hill on a meadow that is used for cow grazing. During the excavations in the 1980's the former shore area of a lake was excavated. In prehistory it was directly connected to a nearby settlement on higher ground. It was possible to differentiate four occupation phases, probably summarizing up to seven single occupation events. These events were characterized by sandy layers within the genuine peat, which resulted from erosion phases that subdivided the overgrowing process of the lake. The good conditions for preservation of organic remains made it possible to date the phases directly via radiocarbon dating and cross-check the results with relative datings by palynological analyses and peat-growth estimates.

The dating of the occupation phases was done by palynological analyses and radiocarbon measurements. The latter were included into a Bayesian model which included peat growth models such as the stratigraphy of the site.

Compared to the size of excavation quite a high number of radiocarbon samples was taken so that a fairly sound chronological model was established. Nevertheless it became obvious that there might be problem of conventional dates of plant material as these samples

turned out to give too young dates compared to AMS dated ones. Furthermore the radiocarbon plateaus in the beginning and end of the Preboreal are hard to deal with because high resolution dating is not possible without further ado. With regard to this, the peat growth model gave good hints to refine the AMS results with high standard deviations. Vice versa it was possible to refine the model itself with respect to the Bayesian modelling. Generally it can be said that the dating of unstratified or bulk samples are highly disputable in lake shore environments and that it is important to have a good idea of the stratigraphy to apply an adequate dating strategy.

Dealing with the plateaus in the early Holocene, and especially the Preboreal, is one of the most important tasks for the future. As long as the onset of Mesolithic traditions in the northern European lowlands is not clearly dated it will be impossible to solve the questions why and when these people immigrated into the area. Additionally, their reaction to the immense environmental changes at the beginning of the Holocene can only be understood if sites and environmental events are reliably parallelized. Therefore it is important to refine the chronology, not only by radiocarbon dating, and understand when and why the change from the Palaeolithic to the Mesolithic took place in different regions. Wet-land-sites bear the probably best potential to approach these questions as they give the most comprehensive material for environmental and archaeological research.

ORAL

### 3. THE MESOLITHIC BOG SITE DUVENSEE 11, NORTHERN GERMANY. FIRST RESULTS OF THE SPATIAL, TECHNOLOGICAL AND CHRONOLOGICAL ANALYSIS.

*Lübke, Harald (ZBSA, Schleswig) harald.luebke@schloss-gottorf.de*  
*Meadows, John (ZBSA, Schleswig) jmeadows@leibniz.uni-kiel.de*  
*Göbel, Karin (ZBSA, Schleswig) goebel@schloss-gottorf.de*  
*Groß, Daniel (ZBSA, Schleswig) daniel.gross@schloss-gottorf.de*  
*Bokelmann, Klaus (ALM SH, Schleswig (retired) affodil@aol.com*

The Duvensee peat bog, Northern Germany, represents one of the most prominent Stone Age palaeo landscapes in Northern Europe, with several Stone Age campsites on small islands or peninsulas on the western border of the former Holocene lake. The outstanding preservation of these campsites allows detailed examinations of the spatial organisation of prehistoric hunter-gatherer campsites.

The most recently excavated is the boreal Mesolithic site Duvensee 11, where a concentration of hazelnut roasting hearths, bark-mat layers and incorporated small knapping areas with a diameter of about 4m was found. What initially appeared to be a uniphase central fireplace of a larger settlement area turned out to be a multiphase structure, which had accumulated intermittently on the highest and driest spot of a former island over an extended period.

Based on the existing excavation records (840 excavation plans, 8 section drawings, 65000 measurement points), a GIS-based 3D model of the site was created, which is used also for detailed intra-site analyses of the flint artefacts. A Bayesian chronological model was built, incorporating the 34 radiocarbon results (mostly from bark, hazelnuts and wood charcoal, dated at the Leibniz-Labor, Kiel, in 2000–2002), and the stratigraphic sequences illustrated in the 3D model. The model has 4 components: 3 vertical sequences (western and eastern bark-mat stacks and a series from the central fireplace), and a group of 6 unstratified samples from the shore area. The sequences are linked together both as components of the overall site occupation, and by cross-referencing events that affect more than one sequence.

The main period of activity spanned c.200 years. Site 11 was not occupied continuously throughout this period, as peat had started to form over some bark mats, but people may have returned to this location every few years, before trees could cover it from view. This pattern is consistent with the number of bark-mat layers, which (if each layer represents a single season) implies that the site was used at least once a decade, on average. Soon after 8500 cal BC it was abandoned, and the site was overgrown with peat, but there was at least one brief occupation episode afterwards, probably between 8400 and 8300 cal BC.

Radiocarbon measurements since the 1970s show that at least 7 sites at Duvensee date to the calibration plateau between 9000 and 8300 cal BC. Site 11 was probably the most frequently and extensively occupied of these sites. Radiocarbon dating has become more precise over time, but inspection of calibrated dates still gives exaggerated impression of site longevity. The Bayesian model for site 11 gives a more realistic idea of site chronology and helps to identify re-occupation of abandoned sites.

ORAL

#### 4. SOME RESULTS FROM AN ANALYSIS OF MESOLITHIC ANTLER FRONTLETS

*Wild, Markus (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM)  
wild@rgzm.de*

Supposed Mesolithic antler head-dresses from Star Carr have been interpreted as either shamanic garb and/or hunting disguise (Clark 1954). This has had a lasting impact on our interpretation of Mesolithic and hunter-gatherer societies overall. The hypothesis that these objects were worn as a mask or head-dress has not yet been proven. However the recovery of comparable objects from sediments of roughly contemporaneous or slightly earlier age across the Northern European Plain keeps this model alive. Apart from the fact that these comparable artefacts are not yet well defined and their precise use and function still remains unclear and requires more detailed investigation, the apparent significance of the presence or absence of antler frontlets in extensively excavated Early Mesolithic bog sites across Central and Northern Europe is generally still not well understood.

16 out of a total of 37 modified cervid skulls with attached antlers from 8 sites which have been discussed in the context of the Star Carr antler frontlets have recently been re-examined morphometrically and technologically by the author. The following parameters were recorded for the specimens: animal species, minimum age, weight and preservation, abiotic and biotic modifications that include breakage patterns, perforations, cut marks and notches.

The analysis of these parameters allows for the division of the group of modified deer skulls into four distinct groups of which one is discussed here: Besides the artefacts from Star Carr already mentioned, only one intensively modified red deer skull each from Hohen Viecheln and from Berlin-Biesdorf and two laterally perforated deer skulls from Bedburg-Königshoven – are classed as belonging to the newly created group of *Hirschgeweihkappen* [deer antler caps].

*Hirschgeweihkappen* are a rare spatial and temporal occurrence, within the Northern Technocomplex (David 2005) of osseous material working [artefacts] during the Middle to Late Preboreal. Their occurrence is biased towards larger Early Mesolithic sites in the vicinity of lacustrine environments although they are absent from comparable sites like Friesack where the osseous

material otherwise shows technological parallels to that of sites with *Hirschgeweihkappen*. This phenomenon should be linked to the still poorly understood function of this latter type of artefact.

ORAL

#### 5. DANISH MESOLITHIC WETLAND SITES: LANDSCAPE RECONSTRUCTIONS AND ARCHAEOLOGICAL EVIDENCE

*Jessen, Catherine (The National Museum of Denmark)  
catherine.jessen@natmus.dk  
Mortensen, Morten F (The National Museum of Denmark)  
morten.fischer.mortensen@natmus.dk*

Denmark has a rich and important record of wetland archaeological sites from the Mesolithic period. Many of these sites were excavated in the middle of the last century, often as multidisciplinary studies which included extensive pollen analyses along with detailed descriptions of the bog profiles. The interpretation of these data in terms of landscape and resources involves the disentangling of proxy responses in a period of rapidly changing climate, the immigration of tree species and formation of woodland, sea-level changes and the impact of humans. Recent evidence from Lundby Mose, Sjælland has suggested that different landscape types are associated with different types of archaeological deposits. Here we present a synopsis of the important Danish Mesolithic wetland sites in relation to this new data and compare the environmental responses with those of the late glacial period. Additionally, this synopsis attempts to highlight any geographical, chronological and/or environmental patterns in the landscape changes associated with the known archaeological evidence.

ORAL

#### 6. NEW EXCAVATION RESULTS FROM THE BOG RÖNNEHOLM MOSSE, CENTRAL SCANIA, SOUTHERN SWEDEN

*Larsson, Lars Rönneholms mosse was a part of a large lake in the central part of Scania, southern Sweden. It was filled up with organic litter during a long period lasting until the mid part of the Atlantic. Due to vast turf exploitations of the bog (Institution of archaeology and Ancient History) Lars.  
Larsson@ark.lu.se  
Sjöström, Arne (Institution of archaeology and ancient history) Arne.Sjostrom@ark.lu.se*

Rönneholms mosse was a part of a large lake in the central part of Scania, southern Sweden. It was filled up with organic litter during a long period lasting until the mid part of the Atlantic.

Due to vast turf exploitations of the bog excavations and surveys have been conducted during a number of years. A large number of sites has been detected most of them very small with a fireplace and a small number of artefacts. They seem to have been used during a short stay lasting from a few hours until a few days. At one of these sites the proximal part of an arrow with the microlithic still intact was found. The area also includes a number of camp sites that was used for a somewhat longer time.

---

ORAL

## 7. RADIOCARBON CHRONOLOGY OF WOODEN STRUCTURES ON THE SITE ZAMOSTJE 2 (MESOLITHIC-NEOLITHIC, CENTRAL RUSSIA)

*Lozovski, Vladimir (Institute for the History of Material Culture of the RAS) zamostje68@gmail.com*

*Lozovskaya, Olga (Institute for the History of Material Culture of the RAS) olozamostje@gmail.com*

Investigations on the site Zamostje 2 in 1989–2014 revealed a special fishing zone of the settlement with a high concentration of various fishing facilities from different periods.

The complex of fishing structures consists of three fish-traps of conical shape made from pine and fir splinters and bound by reed grass; two movable fences made from long pine and willow splinters (more than 4 m in length) with bindings from bulrush, which have been found in the bed of the Dubna river; as well as 230 wooden piles (including 150 piles found in the Dubna river bed). The radiocarbon dating revealed they belong to the different chronological periods. Results of morphological analysis of wood piles are of particular interest as well.

The findings of mobile fences in the river Dubna bed date to the Late Mesolithic – 7200 BP, the remains of the three fish-traps date to the Early Neolithic Upper Volga Culture — 6500 - 6400 BP. Selective dating of the piles found both in the Dubna bed and in the excavation site revealed a clear breakdown of the all piles into four chronological groups: the first group dates to the Late Mesolithic (7200 BP), the second group dates to the end of the Early Neolithic Upper Volga Culture (6300–6200 BP), the third one is clearly grouped around 6000 BP,

i.e. the transition period from the Early Neolithic to the Middle Neolithic. The last group dates back to the Middle Neolithic (5800–5200 BP). According to data from morphological analysis, hornbeam was the most popular material (23% of all piles), poplar goes second (17%), then bird cherry tree (16%), i.e. 56% of all items were produced from these species, other piles were also made of broad-leaved trees (willow, elm, alder, maple, ash). Pine and birch were used in only 9% and 2% of items, respectively.

It is worth mentioning that such chronological distribution of wooden structures partially contradict to the classical stratigraphic sequence traced during long-term excavations in Zamostje 2. Briefly, the local stratigraphy is as follows: 7900–7800 BP — Lower Mesolithic layer, 7400–7200 BP — Upper Mesolithic layer, 7100–7000 BP — Final Mesolithic layer, 6800–6100 BP — Early Neolithic Upper Volga Culture horizon, 5800–5200 BP — Middle Neolithic layer.

Thus, the wooden structures reveal objects constructed during the Upper Mesolithic, Early and Middle Neolithic periods. For periods of the existence on the site of the lower layer and final Mesolithic layers any structures have not been traced. And vice versa, quite a large group of piles dated back to about 6000 BP, i.e. the transition period from the Early to the Middle Neolithic, is not reflected as a separate layer in the classical stratigraphy of Zamostje 2. Also, for almost two millennia, from the Upper Mesolithic (7300 BP) to the Middle Neolithic (5200 BP), ancient inhabitants of Zamsotje 2 preferred broad-leaved species, and in particular hornbeam. This data contradicts the modern concepts of the vegetation development during the Early and Middle Atlantic, which are based on the palynological analysis.

# B42 The adoption of pottery in Prehistory: a functional perspective

## 1. DATING EARLY POTTERY IN EAST ASIA

*Bar-Yosef, Ofer (Harvard University) ofer.baryosef@gmail.com*

The constant debate whether the invention of pottery occurred independently in several geographic localities within East Asia or emerged in a core area as a new technique for the production of usable making objects cannot be resolved with the currently available evidence.

This study, jointly conducted with Prof. Xiaohong Wu and Chi Zhang (Peking University), Paul Goldberg and David Cohen (Boston University) Prof. Yuan Jiarong (Institute of Archaeology, Hunan Province) and collaboration with colleagues from Jiangxi Institute of Archaeology, was carried out in the radiocarbon labs of Peking University and Weizmann Institute of Science.

Stratified pot fragments are currently dated in south China to 20-18,000 cal BP in three cave sites – Xianrendong, Diaotonghuan and Yuchanyan. In the Japanese archipelago first pots are dated to 16.5-15.0 cal BP in Odai TYamamoto and other sites, and somewhat similar dates were obtained in sites in Eastern Siberia. However, the vast landmass in between, the central plains of China produced only dates in the range of 11.5-10.5 cal BP. While the Southern Chinese pots are found in contexts of cobble-tools (e.g., choppers, cores and flakes with a few bone tools and Unio shell tools), those in central China, Siberia and Japan occur within assemblages dominated by microblades.

Thus, the debate on the origins of pottery making in East Asia cannot be resolved without further research in central China, where site of Terminal Pleistocene and early Holocene are buried under late alluvial accumulations.

ORAL

## 2. THE EARLIEST AFRICAN CERAMICS: MORE THAN 10,000 YEARS AGO BETWEEN THE SAHEL, THE SAHARA AND THE NILE VALLEY

*Huysecom, Eric (University of Geneva) eric.huysecom@nige.ch*

A vast complex of open-air sites in the Dogon Country in Mali, Ounjougou presents highly varied human occupations within a geological and paleoenvironmental sequence extremely rich in vegetal micro- and macro-re-

mains. The conditions necessary to link cultural, climatic and environmental variability over a long chronological period are thus exceptionally well met here.

The lowest layers in the sites of Ravin de la Mouche and Ravin du Hibou have yielded many new elements. Indeed, the stratigraphic sequence and the many dates obtained by C14 and OSL have provided a *terminus ante quem* of 9,400 cal BC for ceramic sherds found in association with a lithic industry containing small bifacial weapons. Geomorphological and sedimentary analyses indicate a powerful hydrological regime that remodeled the landscape of the bottom of the Yamé Valley where the Ounjougou site complex is found.

This allows us to confirm that the emergence of this techno-typological complex took place during one of the humid phases of the Pleistocene-Holocene transition recently identified in West Africa, most likely the climatic amelioration between 10,200 and 9,400 cal BC. Recent syntheses have confirmed that the monsoon front reached 14° N latitude around 9,500 cal BC. Our paleoenvironmental analyses indicate the landscape was transformed: surfaces that had been desert for several millennia were covered with an open steppe with grasses, some of them edible. This situation allowed the spread of prehistoric humans across the continent and probably favored a new behavior: the practice of selective and intensive gathering, that is, the targeted and rational harvest of wild grasses. Yet the seeds need to be not only kept dry and protected from rodents, but also need to be cooked for the body to absorb the starch, human lacking the necessary digestive enzymes to break it down; hence the utility of pottery. This suggests an invention context for pottery similar to that in the Far East, parallel to the production of weapons adapted in size to hunt small prey frequenting the open savannas.

The discoveries at Ounjougou this evidence the emergence of pottery south of the Sahara in relation to the spread of grasses in tropical Africa. This invention seems to have then spread toward the Sahara during the Early Holocene, at the end of the 10<sup>th</sup> and early 9<sup>th</sup> millennium BC, while the desert zone became increasingly green.

*Les découvertes à Ounjougou témoignent de l'émergence de la céramique au sud du Sahara en relation avec le redéploiement de la couverture végétale graminéenne en Afrique tropicale, et ce avant 9'400 BCcal. Cette invention semble avoir diffusé ensuite en direction du Sahara durant l'Holocène ancien, dès la fin du 10e et le début du 9e millénaire BCcal, alors que la zone désertique se couvrait de végétation.*

ORAL

### 3. SHIFTING PARADIGMS. THE ADOPTION OF POTTERY IN UPPER MESOPOTAMIA

*Nieuwenhuysse, Olivier (Leiden University)  
o.nieuwenhuysse@arch.leidenuniv.nl*

New discoveries on the Upper Mesopotamian plains are radically altering our paradigms for understanding early ceramic adoption and use in Western Asia. For decades many Near Eastern archaeologists assumed that pottery was initially adopted to facilitate cooking and bulk storage, thus allowing the successful establishment of the Neolithic economy. As well, implicit in many models was the assumption that following the initial adoption ceramic evolution followed a linear trajectory from coarse, experimental undecorated vessels towards increasingly stylistically and technologically elaborated products. These assumptions remained largely unchallenged for long, due to the near absence of well-dated early ceramic sites. This has changed over the past two decades as several early Pottery Neolithic sites have been excavated. They yield an early ceramic horizon well dated to between 7000-6700 cal. BC. The ceramic containers recovered from these sites do not confirm to our earlier expectations at all.

I shall summarize current work on the Late Neolithic (7th millennium) ceramics from Tell Sabi Abyad, northern Syria. Tell Sabi Abyad is one of several sites yielding an early ceramic horizon dated to ca. 7000-6700 cal. BCE. The archaeometry of the pottery is being studied with microscopic, petrographic, chemical and residue trace analyses.

The work at Tell Sabi Abyad and contemporaneous Late Neolithic sites across Upper Mesopotamia opens up new perspectives on the initial adoption of pottery in the region. The earliest pottery at the site was definitely not used for bulk storage. Its role as a facilitator of cooked food remains matter for debate. While cooking clearly seems to have been amongst its uses, the very low quantities of ceramic vessels at this early stage caution against a whole-sale culinary 'revolution'.

These important functions of pottery emerged at much later stages. The early ceramic containers are small and light weight, hence easy to carry around; indeed there is strong evidence to suggest that they circulated in networks of exchange. The great care with which they were crafted, finished, and sometimes decorated suggests that they played a role in stylistic signaling among Ne-

olithic communities. Pottery at this stage was certainly not the only material from which small-sized containers were crafted. Pottery vessels may have circulated in the same social framework as vessels made of stone.

ORAL

### 4. DEFINING EARLY POTTERY USE THROUGH LIPID RESIDUE ANALYSES

*Roffet-Salque, Mélanie (Organic Geochemistry Unit, School of Chemistry, University of Bristol, Cantock's Close, Bristol BS8 1TS, UK.) melanie.salque@bristol.ac.uk  
Evershed, Richard P. (Organic Geochemistry Unit, School of Chemistry, University of Bristol, Cantock's Close, Bristol BS8 1TS, UK.) R.P.Evershed@bristol.ac.uk*

Pottery is the most common artefact excavated at archaeological sites from the Neolithic onwards and the determination of preserved organic residues can provide major insights into vessel use and wider aspects of resource acquisition and diet. Such investigations shed light on whether vessels were used in food preparation or served other functions. The determination of lipids preserved in the porous fabric of potsherds is a particularly productive avenue of enquiry, with specific lipid biomarkers allowing the identification of animal fats, beeswax, resins, tars, plant lipids, etc. (Evershed 2008a). The application of stable carbon isotopic analyses of preserved fatty acids significantly increases resolution, enabling distinctions to be drawn between non-ruminant and ruminant animal fats, carcass and dairy fats (Dudd and Evershed 1998), and fats/oils from freshwater and marine organisms (Cramp and Evershed 2013). The detection of thermally altered fatty acids point to heating regimes above certain thresholds, e.g. ketones (Evershed *et al.* 1995) and  $\omega$ -(*o*-alkylphenyl)alkanoic acids (Hansel *et al.* 2004) both require heating in excess of 250°C to drive the transformations. The latter, together with long-chain dihydroxy fatty acids and isoprenoid acids, further help to define the sources of preserved fats and oils. Experimental approaches, zooarchaeological and palaeobotanical evidences are routinely used to build interpretive frameworks (Evershed 2008b).

Here we consider the use of early pottery vessels from the perspective of lipid residue analyses of potsherds from Early Neolithic contexts from the Near East and Europe, defining pottery use and the wider economic implications through characterization of their lipid contents.

---

ORAL

## 5. THE ADOPTION OF POTTERY IN EASTERN MEDITERRANEAN: A LOOK THROUGH THE USE OF CERAMIC VESSELS.

*Vieugue, Julien (French research Center in Jerusalem)  
archeojulien@hotmail.com*

Pottery appears in the Northern Levant around 6900 cal B.C. Its invention occurs long after the development of agriculture and livestock. From this region, the production of ceramic vessels spreads toward Southern Levant and Anatolia, then into South-eastern Europe. In this last region, the pottery is introduced around 6500 cal B.C., like the agriculture and livestock.

It is generally known *when* and *where* the pottery appears, there are still many questions surrounding the factors that have caused to the emergence of this new technology. In other words, why did the populations from the 7<sup>th</sup> millennium cal B.C. start to use fired clay containers? The hypothesis that the ceramic vessels were used for food storage and cooking has been rejected several times over the past two decades. This paper seeks to contribute to this controversial debate through a functional study of pottery.

Analyses were recently undertaken regarding the function of the earliest ceramic productions from South-Eastern Europe and Southern Levant (6500-5800 cal B.C.). The research was carried out on a significant amount of pottery, including 2026 vessels and 72 128 sherds from 12 sites. The study was to combine the typometric characteristics (shape, size, volume, thickness) and the use-wears (residues and attritions) of Neolithic pottery.

The analyses have shown the diversity in the uses of the pottery. Fired clay containers had been involved in the storage and transfer of liquids, the cooking of meat, the preparation of bone powder, the grinding of materials or the consumption of foodstuffs. Although chronological changes are noticeable, the use range of pottery appears overall similar from the beginning to the end of the sites occupation. In parallel, the composition of ceramic assemblages presents strong regional variations. In Northern Levant and Thessaly, pottery used for the individual consumption of foodstuffs are prevailed. In the Southern Levant, Storage vessels and cooking pots are the most frequent functional categories.

Regional variations in the proportion of different functional classes of ceramic vessels indicate that the pop-

ulations from the 7<sup>th</sup> millennium cal BC. Did not adopt pottery for the same socio-economic purposes. The causes seem to be multiple. Depending on the cases, the adoption of pottery could be linked to a problem in the dietary resources management or to an economic reorganisation of societies.

## 6. THE ADOPTION OF POTTERY IN THE MIDWESTERN UNITED STATES:

*Skibo, James (Illinois State University) jmskibo@ilstu.edu  
Malainey, Mary (Brandon University) Malaineym@BrandonU.CA  
Kooiman, Susan (Michigan State University) kooimans@msu.edu*

Pottery appears in the Midwestern United States and signals the beginning of the Early Woodland Period. Although the timing for pottery varies considerably, it first appears by about 1,000 B.C. and then is found widely across much of the northern portion of the Midwest. The pottery has a number of regional names, such as Schultz Thick, Marian Thick, and Vinette I, but shares a number of basic attributes: thick, heavily grit tempered, with an open bowl form. A fundamental question that underlies the adoption and use of this new technology is, "What were they used for?" Ozker (1982) suggested long ago that the pottery at the Schultztz site, located at the confluence of the Tittabawassee and Shiawassee Rivers near present-day Saginaw, Michigan, was used to process acorns. Recently, we have identified nut lipids in early ceramic sites on Grand Island, Michigan using high temperature gas chromatography and mass spectrometry. Using a similar approach, in this study we test Ozker's hypothesis by examining the lipids from a sample of Schultz Thick to see if lipids associated with nut oil or other foods can be identified.

ORAL

## 7. INVESTIGATING THE EARLIEST APPEARANCES OF POTTERY IN THE ALASKAN ARCTIC

*Harry, Karen (University of Nevada Las Vegas), Liam Frink - liam.frink@unlv.edu (University of Nevada Las Vegas) karen.harry@unlv.edu*

The earliest pottery in the Alaskan Arctic dates to between 1500 and 500 B.C. Evidence suggests that the technology was introduced from Siberia, and that (like later pottery) the earliest ceramics took the form of utilitarian cooking pots and oil lamps. In this paper we explore what triggered the initial adoption of ceramics in this region.

We rely on data obtained from multiple sources, including the archaeological record, ethnoarchaeological and experimental studies, and nutritional reports.

Our results indicate that, unlike other areas of the world, the adoption of the cooking pot was not triggered by a major dietary shift or the introduction of new foods, nor did it offer any nutritional advantages over other food preparation techniques. Instead, we suggest that pottery was adopted because it made efficient oil lamps and allowed the Arctic people to expand their culinary experiences. But the need for oil lamps and the desire for culinary variety could not have been new. If the appearance of pottery cannot be explained by newly created needs. what does explain its adoption?.

We propose that the answer to this question lies in understanding both the nature of pottery production in the Arctic and the nature of the sites at which the earliest pottery is found. In the Arctic, the production of pottery would have been limited to a short window in the summer (Frink and Harry 2008) and required the use of oil as a coating for the necessarily porous vessels (Harry et al. 2009). However, access to oil in the summer would not always have been possible. We suggest that the appearance of pottery coincides with the appearance of new technologies (specifically, the seal float and the seal poke) that made it possible to (a) reliably harvest sea mammals and thus obtain sea mammal oil during the summer months, and (b) store oil for long periods of time. This conclusion is based on the co-occurrence of the earliest ceramics with the earliest-maritime based sites to yield evidence of reliance on open sea hunting.

We conclude that the adoption of pottery in Alaska was not triggered by new dietary needs, but resulted from a desire for culinary variety and efficient oil lamps. We

further conclude that the timing of its adoption is explained by the appearance of new technologies that made it possible to overcome, for the first time, the environmental challenges associated with making pottery in the Arctic. These findings demonstrate the importance of understanding the full suite of technologies available to a society when considering why one particular artifact was adopted.

*Spanedda, Liliana (Departamento de Prehistoria y Arqueología. Universidad de Granada) spanedda@ugr.es.*

While performing the works of Jaén Tramway System passing through Marroquíes archaeological site, various archaeological contexts were investigated. Especially in the so-called Section 3 a concentration of funerary features was located. Their analysis has documented a series of ritual practices involving the displacement of human remains between neighboring graves and sacrifice-offering of numerous animal remains for an extended period of time between the Chalcolithic and Bronze Age (2600-1750 cal BC). To assess possible changes in the environment and especially in the diet during this period and analyze possible differences between individuals, a study of carbon and nitrogen isotopes has been undertaken.

65 human bone samples from 9 different pits have been selected for isotope analysis. 18 of them have been C14 dated in order to get a chronological frame. 33 samples belong to female remains and 23 to male ones. 54 individuals are adult, 9 are infant and 2 are young individuals. Collagen extraction has enabled  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  analysis by Elemental Analyser (Carlo Erba Model NA1500 NC Series 2) and a Mass Spectrometer (Delta Plus XL).

Temporal changes can be appreciated in  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values. Other differences can be related to age, sex or burial pit.

According to  $\delta^{15}\text{N}$  values two groups of women can be found and lower values belong to the few young individuals which have been studied. An increase in the

consumption of animal protein and arid conditions can be suggested in this area between the 3<sup>rd</sup> and 2<sup>nd</sup> Millennium BC.

ORAL

**2. UNBURIED NEANDERTHALS IN IBERIA? PALEOANTHROPOLOGICAL, FORENSIC AND EXPERIMENTAL APPROACH TO CARNIVORE MODIFICATION OF HOMINID INHUMATIONS**

*Harvati, Katerina (Senckenberg Center for Human Evolution and Paleoenvironment - Eberhard-Karls-Universität Tübingen) katerina.harvati@ifu.uni-tuebingen.de*

The identification of neanderthal intentional burials is not common, although there are several examples of such phenomena. The main problem that complicates their interpretation in the archaeological record is related with taphonomic processes erasing the evidence that would allow inferring inhumation practices. One of those taphonomic agents that most contribute to this lack of record are the large carnivores. A form of indirect interaction between hominins and carnivores is the alternate use of caves by both agents to develop different activities. Our previous experimental and archaeological research has shown that due to this alternation, the anthropic spatial structure of a site is altered and a significant part of the record is erased. Human burials may have also been susceptible to being destroyed during the Pleistocene as a result of such interaction. Is it possible then to recover this information?

We studied several neanderthal bones from archaeological sites from the Iberian Peninsula, such as Cova Negra (Valencia), Valdegoba (Burgos), Jarama VI (Guadalajara) and Los Moros de Gabasa (Huesca). They all presented carnivore damage on their bone surface, that compared to actualistic forensic observations, differ from the bone modification pattern resulting from a carnivore attack.

Therefore, bone damage on neanderthal bones suggests carnivore scavenging on exhumed hominin corpses by carnivores. This interpretation is supported by experimental series that show how carnivores are capable of erasing evidence of human inhumations.

Results show that there are strong paleoanthropological, forensic and experimental evidences to suggest that the neanderthal bones we analyzed are the result of scavenged corpses that may have been exhumed by large carnivores. This would mean that in some specific archaeological contexts, where the interaction between hominins and carnivores is present in the form of an alternation in the use of common spaces, the research concerning neanderthal burials has to be conducted from a different perspective. It is important therefore to reconstruct all the processes that have erased and destroyed the evidences of intentional inhumation. In this sense, it is necessary to apply a methodology were a taphonomic approach to bone surface, the development of experimental series and a forensic perspective are all combined to develop a useful research frame.

Our results are compared with other similar cases of modified neanderthal bones such as the femur from Hohlestein Stadel (Germany) and the navicular from Kalamakia (Greece), with the aim of obtaining a general framework on a phenomenon that seems to be common among Middle Paleolithic hominin remains.

Our methodology is a valid approach to recover information related to Neanderthal burials and therefore to understand a modern patterned social practice.

ORAL

### 3. BUILDING CHRONOLOGIES FROM BURIAL CONTEXTS TO TEST LATE NEOLITHIC AND CHALCOLITHIC SOCIAL DYNAMICS IN EASTERN IBERIA.

In this paper we present direct radiometric AMS datasets, paleodietary results from stable isotopes, and microwear analysis of teeth from Late Neolithic and Chalcolithic human remains from the Valencia region (Eastern Spain) to discuss diachronic social patterns. Most of the data generated come from three funerary contexts (Llometes, Pastora Cave, and La Vital) in the framework of recent research projects investigating social dynamics through funerary practices.

We compare this information with patterns observed in intra- and inter- site storage capability at settlements in order to obtain new insights for testing social inequalities.

The results suggest that different patterns can be observed based on the dataset, reinforcing the need to advance several lines of evidence in order to characterize the nature and underlying factors of shifting social patterns during these periods.

Within the framework of the research project "Approach to the first Neolithic communities from the north-east of the Iberian peninsula through their burial practices" our main goal is to get to know better the agricultural and farming societies who lived during the 5<sup>th</sup> and 4<sup>th</sup> millennia in this area. The archaeological context is unique due

to the inhumation in single burials and occasionally next to another individual.

In this paper we would like to show not only the new results of analysis and methodologies employed but the working strategy we have developed. Thus, there are two fundamental aspects: 1) the absolute dating is the main focus and 2) the collaboration with other researchers and laboratories need to be close (It is not our intention to ask for results to a laboratory, but to work with the people involved in the sampling since they know the advantages and disadvantages of each of the employed techniques).

The first results have already given information about the timing of these funerary practices, the morphology of the burials, the use of the perishable material, the diet and the degree of mobility of the populations, the kinship as well as the diary activities.

The ongoing analysis will offer us insights of multiple views of those first Neolithic groups through the analysis of the individuals.

*Richards, Michael P. (University of British Columbia / Max-Planck Institute for Evolutionary Anthropology / University of Durham) michael.richards@ubc.ca*

We report here on the results of carbon and nitrogen stable isotope analysis of humans and fauna from more than twenty Mesolithic and Neolithic sites from Eastern Iberia. In other parts of Europe there is isotopic evidence for an abrupt change in diet between these periods, especially in coastal regions of Northwestern Europe. To date, there are few isotopic studies for these periods from the Mediterranean. This poster reports new isotopic data from the eastern Iberian Peninsula, from sites dating to the Mesolithic, and early, middle and late Neolithic. The

results show no major diet shift between these two periods, and suggest that some dietary changes were introduced during the last stages of the Neolithic.

### 6. INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY FOR ANALYSIS OF ARCHAEOLOGICAL BONES FOR RECONSTRUCTION OF PALEODIET

*Santamaría Herrera, Alba (Universidad de Burgos) ash0016@alu.ubu.es*

*Palmero Diaz, Susana (Universidad de Burgos) spaldi@ubu.es*  
*Carmona Ballester, Eduardo (Universidad de Burgos) educarmonaball@gmail.com*

*Colina Santamaría, Álvaro (Universidad de Burgos) acolina@ubu.es*

The elemental composition of archaeological bones provides useful information for the dietary habits of ancient people because of food is considered as one of the patterns that best define the characteristics of the different populations, the environment in which they live and their adaptation.

Considering food as main factor incorporation of organic and inorganic substances to human body, it is possible to establish a direct relationship between the presence of certain substances in human bones and consumption of foods that provide these elements. The metals most frequently used in studies palaeodiet are: barium, copper, magnesium, iron, vanadium and zinc. It is also very important to consider aspects such as the choice of samples, cleaning processes to which they are subject or the possible effects of pollution thereof.

Human remains used for the study come from the archaeological site of Arroyal I, located in the town of Arroyal (Burgos, Spain). Bones were recovered through archaeological excavation conducted by a team from the Archaeology Area of the University of Burgos. We have tested a total of 15 samples for analysis, of which 9 are humerus and 6 are ulna, trying to have variability in sex and age of selected individuals. Non spongy part of the bone is taken because a part of the bone that has a sufficient thickness so as to eliminate contaminated surface before taking the sample for analysis is preferred.

The sample is subjected to a calcination process and subsequent acid solution of ash. The analysis of the met-

als of interest is performed by ICP-MS technique to detect metal portions level per billion (ppb).

A principal component analysis with the concentrations calculated from the analysis was carried out. Initially, samples are separated into three groups. For one side, samples with a higher content of zinc and copper (predominant metals in carnivorous diet) and moreover the samples with higher concentrations of strontium, vanadium, and barium (metals associated with rich diets) and finally samples containing predominantly iron and magnesium. In this separation no differences in sex or age of individuals is observed.

Thus, ICP-MS of archaeological bones permits the successful determination of elements, important for paleodiet reconstruction. This is a serious advantage of the method over existing methods when complex investigations with numerous samples are to be performed. The interpretation of the analytical data indicates that the population under study time in Arroyal I has not dominantly vegetarian or carnivore diet. The pattern suggests a non-restrictive access to food resources. In social terms, the study has shown that differences are related to individual habits of consume, not linked to sex or age.

**1. FORTIFIED SETTLEMENTS IN PORTUGUESE ESTREMADURA DURING THE THIRD MILLENNIUM BCE. RADIOCARBON CHRONOLOGY FOR VILA NOVA DE SÃO PEDRO (AZAMBUJA, PORTUGAL).**

*Gonçalves, Victor S (UNIQ: University Of Lisbon) vsg@campus.ul.pt*

*Sousa, Ana Catarina (UNIQ: University Of Lisbon) sou-sa@campus.ul.pt*

*Boaventura, Rui (UNIQ: University Of Lisbon) rui.boaventura@campus.ul.pt*

The Portuguese Estremadura is the region with the highest concentration of fortified settlements in Central and Southern Portugal.

Within this territory there are available now more than one hundred <sup>14</sup>C dates from a dozen of these sites: in the North bound (Lisbon Peninsula) Leceia, Zambujal, Penedo do Lexim, Olelas, Penha Verde, Castelo and Pragança; and in the South bound (Setúbal Peninsula) Rotura, Chibanes and Outeiro Redondo.

The discussion of absolute and relative chronologies of fortified sites in the Portuguese Estremadura started somewhat late: firstly with the relative chronology of Rotura (Gonçalves, 1966), then with the first radiocarbon dating of Zambujal (Schubart, 1975) and later with the important sequence of Leceia (Cardoso e Soares, 1996). Vila Nova de São Pedro (Azambuja), eponymous site of the 'Vilanovense' Culture during the historical-cultural paradigm, remains out of focus on all the interpretive proposals.

In 2010, following an emergency situation, the authors made a small rescue intervention in Vila Nova de São Pedro, cleaning a section and recovering some material (organic and artifacts). This is unpublished research data from the Work Group on Ancient Peasant Societies.

The first absolute dating from Vila Nova de São Pedro contributes to the review and discussion about the set of radiocarbon dating available for the fortified sites within the Portuguese Estremadura. Questions of chronology and patterns of use will be analyzed in connection with the information available for fortified settlements in other regions of Central and Southern Iberian Peninsula.

ORAL

**2. A BIOGRAPHY OF AGGREGATION PLACES: APPROACHING IBERIAN LATE PREHISTORIC DITCHED ENCLOSURES THROUGH BAYESIAN MODELING.**

*Balsera Nieto, Verónica (Instituto de Historia, CCHS, CSIC) veronica.balsera@cchs.csic.es*

The aim of this presentation is to analyze the spatial dynamics of ditched enclosure building of Iberia through the use of Bayesian modeling of radiocarbon determination. One of the key issues at play in the debate concerning the functions and use of these kinds of sites relates to their temporality. The lack of academic consensus suggests that other research lines should be considered in order to avoid falling into the already traditional interpretation.

As it has been demonstrated through groundbreaking investigations in the UK, the application of Bayesian modeling has turned into an extremely useful tool for the interpretation of the chronological sequences of these sites and thus for the understanding of their life histories. The advantages should be particularly useful when applied to the Iberian Copper Age, where multilayered sites are unusual and where the contemporaneity of the features becomes crucial. Contrasting chronological models allow assessing their likelihood, working as an "experimental laboratory" of alternative hypothesis.

Our presentation will focus on two well-known Iberian Copper Age enclosures: Camino de las Yeseras (San Fernando de Henares, Madrid) and Perdigões (Évora, Portugal). Both sites have an important set of published <sup>14</sup>C determination, allowing alternative models and different internal biographies that can be contrasted through robust statistical analysis. Our modeling is aimed to shed light on the temporal dynamics of ditch construction and its relation to dated mortuary practices inside these sites.

ORAL

**3. CURRENT STATE OF RESEARCH ON CHALCOLITHIC SOUTHERN IBERIAN DITCHED ENCLOSURES.**

*Marquez-Romero, Jose E. (Universidad de Malaga) jemarquez@uma.es*

*Jimenez-Jaimez, Victor (University of Southampton) V.J.Jimenez-Jaimez@soton.ac.uk*

Until recently, the discovery of a Chalcolithic ditch in Southern Iberia was automatically identified with the need for defence or drainage of a number of hypothetical villages that marked the consolidation of sedentism and, sometimes, the emergence of social complexity. The layout of the enclosures was often unclear, as well as the number and spatial organisation of the archaeological structures or the geographic distribution of the sites. The prevailing methods and techniques applied were surface survey and more or less small-scale trenching, while temporality and chronology were the focus of little research. In general terms, known sites were exclusively analysed within geographic environments of reduced size. In only a few years the situation has changed considerably. Documented examples have multiplied, especially in Southern Portugal. The quality and quantity of information about each one of them has grown, mostly because of the application of a wider range of methods and techniques, such as aerial photography and geophysical survey. Temporality has started to receive the attention it deserves, and new interpretive models have arisen. In this contribution we will describe the current state of research as regards Southern Iberian ditched enclosures, focusing on these and other relevant aspects.

ORAL

#### **4. PIT-DIGGING AND GRAIN STORAGE IN SOUTHERN IBERIAN CHALCOLITHIC DITCHED ENCLOSURES. A NON-REDUCTIONIST APPROACH.**

*Jimenez-Jaimez, Victor (University of Southampton) V.J.Jimenez-Jaimez@soton.ac.uk*  
*Marquez-Romero, Jose E. (Universidad de Malaga) jemarquez@uma.es*

Prehistoric and historical archaeology of Western Europe is full of examples of underground features, pits, interpreted as subterranean granaries, being particularly prolific the Neolithic and Copper Age, the Iron Age and the Middle Ages in some European and Iberian regions. In the southwest of the Iberian Peninsula, the idea of pits as storage facilities for grain has been very widespread since the end of the XIXth century, allowing for the interpretation of the countless underground features known, both within enclosed areas and in unenclosed pit sites dating from the IV and III millennia BC (Neolithic and Copper Age), as silos. Some observers have gone beyond that: the notion of pit as silo has often been the starting point for scientific postulates arguing an intensification of agricultural activities and

cultural complexity in the Southern Iberian Copper Age. Therefore, the way archaeologists position themselves as regards this issue has considerable implications at the level of historical interpretation, beyond the simple attribution of functions to archaeological structures.

In this paper we will challenge the prevalent ideas on the basis of historical, ethnographic and archaeological sources.

ORAL

#### **5. IDENTIFYING HOUSEHOLD CLUSTERS AT LATE NEOLITHIC EXTENSIVE PIT-SITES IN THE CENTRAL AREA OF THE MEDITERRANEAN COAST OF THE IBERIAN PENINSULA.**

*Gómez Puche, Magdalena (IPHES) mgomez.puc@gmail.com*  
*Bernabeu Aubán, Joan (Departament de Prehistòria i Arqueologia. Universitat de València) jbauban@uv.es*

In this work we propose a new methodological approach to identify household units at Late Neolithic pit-sites. Pit-like features represent the most common and visible habitation structure of the Neolithic in the Iberian Peninsula. Its documentation in the Spanish open-air site archaeological record is dated to Early Neolithic (c.5400-5200 cal BC), although their number meaningfully increases in subsequent Neolithic phases, especially during the Late Neolithic and Chalcolithic (c.3600-2200 cal BC) when they reach their maximum number and functional diversity.

Despite its ubiquity in the Iberian archaeological record, very little attention has been paid to defining intra-site functional clusters of domestic units. Besides, on the last decade fieldwork results have provided numerous examples of nucleated villages composed by clusters of underground features, some of them surrounded by ditch enclosures.

Beyond different approaches that have specifically addressed the functional and socio-economic interpretation of pit sites, as those that have focussed on pit deposition practices (examining cultural vs. ritual filling patterns), and those who try to quantify the scale of storage practices, we believe that the recognition of household units and the understanding of the spatial organization of domestic activities, merits a great attention since the estimation of household units and its evolution throughout the Late Neolithic is bound up with fundamental socioeconomic changes

such as dissolution of kinship networks, agricultural intensification, resource accumulation and aggregation processes.

Methodologically, this work will be supported on the morphological trends of the best-preserved examples of Late Neolithic houses, recently discovered in the central area of the Mediterranean coast of the Iberian Peninsula. Then, through combined GIS spatial and statistical analyses we will investigate intra-site distribution patterns of pit structures and archaeological materials to falsifying the following assumptions: (i) pit structures are randomly distributed in Late Neolithic sites; (ii) big pits contain biggest amount of archaeological findings; (iii) there is a spatial correlation among some archaeological categories and specific areas. Finally, we will run a cluster analysis based on the structure's location to establish the association of pits in spatial clusters. We will illustrate this procedure with three study cases from different Late Neolithic and Chalcolithic sites of Eastern Spain.

The result has implications not only for understanding the intrasettlement spatial structure of IV-III millennium cal BC sites, but also for demographic reconstructions in population size that allow specifying the scale of social relationships and socioeconomic processes occurred along Late Neolithic and Chalcolithic periods.

## 6. ELEMENTS OF PRESTIGE RESIDENTIAL STRUCTURES VALENCINA DE LA CONCEPCIÓN (SEVILLA).

*Pajuelo Pando, Ana (Universidad de Sevilla) anapajuelo@gmail.com*

*López Aldana, Pedro Manuel (Universidad de Sevilla) aldanaostrogodo@gmail.com*

Social formations of the III millennium a.n.e. have left us a body of evidence that manifest with high complexity for understanding and possibilities of explanation from the material record. In the Chalcolithic settlement Valencina de la Concepción (Sevilla) this difficulty meridian way showing.

The structural variability, the problems of their location under the current population, the excavated space sparse compared to its size (over 400 ha.) makes scientific reading is subject to strong and healthy disagreements among different researchers. Based on the questionable basis of the existence of two major functional areas within the reservoir (necropolis area and residential

/ productive area), a model that we share, we present certain distinctive elements provided by the excavation in C / Trabajadores in Valencina de la Concepción where occupational sequence spanning much of the III millennium BC was obtained and provided significant elements of the organization of this human settlement in the Valley of the Guadalquivir.

Metallurgical products in copper and gold, in coexistence with other elements, speak of a complex and unequal social organization, with groups of skilled artisans at the power instituted sustained on a structured ideological apparatus.

## 7. A NEW READING ON CHALCOLITHIC FORTIFICATIONS AT CERRO DE LA VIRGEN (ORCE, GRANADA, SPAIN)

*Cámara Serrano, Juan Antonio (Departamento de Prehistoria y Arqueología. Universidad de Granada) jacamara@ugr.es*  
*Molina González, Fernando (Departamento de Prehistoria y Arqueología. Universidad de Granada), fmolina@ugr.es*  
*Pérez Bareas, Cristóbal (Arqueólogo Cerro de la Virgen located at Orce municipality is an important archaeological site in the eastern area of Granada province.*

Chalcolithic and Bronze Age occupations have been defined and certain features have been continuously referred by their )

Cerro de la Virgen located at Orce municipality is an important archaeological site in the eastern area of Granada province. Chalcolithic and Bronze Age occupations have been defined and certain features have been continuously referred by their importance in the study of Southeastern Iberia Chalcolithic such as round mud-brick houses, irrigation channel and fortification walls with herringbone pattern masonry.

Thanks to a protective intervention on the Cerro de la Virgen, which did not affect the unexcavated deposits, the situation of different stretches of fortification walls identified by W. Schüle has been analyzed.

It was possible to confirm the existence of levels dated prior to the erection of the main wall which in any case was built in an old time of the sequence, radiocarbon dated circa 2450 cal BC. The modification of the access area with the building of a new wall that seals the gate in the Bronze Age, around 2000 cal BC, has also been

attested. Anyway, the most interesting hypotheses have to do with the Chalcolithic parallel walls that had been previously proposed by W. Schüle.

Although these new proposals should be contrasted from extensive excavations, we can suggest that these parallel walls were originally part of the main wall and fell down in a depressed area generated by trimming vertical rock under the main wall which would be over 6 m high. In this sense the proposed irrigation channel could actually be a boundary ditch.

## 8. VALENCINA AND MARINALEDA, SETTLEMENTS WITH DITCHES IN THE IIIIRD MILLENIUM B.C.

*Mejías García, Juan Carlos (Universidad de Sevilla)*

*jcmejias@us.es*

*Cruz-Auñón Briones, M<sup>a</sup> Rosario (Universidad de Sevilla)*

*rcab@us.es*

Rising prehistoric settlements IIIrd millennium BC, where ditches are documented, holds a debate which focuses attention on the special functionality that they want to attribute to them.

Far from understanding these settlements as true villages with special characteristics, that should be explained within its socio-economic context and the territoriality involving their spatial distribution, they generate theories that interpret them as bounded spaces for ritualized practices, for inter and intragroup cohesion, for the defense, etc.

Therefore we present a depth analysis and research that we have done in the last 5 years in the settlements of the IIIrd millennium BC of Valencina and Marinaleda. This study allows us to handle a volume of data and information that shows clearly the daily life in these villages, the economic activities that transcend the boundaries of the site itself, and how death is used, including a planned way, to express strong social inequalities that are close to the definition of social classes.

To get our aims we have designed a Geographical Information System (GIS) to manage, to process, to analyze and to map the information about the sites and the results of the research.

We show examples of habitat structures, economic activity, planning and partitioning of interior spaces, planning and organization of the space of the necropolis,

and of course, the existence and use of ditches those in some cases for reinforcing and giving meaning to our particular hypothesis about these settlements.

Finally we'll share a project that we are developing, called SIAC (Shared Archaeological Information System), in which all data and information of our work is offered to the research community for their disposal and use.

The phenomenon is becoming so large and widespread that it becomes increasingly difficult to sustain these monofunctional approaches. If those theories are true we must ask: where people live? Moreover we do not reject that these features may be a part of the characteristics of the settlements.

Our approach goes through to vindicate the evidences in these settlements as true villages where the daily life of people is developed and in where social relations hold a mode of production in which the evidence of the existence of social classes are becoming stronger.

## 9. SETTLEMENT PATTERNS ON THE LOWER GUADIANA DURING THE THIRD MILLENNIUM BCE

*Inácio, Nuno (Universidad de Huelva) nuno.inacio@dhis1.uhu.es*

*Nocete, Francisco (Universidad de Huelva) nocete@dhis1.uhu.es*

*Bayona, Moisés (Universidad de Huelva) moises.rodriguez@dhis1.uhu.es*

In this congress we present the general objectives of MISURP (Mining and Metallurgical Activity of III Millennium BCE in Lower Guadiana) project and the preliminary results of the archaeological prospection survey developed on the left bank of the lower Guadiana (Alcoutim and Mértola Municipality). Within Iberian Pyrite Belt, one of the most important mining districts in the world, this project was designed with the aim of providing empirical information to the identification of settlement patterns associated with procurement processes, exploration, production and distribution of copper.

**10. THE TWO FORTIFIED SETTLEMENTS OF S. PEDRO'S SITE (REDONDO, ALENTEJO, PORTUGAL).**

*Costeira, Catarina (Uniarq) catarinacosteira@gmail.com*

The archaeological site of S. Pedro was located on top of prominent elevation within the village of Redondo (Central Alentejo, South of Portugal). The archaeological excavation was carried out by the archaeologist of the municipality of Redondo, it was motivated by the construction of a road that would condition the conservation of the site.

At the S. Pedro's site were identified five major moments of occupation, framed chronologically between the end of the 4th millennium BCE and most of the 3rd millennium BCE, two of which were characterized by the construction and use of two fortification structures with different dimensions and architectures.

In this communication we intend to analyse the structural characteristics of the two fortifications, in relation to the size, morphology and constituent elements (walls, towers, gates), as well as presenting the interior and exterior spaces demarcated by them. The intersection of all these data will allow reflection on the functionality and dynamic construction / reconstruction and abandonment of these structures fortification.

ORAL

**11. WALLS WITHIN WALLS WITH DITCHES INSIDE: BACK TO THE THIRD MILLENNIUM AT VILA NOVA DE S. PEDRO (AZAMBUJA, PORTUGAL).**

*Arnaud, José (Associação dos Arqueólogos Portugueses) jarnaud@sapo.pt*

*Diniz, Mariana (UNIARQ e Associação dos Arqueólogos Portugueses) m.diniz@fl.ul.pt*

*Neves, César (UNIARQ e Associação dos Arqueólogos Portugueses) c.augustoneves@gmail.com*

*Martins, Andrea (Associação dos Arqueólogos Portugueses) andrea.arte@gmail.com*

Vila Nova de S. Pedro (VNSP), (Azambuja, Portugal) is a major Chalcolithic site in Western Iberia, systematically excavated since 1936 until 1966, then episodically in the 80's, that have been almost forgotten during the last decades in the debate while archaeological research moved to the vast enclosures recently identified in

Southern Portugal. The vast amount of artifacts from the 30-60's campaigns is kept in the Carmo Archaeological Museum (Lisbon) and since then several analyses have been made concerning particular groups of materials.

This paper is intended to be the departure of a research project focused within and around VNSP walls in which early data from previous excavation and some future specific field work will be used - under a third millennium agenda and methodology - to discuss Chalcolithic landscapes and cultural systems.

In order to fulfill this aim, a review of all the literature published relating to the site will be made, using new data to understand old archaeological excavations results. Particular attention will be paid to what concerns VNSP structures, stratigraphy and settlement diachrony. The descriptions and the graphic information produced throughout the 30's - 60's excavations carried out by Afonso do Paço and Eugénio Jalhay will be critically examined in detail.

What was described in the literature as VNSP's foundational deposit and a careful reading of what Paço (1943-44) published of its finding context, points to the existence of at least one ditch in VNSP. The description of the work done and the figure that illustrated that area, leaves no doubt about what was in fact being excavated: an asymmetrical ditch with 2 m depth where, as in other ditches, an intentional deposition of things - at least animal bones and a complete pottery vessel - seems to be present. After the ditch was fulfilled, at least in that sector, the occupation at VNSP goes on, which is reflected by the existence of a Chalcolithic hut floor on the top of the ditch.

Whether this was or not a foundational deposit, a symbolic, intentional, *ab initio* gesture at VNSP or just part of a ditch intentional fulfilling process is something that only future research may clarify.

The existence of at least one ditch previous to the walls in VNSP makes this settlement's history even more complex than it was previously assumed. Radiocarbon dating of the organic material from VNSP's stratigraphical sequence and in particular from this ditch could result in adding a VNSP 0 phase, to the traditional three phase picture.

---

**12. LOWER VALLEY OF THE TAGUS RIVER, BETWEEN WALLS AND DITCHES, IN THE 3RD MILLENIUM BCE**

*Gonçalves, Victor (UNIARQ - University Of Lisbon) vsg@campus.ul.pt*

*Sousa, Ana Catarina (UNIARQ - University Of Lisbon) sou-sa@campus.ul.pt*

In the 3rd millennium BCE, in Lower Tagus we can see emerging new forms of social and territorial organization, also structured settlements, probably with different levels of hierarchy. On the global scale of central and southern Portugal we find different realities in different landscape units, reflecting their internal dynamics, exogenous influences and interactions with the landscape. It is particularly relevant the difference between the Estremadura and Alentejo. These areas have different research routes: Estremadura with mainly old research and Alentejo highlighting the new results carried out by preventive archaeology.

At the Lisbon peninsula the settlement is often represented by fortified sites. The sites with pits and ditches are practically absent. In the Alentejo, recent studies demonstrated the existence of a network of complex settlements with the coexistence of enclosures and fortified settlements. The sites with ditches begin before the 3rd millennium and persist until the end of the 3rd, probably assuming different meanings. The fortified settlements only begin around 2800 BCE and in the middle of the 3rd millennium are already under ruin. The Lower Tagus lies well between walls and ditches. On the right bank we found a set of fortified settlements on the edge of the Tagus basin. On the left bank, the information is very scarce. In addition to specialized sites on the exploitation of salt, in the vestibular area of the Tagus river, only the Sorraia area, a tributary of the Tagus (county Coruche) is actually under systematic research. In the Sorraia valley, the authors have been developing a research project to identify the network of settlements. It was possible to carry out excavations and geophysical surveys at two of the sites identified resulting in both cases in the discovery of ditches.

In Cabeçodo Pé da Erra, a small Copper Age farm near Coruche, the intervention area already amounts to 356 m<sup>2</sup>. Around the farm, we have found a defensive ditch with two phases of use, bordering a residential area with a minimum of seven huts with stone foundations and walls of clay, and functional areas (kitchens and

combustion areas, traces of cereal processing, milk, cheese and salt use...). The absolute chronology indicates a short occupation of the site in the 3rd quarter of the 3rd millennium.

Barranco do Farinheiro is located just 4 kilometers from the Cabeço do Pé da Erra. A preliminary survey revealed the presence of a ditch. The absolute chronology indicates an occupation in the middle of the 3rd millennium. The current vegetation difficult a reading of the surface, but it is likely that this site is older and bigger than Cabeçodo Pé da Erra.

The valley of the Tagus, on the left bank, is historically a privileged area of movement. In the Chalcolithic different influences seem to converge here at the level of material culture and the morphology of the settlements. We will present explanatory hypotheses for the specific dynamics of this territory and a generic perspective of the entire central and southern Portugal during the Chalcolithic.

**13. NEW CAUSEWAYED ENCLOSURES IN NORTHERN SPANISH PLATEAU.**

*García García, Marcos (Universidad de Valladolid) mggarcia@fyl.uva.es*

The aim of this paper is to present 18 causewayed enclosures discovered in northern Spanish Plateau in the last 20 years. These sites are spread over the Douro basin, throughout the fertile sedimentary lands of several provinces of the Castile and Leon region: Palencia, Salamanca, Segovia, Valladolid and Zamora. Causewayed enclosures are a well-known kind of prehistoric sites in Europe, and they have been increasingly found in Spain and Portugal since the eighties. They show the same characteristics as their European 'relatives': one to three concentric and discontinuous ditches in a circular or oval design that surround sites between 0.5 to 4 hectares.

The majority of our enclosures were founded in the third millennium BC. In fact, the available radiocarbon dates offer an approximated range of 3300-2350 cal. BC. Some of them were reoccupied during the Bronze Age. Nevertheless, as far as we know from El Casetón de la Era II, ditches were filled after their desertion in 2350 BC. The confluence of several climatic phenomena (known as '4,0 ka BP event') on that date has led us to consider the change into a drier and warmer climate as a most

likely explanation for the end of the occupation of the enclosures.

Their structures have been identified using aerial photography. However, the archaeological data come from different research projects, including non-prehistoric or even emergency excavations. The camerawork is also heterogeneous: either oblique and orthographic or real colour and infrared. Anyway, we were able to find orthographic frames or, at least, to correct and georeference the oblique pictures. After that, we followed the visible alterations on the crop marks to draw a clean interpretation of the ditches using GIS and Remote Sensing software. Since the new data was georeferenced, it was easy to measure their parts and analyse their relationship with different geographical features such as rivers, heights and potential land uses. Therefore, we have stated several hypotheses of their possible strategies of subsistence and about their functionality from the analysed data.

Our conclusion is that the causewayed enclosures of the Douro represent the agrologic colonization of this region. From that point of view, their monumentality and singular deposits of entire animals symbolize the ritualization of new ways of production and social organization related to Sherratt's secondary products revolution.

29 samples were studied. Among the methods used, highlight the sedimentological analysis (grain size and texture), mineralogical (with the application of X-ray diffraction), chemical analysis (pH, conductivity and determination of organic matter) and finally, in one case, the micromorphological study (with thin sections).

These analyzes were performed in different laboratories of the Autonomous University of Madrid, and in the case of micromorphology in the McBurney Geoarchaeology Laboratory, University of Cambridge.

Mainly, we want to know the processes that led to a filling of the trenches, and determine if they are caused to a natural genesis, or conversely, whether a human intentionality in its existence. We present this communication because we can not always know the nature of the sedimentary fillings, unfortunately, by human disturbance (agriculture and other activities affecting soils) or by catastrophic environmental changes.

## 1. ARCHAEOZOOLOGY AND IDENTITY: THE SYMBOLOGY OF ANIMALS IN THE IRON AGE SOCIETIES

*Albizuri Canadell Silvia (Universitat de Barcelona) silvia.albizuri@upc.edu*

*Nieto Espinet, Ariadna (Universitat de Lleida) nevolote@hotmail.com*

The presence of animal remains in the form of singular deposits and/or offerings in necropolis as well as in towns is a very usual fact in Catalonia during the Iron Age. The inherent complexity of the study on the animal role at the core of human societies pushes us beyond what's strictly the economical field and makes us taking into account aspects as, for instance, the collective imaginary, the social complexity, the symbolic codes, the beliefs, the import of new traditions and the affective relationships, fruit of their interaction with people. For this reason, the study of these singular practises and/or ritual patterns is an important contribution in the analysis of the construction and the evolution of the regional and/or local identity of a society. The symbols are the ones to help us when establishing the borders between territories and towns, the ones that allow the distinctness for ethnic groups, social status or genders. Symbols that are many times exemplified based on certain animals. And depending on the physical, ethological and ecological characteristics of these animals they will end up becoming totems or elements of prestige. Symbols that, through the sacrifice and the offering, perpetuate the collective imaginary in life and in death of a community.

This paper wants to offer a territorial radiography of the content, selection, context and location of the different deposits with animal offerings. All of this by analysing the regional particularities, the evolution of the above mentioned practises and their sociocultural implications from the end of the Bronze to the Iberian Age in Catalonia.

The results are obtained from integrated studies of faunal remains in various sites of the Iron Age in Catalonia. The most important are the Iberian settlement of Ca n'Oliver and the Early Iron Age settlement of Can Roqueta, in the pre-littoral depression, and the Iberian settlement of Vilars in the western plain.

The most representative bone assemblages of ritual practices are studied.

ORAL

## 2. ETHNICITY AND ARCHAEOLOGY IN CELTIC IBERIA. WHAT WAS TO BE VETTON, VACCEO, LUSITANIAN OR GALLAECIAN IN LATE IRON AGE?

*Álvarez Sanchís, Jesús Rafael (Departamento de Prehistoria (Universidad Complutense, Madrid) jralvare@ghis.ucm.es*

The ethnic groups of ancient Iberia, like many ethnic groups throughout the Celtic Europe, were not ultimately racial, linguistic, religious or cultural communities, but social groups whose origins were just as often imagined as they were real. The potential of material culture as an indicator of ethnic identity constitutes a difficult avenue of research, but one with future. For purposes of examining the emergence of ethnic groups during the Iron Age, we need to focus on expressions through material culture that survive the passage of time. By the III-I centuries BC some ethnic groups had a highly developed society which can be labelled as a "tribal states" comparable with those in other parts of central Iberia and in temperate Europe. Like these other states it possessed urban settlements (oppida) and a hierarchical society, apparently dominated by a military aristocracy. However, it had many characteristics which distinguish it from its contemporary societies, but we still need extensive field work and excavation of settlements to understand better how it functioned.

In this work, I examine evidence for some of the ways that Late Iron Age peoples of western and central Iberia created, transformed and expressed their identities. I shall highlight three principal problems: (a) the nature of the written sources, (b) how greek and roman authors perceive and express identities of peoples they encounter and (c) how that peoples restructured and reinforced their identities in response to the ways that romans represented them.

ORAL

## 3. BREAKING UNIFORMITIES: ETHNIC INDICATORS IN PRE-ROMAN CENTRAL SPAIN.

*Arenas Esteban, Jesús Alberto (Universidad a Distancia de Madrid) jesusalberto.arenas@udima.es*

Pre-Roman communities of the eastern Spanish Plateau have traditionally been categorized under the generic name of Celtiberians. This ethnonym was coined by historians who accompanied the Roman troops in their

confrontation with the Carthaginians during the Second Punic War. Hence, it is an etic interpretation of a complex cultural reality, in which foreign observers identified cultural traits they had met previously in other places: the Celtic world in central and western Europe and the "Mediterranean" Iberian Culture of the eastern coast of the Iberian Peninsula.

The development of new interpretive models, however, has allowed the static vision of Celtiberia as a cultural complex almost unchanged during its more than 500 years to be replaced by a more dynamic one, which is beginning to recognize some social and ideological internal processes, sometimes parallel in time. And against this cultural background, the configuration of specific identity spaces is taking increasing relevance.

Already in the formative process of the Celtiberian world, it is possible to recognize the confluence of different cultural traditions, of both indigenous and exogenous origin; traditions that have their own reflection in specific and perfectly distinguishable material manifestations. But it is during the plenitude stage of the Celtiberian culture, between the IV and II centuries BC, when this confluence becomes more apparent, especially because it manifests itself both in the settlement patterns and in the material culture. In those moments it is possible to recognize "intrusive cultures" in the static world construed by traditional Iron Age archaeology.

This paper analyzes the material evidence that may reflect specific identity frameworks. On the one hand, the specific configuration of some settlement patterns will be studied, together with the architectural traits associated; on the other, the adoption in pottery of decorative patterns highly distinctive with respect to the material environment into which they are embedded.

This research leads to the recognition of the arrival of a series of cultural stimuli from the Mediterranean coast. Its appearance could be linked to large geostrategic control infrastructures. This phenomenon could imply, at least at its beginning, the arrival of human groups who established their identity by means of a distinctive material culture, clearly discernable from the dominant cultural environment.

#### **4. CRAFT-PRODUCTIONS OF VERRACOS SCULPTURES AS ETHNICAL SYMBOLS FROM SPANISH IRON AGE: NEW APPROACHES TO AN OLD SUBJECT.**

*Berrocal-Rangel, Luis (Universidad Autónoma de Madrid)*  
*luis.berrocal@uam.es*

*García Giménez, Rosario (Universidad Autónoma de Madrid)*  
*rosario.garcía@uam.es*

*Manglano Valcárcel, Gregorio Ramón (Universidad Autónoma de Madrid)*  
*gregorio.manglano@gmail.com*

Great walls with stone masonry and big animal sculptures, both usually made in granite rocks, are the most characteristic productions in the Archaeology of the Late Iron Age in Western of Iberian Peninsula. The second ones, animal sculptures are representations of male boars and bulls known as "verracos", are the most important skilled labours between the stone's craft productions from these communities, the "Vettonos" according to Roman and Greek classical writers. Recent investigations have interpreted them as a technical borrowing from the Iberian people, who lived in Mediterranean Iberia from 5<sup>th</sup> Century B.C. forward, but also it is proposed the existence of a link between the ethnical and communal values of the older "verracos" and a functional change to funerary monuments during Roman times, with individual meanings. Our approaches through petrological and macro-wear analyses for identifying differences in the making of these sculptures that help to explain these functional and meaning changes and develop our knowledge about these sculptures, as popular as usually without archaeological context. From these approaches we have defended the earlier presence of itinerant craftsmen, authors of sculptures in blocks or slabs from quarries and in the same bed rock, but also it is possible define the existence of later factories, places where the figures were shaped through standardized process. Between them, the production of "verracos" shows an intermediated stage, where the links between the place of making the sculptures and the communities that produced them started to be fixed, but sizes, shapes and spatial relationship with nearest *oppida*, allow to defend new values of ethnical and communal nature, that matched very well with the first Mediterranean presences (Carthaginian and Roman armies...) in the Western Meseta.

---

ORAL

#### **5. NEGOTIATING IDENTITIES: ETHNIC AND POLITICAL CONSTRUCTS IN IRON AGE EUROPE**

*Fernández-Götz, Manuel (University of Edinburgh)*  
*M.Fernandez-Gotz@ed.ac.uk*

The possibility of exploring identities in past societies

constitutes one of the most exciting fields of Iron Age research. In European archaeology, much of the interest in ethnicity has been centred on the First Millennium BC, which is natural since the incipient availability of texts and ethnonyms stimulates the search for ethnic identities in the archaeological record. Building upon the reassessment of the conceptualization of ethnicity in the human sciences, this paper will focus on the frequent identification between ethnic and political processes.

Both elements complement each other perfectly in processes of collective construction. Instrumentalist perspectives have underlined the important role of ethnicity when reinforcing and harnessing socio-political formations. In fact, the Ancient world is filled with examples of political entities being imbued with strong group identity, from the Greek poleis to the Late Iron Age Gallic polities. This paper will argue that a distinction between city-states and tribal-states is useful for gaining a better understanding of Iron Age communities. Moreover, in both cases sanctuaries and the worship of founding heroes played a key role in the symbolic construction of political and ethnic communities.

ORAL

## 6. BORDERLANDS IDENTITIES IN SOUTHWESTERN IBERIA IN THE 9TH TO 6TH CENTURIES BC

*Marín Aguilera, Beatriz (Universidad Complutense de Madrid) beatriz.marin@ghis.ucm.es*

By the early first millennium BCE, Phoenicians had established permanent colonies all across the Mediterranean. Southern Iberia was the area where most of those settlements were founded (9<sup>th</sup> to 6<sup>th</sup> centuries BC). The nature of the relationship between Phoenicians and locals in Iberia during this period is still a controversial matter, although scholars seem to agree that in terms of economy such a relation was based on mutual dependence. However, studies of South Iberian material culture have traditionally been dominated by art historical approaches that have greatly emphasised the Orientalisation of local elites, i.e. the Phoenician supremacy.

Consequently, analyses have been focused on the nature of the Oriental imports (serving ware, amphorae, etc.) and Phoenician customs (funerary banquets) in local cemeteries. Problems arise when local necropoleis are studied in depth, because funerary ware and practices are quite different from the Oriental rituals and very

similar to the traditional ones. This paper seeks to analyse the pottery assemblage of La Joya Necropolis, located in Huelva (Spain) as a case study to quantify and qualify the impact of the Oriental influences and practices on local communities between the 9<sup>th</sup> and 6<sup>th</sup> centuries BC.

Ritual consumption vessels at La Joya necropolis can be divided into three different categories: tableware, serving ware, and storage/offering ware. Local-style pottery is present in more than 50% of both tableware and storage ware. A Phoenician ritual assemblage is only present in Tombs 17 and 18, i.e. two of nineteen, and even in such tombs a bronze vessel service composed of a piriform jar and/or a ritual recipient replaces Phoenician serving pottery in both tombs.

Before the Phoenician arrival, South Iberian communities already had ritual funerary banquets, and they continued to have them during the Phoenician presence in their territory (9<sup>th</sup>-6<sup>th</sup> centuries BC). Moreover, local elites at La Joya commonly used traditional pottery shapes as both serving ware and tableware between the 9<sup>th</sup> and 6<sup>th</sup> centuries BCE instead of Phoenician assemblages. Ritual banquets and offerings were thus connected to local cuisine and deeply rooted in traditional practices, not in Phoenician ones.

ORAL

## 7. PRE-HISTORIC LANDSCAPE 3K YEARS AGO: CHARACTERIZATION VARIABLES FOR ARCHAEOLOGICAL PREDICTIVE MODELS IN DEMPSTER-SHAFFER THEORY USING GIS PLATFORM.

*Maximiano Castillejo, Alfredo (IIIIPC University of Cantabria) maximianoam@unican.es*

This dissertation is part of a scientific initiative namely: *Prehistoric Landscape Research in the northern mountainous area of Burgos via geocomputacional technology*. We introduce the results of archaeological survey oriented by spatial predictive models about fortified habitats around 3k BP years.

The main difficulty of this study was the very low population ( $n = 3$ ) (Bohigas *et al.* 1984; Peralta Labrador ...; Sacristan de Lama 2007) and total absence of archaeological excavations in extensive area -100sq km- (a sector inside Natural Park of *Hoces del río Ebro y Rudrón*). In this circumstances, we could not apply conventional spatial prediction methodology like *Logistic regression, Boolean algebra, Bayesian statistics, or*

*cellular automate* (Leusen 2002; Verhagen 2006). The use of spatial predictive modeling is something significantly useful not only for predicting archaeological locations, but also it is an exercise in understanding the landscape characterizing and weighting of certain variables and attributes (e.g. topography, geomorphology, anthropology, ecological ...).

With this, we could establish a holistic perception of territory in which a particular set of social actions performed in certain historical moments (*Landscape*). From methodological issues, our spatial predictive modeling is based on the Dempster-Shafer theory (Beynon *et al.* 2000, Canning 2005), with our low population and the complex problem in determinate an answer to the predictive modeling question in terms of binary opposites (site/non-site); however we work with degree of probability (through different levels of certainty-uncertainty) that a given event (presence/nascence of site) happens or not. In other words, the DS models are used to assess the degree to which evidence provides concrete support for a hypothesis (belief) and the extent to which it does not disprove the hypothesis (plausibility). We employed as a cross-tool, a GIS in which we quantified and reclassified variables with spatial implications about territory. Alongside this, we included a number of historically parameters linked with the social dynamics of fortified settlement 3k years ago in this area of the Iberian Peninsula (e.g. visual control, easy defense, accessibility to resources, mobility in territory...)

Finally, we create a predictive model where we achieved positive results in finding new archaeological sites; but also, we have characterized a set of relationships -statistically significant- between environment and social practices: Landscape of Iron Age in the concurrence of Castilla-León plateau and Cantabrian Mountains.

ORAL

## **8. VILLANUEVA DE TEBA NECROPOLIS (LA BUREBA, BURGOS): GENDER AND SOCIAL HIERARCHY.**

*Ruiz Vélez, Ignacio (UNED. Burgos) igruvel@yahoo.es*

Villanueva de Teba necropolis, which dates back to the second Iron Age, has some common features to that of its time, but also specific ones that somehow allow us to identify interesting social aspects related to gender and social hierarchy. The study of the bones at cremation and the reachness of its trousseaus lend themselves to deduce some conclusions. This necropolis proves that

there are also arms in female tombs as an indicator of their social status; and that the ratio of men to women is similar to that of other necropolis, dating back to the Iron Age, within the Iberian Peninsula. It also proves that there are no infant tombs and that the trappings of horses also indicate the social status.

On the other hand, social hierarchy is shown by certain funerary objects. The large belt brooches show a high social class; the trappings of a horse, the brooches of belts of Iberian type and the fibula, allow us to know the in-between periods. Needless to say, all the funerary objects are of great beauty and have a big size.

ORAL

## **9. RECENT PERCEPTIONS ON IRON AGE LANDSCAPES.**

*Ruiz-Zapatero, Gonzalo (Complutense University, Madrid) gonzalor@ghis.ucm.es*

In the last two decades different European archaeological traditions have been approaching in different ways landscapes lived and perceived by Iron Age peoples. In fact the approaches have used different scales of time and space inside a diversity of theoretical paradigms. But a more or less general agreement seems to consider as the right question: How Iron Age peoples perceived and understood their worlds?

Approaching landscapes involve a wide range of methodologies which have included: a) agricultural archaeology, b) symbolic dimensions embebed in landscapes, c) exploration of landscapes as dynamic entities through practice and activity, d) attempts of getting insights on non-visual sensory experience in landscapes, e) propositions for discovering the sense of being and maenings behind creating Iron Age sites in particular settings, f) understanding ancient skyscapes as inspiring objects decoration and special patterning of site features in relation to wider landscape.

In this paper I review different case studies on different Iron Age landscapes through Europe dealing with those approaches in order to develop operative research lines and to evaluate how the diversity of European traditions enrich our ways of thinking ancient landscapes.

## 10. LANDSCAPES AND ARCHITECTURE IN THE IRON AGE OF ATLANTIC SCOTLAND.

*Sharples, Niall (University of Cardiff) sharples@cardiff.ac.uk*

In this paper I will examine the location of the monumental roundhouses, brochs, of Atlantic Scotland. These structures are normally understood through examination of their architecture which is striking and dramatic, with walls standing up to 13m in height at the best preserved example, Mousa in Shetland. However, I will argue that the significance of these structures is best understood by examining their location in the landscape. The occupants and builders use the drama of landscapes that are characterised by sea cliffs, lochs, cliff defined hills, bog and ancient monuments to draw important distinctions between wild and domesticated that provide clear signposts to the social significance of the architecture and the role of the occupants.

ORAL

## 11. SETTLEMENT PATTERNS, AGRICULTURE AND ENVIRONMENTAL DYNAMICS IN NW IBERIA DURING THE IRON AGE.

*Tereso, João Pedro (CIBIO - Research Center in Biodiversity and Genetic Resources - University of Porto) jptereso@gmail.com*

The Iron Age in northwest Iberia is a period of increasing complexity. In the sequence of Late Bronze Age trends, settlements became more solid and complex, reinforcing themselves as territorial marks. Being a time of well-known changes in terms of climate, vegetation and soil erosion, it is determinant to understand how human communities coped with it, namely regarding their subsistence strategies. Here we will focus the trade-offs between climate, landscape and agriculture during the Iron Age in NW Iberia.

A thorough revision of archaeological and carpological data was made. To allow comparisons between sites, the revision of data was preceded by a homogenization of crops' nomenclature. Carpological data was contrasted with the abundant palynological and sedimentary data available for the region. The chronological parameters used were those presented in the bibliographic references specific to each site and whenever the information concerning the provenience or chronology of archaeobotanical material

was considered unreliable, those sites were excluded from this synthesis.

Data from Iron Age sites in northwest Iberia document a complex and diverse agricultural system based on different cereals. The more abundant cereals are *Panicum miliaceum*, *Avena*, *Hordeum vulgare* subsp. *vulgare* and hulled wheat (mostly *Triticum turgidum* subsp. *dicoccum* and *Triticum aestivum* subsp. *spelta*). Still, the presence of naked wheat - *Triticum aestivum/durum/turgidum* - is very significant. On the other hand, there is little diversity of non-cereal crops and only *Vicia faba* has been constantly retrieved in the excavations. Hence, there is an increasing relevance of hulled wheat in the Iron Age, contrasting with previous periods. This trend is in clear contrast with other well studied Iberian regions.

Palaeoenvironmental data demonstrates the Iron Age is a period of marked anthropogenic landscape change, namely regarding deforestation and soil erosion. On what climate is concerned, a cooler and wetter period seems to have begun in the early phases of Iron Age. This scenario may have favoured the use of hulled wheat, since they are more productive in case of climate deterioration and poor soils. Still, the growing importance of hulled wheats and the predominance of crops adapted to harsh environmental conditions must be interpreted not only on the basis of paleoclimate data but mainly in the context of relevant social and settlement changes. In fact, in a region where communities were losing mobility and territorialisation was enhanced, boundaries are likely to have emerged, constraining and regulating human action. Thus, when agricultural soils became weary, mobility was no longer an option and communities were limited to whatever solution their own land would provide. They had to develop ways to restore fertility, adapt their crops and optimize the use of their territory. The main characteristics of Iron Age agriculture and landscape are, thus, a result of long-term dynamics regarding settlement patterns, territorialisation and crops' preferences. Environmental factors such as soils and climate may have acted as significant constraints.

In Western Europe, recent studies show that emerging urban worlds developed during the Iron Age, yet there are many questions surrounding the dynamics of these occupations, the non-linear processes of urbanisation, long-term socio-environmental interactions and land use history .

The AYPONA programme (dir. Y.Miras & F.Vautier) represents an innovative and integrated project that aims to better understand these agglomerations in the long term, through geoarchaeology, environmental archaeology and geomatics. This combination of palaeoenvironmental and archaeological datasets will be used to provide a more complete knowledge of the

origin of these agglomerations, their characteristics, the drivers of their evolution, their environmental impacts, and their connections with the rural environment.

The volcanic plateau of Corent situated 250 m above the valley of the River Allier in Auvergne (France), is an agglomeration with a long archaeological record covering the last 5000 years, including an Iron Age oppidum which may have been the capital of the Arverni. Archaeological work directed by M.Poux and P.Y.Milcent since 2001 has revealed monumental urban characteristics, but also impressive commercial and cultural wealth, showing early links with Mediterranean world. This original setting in a high plateau over the well-known context of Limagne plain, a long-term occupation and first order archaeological importance, makes Corent an exceptional site to conduct the AYPONA programme.

This paper introduces the geoarchaeological objectives of the AYPONA programme, which are threefold:

- i) characterize geomorphologic impacts of human occupation on the plateau slopes and alluvial plain of the Allier river in terms of connectivity and morphological evolution.
- ii) determine whether human activity or climate variability are the primary drivers of physical processes (erosion-sedimentation rates, thresholds in sediment fluxes due to major changes in landscape use).
- iii) use the findings to produce a geomorphological evolution model.

Geoarchaeological work will be developed in four phases:

- i) a preliminary phase, comprising geomorphological characterization and mapping through fieldwork, geological and archeological information analysis, carto-photointerpretation and LiDAR data exploitation.
- ii) secondly, specific prospection will be focused on areas with geoarchaeological potential, with coring and trenching.
- iii) laboratory analysis, including granulometry, micromorphology, anthracology, magnetic susceptibility and geochemistry in order to evaluate and characterize the origin and nature of sediment fluxes, human impact and erosive phases of high geomorphological connection between slopes and alluvial plain, vs. phases of stability and soil formation.
- iv) finally, reconstructing

slopes and alluvial palaeodynamics and comparing their connection phases to occupation periods and human activity, but also with natural hydroclimatic phases, will allow an appreciation of the origins of forcings that will permit the production of a geoarchaeological evolution model.

To date the first phase of geoarchaeological work at the Oppidum of Corent has produced valuable information detailing the geomorphological setting and processes, providing a robust basis for further work. Most importantly, it has allowed the detection and characterization of areas, on the top of the plateau, the slopes and low alluvial plains, where sediment accumulation probably dates from the late Holocene (especially the Iron Age). This will be highly useful for focusing geoarchaeological work in the following phases of investigation.

**13. QUARRIED LANDSCAPE IN IRON AGE TALAYOTIC SETTLEMENTS: MENORCA, SPAIN.**

*Perez-Juez, Amalia (Boston University) amaliapj@bu.edu*  
*Goldberg, Paul (Boston University) paulberg@bu.edu*

The island of Menorca, Spain, hosted the development of the Talayotic Culture in the first millennium BC. During this period, the landscape was transformed by the construction of megalithic structures, both for public buildings –watchtowers and sanctuaries- as well as private buildings –domestic spaces, storage areas-. These striking features have been extensively studied in recent decades. Major archaeological projects have been carried out in buildings, dealing primarily with the architecture and the objects found in them. Interestingly enough, although all these structures are built with a specific local limestone, there has been very little attention paid to the provenance of raw materials and quarrying techniques. A similar lack of interest applies to the inter-building spaces in the settlements or non-architectural environment, which have wonderful potential for understanding the complete fabric of the living space.

Quarrying of the limestone took place both within buildings, as well as within open public space, and most likely from nearby outcrops. Jointing of the bedrock plays a major role in quarrying activities, which in turn determines the shape of the buildings and their internal organization. Moreover, the overall site layout – structure public spaces, open areas, circulation paths – is

conditioned by the underlying bedrock and the way it was exploited.

In this poster we present some initial results of our excavations and interdisciplinary research at Torre d'en Galmés, Menorca, that contribute to a greater understanding of the large site complex as a whole, quarrying and building methods specifically, and how all this relates to other sites in the Balearic Islands.

Although there have been attempts to locate Talayotic quarries, a new approach is needed to further document the use and source of building materials. Prehistoric quarrying was carried out everywhere, both within sites and in the open landscape. At Torre d'en Galmés, Menorca, we have carried out an interdisciplinary approach to provide holistic insight into non-traditional areas of study. By applying geoarchaeology, micromorphology, as well as the study of phytoliths, charcoal, bones and pottery we have come to a variety of conclusions that we present in this poster.

---

POSTER

**14. NURAGIC SETTLEMENT DYNAMICS BETWEEN BRONZE AND EARLY IRON AGE: THE CASE STUDY OF THE SOUTHERN SULCIS (SOUTH-WESTERN SARDEGNA, ITALY).**

*Velli, Adriano (Universidad de Granada) adrianoveli@libero.it*  
*Velli, Emiliano (Independent researcher) geminiem@tiscali.it*  
*Cabras, Marco (Universidad de Granada) marcocabras@correo.ugr.es*

In this paper we discussed the settlement dynamics related to a portion of sulcis (south-western sardinia) between the bronze and early iron age. More generally it fits in the now more frequent studies of landscape archaeology that analyze the potential applications of statistical and spatial analysis in a GIS-based research aimed at evaluating the settlement choices of nuragic civilization in sardinia. Despite the small amount of data from archaeological excavations, together with the increasing risk to which the archaeological heritage of the area is exposed due to the poor protection made by the relevant authorities, the important remains of the bronze and early iron age that characterize and mark still so deeply this area make important to fully understand the relationship between men and environment and settlement strategies adopted by the sardinian populations of recent prehistory.

More precisely, this is a 68 square kilometres morphologically heterogeneous area composed by a broad alluvial plain enclosed by the sulcis massif and the sea. This is an inclusive area among the rivers rio gutturu saidu and the rio palmas, and is bordered to the east by the hills of masainas and sant'anna arresi and from the gulf of palmas coast to the west. The earliest evidences of anthropic settlements from this area date back to neolithic. The following paper tries to explain the settlements pattern of the nuragic age in this part of sulcis analyzing 32 sites dated back between the bronze and the early iron age. In most cases investigations have highlighted badly preserved structures which, however, testify to a particular settlement choices related to specific territorial features. This work was conducted with the most modern methods of landscape studies: statistical analysis methods (cluster and principal components analysis) and other tools for GIS-based analysis for the study of relationships between sites and territory (map algebra, viewshed analysis, cost surface analysis, least-cost path).

This research, developed through a series of field surveys carried out by the authors, have shown the presence of at least 7 unknown nuragic sites, never described before. The GIS analysis applied to the settlement pattern have also shown particular interest in certain sensitive areas, and more suitable for specific economic activities.

In conclusion this work shows that the sites are mostly concentrated in the areas closest to the inner portions of the territory, near the hills that surround the alluvial plain, to control the access routes to the proximal mountain regions known for the abundance of minerals. The coastal area seems to be also settled, especially for agricultural activities. The archaeological record therefore suggests a massive occupation of the considered area from bronze till early iron age for purposes strictly related to environmental features.

Funded by grants from the German Research Foundation, anthropologists and archaeologists are working together intensely on three projects concerning the population and settlement history of prehistoric Central, Southeast and Western Europe. Our first study region is the Middle Elbe-Saale region in Central Europe, the second is the Carpathian Basin, which played a key role in the early Neolithic settlement in Central and Southeast Europe, and the third region is the Iberian Peninsula. This latter has been proposed to be the scene of a contemporaneous but independent Neolithic cultural history, especially in comparison with the other two study regions. The three projects share a coherent underlying concept. First, this concept involves an integrated multi-disciplinary approach including archaeological, anthropological, molecular, biochemical and geochemical methods. Secondly, our aim is to generate an overview of the Neolithization of Europe by regarding not only the route from the Middle East through the Balkans towards central Europe. We also investigate how data from Germany, Hungary, Croatia and the Iberian Peninsula can be utilized in the light of developing a broader, pan-European understanding of population dynamics in the Neolithic.

Stable isotope analysis is a powerful tool to reconstruct the diets of prehistoric and historic populations. Until now only few isotopic studies have been carried out for the prehistoric Iberian Peninsula. In the present study human and animal bones from four different sites (Cueva de Els Trocs, Alto de Reinoso, Humanejos, and La Bastida) dating from the Early Neolithic to the Bronze Age (El Argar culture) were sampled and stable carbon and nitrogen isotope analysis were conducted. For each site isotopic values and diet reconstructions will be discussed in detail in context to their anthropological and archaeological settings. For the site of La Bastida findings on weaning practices will also be presented. Comparing the four sites we demonstrate how diet was influenced by subsistence patterns, settlement systems, cultural factors and by the specific environmental givens.

Coutelier, Clément (Université Bordeaux Montaigne - Ausonius) clement.coutelier@u-bordeaux3.fr

Couture-Veschambre, Christine (Université de Bordeaux - PACEA) christine.veschambre-couture@u-bordeaux.fr

Tillier, Anne-marie (Université de Bordeaux - PACEA) anne-marie.tillier@u-bordeaux.fr

Rottier, Stéphane (Université de Bordeaux - PACEA) stephane.rottier@u-bordeaux.fr

Deguilloux, Marie-France (Université de Bordeaux - PACEA) marie-france.deguilloux@u-bordeaux.fr

Paleogenetics, like other bioarchaeological methods, have greatly benefited the last years from major technical advances. Various funerary and population questions could be addressed through ancient DNA analyses. Our aim is to illustrate some aspects of this advancement through the exceptional example of the Neolithic site Gurgy 'Les Noisats', in the French Paris basin.

This site consists of a necropolis (4900 - 4500 BC) grouping 128 individuals. Mitochondrial DNA markers (HVRI and SNP analysis) were analyzed on 102 individuals and HVRI sequences were successfully recovered for 39 individuals.

Characterization of the maternal genetic pool, the biggest obtained so far for the Neolithic period, provides new and major arguments in the discussion of local and regional/continental questions.

Thanks to a Geographic Information System (GIS), a first intra-population approach was conducted to highlight potential correlation between genetic structure of the group and archaeological parameters (spatial distribution, chronology and funerary data). Some specific links were found between graves and enabled us to propose interesting hypotheses concerning the site organization.

Furthermore phylogeographical analyses were made with regard to the debate of European neolithisation. The chronological and geographical position of Gurgy 'Les Noisats' site is particularly significant to this debate. Indeed, in Early and Middle French Neolithic, Gurgy 'Les Noisats' is the most important necropolis located at crossroads between the Danubian and Mediterranean waves of neolithisation. The results of the phylogeographic analyses (Fst, shared haplotypes, haplogroups frequencies) point out an equal contribution of Central and Southern European Neolithic populations in the elaboration of the Gurgy genetic pool. These results support the archaeological arguments previously collected on the site.

Then, the data obtained from these French Neolithic farmers represent a major contribution to the understanding of population movements in the Neolithic time and illustrate the multiple interests of a paleogenetic approach to various archaeological questions, from local to continental scale.

*Alt, Kurt W. (Integrative Prehistory and Archaeological Science, Basel University, Switzerland; Danube Private University, Krems, Austria; State Office for Heritage Management and Archaeology Saxony-Anhalt and State Museum of Prehistory Halle, Germany) alt.kurt@unibas.ch*

The Neolithisation of Iberia is one of the major topics of recent Prehistory. The profound and quick changes experienced by human populations have always stimulated diffusionists accounts which explain those transformations in terms of a true colonization by groups coming from outside the Peninsula, mostly from the Mediterranean realm (cardial pottery standard model). Recent discoveries show that perhaps the arrival of the production economy could be earlier than previously thought, and different hypotheses are also being proposed whether the origin of this eventual demographic input is to be searched in different areas of the Mediterranean or through inland routes crossing the Pyrenees.

However, since the last decade other proposals emerged in the Iberian research which stressed the important role of local Mesolithic hunter gatherers in the adoption process of this whole new way of life. Even some scholars have tried to argue about an eventual local or autochthonous domestication of plants and animals. The impact of radiocarbon debates on the basis of a much more ample database of samples analyzed in the last decade has strongly pushed these debates into strong disagreements.

An overview of the current debate on this topic is offered here, as a theoretical framework necessary to understand the new lab data (DNA, isotopes) that the rest of the communications are going to present in order to better understand the empirical support of the different models which explain the appearance of the

Neolithic in the Iberian Peninsula.

*Alt, Kurt W. (Integrative Prehistory and Archaeological Science, Basel University, Switzerland; Danube Private University, Krems, Austria; State Office for Heritage Management and Archaeology Saxony-Anhalt and State Museum of Prehistory Halle, Germany) alt.kurt@unibas.ch*

The Neolithic lifestyle developed in the Near East about 12,000 years ago and spread into Central Europe and the Iberian Peninsula via different routes during the following millennia. Subsequently, a number of significant phenomena emerged, like the construction of large residential areas, the emergence of fortified settlements, the development of elaborate burial customs, the production of metals as well as an increasing social stratification with the establishment of Elite societies. Each newly introduced cultural or social element raises questions to its origins and dissemination, whether this was achieved via an exchange of ideas or directly via human migration. Here, palaeogenetic studies can step in by opening a window directly into the past and tracing population shifts on a genetic level. So far, ancient DNA studies based on mitochondrial DNA have revealed discontinuities between Central Europe's autochthonous hunter-gatherers and early farmers as well as between the latter and the present-day population. Furthermore, new data of a comprehensive study of subsequent Neolithic to Bronze Age populations from Central Europe revealed multiple population dynamic events during the Neolithic which involved genetic influx from various regions. Ancient DNA data from the Iberian

Peninsula suggest that a number of characteristic *Linear Pottery Culture* lineages also spread through the Mediterranean region, although at least in Spain and Portugal a larger fraction of hunter-gatherer lineages was retained. However, statements about population dynamics after the initial Neolithic in Western Europe are rare and based on limited data. We will compare a comprehensive mitochondrial dataset of more than 200 published and new Mesolithic to Bronze Age individuals from the Iberian Peninsula to contemporaneous data from Central Europe in order to expose commonalities and differences in population dynamics between the arrival of the first farmers and the establishment of Early Bronze Age societies.

Over the last decade, new projects and publications on ancient DNA (aDNA) and/or stable isotope analyses have been contributing to archaeological research to an increasing extent. However, for archaeology and the natural sciences to successfully cooperate, it is essential that there is a mutual awareness of the potential but also of the pitfalls of specific analytical methods and approaches. At the outset of every interdisciplinary project between archaeology and bioarchaeology should stand the two most basic questions: "What answers can bioarchaeological procedures provide with regard to the specific research question?" and "What requirements must be met in order to successfully conduct the appropriate analyses?". For example, contamination-free sampling is crucial for successful ancient DNA analyses and should ideally be conducted as early as during the excavation itself. This talk will give an overview about factors that influence DNA preservation,

about comparative samples needed for isotope analyses (carbon/nitrogen, strontium, and oxygen), sampling strategies, and the general work-flow of the analyses themselves.

*Alt, Kurt W. (Integrative Prehistory and Archaeological Science, Basel University, Switzerland; Danube Private University, Krems, Austria; State Office for Heritage Management and Archaeology Saxony-Anhalt and State Museum of Prehistory Halle, Germany) alt.kurt@unibas.ch*

Ancient DNA studies focusing on the Iberian Peninsula have mainly investigated the Mesolithic-Neolithic transition in few areas due to the limited data available. Within a comprehensive international project founded by the German Research Foundation, we genetically analysed more than 300 Mesolithic to Early Bronze Age individuals from the Iberian Peninsula. Altogether, mitochondrial results of 250 individuals could be successfully reproduced.

Together with published data from the Iberian Peninsula, results were pooled into 19 groups of different chronological and regional context all over the research area. We applied several statistical methods to reveal continuities and discontinuities among populations on chronological as well as spatial level and will here present the results for the first time.

ORAL

**8. RESIDENCE AND MARRIAGE PATTERNS AMONG LATE HOLOCENE COASTAL HUNTER-GATHERERS IN SOUTHERNMOST AFRICA FROM D15N IN BONE AND DENTIN**

*Sealy, Judith (University of Cape Town) judith.sealy@uct.ac.za*

During the second half of the Holocene, we can trace significant changes in population size, technology and social organization among hunter-gatherer societies in southern Africa. Along the south coast, communities became more sedentary, occupying well-defined territories and probably defending their boundaries. Thus far, the area that has been studied in greatest detail is the Robberg Peninsula and adjacent Plettenberg Bay. This area offered especially rich marine foraging opportunities, including access to a mainland seal colony and unusually productive localities for shore-based fishing, leading to very high  $\delta^{15}\text{N}$  values in human skeletons. In contrast, skeletons from Matjes River Rock Shelter, only 14 km to the east, have lower  $\delta^{15}\text{N}$  values, indicating less reliance on high trophic level marine foods. These analyses are of bone collagen, representing long-term averages of the diets eaten over many years of the individual's life. Such a marked discrepancy indicates significantly different marine foraging strategies at Robberg and Matjes River: in effect, an economic difference between the two sites that could only have been maintained by long-term segregation of the two communities. Through the intervening coastal plain flows the estuary of the Bietou/Keurbooms River, which likely marked the boundary between two hunter-gatherer territories.

New research compares  $\delta^{15}\text{N}$  in the dentin of early-forming permanent teeth (incisors and first molars) with bone from the same skeletons, in order to ascertain whether people from Robberg/Plettenberg Bay married within their own group (in which case both dentin and bone should show high  $\delta^{15}\text{N}$ ), or whether they sought marriage partners from further afield (in which case  $\delta^{15}\text{N}$  in dentin should be lower than in bone).

The preliminary data set available thus far supports within-group marriage. This raises interesting questions about group size (how large did groups have to be to maintain long-term viability?) and about the nature and extent of regional networks at this time.

ORAL

**9. THE ARCHAEOLOGY AND BIOARCHAEOLOGY OF THE MIDDLE NEOLITHIC SITE OF ALTO DE REINOSO (FRESNO DE RODILLA, BURGOS)**

*Tejedor, Cristina (Fundación del Patrimonio Histórico de Castilla y León, Valladolid, Spain) tejedor.cristina@gmail.com*  
*García-Martínez de Lagrán, Inigo (Postdoctoral Program of the DEUI of the Basque Government, University of the Basque Country, U.P.V./E.H.U., Spain) igmtzl@gmail.com*

*Alt, Kurt W. (Integrative Prehistory and Archaeological Science, Basel University, Switzerland; Danube Private University, Krems, Austria; State Office for Heritage Management and Archaeology Saxony-Anhalt and State Museum of Prehistory Halle, Germany) alt.kurt@unibas.ch*

Both artefacts and radiocarbon dates (3769 - 3540  $2\sigma$  cal BC) assign the Megalithic tomb of Alto de Reinoso to the Middle/Late Neolithic of Spain. The tomb was analysed following an integrative concept with a close collaboration between archaeology, physical anthropology, molecular genetics (ancient DNA) and biogeochemistry. For a comprehensive characterization of the interred individuals we used different osteological parameters as well as ancient DNA and isotope analyses to explore the group's demographic structure, health status, possibly kinship relations, and to reveal information on mobility and dietary strategies. Skeletal material from Alto de Reinoso included complete and incomplete skeletons as well as a large number of isolated bones with a moderate poor state of preservation.

The minimum number of individuals buried at Alto de Reinoso was estimated at 49 individuals. The demographic and genetic profiles of the group, intra-group kinship, homogenous dietary data, restricted mobility, moderate disease frequencies, and a low incidence of stress markers draw a picture of a rural population not exposed to great external hazards.

The result of our integrative study provides notable insights into the social organization and structure of this community.

Quanchao Zhang (Department of archaeology, Jilin University) [py2000sdqy@sina.com](mailto:py2000sdqy@sina.com)

Hong Zhu (Department of archaeology, Jilin University) [zhuhong@jlu.edu.cn](mailto:zhuhong@jlu.edu.cn)

Stable isotope and dental microwear analyses are integrated to determine diet at the prehistoric site of Zhoujiazhuang, China, 2250 B.C. The Zhoujiazhuang site is located in central Yellow River area and belongs to the late Neolithic Longshan culture. During this period, civilization was originating and cities were emerging. The evidence for reconstructing diet of the Longshan population can be obtained by dental microwear analysis directly and effectively.

Dental microwear analysis focuses on the microscopic scratches that formed on tooth's surface as the result of chewing. Different microwear patterns of scratches on the buccal surface indicate different dietary composition. In this study, scratches of the buccal surface have been studied on molars from the Zhoujiazhuang site. All samples have been observed at 200X magnification by scanning electron microscope. The length and orientation of each scratch on the buccal surface have been determined and measured. We also use stable isotope ratios of carbon and nitrogen in bone collagen to examine the diet of the Zhoujiazhuang population.

The results obtained show that people of the Zhoujiazhuang site ingested both plant products and animal products. This result is concordant with the result of stable isotope analysis. Nitrogen isotope ratios of bone

collagen also show that these inhabitants ate animal products and plant products. Carbon isotope ratios of bone collagen show that most plant products came from C<sub>4</sub> plants. That means subsistence of the Zhoujiazhuang population included agriculture and animal husbandry. This study demonstrates the importance of integrating different analytical methods when reconstructing diet of prehistoric populations.

Pichler, Sandra (Integrative Prehistory and Archaeological Science, Basel University, Switzerland) [sandra.pichler@unibas.ch](mailto:sandra.pichler@unibas.ch)

The Megalithic tomb of La Mina (Alcubilla de las Peñas, Soria), dating to the early 4<sup>th</sup> millennium BC, was excavated in 2009-2011. The undisturbed communal burial chamber held a minimum number of twenty individuals. Tomb, artefactual and bioarchaeological remains are in the focus of ongoing investigations directed at cultural as well as bioarchaeological issues. The human skeletal remains are analysed in a Master's project at the University of Basel which will cover individualization, demographic and palaeopathological analyses as well as the collection of dietary data.

The excavation of the skeletal remains was difficult because of the fragility of the bones. To prevent further fragmentation, complete bones were recovered in blocks using linen bandages and glue as a binding

agent on-site. In these blocks the bones could be safely transported. In the lab analysis, this mode of salvaging the remains presents challenges which impact the analysis of the skeletons. As an advantage, it is possible to take direct bone measurements prior to removal of the caskets. On the other hand, the stability of the blocks hinders an easy removal of the skeletal parts. This is especially problematic with fragile elements such as the pelvic bone. The poster discusses the pros and cons of different methods to remove the block bindings as well as their impact on the further analyses of the skeletal material.

## 1. CLIMATE CHANGE, HUMAN SOCIETY, AND PRE-HISTORY IN THE YUCATAN PENINSULA

*Cobos, Rafael (Universidad Autónoma de Yucatán) rachcobos@aol.com*

Underwater archaeological research conducted in sinkholes in the Yucatán peninsula reveals submerged contexts containing faunal as well as human skeletal remains. These contexts were dry at the end of the Pleistocene and the beginning of the Holocene. The presence of human and faunal remains dating back more than 10,000 years before present, suggests that climate conditions in southeastern México provided the appropriate environment for nomadic hunters and their prey. This way of life is very similar to what has been documented elsewhere in the world.

ORAL

## 2. MINERAL RAW MATERIALS AND PROCUREMENT MODALITIES DURING LATE PRECERAMIC AND EARLY FORMATIVE IN MEXICO

*Espinosa Vázquez, María Alejandra (Universidad Autónoma de Yucatán) maeva1999@yahoo.fr*

Utilization and exploitation of siliceous rocks has been a minor research topic within the archaeological investigations carried out in Mexico. Overall, research has been mainly focused on description of archaeological artifacts, mostly without a previous geological investigation. In the state of Yucatan, identification of raw material, procurement, and circulation as well as the fabrication process of stone tools are topics of research still to explore in a systematic way. In this paper I present, as an example, a research concerning raw materials supply and exploitation during late Preceramic and early Formative in the Valley of Oaxaca. The case of Oaxaca provides methodological information in the development of further research in Yucatan.

In this paper I present a research regarding the main lithological formations and diverse modalities of procurement carried out by late hunter-gatherers and early sedentary farmers at the Valley of Oaxaca. The data obtained allowed the determination of the geological origin of the rocks employed for the fabrication of

tools during late Preceramic and early Formative as well as analyzing the supply and exploitation modalities employed by human groups during the mentioned periods. A comparative analysis of the chipped stone material from three archaeological sites was carried out through a technological approach and an in-depth study of the raw materials. In order to characterize and determine the geological origin, the study of the raw materials was accomplished through geological survey and petrographic analysis. Thus, this research project addresses a pluridisciplinary approach, linking archaeology and geology, clarifying aspects thus far maintained as assumptions.

This example illustrates the relevance on developing geoarchaeological research based on a similar approach in the state of Yucatan. Research in the Maya area has covered broad issues from varying angles of view through out all the chronological sequence documented so far. In spite of the vast amount of data generated, archaeological evidence of early occupations as well as data related to the first inhabitants in the state of Yucatan is extremely rare. A step further in this emerging line of investigation relates to the identification and location of siliceous rock sources in Yucatan.

Comparing data from a late Preceramic rockshelter and from two early Formative agricultural villages allowed to clarify aspects concerning the context of stone tool production and the differential use of raw materials available in the Valley of Oaxaca. This approach represents a further research guideline on sources of mineral raw material in the state of Yucatan.

ORAL

## 3. LA VIDA COTIDIANA DE LOS MAYAS PREHIS-PÁNICOS: APROXIMACIONES RECIENTES EN AR-QUEOLOGÍA

*Fernández Souza, Lilia (Universidad Autónoma de Yucatán) fsouza123@yahoo.com*

Food preparation and consumption are some of the human ubiquitous activities. Ingredients, preparation techniques and cooking, as well as kitchen implements have been studied in relation to environment management, gender relations and roles, ethnicity, agency and performance, to mention only a few aspects. The goal of this paper is to offer a review of existing data from early Maya contexts in search of artifacts that may inform us about food preparation and to discuss possible

pattens and variations in practices and techniques of elaboration and consume. I will emphasize on grinding and cutting artifacts, as well as in their relation with animal or vegetal remains, when possible. Finally, I will discuss how conjunctive and transdisciplinary approaches may contribute to a finer understanding of past culinary technology.

This is a conjunctive approach reviewing contextual, artifactual, ethnoarchaeological and, when possible, archaeometry and paleobotany data related to grindining stones and cutting artifacts. I will search for: location and spatial relation of the artifacts, between them and with ecofacts; forms, variations and possible functions; registered use marks; modern evidence of artifactual variation as a result of different processes and techniques.

ORAL

#### **4. EARLY CULTURAL MANIFESTATIONS OF THE YUCATAN PENINSULA: LANDSCAPE AND PREHISTORIC MATERIAL EVIDENCE**

*Hernandez, Hector (Universidad Autónoma de Yucatán)  
hhernandez@uady.mx*

Along decades it has been debated the relative absence of solid evidences concerning the origin of prehistoric man on the Yucatan peninsula. Nevertheless, recent research has demonstrated that the climatic ans landscape changes during the end of the Pleistocene and the beginning of the Holocene periods encouraged the presence of the first human groups in the peninsular context.

This paper is an attempt to summarize the new archaeological, paleoclimatic, and paleobotanical evidence about the presence of early humans in the northern Yucatan palins. Our goal is to synthesize the recent discoveries dealing with early cultural developments and landscape modifications to discuss the adaptation of a pre-Maya presence in Yucatan.

Preceramic remains do exist in Yucatan and have existed for a considerable length of time. Recent explorations have shown that the evidence of early cultural developments in this region is limited mostly to caves and cenotes. Instead of that, with some data from lacustrine sediment samples, I will try to reconstruct the vegetation changes that occurred in Yucatan during the Holocene. The emphasis will be on the anthropogenic

modifications through the Paleoindian, Archaic, and Prehispanic Maya periods.

We must approach this problem in a different way by combining archaeological, paleoclimatic, paleontologic, and paleobotanic evidence that deals with the setting of the first peninsular populations.

---

ORAL

#### **5. THE FIRST SIGNS OF MAN IN SOUTHEAST MESOAMERICAN.**

*Mier Aragón, Román (Universidad Autónoma de Yucatán)  
roman.mier@uady.mx*

The main part of these beginnings is intimately linked to the way in which man nature of collectors, hunters and fishermen fits; you must also take into account the prehistory of our continent is taken as an event that has great preponderance in evolution, because you get to consider Latin American history begins with the arrival of the conquerors.

But it may be mentioned that even before this event and the Latin American peoples had a history itself; assumes that human activity takes place in America later compared to their peers in other continents manner.

to do our work for the analysis of research related to the theme for the Mesoamerican Southwest necessary; that allows us to have a more complete picture ideas for this region.

In the Maya area, specifically Yucatan can be localized prehistoric evidence Loltún Cave (Pleistocene) ranging from cave paintings, negative hands up bones of different animals typical of the time ; to El Salvador this period is clearly exemplified in the Cave of the Holy Spirit where besides rock art paintings and artifacts used for the activities of this group during the practice of their daily activities were located.

A complete collection of the main signs of early man to the area of southeastern Mesoamerica, emphasizing the features that can be placed to Yucatán.

ORAL

## 6. POPULATION , CULTURE AND IDENTITIES IN ARCHAIC YUCATAN PENINSULA AND CENTRAL AMERICA

*Pool Cab, Marcos Noé (Universidad Autónoma de Yucatán)  
poolcab@hotmail.com;marcos.pool@uady.mx*

Late Paleoindian period and during the Archaic ( 11 000 and 6000 BC ) occurred human adaptations in various environmental areas of southern Mesoamerica and Central America. The changes known occurred for example in the Pacific Coast of Chiapas are seen in contexts dated to 5500 BC . Such changes should promote human exploitation of certain biospheres.

Moreover, the evidence of human occupation between the Paleoindian and Archaic , basically been observed in caves. Evidence oriented artifacts using lytic, paints and pollen traces , of domesticated plants such as corn.

pictographs, stone and paleobotanical data

The present paper aims , through a review of the major works that have been made in the Yucatan and Central America, know who they were, what they did and how human groups who settled in the region lived ( though perhaps not permanently ) , on dates as far back as the Archaic and the end of the Paleoindian.

Farming in the Yucatan Peninsula and parts of Central America dating from the Archaic period is manifested in the form of organization, as an exogamous tribes. During this period, human groups settled in what is now known as Maya area are primarily gatherers, hunters and / or fisherman. It has the company of animals to accompany him and his leadership is based on the theory of the fittest, who must prove his supremacy in order to retain the leadership of the group. Moreover, the change in the way of living also influences technological change. Magic let their religious beliefs reflected through paintings and gafitis was also a feature of the region under study.

ORAL

## 7. LA EXPANSIÓN DE LAS PLANTAS DOMÉSTICAS EN EL ÁREA MAYA

*Zimmermann, Mario (Universidad Autónoma de Yucatan)  
zimmermann.fca.uady@hotmail.com*

During last two decades, research on ancient Maya agriculture turned up evidence for the appearance of domestic crops prior to the Preclassic period. This paper represents a summary of available information including new botanical data for Yucatan's northwestern plains. Specifically, pollen analysis results for a sediment core taken close to the Mayapan site will be presented. Based on this empirical knowledge, the sociocultural panorama for the Maya Area during the Archaic will be re-evaluated.

# B51 Reconstructing human mobility in the Palaeolithic: building new frameworks

**1. MOBILITY OF MATERIALS, MOBILITY OF PEOPLE: MISCONCEPTIONS AND FACTS, EXAMPLES FROM THE DU PALAEOOLITHIC OF HAUTE-LOIRE (MASSIF CENTRAL, FRANCE)**

*Raynal, Jean-Paul (CNRS) jpraynal@wanadoo.fr*  
*Fernandes, Paul (Paleotime / CNRS) paul.fernandes@paleotime.fr*  
*Delvigne, Vincent (Univ. Bordeaux 1) vincent.delvigne@hotmail.fr*

The alteration of flint sometimes leads to a misleading homogenization of their textures, for example confusion between Jurassic and Cretaceous flint, or between a lacustrine/marine and silcrete. The detection of these "false friends" within archaeological assemblages may substantially alter the assumed origins and direction of movement of mineral raw materials, thereby changing the archaeological interpretation. A detailed study of the state of flint alteration is essential and usefully contributes to the reconstruction of raw material exploitation in the Middle and Upper Paleolithic.

Three case studies of misidentification are presented:

Oligocene lacustrine flint from Cantal vs. Stampian lacustrine flint from the Etampes region (final Upper Magdalenian of St. Anne II and Badegoulian of Roche Tavernat)

Alluvial flint in secondary context from the Aalenian - Bajocian in Lozère vs. Bedoulian Ardèche flint / Upper Turonian Indre -et-Loire flint (Mousterian at Baume-Valley and Badegoulian at Rond-du-Barry)

Turonian flint from Loir-et-Cher vs. Miocene silcretes from the Upper Loire (Gravettian from Blot).

The distances for raw material collection are reduced in these examples, but new directions for sourcing also demonstrated, improving our picture of the regional sphere of lithic exploitation.

ORAL

**2. ASSESSING SCALE AND RESOLUTION IN ANALYSES OF PALEOLITHIC MOBILITY: CASE STUDIES FROM LIGURIA**

*Riel-Salvatore, Julien (University of Colorado Denver) julien.riel-salvatore@ucdenver.edu*

In spite of its central importance, the concept of mobility in the Paleolithic remains often poorly defined and operationalized. Even focusing on a single artifact class doesn't necessarily resolve this issue since, for instance, stone tools comprise multiple dimensions (e.g., raw material, technology, reduction intensity), each of which might give a different 'signal' of prehistoric mobility. The challenge for archaeologists lies in reconciling these various dimensions into coherent interpretations. Furthermore, it is crucial to ensure that individual assemblages can be used to diachronically track shifting manifestations of the phenomenon of mobility at the level of the site, and that data recovered from distinct excavations are made commensurate in order to compare distinct sites and archaeological levels to one another. Thus, the scale at which mobility is looked at is critically important to the kinds of questions about it that can be asked and the kinds of answers we can hope to provide to them. In a like manner, the level of resolution of the archaeological data used in answering questions related to Paleolithic mobility is also key, in that it determines whether assemblages and/or sites can be integrated in single analyses. One specific aspect of resolution, whether data from excavations conducted several generations ago commensurate with those collected from present-day projects (or several different modern projects), is especially relevant in these discussions. To highlight some of these conceptual issues, two Ligurian case studies – Riparo Bombrini and Caverne delle Arene Candide – are presented. The region of Liguria (NW Italy) provides an interesting backdrop for this as it is largely devoid of high-quality lithic raw material, which imposed a further set of constraints on how to think about mobility on the basis of lithic material. The analysis shows that differences in scale and resolution of the available data are not necessarily fatal to integrated models of Paleolithic mobility within a constrained region, though they can impose biases that can mistakenly be given behavioral significance.

ORAL

### 3. RECONSTRUCTING MIDDLE PALEOLITHIC MOBILITY IN THE CENTRAL COAST REGION OF PORTUGAL USING PIXE ANALYSIS ON CHERT ARTIFACTS.

*Pereira, Telmo (ICArEHB) telmojrperreira@gmail.com*  
*Alves, Luis (Laboratório de Aceleradores e Tecnologias de Radiação (IST) lcalves@ctn.ist.utl.pt*  
*Alves, Eduardo (Laboratório de Aceleradores e Tecnologias de Radiação (IST) ealves@ctn.ist.utl.pt*  
*Haws, Jonathan (University of Louisville) jonathan.haws@louisville.edu*  
*Benedetti, Michael (Department of Geography & Geology, UNC-Wilmington) benedettim@uncw.edu*  
*Manso, Claudia (Camara Municipal do Bombarral) claudiammanso@gmail.com*  
*Bicho, Nuno (ICArEHB) nbicho@ualg.pt*

Paleolithic archaeologists have long focused on mobility in their reconstructions of past human behaviour. Many models emphasize the acquisition of lithic raw materials as a means of understanding prehistoric mobility patterns. Determining the source of the raw material is therefore key to tracing the movement of raw material across landscapes and understanding human decision-making. There are several destructive and non-destructive analyses that allow for geochemical fingerprinting of lithic materials. Here we use Proton Induced X-Ray Emission (PIXE) to characterize chert sources and provenance of Middle Paleolithic artifacts from sites in the central coast of Portugal. The sites, Praia de Rei Cortiço, Mira Nascente and Gruta Nova da Columbeira, represent a time span from ~100 to 41 ka. Praia Rei Cortiço and Mira Nascente are open-air, single component archaeological sites located in the coastal cliffs. Praia Rei Cortiço is located within quartz and quartzite gravel deposits but contains chert artifacts that likely originated from presently known chert outcrops >5 km away. Some nodules might have been available closer in the past. Mira Nascente is located 10 km from primary chert sources. Gruta Nova da Columbeira is a multi-component cave site located ~13 km inland, with the chert rich Cesaredas Plateau in between. The river that runs along the foothill carries quartz, quartzite and some chert.

The assemblages from Praia Rei Cortiço and Mira Nascente have low chert variability while Gruta Nova da Columbeira has a large variability with nodules presenting different types of cortex, which might suggest their acquisition in primary, sub-primary and secondary sources.

Most artifacts are spotted, banded and smudged which demanded more than one reading for some. Analyses were also made on several artifacts from a same refitted block in order to understand variability within a single nodule.

Our results suggest low relation between sites, which was not a surprise for Mira Nascente since it is 35 km from Praia Rei Cortiço and 43 km from Gruta Nova da Columbeira. However, Praia Rei Cortiço and Gruta Nova da Columbeira are only 14 km distant from each other. This suggests a close range of chert acquisition, probably under a 7 km radius. The chert variability seen in the archaeological record is not yet completely covered by the regional geological sources meaning that more analysis will be performed in the future and, consequently, these results must be seen as preliminary. Despite their preliminary nature, the current results have implications for our understanding of lithic raw material use, human movement and mobility patterns during the Middle Paleolithic.

We would like to thank the Archaeological Institute of America for funding the PIXE analysis, the Laboratório de Aceleradores e Tecnologias de Radiação (IST) for the analysis and Câmara Municipal do Bombarral to allow us to study the Gruta Nova da Columbeira assemblage.

ORAL

### 4. WHY DID EARLY HUMANS MIGRATE?

*Bouissac, Paul (University of Toronto) paul.bouissac@utoronto.ca*

We now take for granted that modern humans migrate in search of a better life. Anticipation and motivation are fed by communication. Many animal species, notably birds and fishes, seasonally migrate over long distances. Primates, however, are limited in their capacity to engage in long migrations toward unknown lands. Finding out why early humans started their journey out of Africa to eventually populate most of the planet is a tantalizing question. Did they spread over successive short distances, or did they engage in deliberate long migrations once they had become bipedal? Did they move opportunistically, or were they displaced by external forces, natural or social. Some conditions are necessary for such adaptive migrations to occur: perceptual, cognitive, and social adaptations are prerequisites. Perception must have evolved to cover distal space since surviving in a savannah environment required the

processing of information from a greater distance than what is optimal in arboreal niches; moreover, migrating humans needed advanced cognitive capacities to project actions beyond the immediate future and plan longer-term, adequate strategies; finally, successful migrations must be sustained by a sufficient level of social organization. This paper examines the perceptual and cognitive conditions for dispersal beyond proximal boundaries and discusses the evolution of the sense of perspective and its limitations as a determining factor in priming long distance migrations.

ORAL

## 5. MOBILITY OF LITHIC RAW MATERIALS IN THE MIDDLE STONE AGE OF MOROCCO.

*Fernandes, Paul (Paleotime / CNRS), RAYNAL Jean-Paul - jpraynal@wanadoo.fr (CNRS) paul.fernandes@paleotime.fr*

The Mousterian-Aterian lithic assemblage of the Grotte des Gazelles in DarBouazza (Morocco) is composed of two groups of flint. The majority were collected on fossil beaches, close to the cave: they are nodules of small size representing evolved facies of the phosphatic flint from the region of Houribga, transported to the ocean by the Oued Mellah river and redistributed by longshore currents onto beaches south of Casablanca. A second smaller group consists of similar but less evolved flint. This demonstrates direct collection from the phosphate plateau 70 km to the east, therefore a probable movement of people between the hinterland and coastal Middle Stone Age in this part of Morocco. Details and timing of this mobility remain to be further explored.

ORAL

## 6. STABLE BUT NOT STATIC: CHANGES IN RAW MATERIAL PROCUREMENT AT ROCA DELS BOUS (EASTERN PRE-PYRENEES, IBERIA)

*Roy Sunyer, Miquel (CEPAP-UAB) miquel.roy@uab.cat*  
*Roda Gilabert, Xavier (CEPAP-UAB) javier.roda@uab.cat*  
*Mora Torçal, Rafael (CEPAP-UAB) rafael.mora@uab.cat*  
*Martínez-Moreno, Jorge (CEPAP-UAB) jorge.martinez@uab.cat*

Properties of the physical environment and its resources have major effects on the organization of human activities as well as the importance of cultural tradition. Both factors contribute to the decision-making process and this is reflected in the archaeological sites. To explain

the meaning of the patterns observed in landscape management is essential to analyze the notion of mobility, a key attribute in the organization of Pleistocene human groups.

Variations in raw material procurement are an option to assess the relevance of a particular resource. These let us wonder about behavioral features of human groups such as the use of the landscape, the knowledge of the environment or the patterns of mobility of human groups. Likewise, variations in the choice of raw materials can co-vary with other aspects such as the technological configuration of lithic assemblages.

Assuming these principles, we propose to analyze the variations that are seen in the archaeological units N10, N12, N14 and S9. These belong to the Middle Palaeolithic and are assigned at the end of MIS 3.

The abrupt changes detected in the supply of rocks rheologically different such as flint, quartzite and limestone, allow the analysis of various aspects related to the management of these resources.

The variety of strategies in raw material procurement identified in Roca dels Bous suggests radical changes in the organization of settlement patterns. The causes for these changes in the Middle Palaeolithic subsistence will be discussed.

ORAL

## 7. A COMPARATIVE STUDY USING SOCIAL CARNIVORES TO UNDERSTAND MOBILITY AMONG NEANDERTHALS

*Croxall, Elinor (Leiden University) ecroxall@gmail.com*

Mobility is an integral part of the interpretation of archaeological sites, regional patterns and the behavioural characteristics of particular hominins (Binford 1980, Grove 2009). The Neanderthal archaeological record in particular has been interpreted as differing from that of modern humans due to a higher frequency of residential moves and lower intensity of site use. Neanderthals are known to have exploited mobile resources in highly seasonal environments, but in such contexts behavioural models would predict a pattern of mobility different to that associated with Neanderthals (Charnov 1976). To explore the behavioural options available to Neanderthals in the colder and more seasonal parts of their range, a comparative framework is presented that

investigates patterns of spatial behaviour among large social carnivores and their similarities and differences to patterns among mobile human societies. Species and populations are selected where there is a seasonal climate and/or availability of resources. Annual and seasonal movements are therefore analysed among wolves (*Canis lupus*) in different seasonal environments and different species within the Serengeti (*Panthera leo* and *Crocuta crocuta*). This is then compared against the large literature of human mobility patterns in mobile societies.

Contrary to assumptions, but consistent with foraging models, social carnivores rarely follow migratory prey. Overall patterns are very similar to human populations in similar environments. Spatial behaviour among both carnivores and hunter-gatherers is strongly influenced by the importance of fallback prey and other foods, territoriality and a number of reproductive and social reasons for the use of central places. The specific patterns each species adopts relies heavily on a combination of particular ecological, social and reproductive factors. Simple comparisons between human and other animals are therefore found to be less dichotomous and are combined into a detailed predictive framework of mobility responses.

Rather than trying to recognise patterns of mobility against direct analogues it is important to understand the reasons for different aspects of mobility patterns. For Neanderthals diet, reproductive and social strategies and population density are of particular importance in predicting aspects of mobility patterns that can then be tested in the archaeological record. With current evidence in these areas a mobile pattern can be envisaged, but within a relatively small annual range compared to the distances travelled by any migratory prey. Future research in these areas will be able to refine these predictions. Similarly, another key area for research is the potential plasticity of ungulate social behaviour in warm and cold Pleistocene environments. The movement of prey animals is a large part of the predictions for Neanderthal behaviour. The predictive framework developed provides an ecological basis for framing questions about mobility that are independent of assumptions regarding intelligence and cultural complexities.

## 1. CHRONOLOGICAL FRAME OF ACHEULIAN SITES IN EUROPE AND IN ASIA

*Falguères, Christophe (CNRS/MNHN) falguere@mnhn.fr*  
*Bahain, Jean Jacques (MNHN) bahain@mnhn.fr*

When we look at some important chronological marks for the Acheulian technique, we can observe that its arrival is around 1.4 Ma in Middle East, circa 1Ma in China, then a little bit later in Indonesia and India at the Brunhes/Matuyama boundary (0.8 Ma). However, it appears that some wide continents such as China and India did not reveal all their secrets about this topic. In Europe, more and more data suggest that this « culture » settles around 0.6-0.7 Ma both in Northern part of Europe and around the Mediterranean Basin. These ages rise the issue about the author of this culture which possibly would be not *Homo heidelbergensis* knowing that several sites yielding bifaces are older than the age of Maüer mandible dated to 610 ka (Wagner et al., 2010). A number of sites containing bifaces range between 200 and 500 ka among some of them having yielded artefacts flaked according to the Levallois technique.

Today, even though the gap for the appearance of Acheulian tends to decrease, it remains 300 ka difference between the oldest Acheulian asiatic sites and the oldest Acheulian European sites.

ORAL

## 2. PRELIMINARY DATING OF SOUTH KOREAN EARLY PALEOLITHIC SITES USING COSMOGENIC NUCLIDES <sup>26</sup>Al AND <sup>10</sup>Be

*Lebatard, Anne-Elisabeth (CEREGE-CNRS) lebatard@cerege.fr*  
*Bourlès, Didier L. (CEREGE-AMU) bourles@cerege.fr*  
*Braucher, Régis (CEREGE-CNRS) braucher@cerege.fr*

Recent discoveries of numerous early Paleolithic sites in South Korea raised the question of their chronological framework. Using the pair of in-situ produced <sup>10</sup>Be and <sup>26</sup>Al cosmogenic nuclides, coherent burial ages for quartz pebbles from the Mansu-Ri (Loc. 4) and Wondang-Jangnamgyo sites were first determined. New results obtained using the same burial dating method at other early Paleolithic sites in South Korea, among which the Cheongok-ni (Loc. 3) site, will be presented. These

dating will allow providing an absolute chronological framework for the South Korean lithic industries and to confront it to other early Paleolithic sites in occidental Europe, Africa and Asia.

## 3. RUPTURES, TECHNOLOGICAL CONTINUITIES AND VARIABILITY FACTORS OF TECHNOLITHIC SYSTEMS IN MIDDLE PLEISTOCENE OF EUROPE AND ASIA

*Celiberti, Vincenzo (Cerp Tautavel UPVD Perpignan, UMR 7194 CNRS) vincenzo.celiberti@cerptautavel.com*  
*Cauche, Dominique (Laboratoire Départemental de Préhistoire du Lazaret, Nice, UMR 7194 CNRS) dcauche@yahoo.fr*  
*Notter, Olivier (MNHN, UMR 7194 CNRS, Musée d'Anthropologie préhistorique de Monaco) notterolivier@hotmail.com*  
*Rossoni-Notter, Elena (Musée d'Anthropologie préhistorique de Monaco) elenarosso@hotmail.fr*  
*Grégoire, Sophie (Cerp Tautavel UPVD Perpignan, UMR 7194 CNRS) sophie.gregoire@cerptautavel.com*

Lithic productions in Europe and Asia during the Middle Pleistocene are characterized by the presence of bifacial pieces associated with pebble and *débitage* productions. This common finding in these two broad geographical entities hides a cultural mosaic specificity. While in Europe, sequencing of ancient Palaeolithic phases was established thanks to developments in the technocomplexes (gradual disappearance of bifacial pieces, *débitage* becoming dominant, appearance and expansion of *Levallois* method), these ruptures are more fleeting in east Asia and do not take this aspect. Also raises the question of technical phases disseminations and isolations between these two continents. The lithic assemblages allow us to speculate on the nature and sense of technical evolution, the modalities of manufacture, use of the technical objects, these phenomena in terms of innovation, invention or technical transformation.

Long stratigraphic and cultural sequences in Europe, including in particular the Caune de l'Arago (Tautavel, France) and the Gran Dolina site (Atapuerca, Spain), but also the French Mediterranean sites such as Terra Amata, the Baume Bonne, Orgnac 3 and the Lazaret, let us appreciate the variability of technoeconomic behaviors, their continuity and evolutions.

Many sites dated and assigned to the Middle Pleistocene have been recently discovered or/and studied in India,

China (the Bose Valley in South China, the Yunxian site), the Korean peninsula and in Southeast Asia. However, compared to the long stratigraphic and cultural sequence of Zhoukoudian (China), most of them have a less extensive and a more partial sedimentary and chronological record. Nevertheless, the lithic assemblages of these deposits enable us to highlight the technological behaviours, cultural traditions and specific characters of these groups. Moreover, the presence of handaxes and cleavers in most of these assemblages questions the nature of Asiatic Mode 2 and more generally the bifacial phenomenon.

What are the cultural specificities of each site? Each geo-cultural area? What are the similarities and major differences? Are we globally confronted with a model of diffusions and assimilations? Or rather a cultural convergence? Can we follow the Acheulean cultures of Europe as guidelines and try to interpret the Asiatic middle Pleistocene?

POSTER

#### 4. NEW EVIDENCE OF LITHIC ASSEMBLAGE CONTAINING TARDIVE BIFACES IN SITU FROM THE HOUFANG SITE IN THE HANSHUI RIVER VALLEY OF CENTRAL CHINA.

*Yinghua, Li (School of History, Wuhan University, China) ly-hfrance2005@yahoo.fr*

*Xuefeng, Sun (School of Geographic and Oceanographic Sciences, Nanjing University, China) xuefeng-sun@163.com*

Since the proposition and determination of "Movius Line", the presence or not of bifaces in China, their relationship with Acheulean industries of Europe and Africa as well as the nature and characteristic of Chinese Paleolithic cultures have been hotly debated. Now the existence of bifaces in Chinese Paleolithic is beyond question in light of their discovery in several site complex including Bose Basin, Luonan Basin and Hanshui River Valley. However, until now, most of bifaces were surface finds and only in a very few of sites were they unearthed in primary context and dated. These sites include Fengshudao, Damei Nanbanshan in Bose Basin, Shuangshu in the Hanshui River Valley and Liangshan Longgangsi, which were all dated to over 600 ka (late Early Pleistocene to early Middle Pleistocene). As a matter of fact, up to present few lithic industries with the association of bifaces *in situ* and reliable date to later period (e.g. Late Pleistocene)

have been formally reported. In view of this, our newly-discovered site, the Houfang site from the Hanshui River Valley which yielded a lithic assemblage containing bifaces *in situ* and dated to Early Late Pleistocene will provide new well-documented evidence of tardive bifaces and contribute greatly to our understanding about the nature and evolution of lithic assemblages containing bifaces in China and East Asia.

A total of 162 stone artifacts were unearthed, including 89 pieces from the 2<sup>nd</sup> layer and 73 pieces from the 3<sup>rd</sup> layer.

In order to explore cognitive modes of hominids and compare different lithic assemblages between different regions of the world, the lithic technological and techno-functional method was proposed and applied to many industries of Paleolithic in the world. It was proven to be a new perspective for study of lithic industries. Yet this methodological system has never been applied to Chinese Paleolithic industries in a systematic way, so we used this method in study of lithic artifacts from the Houfang site in an attempt to provide a reference for future work and construct the basis for comparing lithic industries of Europe and Asia.

In summary, two characteristics concerning the lithic assemblage bearing bifaces in the Houfang site were clearly made: in statistical level, the percentage of bifaces in the Houfang site is much lower (<3%) than in classical Acheulean Complex; in technological perspective, the concept and method of producing typical bifaces of the Houfang site are totally different from those of typical Acheulean implements.

In conclusion, our discovery of the Houfang site indicated that bifacially-worked concept and implements did exist in China but they had a very low percentage in the assemblage (<3%) and were technologically different from those of classical Acheulean implements. The only common characters between them would be convergent morphology and bifacial knapping. This discovery provides new evidence for existence of bifaces in Late Pleistocene of East Asia and brings new clues for exploring the nature and evolution of biface-bearing industries in East Asia and discussing the cultural relationship between the East and West.

## 5. LA CULTURE DE L'HOMME DE YUNXIAN EN CHINE

*Feng, XiaoBo (College of applied Arts and Science BUU)  
fdd1994@sina.com*

Le site de Xuetingliangzi ou site de l'Homme de Yunxian se trouve à quelques centaines de mètres au nord de la rivière Han, à proximité d'une école (école de Mituosi ou école de l'ancien temple d'Amidha), près de Quyuanhekou, à 1 km à l'ouest du confluent des rivières Han et Quyuan. Il est situé à 10 km au sud du bourg de Qingqu, à 40 km à l'ouest de la ville de Yunxian, à 34 km au nord-nord-ouest de la ville de Shiyan et à 550 km au nord-nord-ouest de Wuhan, dans le nord-ouest de la province de Hubei, Chine du sud.

L'outillage est essentiellement taillé sur galet massif: choppers, chopping-tools, choppers à bords convergents, pics, bifaces. Présence de nombreux remontages. Des éclats ont été débités sur place à partir de nucléus; les chaînes opératoires de débitage sont complètes. Des outils ont été façonnés sur place; les chaînes opératoires de façonnage sont complètes.

Sur les sites de plein air qui correspondent à des haltes de chasse une industrie caractérisée par les galets aménagés est présente, aussi bien en Chine qu'en Europe du Paléolithique inférieur.

Autre la taille des éclats et des outils, dans ces campements de longue durée du fait d'une forte exploitation de la matière, la tradition culturelle reste bien évidente.

Les petits outils, nous informent de l'évolution technologique de chaque culture. Ainsi leur diversification des types et standardification des mêmes permet de bien caractériser leur stade culturel.

Sur les sites les plus anciens (Yunxian et terrasses de Roussillon) ces petits outils ont des fractures primitives, avec des rares retouches continues. Et sur les sites plus évolués, ce sont des racloirs, grattoirs, avec une diversité de formes. Notons la présence de ces deux types d'aménagement des petits outils dans les sites vieux de 700 000 ans, tel que la Pineta en Europe méridionale.

ORAL

## 6. THE LOWER AND MIDDLE PALAEO-LITHIC SEQUENCES OF EL KOWM (SYRIA) IN COMPARISON WITH THOSE OF ATAPUERCA AND TAUTAVEL

*Le Tensorer, Jean-Marie (University of Basel IPNA) jean-marie.letensorer@unibas.ch*

Due to the intensity of its archaeological remains, the region of El Kowm, in Central Syria, has been under particular scientific attention for 30 years. Huge stratified well-sites or surface scatters in the vicinity of raw material outcrops vouch for a continuous occupation of the area since the Lower Pleistocene. The four major sites of the region, Aïn al Fil, Hummal, Nadaouiyeh Aïn Askar (Swiss-Syrian team) and Umm el Tlel (French-Syrian team), taken together cover 2 million years of human settlements and evolution. The area encompasses some of the biggest archaeological sequences in Eurasia.

Hummal presents the longest archaeological sequence. Numerous archaeological levels allow an exceptional insight into technological traditions ranging from Oldowan culture to the beginning of Upper Palaeolithic. Plenty of faunal remains enable a diachronic observation of a distinctive fauna in an arid environment. The lithic assemblages contribute to current discussions about Pleistocene human dispersal and adaptation in the Middle East. For the first time a Lower Palaeolithic Oldowan culture has been found in central Syria. The Post-Acheulean sequence includes Yabrudian, Hummalian and Mousterian assemblages and their technological variability delivers further information about the emergence of complex blade and flake producing industries at around 250'000 years BP. Human remains were uncovered in Mousterian layers. They contribute another piece of evidence to the human adaptive diversity in Middle Palaeolithic sites of the Levantine region.

The site of Nadaouiyeh shows a sequence roughly covering a span-time of 600,000 years. The older part is especially well documented. The spring site comprises 32 layers of Acheulean and levels of Yabrudian, Hummalian and Levallois-Mousterian. Most certainly, with a 32 m thick stratigraphy, the Nadaouiyeh sequence is the most extensive site for the Acheulean cultures in the Levant. This steppe area played an important role in the conquest of Eurasia. This was underlined in 1996 by the discovery of a large cranial fragment of *Homo erectus* at the site of Nadaouiyeh. The site of Umm el Tlel shows a very long sequence from the Acheulean to the Neolithic with a

remarkable Mousterian and Initial Upper Palaeolithic stratigraphy. The site has been yielding several Middle Palaeolithic Human remains.

The aim of this study is to provide an overview of the natural and cultural context and evolution during the Pleistocene in the Syrian Desert in comparison with the large sequences at the Sierra de Atapuerca on the one hand, especially for the sites of Sima del Elefante and Gran Dolina and, on the other hand, with the huge stratigraphy of la Caune de l'Arago.

ORAL

## 7. THE DISTRIBUTION OF ACHEULEAN CULTURE AND ITS POSSIBLE ROUTES IN TURKEY

*Taskiran, Harun (University Of Ankara) htaskiran@ankara.edu.tr*

As it is known Turkey is a country located at the crossroads of possible migration routes between the three continents and plays a pivotal role in the distribution of Acheulean culture into the Eurasia.

Although Acheuléen culture, which is considered to have reached Turkey via the Levant corridor, shows a wide distribution in Turkey's Anatolian side, it cannot be seen in the Thrace part of Turkey. Therefore, the dissemination of Acheuléen culture from Turkey towards Balkan Peninsula or Southeastern Europe via the Turkish Thrace cannot be mentioned. Although there is not much evidence yet, the geographical situation of the Aegean Sea and the possible land bridges in Pleistocene should not be ignored.

However, the cultural remains of Acheuléen culture are seen densely in the Eastern and Southeastern regions of Anatolia. The Acheulean cultural remains, especially bifaces which found on the open air sites taking place on the old river terraces, generally in the Euphrates and Tigris Basin are strong evidence indicating the distribution of Acheulean culture in Anatolia and also the possible migration route of *Homo erectus* from Anatolia to the Caucasus. Many Acheulean sites which have been recently identified in the Caucasus and ancient *Homo erectus* fossil remains found in Dmanisi (Georgia) seem to support this distribution as well.

In this paper, according to the geographic regions the distribution of Acheulean culture and possible routes in Turkey will be discussed.

ORAL

## 8. GENERAL VIEW OF MIDDLE PALEOLITHIC IN TURKEY

*Özçelik, Kadriye (Ankara University) kozcelik@ankara.edu.tr*

It is observed in Turkey that Mousterian culture has a wide dispersal area, especially in Anatolian peninsula. This peninsula, so, has a unique significance for its geographical position between Asia and Europe.

In many of Turkey's open-air sites and caves, the traces of this culture can be realized. Karain cave, placed between these sites, situated near Antalya with its very favorable environmental conditions and geographic location, has presented a very long sequence of stratification for the Middle Paleolithic period in comparison with other caves.

Karain Cave is comprised of many chambers separated from each other with calcific formations. Chambers E and B within the same structure contain remains of Middle Paleolithic cultures. Dates obtained through TL and ESR indicated 160.000- 60.000 for the Middle Paleolithic of Karain E. The term "Karain Type Mousterian" is regarded as industries whose tools are dominated by side-scrapers and points, and in which the Levallois technique is observed intensely between the geological levels I.1- III.2. Other tools from this industrial group include perforators, discs, denticulated and notched pieces. The variety observed in raw materials is noteworthy. While large flakes and tools were knapped from quality flint of distant origins, knapping wastes and some tools were manufactured from local radiolarite.

Beneath "Karain Type Mousterian" are Charentian characters between the geological levels III.3 and III.4. Simple, convergent and transversal side- scrapers were shaped with stepped scaled retouches. Between the geological levels of III.5 and IV.5, the materials are mostly proto-Charentian or denticulated Charentian. The Levallois technique disappears entirely. The stone assemblage is comprised mostly of denticulated pieces. Chamber E Karain Cave contains not only three phased Middle Paleolithic industries but also the remains of bones and teeth belonging to a Neanderthal man who produced these industries.

Although work was conducted only in a very limited area, chamber B reveals clearly the presence of "Karain Type Mousterian".

Karain Cave sets a privileged example that features a Middle Paleolithic chronology in Turkey, especially with the techno-typological features and varieties of its industries in the stratigraphic sequence as well as the presence of skeletal remains of Neanderthal man.

Turkey, especially the Anatolian peninsula with its bridging role between Asia and Europe, did the honors to Neanderthal man being inhabited for a long time in Middle Paleolithic period.

ORAL

### 9. SPECIFICITIES OF THE ECONOMIC PATTERN ASSOCIATED TO THE HANDAXES CULTURES IN MEDITERRANEAN EUROPE. THE CONTRIBUTION OF LITHIC RAW MATERIAL SUPPLY.

*Grégoire, Sophie (Centre Européen de Recherches Préhistoriques de Tautavel, Université de Perpignan Via Domitia, UMR 7194 du CNRS) gregoire@cerptautavel.com*

In Europe, Middle Pleistocene sequences of the mediterranean region constitute for several years a support of multidisciplinary studies for the understanding of the economic patterns associated to the acheulean cultures. These patterns seem to be different from current models in other prehistoric cultures and so can constitute a signature of acheulean populations and their behavior that we try to define.

For example we will present the evolution of economic pattern during the long sequence of Caune de l'Arago cave in which acheulean levels are sometime succeeded by non-acheulean levels. This type of succession allow us to compare the lithic raw material supply model and define the economic pattern applied on each cultural phase.

With the support of others acheulean occupation like Terra Amata open air site and le Lazaret cave, in south of France, we will try to define the specificities of the economic patterns of the acheulean culture.

The aim of this study will be finally to observe if these specificities also exist in the handaxes cultures known in Asia with the purpose to identify the degree of filiation between both cultural groups.

### 10. THE HOMO HEIDELBERGENSIS ASIAN EXPANSION: A RELEVANT INQUIRY?

*Vialet, Amélie (MNHN UMR7194) vialet@mnhn.fr*  
*Chevalier, Tony (UPVD UMR7194) tony.chevalier3@gmail.com*

Since it was coined, in 1908, the species *H. heidelbergensis* has generated a lot of publications. Nowadays, this specimen benefits from a renewed interest for several decades as a result of the increase of the fossil record in Europe. However, the studies have focused on the skull, on the one hand, and were based on the African and European hominids, on the other hand. In addition, the recent contribution of genetic analysis in the taxonomic interpretation of Central Asian populations has extended the range of Neanderthals 2,000 km further east. Thus, issues related to Neanderthals cannot be restricted anymore to Europe and the Levant. In the same way, the extension of *H. heidelbergensis* (consensually considered as the ancestor of Neanderthals) in Asia has to be examined in the light of the new paleo-genetic data.

Thereby this study aims at making a global synthesis of the available data from post-cranial and cranial material together with a re-examination of some fossils mostly from Asia such as Hathnora, in India, Nankin 1, Zhoukoudian L-C, Hexian, Dali, in China. The concept of variability (intra- and inter-groups) which is needed to assess the definition of *H. heidelbergensis*, will be integrated in this overall reflection and considered from sites such as the Arago cave in Tautavel or Atapuerca (Gran Dolina and Sima de los Huesos).

This synthesis, bringing together diverse and sometimes unpublished data, will try to:

- Make a "state of art" of this issue (historical discoveries, fossil data, state of preservation, geographical and chronological distribution, taxinomic and phylogenetic interpretations, contribution of genetics)
- Identify consensual notions as a basis for our study (geographic expansion, post-cranial and cranial anatomical characteristics, phylogenetic position ...)
- Assess the contribution of Asian fossils to the understanding of the taxon *Homo heidelbergensis*.

ORAL

## 11. HOMININ VARIABILITY AND POPULATION DISCONTINUITY IN MIDDLE PLEISTOCENE ASIA AND EUROPE: THE DENTAL EVIDENCE.

*Martinón-Torres, María (Centro Nacional de Investigación sobre la Evolución Humana) maria.martinon.torres@gmail.com*

*Song Xing (Institute of Vertebrate Paleontology and Paleoanthropology (Beijing) xingsong@ivpp.ac.cn*

*Wu Liu (Institute of Vertebrate Paleontology and Paleoanthropology (Beijing) liuwu@ivpp.ac.cn*

*Bermúdez de Castro, José María (Centro Nacional de Investigación sobre la Evolución Humana) josemaria.bermudez-decastro@cenieh.es*

In previous studies we proposed a “sink and source” model where the variability of the fossil hominin samples in Early and Middle Pleistocene Europe were explained as a result of repeated population dispersals, fragmentation, and re-combination of surviving populations inside Europe in response to climatic fluctuations, and also as result of repeated episodes of immigration from Southwest Asia<sup>1-3</sup>. “Source” populations would have lived in those parts of southern Europe where hominins could have survived glacial periods. “Sink” populations would have been in those areas that were only suitable for occupation in warm interglacials and often, they would have depended upon “source” populations for recruitment to maintain a stable occupation. When environmental conditions deteriorated, many “sink” populations would have become extinct and/or retreated to the southern refugia where they would have mixed with the resident groups. This pattern of isolation, local extinction and recombination would explain the high morphological variability maintained by European populations throughout the Middle Pleistocene. Recently, the retrieval and analyses of ancient DNA sequences from Denisova (Siberia) or Sima de los Huesos (Atapuerca)<sup>4-5</sup> seem to ratify a scenario of complex population interactions *within* Eurasia including the possibility of hybridization between “paleontological species”.

While the European fossil record is relatively well-characterized, only recently new specialized studies on old and new dental findings have started to contribute to a more precise picture of human evolution in Asia<sup>6,7</sup>. The analysis of the rich dental collections from the Asian Middle Pleistocene such as Zhoukoudian, Hexian, Chaoxian or Panxian Dadong expands the metrical and morphological variation known for the East Asian hominins.

Our study warns about the possibility that the Asian hominin variability may have been taxonomically oversimplified. Like in Europe, primitive-derived gradients in Asia are not satisfactorily fitted along a chronological sequence and suggest complex evolutionary scenarios with the coexistence and/or survival of different human lineages. Future research should explore whether the “sink and source” model proposed for Europe can be suitable to explain human evolution in Asia.

ORAL

## 12. MOBILITY DURING MIDDLE PLEISTOCENE ACROSS EURASIA: FAUNA, PEOPLE AND TECHNIQUES

*Violet, Amélie (MNHN UMR7194) violet@mnhn.fr*

*Moigne, Anne-Marie (MNHN UMR7194) moigne@mnhn.fr*

*Notter, Olivier (MNHN MAP Monaco) notterolivier@hotmail.com*

*Gaillard, Claire (MNHN UMR7194) gaillacl@mnhn.fr*

At the Eurasian scale, two main geographical units appear to operate differently during Quaternary: the Palaeartic zone ruled by alternation of glacials and interglacials and the subtropical / Mediterranean zone with more stable conditions allowing regular occupation.

Between these two large regions different technical traditions are observed, probably linked to the relation with the natural habitat (mineral, animal or vegetal) whether for food or for raw material. East-west movements are recorded from 800 ka onwards. However, while arrival of Asian fauna occurs in the West and contributes to a clear renewal of the faunal assemblages, these do not change much in the East. Similarly the lithic industries remain stable while a “true” Middle Palaeolithic develops in Europe.

Regarding the hominid remains, they are clearly lacking in the Palaeartic zone unlike southern regions. In the latter, the amplitude of variability among fossils in Europe, on the one hand, and among those of Asia, on the other hand, can be considered in order to distinguish specific settlement dynamics (regular intake of gene flow in the West versus evolutionary stasis in the East). All combined these sets of data allow to better approach the circulation of fauna across Eurasia during the Middle Pleistocene and to assess the possible correlation with movements of human groups on the basis, when fossils are missing, of lithic industries where both permanent traditions and new adaptations to local conditions are imprinted.

# B53 The archaeology of early fire use

## 1. IS THIS THING BURNT? ON THE NATURE OF EVIDENCE FOR HUMAN USE OF FIRE IN THE PALEOLITHIC

Miller, Christopher E. (Institute for Archaeological Sciences, University of Tübingen) [christopher.miller@uni-tuebingen.de](mailto:christopher.miller@uni-tuebingen.de)  
Stahlschmidt, Mareike (Institute for Archaeological Sciences, University of Tübingen) [mareike.stahlschmidt@uni-tuebingen.de](mailto:mareike.stahlschmidt@uni-tuebingen.de)

Mentzer, Susan (Institute for Archaeological Sciences, University of Tübingen) [susan.mentzer@uni-tuebingen.de](mailto:susan.mentzer@uni-tuebingen.de)

The use, control and production of fire represent crucial steps in the behavioral and biological evolution of humans. Fire provided warmth, light and protection, and was essential for the development of technological innovations including the modification of raw materials and cooking. Because of the central and daily role that fire plays in modern hunter-gatherer societies, many archaeologists assume that the control of fire was a prerequisite for demographic expansions out of Africa into colder regions of the world, including Northern Europe. Despite the significance afforded fire in the evolution of humans, there is little consensus among archaeologists about the timing and nature of its emergence. Some researchers suggest that fire was an essential part of human adaptation beginning in the Lower Paleolithic, whereas others suggest humans did not fully control fire until the beginning of the Upper Paleolithic. Adding to the ambiguity surrounding the debate on the origins of pyrotechnology is the nature of the archaeological evidence for fire use. Archaeologists usually rely on qualitative macroscopic characteristics, such as color, to determine if materials have been heated. The evidence is usually reported as combustion residues, such as charcoal and ash, or burnt bone, and heated rocks or sediment. However, numerous studies have shown that the qualitative characteristics that archaeologists commonly associate with heating can be produced by other non-anthropogenic processes, such as manganese staining and freezing. Even if the

presence of burnt materials can be firmly established at an archaeological site, its mere presence alone is not sufficient to demonstrate that humans were using or producing fire, since natural fires produce burnt and heated materials that can be deposited at an archaeological site without human intervention. Here we look at the nature of different lines of archaeological evidence for fire use, production and control and discuss its reliability for evaluating different hypotheses about the timing and nature of the emergence of pyrotechnology in the Pleistocene. We argue that the current discussion should move away from simple debates about presence or absence of evidence for fire. Rather, we should look at the variety of evidence in the archaeological record to investigate possible diachronic variation in fire-related behaviors.

ORAL

## 2. METHODS INTEGRATION IN THE STUDY OF PALEOLITHIC COMBUSTION FEATURES: PROMISES, PITFALLS AND PRESENTATION OF LARGE DATASETS

Mentzer, Susan M. (Institute for Archaeological Sciences, University of Tuebingen) [susan.mentzer@ifu.uni-tuebingen.de](mailto:susan.mentzer@ifu.uni-tuebingen.de)

Although micromorphology is now considered a standard approach in the identification of ancient combustion features, the technique is increasingly supplemented by a variety of complementary elemental, isotopic, and mineralogical analyses. Several of these analyses can be conducted directly on petrographic thin sections or resin-impregnated sediment blocks, which, in theory, enables the analyst to easily integrate results.

Here, a series of Paleolithic-age combustion features from a variety of sites will be investigated using a combination of high-resolution microarchaeological methods. Methods will include: (1) micromorphology, (2) stable carbon and oxygen isotopic analyses on loose sediments or materials drilled from resin-impregnated blocks, (3) Fourier transform infrared (FTIR) analyses on loose sediments and micro-FTIR measurements on thin sections and resin-impregnated blocks, (5) micro-X-ray fluorescence (XRF) measurements on resin-impregnated blocks, and (6) cathodoluminescence and/or scanning electron microscopy.

Under the best circumstances, this combination of methods can be used to identify burned materials and their spatial relationships within the broader "feature," to determine temperatures of heating of bones

and sediment, to identify calcareous and siliceous components of ashes in various states of preservation, and to reconstruct the past chemical environment at the site. In reality, this combination of methods can produce contradictory results that may or may not support for the hypothesis that human-controlled fire was present at an archaeological site. Nevertheless, researchers should be encouraged to integrate a wide variety of analytical methods and present complete datasets to the broader archaeological community.

ORAL

### 3. GESHER BENOT YA-AQOV: THE EARLIEST EVIDENCE FOR THE USE OF FIRE IN EURASIA

*Alperson-Afil, Nira (Bar-Ilan University) [alperson@mscc.huji.ac.il](mailto:alperson@mscc.huji.ac.il)*

*Goren-Inbar, Naama (Hebrew University Jerusalem) [goren@cc.huji.ac.il](mailto:goren@cc.huji.ac.il)*

The Acheulian site of Gesher Benot Ya'aqov (GBY) is located on the shores of the paleo-Lake Hula in the Levantine Corridor. A 34 m depositional sequence was exposed in the study area, documenting an oscillating paleo-lake and considered to reflect global climatic changes assigned to OIS 18-20.

Embedded within the sequence are some 13 archaeological horizons indicating that Acheulian hominids repeatedly occupied the lake margins, where they processed meat, extracted marrow, quarried and transported different kinds of rock, skillfully produced stone tools, and gathered a vast range of plant foods.

The presence of fire at GBY is documented by burned flint artifacts, charcoal fragments, burned wood, and burned seeds, all recorded along the entire stratigraphic sequence. The identification of burned flint is based on macroscopic signs of heat alteration, which is confirmed by thermoluminescence (TL) analyses.

The fact that fire at GBY was controlled and used throughout the long cultural sequence is documented by the repeated occurrence of clusters of burned flint microartifacts, considered to be phantom hearths.

Spatial analyses further suggest that these hearths were focal points for a variety of activities such as stone knapping, tool use and modification, consumption of aquatic resources, and nut cracking. The spatial association between these activities and the hearths is

an indicator of the expansion of the human diet resulting from the use of fire.

GBY is an open-air site that preserves a long stratigraphic sequence of sealed multiple strata without pronounced postdepositional processes. The occurrence of phantom hearths and their associated activities in this unique setting provides the earliest evidence of controlled fire use in Eurasia.

Evidence suggesting fire was tended inside this large rock-shelter occurs deep in sediments magnetostratigraphically dated to >0.78 Ma (Scott and Gibert, 2009, *Nature* 461: 82-5). Biostratigraphical findings indicate 0.7 Ma (Walker *et al.*, 2013, *Quaternary International* 294: 135-159). The Palaeolithic assemblage includes *Homo cf. heidelbergensis* teeth, a limestone hand-axe, numerous small retouched chert artifacts, including flakes struck by repetitive centripetal flaking of small cores, and knapping débris (*ibidem*); the chert came from nearby conglomerates and gravels (Zack *et al.*, 2013, *Quartär* 60: 7-28).

Excavation of 2 m<sup>2</sup>, 5 m behind the entrance, of a deposit -4.5 m below the top of the sedimentary sequence, uncovered evidence that fire may well have affected bone and Palaeolithic chert artifacts (in "unit VI", the lowest: Walker *et al.*, 2013, *loc. cit.*; equivalent to "complex 3-2": Angelucci *et al.*, 2013, *Quaternary Science Reviews* 89: 195-199). Burnt bone is analyzed by electron spin resonance and Fourier Transform infrared spectroscopy, burnt chert by thermoluminescence, and sediment by thin-section micromorphology and mineral analysis.

Excavation (A.L-J., M.L-M., M.H-U., M.J.W.) revealed both charred bone and numerous white calcined bone fragments, including some with conjoined lengthwise long-bone spalling typical of circumferential shrinkage after thermal volatilization of organic components (cf. D.H.Uberlaker, 1999 [2004], *Human Skeletal Remains*. Washington DC, Taraxacum, 35-38). Thermally-altered lustreless chert fragments abound. They include a nodule cracked open by heat revealing both a pot-lid fracture and many small razor-sharp splinters still in place, like petals of a flower, and an artificially-struck flake likewise cracked open by thermal shock with sharp conjoinable fragments still in place; following thermal alteration those two pieces can hardly have undergone displacement of more than a few centimetres without greater separation of their fragments occurring. Thermoluminescence analysis is underway (J-L.S.). Geoarchaeological evidence

(A.D.E., A.D.) may be consistent with combustion (Angelucci *et al.*, 2013, *Quaternary Science Reviews* 80: 195-9). Sediment minerals were investigated using X-ray fluorescence, X-ray diffraction, and thermogravimetric analysis with mass spectrometry (T.R-E). Taphonomical analysis (S.E.R.) and scanning electron microscopy and energy dispersive X-ray spectrometry of bone (S.E.R., Y.F-J.) attribute discolouration to burning, not to post-depositional mineral staining, and both Fourier Transform infrared spectroscopy (F.B.) and electron spin resonance analysis (A.S.) imply firing temperatures ca. 550-600° C.

Evidence suggests high temperature reached inside Cueva Negra may have been due to fire tended within it. Conjecturally, hominins might have taken inside smouldering brands, left behind outside by a forest fire, in order to *establish* and *tend* a fire where rain or wind would not extinguish it. They may have been less afraid of fire outside than other animals they saw fleeing before it, which could have led them to play with fire in order to drive animals towards natural death-traps (e.g. swamps, cliffs) followed by butchery and roasting. This hardly means they could *reproduce* or *control* fire at 0.8 Ma: that probably was attained only *after* 0.5 Ma when evidence of fire-pits or constructed hearths start appearing. Evolutionary consequences for human physiology and cognition are considered.

Unequivocal identification of fire in palaeolithic sites is problematic since evidences use to be few, ambiguous and generally bad preserved. These normally manifest as rufed substrates, cracked pebbles with characteristic colours, charcoals or in the best case, the presence of ashes. Here we report a mineral magnetic study carried out at the TE19 level (~ 200 ky BP) of Sima del Elefante site (Sierra de Atapuerca, Burgos), where in the 2001 field season appeared charcoal remains in close association with bones possibly burnt. The main goal of this study is to characterize the magnetic properties of these samples potentially heated and compare them with the unburnt adjacent sediment in order to verify burning activities. Analyses initially comprised the systematic measurement of low-field magnetic susceptibility (MS) of almost 100 bulk samples from the whole panel (TE19). Afterwards, partial thermomagnetic curves (magnetization vs. temperature) were performed in 50 °C incremental steps from 200 °C to 700 °C in air. These were carried out on a sample from the potential hearth and another from the nearby unburnt area, in order to study their thermomagnetic reversibility. All measurements were carried out at the Laboratory of Palaeomagnetism of Burgos University (Spain).

The obtained MS values oscillate between  $3.25 \times 10^{-6}$  and  $6.71 \times 10^{-7} \text{ m}^3\text{kg}^{-1}$ , with mean values of  $\sim 1.95 \times 10^{-6} \text{ m}^3\text{kg}^{-1}$  for the samples from the potential hearth, indicating that the concentration of ferromagnetic minerals (*s.l.*) is not particularly high. The most striking feature is that the degree of thermomagnetic reversibility in the sample out of the potential hearth is even higher than the sample from it. Taking into account the similarity in the magnetic mineralogy of all studied samples (magnetite as main carrier) and that the intensity of magnetization is similar both in samples out and within the potential hearth, we cannot unequivocally conclude that burning activities took place here but neither reject them. What it should be expected, as shown by experimental recreations of prehistoric fires in clayish substrates under controlled field and temperature conditions, is an enhancement in concentration-dependent magnetic parameters as a consequence of the creation of new ferrimagnetic minerals. It is not excludable, however, that syn and/or post-depositional process might be responsible of the homogenization of the observed magnetic properties.

*Rodríguez, Ágata (Universidad de Barcelona) agata.roci@gmail.com*

*Galván, Bertila (Universidad de La Laguna) bgalvan@ull.es*

We report a series of 12 combustion structures recovered from a MIS 5 archaeo-sedimentary deposit at Abric del Pastor, Alcoy, Spain. The site is a small rockshelter under current large surface excavation. So far, it has yielded a 1.60 meter-thick stratified sequence of alternating blocky and sandy layers bound by sharp contacts. Ongoing integrated interdisciplinary, multi-technique investigations at the site involve: a study of the lithic record based on RMUs, zooarchaeology including the microfaunal record, archaeostratigraphy using GIS, paleochronology using TL dating and amino acid racemization, anthracology including GIS and microstratigraphic geoarchaeology using micromorphology, FTIR, GC/MS and phytolith analysis. This research is complemented by experiments to investigate fire making on blocky substrates. Preliminary results have brought to light evidence of a series of brief human occupations older than 75,000 years ago. Here we present an overview of the combustion record. The combustion features are consistently found at the interfaces between layers.

They show discrete circular morphologies, diameters ranging between 60 and 115 cm and no macroscopically visible ash. In accordance with the nature of their sedimentary substrates their expression in the field is twofold: 1) blackened and reddened cobbles in blocky layers and 2) reddened or blackened patches in sandy layers. These are stratigraphically associated with thermally altered material (flint flakes, bone fragments and small stones). Micromorphology and FTIR analyses have revealed presence of relict wood ash and thermally altered sedimentary substrates. Our experiments on blocky substrates have shown that ash can be readily infiltrated in between loosely packed blocks through gravity and rain. Also, the experimental blocks were blackened and reddened in the same way as those found at the site. In sum, our preliminary results show that the

combustion features from Abric del Pastor represent *in situ* hearths and suggest that fire was an important element of hominin lifestyles in the Alcoy region as far back as 100 ka.

## 7. THE COMPLEXITY OF MAKING FIRE

*Scheffele, Sebastian (Institut für Ur- und Frühgeschichte und Archäologie des Mittelalters, Dept. Ältere Urgeschichte und Quartärökologie, University of Tübingen, Germany) Sebastian\_Scheffele@gmx.de*

*Haidle, Miriam Noël (Research Project The Role of Culture in Early Expansions of Humans ROCEEH, Senckenberg Research Institute and University of Tübingen, Germany) miriam.haidle@uni-tuebingen.de*

While Paleolithic evidence on the control and technical application of fire is increasing, the organizational elements for its maintenance and production have not been examined in a systematic way. Here, a comparative analysis of maintenance and production of fire with different tool kits will be presented.

The studies are based on ethnographic literature and experiments. The reconstructed processes are coded in cognigrams and effective chains, showing the different attention foci (raw materials, tools), actions, and effects of foci on other foci.

Maintaining a burning fire on a spot can be regarded as a simple process. However, the maintenance of fire out of a piece of ember requires already the ability to cope with the concept of composite tools. The production of fire, no matter by which method, can be mastered only with the competence to create and use complementary tool sets.

It can be shown that the control of fire is not a simple question of absence/presence, but represents sequences of development in knowledge and skill, conceptual understanding, and cognition.

## 8. TESTING THE 'EXPEDIENT STRIKE-A-LIGHT MODEL': AN EXPERIMENTAL ASSESSMENT BASED ON THE FIRST IDENTIFIED MIDDLE PALAEOOLITHIC FIRE-MAKER FROM BETTENCOURT (FRANCE)

The use of fire by Neandertals and their predecessors is currently a hot-button issue in the realms of Palaeolithic Archaeology and Palaeoanthropology. By and large, research within this vein focuses on the origins of "habitual" fire use, inferred from morphological changes within the human lineage observed in the fossil record, or from discerning the presence of possible anthropogenic fire features on increasingly older sites. Our research, on the other hand, focuses on identifying direct evidence of fire *production* in the Palaeolithic record by looking for tools used to make fire, namely "strike-a-lights" made from flint or other siliceous material used in conjunction with sulphur- and iron-bearing minerals (e.g. pyrite and marcasite) to make sparks. While strike-a-lights have been regularly identified from the late Upper Palaeolithic onwards, this is not the case for the Middle Palaeolithic. In this light, the "expedient strike-a-light model" has been proposed, which asserts early fire-making tools were likely used on an ad hoc basis for only a short period of time prior to being discarded. This stands in stark contrast to the more "classic" curated strike-a-lights recovered from Neolithic and Bronze Age contexts that show very heavy use traces, indicative of multiple episodes of use. It implies that the traces on Middle Palaeolithic strike-a-lights may be less easily detected in the archaeological record and perhaps the gestures used differed from those in later periods. We present the results of an experimental program that was performed to test this model as well as preliminary results of our evaluation of microwear traces, interpreted as resulting from use as a strike-a-light, observed on the lateral edge of an atypical Levallois point from the Middle Palaeolithic site of Bettencourt (75/85,000 BP; TL-IRSL/ESR) in northern France. To our knowledge, this is the only tool predating the late Upper Palaeolithic that has been described in the literature as bearing fire-making traces after undergoing modern microwear analysis. The traces, as previously described, consist of moderately heavy edge damage (i.e. edge-removals and crushing), minor rounding, polish and striations consistent with short-term application against mineral material, as well as prehension "gloss" from handling the tool in the presence of mineral dust, characteristic of "dirty" tasks like fire making. A tool exhibiting this suite of traces would lend support to the "expedient strike-a-light model". Until now, systematic testing of the veracity of the interpretation of the Bettencourt piece as a strike-a-light against experimental data has not been performed. Thus, we report the results of a battery of new fire-making and non-fire-making experiments conducted in

an effort to replicate the microwear traces observed on the Bettencourt piece.

### 9. FIRE USE FOR EARLY TRANSFORMATIVE TECHNOLOGY: THE EARLIEST KNOWN HEAT TREATMENT OF SILCRETE

*Schmidt, Patrick (University of Tübingen, Department of Prehistory and Quaternary Ecology, Germany) patrick.schmidt@uni-tuebingen.de*

*Porraz, Guillaume (CNRS, USR 3336, UMIFRE 25 and Evolutionary Studies Institute, University of the Witwatersrand, SA) guillaume.porraz@mae.u-paris10.fr*

Since its discovery, fire fulfilled a series of purposes and was used in a variety of processes. Some of the most creative early applications of fire are transformative technologies like the heating of adhesives for composite tools or the heat treatment of stone prior to tool production. South Africa has in recent years gained increasing importance for understanding such fire-related transformative technologies because one of the key elements in the suite of 'modern behaviours' that appeared during the southern African Middle Stone Age (MSA) was heat treatment of silcrete. Until now, there has been no direct archaeological evidence for the exact procedure used for the heat treatment of silcrete and the implications of this process for understanding the investment and actions of its MSA instigators remain unclear.

Conducting mineralogical and crystallographic analyses aiming to understand the parameters necessary for heat treatment of South African silcrete, we found out that this material is particularly undemanding regarding heating speed and temperature and thus, can be heat-treated with most techniques known from ethnographic observations. This is because of its particularly low 'water' content and its large pore space allowing rapid evacuation of steam that otherwise would lead to overheating.

In a second step, we tried to find direct archaeological proof to highlight some of the parameters of MSA heat treatment by conduction a series of experiments aiming to reproduce possible procedures requiring the least investment in time and resources. We found that, when silcrete is heated in direct contact with the glowing embers of a domestic fire, a particular residue may be produced on its surface, a tempering residue, which results from the distillation of plant exudations in

anoxic conditions within the ember-pile. We observed and chemically characterized an identical residue on the surfaces of heat-treated silcrete from Diepkloof Rock Shelter, indicating that the procedure used for heat treatment in the MSA involved such heating in embers. Regular domestic fires, as they are known from many sites dating from the South African Middle Stone Age, can be used for this relatively fast and highly efficient procedure. Our low-investment model of silcrete heat treatment opens for the first time the possibility to discuss the insertion of this technique in the *chaîne opératoire*, the time and resources needed for its realisation and its place in the suite of modern behaviours that appeared during the MSA in South Africa.

Improvements to ancient DNA extraction and library preparation techniques have enabled the reconstruction of genome sequences from Late Pleistocene hominins at an unprecedented level of resolution. High quality genome sequences are now available from early modern humans as well as Neanderthals and Denisovans. The latter is an Asian sister group to Neanderthals that was discovered only a few years ago by genetic analysis. Despite these advances, genetic analysis of hominin remains until recently seemed limited to the Late Pleistocene period due to constraints on DNA preservation. Interestingly, in 2006 Valdiosera and colleagues proposed DNA preservation in bear bones (*U. deningeri*) excavated from the site of Sima de los Huesos in the Atapuerca archeological complex. We reasoned that the more advanced current analytical techniques might allow for the recovery of phylogenetic informative DNA sequences from the bear, and possibly also the hominin remains of the site.

To explore whether DNA sequences can be obtained from the Sima de los Huesos fossils, we first sampled bear bones that were found in a layer together with hominin remains. After DNA preservation was confirmed for the bear bones, we also drilled small holes into pre-existing fractures of a hominin femur. DNA was isolated using a novel silica-based extraction procedure developed to optimize retrieval of strongly degraded ancient DNA. The DNA was then converted into libraries for sequencing using a highly sensitive technique, where each DNA strand can independently become integrated in the library. Libraries were enriched for bear and hominin mitochondrial DNA and sequenced.

We were able to recover nearly complete mitochondrial genome sequences from the bear and the hominin bones. The mitochondrial sequences were assembled from DNA fragments between 30 and 50 base pairs,

shorter than those used in any previous ancient DNA study. From the missing mutations in the two genomes we obtain molecular age estimates for the fossils that are close to 400,000 years, broadly in line with geological dates. The mitochondrial genome of Sima de los Huesos cave bear (*Ursus deningeri*) shows that it is a sister lineage to Late Pleistocene cave bears (*U. spelaeus*). The hominin mitochondrial sequence unexpectedly shows a closer relationship to the ancestors of the mitochondrial genomes of Denisovans than to those of Neanderthals or modern humans.

Our work opens the prospect of genetic studies on Middle Pleistocene hominins. We are currently focusing on recovering nuclear DNA sequences from the Sima de los Huesos hominins. Such data are needed to more accurately determine their genetic relationship to other hominins, for example with regard to Denisovans for which almost no morphological information exist. New sequencing and analysis strategies are currently tested to overcome the technical problems imposed by the extreme state of DNA degradation in the fossils and the presence of human and microbial contamination.

Appropriate identification of goat remains at an archaeological site provides important information about the structure and behaviour (subsistence strategies) of ancient human societies. Traditionally,

Iberian wild goats (*Capra pyrenaica*) and domestic goats (*Capra hircus*) have been differentiated using biometric criteria whereas morphological identification of these species has remained poorly studied.

We tested the biometric and morphological criteria for goat species identification in a set of 35 anatomical elements. From these, 20 bones belonged to modern domestic goats obtained from comparative anatomical collections of the Zinman Institute of Archaeology of the University of Haifa, the National Natural History Collections of the Hebrew University of Jerusalem, and the Department of Archaeology of the University of Sheffield. The remaining 15 bones correspond to fossil material of wild and domestic goat from Paleolithic and Neolithic levels from the site of Chaves in Huesca, Spain.

We used mitochondrial DNA markers to genetically identify the fossil remains through ancient DNA analysis in order to verify the criteria used to differentiate wild from domestic goats with non-genetic analysis. Thus, the genetic results of the ancient material were furthered contrasted to those of modern goats obtained with biometric and morphological analyses.

The identification of modern goats using morphological and biometrical criteria show highly similar results. In the fossil data set we observed a positive correlation between the genetic species assignation and the morphological and biometrical identification.

We observed little discrepancy between the morphological criteria used in this study for the identification of wild and domestic goats and the DNA results. However, the reliability of the identification criteria for some anatomical elements was not clear, particularly for mandibles and metacarpals. This is a pilot study and therefore we are still working in increasing our sample size in terms of individuals but also in terms of the anatomical elements to be analysed.

The Iberian lynx is critically endangered and considered to be the next most likely to go extinct of the feline species. It is the most threatened carnivore in Europe and endemic to the Iberian Peninsula. During the past two centuries, the Iberian lynx has seen a dramatic decrease in habitat. Widely distributed in the Iberian Peninsula during the Pleistocene and Holocene it is now confined to two small populations in southern Spain. Delineating the past geographic distribution of a species has important consequences for conservation strategies and it is necessary to understand its history and evolution. Due to the difficulty of a confident morphological distinction between different lynx species from postcranial remains, there is the possibility for potential misidentification between the Iberian, the Eurasian and the cave lynx.

We analysed ancient mtDNA extracted from a series of bone and teeth remains of lynx species assigned to *Lynx lynx*, *Lynx pardinus*, *Lynx pardinus spelaeus* and *Lynx sp.*, from different Pleistocene and Holocene sites in Spain, France, Denmark and Italy. We compared the genetic identification of the remains analysed to their morphological species assignment in order to test if the traditional palaeontological past distribution of the different lynx species is supported by the molecular data.

Our results have changed the historic distribution of European lynx species confirming that only genetic analysis can provide an accurate lynx species identification from postcranial remains. Furthermore we

resolve the phylogenetic position of the extinct cave lynx, *Lynx pardinus spelaeus*.

Hypotheses on the Near-East origin of European cattle were mainly based on the lack of evidence of *Bos taurus* T mitochondrial DNA haplotypes in European *Bos primigenius*. This was challenged when analyses of mitochondrial DNA from pre-Neolithic Italian auroch specimens fell within the variation found in modern European cattle. Here we carry out further investigation in order to determine the presence of T haplotypes in the Iberian Peninsula before any domestication evidence.

Twenty four samples were selected from the Mendandia site (Treviño, Spain), in the North of the Iberian Peninsula. The site is a rock shelter seasonally used by humans to big game during the Mesolithic (c. 7500 and c. 6450

cal. BC) and Early Neolithic times (c. 6100 and c. 5350 cal. BC). Archaeozoological analyses associated the Mendandia faunal remains with wild taxa, with a high proportion of auroch remains. Some *Bos* sp. and *Sus* sp. remains recovered only from the Level I (Early Neolithic) could be tentatively attributed to domestic animals. Mitochondrial DNA extraction and amplification were performed according to previously published ancient DNA protocols. Modern and ancient *Bos taurus* sequences as well as *Bos primigenius* sequences were used as a comparative sample in a network analysis.

Furthermore, biometrical analyses of a *Bos* sp. second phalanx (MD1 sample) were performed in detail. MD1 Maximum Length (GL), Proximal Breadth (Bp) and Distal Breadth (Bd) measurements were compared with an extended *Bos taurus* and *Bos primigenius* collection in order to better support its wild or domestic adscription. These comparative samples spend a timeframe from Mesolithic to Middle Ages. In total, at least 394 samples were used for comparative.

Seven samples yielded control region mtDNA results. When compare with the comparative collection, 6 samples from Mesolithic and Neolithic levels were identified as *Bos primigenius*, but one (MD1) were associated with the T haplogroup. MD1 appeared in the Neolithic Upper Level III, stratigraphically dated between 6200 - 6100 cal. BC. Moreover, the MD1 sample were directly dated, obtaining a similar age ( $7265 \pm 70$  BP; 6280 - 6000 cal. BC, Ua-34366).

Univariate comparative analysis shows that MD1 is very length and broad for the European *Bos taurus* standards. These results locate MD1 with European (Iberian included) auroch, or with Anatolian populations with similar sizes found on auroch specimens.

The GL/Bp and GL/Bd values show MD1 falling outside the range of variation of the European (Iberian included) *Bos taurus*, but within the range of variation displayed by *Bos primigenius* (from Iberia and Europe) as well as within the variation found for Çatalhöyük remains.

Regarding on its wild or domestic status, MD1 offer two interpretations of quite different consequences. If being from the wild, is no longer possible to use the absence of T haplotypes in European aurochs to rule out a more complex domestication process of taurine cattle. But if being from a domestic animal, the MD1 sample would be the first evidence for productive economy in the Iberian Peninsula.

DNA studies in ancient remains have become an essential tool when trying to find out the geographic origin of a certain population. Population genetics has traditionally based its studies in present populations, which has allowed them to reconstruct the history of the different human groups that inhabit the earth. Despite of this, and as a consequence of the complex historical processes that have shaped the different populations, sometimes it is very difficult to establish the specific origin of the diverse population contributions to each group. That would be the case of North Africa and the Canary Archipelago.

Genetic studies performed in present and archaeological northafrican populations allow us to establish comparisons with the results obtained for the canarian populations. The objective of this review is therefore to present the genetic results from both geographic areas and analyse them in the light of the hypothesis proposed by other disciplines like archaeology or linguistics.

The results of the analysis of the autosomal and uniparental markers, mtDNA and the Y chromosome, of a large, recent and archaeological, population series from the Canary Archipelago are presented. These results are compared with those obtained for North Africa.

The genetic analysis in the Canary Islands have led the researchers to propose the presence of several founding lineages: H1-16260, U6b1, U6c1, 2c y H-CRS. Among them, the U6b1 lineage is very important because up to now it has only been found in canarian populations, and it is a subgroup of the U6 lineage that was originated in North Africa some 30.000 years ago. The study of the different genetic markers has shed light on the processes of conquest and colonisation of the

islands, detecting the existence of a sexual asymmetry in the genetic composition of the present canarian populations, as the maternal lineages are mainly northafrican. The characterisation of these markers has also confirmed the Berber northafrican origin of these populations, being in accordance with the results obtained within other disciplines as archaeology or linguistics.

The present state of the investigations does not allow us to be more accurate regarding the place of origin of the canarian populations, but it does let us conclude that it was a northafrican peopling and that it was not due to an island-by-island independent maritime colonisation from the continent without secondary contacts. Furthermore this process seems to have had more than one colonisation event, without any strong founding effects and with secondary migrations between islands.

From the Middle Paleolithic until their disappearance in the early Upper Paleolithic, Neandertals occupied a large geographical area, ranging from northwestern Europe to southwestern Asia. Neandertals thus lived over a long time and in diverse environments that fluctuated between warm and cold periods, which may have shaped their population dynamics. Recent improvements in ancient DNA extraction and sequencing methodology have made it possible to retrieve large amounts of DNA sequence data from ancient remains. This has allowed, for example, the generation of high-quality genome sequences from Neandertal individual as well as from a Denisovan individual, an Asian population related to Neandertals, which both come from a cave site in southern Siberia. Analyses of these genomes have shown that these archaic groups carried less than half of the genetic diversity seen in present-day Europeans. It has also shown that the parents of the Neandertal individual were related at the level of half-siblings and that breeding between close relatives had also occurred in previous generations. This presentation summarizes our effort to study genetic diversity and reconstruct the population history, particularly of late Neandertals,

by retrieving DNA from Neandertal individuals from across their geographical range, including sites in Russia, Croatia and Spain.

The European ass (*Equus hydruntinus*) appeared in the fossil record around 350.000 years ago, and got extinct during the Holocene in Eurasia. Cranial and limb bone

measurements have closely related *Equus hydruntinus* with the extant hemionus. This evidence is also supported by partial mtDNA sequences.

Although *Equus hydruntinus* has been described in Iberian sites, most descriptions are mainly based on size proportions and dental morphology.

Here we present for the first time a mtDNA HVR-I analysis of a tooth from a Late Pleistocene Iberian equid, tentatively attributed to *Equus hydruntinus*.

An equid third lower right molar (AT-GE-189) was recovered from Galería de las Estatuas site, Cueva Mayor karst system (sierra de Atapuerca, Burgos, Northern Spain). This fossil was found in the Level 3, Sector 1 and it was directly radiocarbon dated.

DNA extraction was performed in the ancient DNA laboratory at Centro Mixto UCM-ISCIII (Madrid, Spain) using silica spin columns. Four primer pairs were used to amplify a mtDNA HVR-I fragment. In order to study the evolutionary relationships of this tooth with other equids, a sample of extant and extinct *Equus* sp. sequences from caballine and non caballine lineages were collected, with special attention to the subgenus *Hemionus*.

The Galería de las Estatuas sample radiocarbon dating revealed an age of 44.000 ± 1900 years BP. The 4 overlapping primer pairs yielded positive results, obtaining partial mitochondrial DNA sequence (np. 15444 – 15946, according to the new *Equus caballus* Reference Sequence, JN398377). The sample AT-GE-189 displayed the 28 bp deletion previously described in other mtDNA HVR-I *Equus hydruntinus* sequences as well as from *Equus kiang*, *Equus hemionus onager* and *Equus hemionus kulan*. Moreover, the phylogenetic analyses showed that our Galería de las Estatuas sample clusters with the *Equus hydruntinus* sample from Scladina (Belgium), dated in around 40.000 years BP.

We report a mtDNA sequence from an Iberian *Equus hydruntinus* and, due to the relationships with the other *Equus hydruntinus* sequences, we suggest the existence of an *Equus hydruntinus* group during the Late Pleistocene in Western Europe.

Horse domestication was a complex process with a principal episode in the Eurasian steppes around 5.000 years BP, enriched with recurrent introgression events from local wild populations through Eurasia. Archaeological studies as well as genetic analyses with modern samples have pinpointed the Iberian Peninsula as an important area involved in the horse domestication process. Mitochondrial DNA analyses with horse ancient remains have supported this hypothesis. In this context, a Bronze Age sample sequences from El Portalón site (sierra de Atapuerca, Burgos), showed the significance of a specific maternal lineage among others, a lineage currently found exclusively on Iberian horse populations and horses from Iberian origin.

With the aim to know in detail the presence and diversity of this Iberian lineage in Iberian Peninsula in earlier times, in this study we analyse the mitochondrial DNA from 22 Chalcolithic and Early Bronze Age horse remains recovered from El Portalón site. Furthermore, we study their relationships with the 19 Iberian Bronze Age Portalón samples previously published, and the persistence of their maternal lineages in the Iberian populations through the time.

### 9. ANALYSIS OF GENETIC POLYMORPHISM IN WOMEN IN BRAZILIAN PRE-HISTORY

*Nóbrega, Judas Tadeu (UFG/PUC Goiás) jtadeunn@gmail.com*

*Nóbrega, Viviane (PUC Goiás) recantovita@gmail.com*

*Verolla, Katia Karina (PUC Goiás) katiakarinar@yahoo.com.br*

Knowing that women, since pre-history, play an important role both in the numerical growth and in the expansion movements of a population, this paper

intends to discuss the influence of endometriosis in women in Brazilian pre-history.

Endometriosis is defined by focus of ectopic implantation of endometrial tissue, identical to the uterine cavity, which, besides the exaggerated presence of strogen receptors, would show defects in the progesterone receptor. Such abnormalities, strogenic or progestational, would be related to alterations that promote endometriosis. Conceptualized as an estrogen-dependent disease, affects pelvic organs, causing debilitating pain and infertility. Relatively common, it reaches 18% of women of reproductive age, and 87% when considering the pelvic pain and infertility.

To assist in the genetic understanding of this mechanism, it is important to identify some polymorphisms such as ARG, rated by their polymorphic repair function in different types of cancer; Phase I CYP1A1 genes encode enzymes involved in the detoxification of estrogen metabolism; GST's xenobiotic substrates, genetically susceptible to endometriosis, highlighting the GSTM1 and important in detoxification of products of oxidative stress GSTT1; GSTs xenobiotic substrates, genetically susceptible to endometriosis, highlighting the GSTM1 and GSTT1, important in detoxification of products of oxidative stress; PROGINS allele, that in women presents an increased risk of developing pathologies in tissues where exposure to progesterone has a protective effect, as in the ovary and the endometrium; and p53, tumor suppressor gene, which controls the regulation of cell growth and cell cycle regulation.

With the analysis of genetic polymorphisms ARG, CYP1A1, GSTM1, GSTT1, PROGINS, and p53, we can elucidate the presence of endometriosis in the prehistoric female population

To do so, you must first extract the DNA from this population.

Due to the peculiarities of soil composition, great difficulties are found in projects which aim the extraction and amplification of DNA from human skeletal material exhumed from the archaeological sites, especially the Brazilian Cerrado. However, as noted, there are bone materials, arising from collections of sites under guard of academic institutions, which are in the condition to extract DNA.

From the analysis of these and other collections, the goal is to collect bone samples and extracting DNA (mtDNA) in the laboratory MGENE / PUC-GO, using a protocol

developed and attested to the characteristics of the Cerrado; separation of the female genetics population from the male; application of primers for polymorphisms of the proposed research; analysis of laboratory results; and evaluation of the results.

As results we have, the ones came from DNA extractions of Burials Prehistoric Project: an alternative protocol for DNA extraction from ancient bones in the Cerrado of Central Brazil, which will guide the procedures with new samples.

It is expected that this genetics analysis of the presence of polymorphisms in DNA (mtDNA), extracted from ancient bone material, and the identification, or not, of the existence of endometriosis in that population, can serve to support the research, both in Archeology and Anthropology, Human Genetics and Medicine, that take into account their disabling consequences.

The iberian peninsula was a refugium for plant and animal species during the last glacial maximum and microsatellite data indicate that horse were among these. It has been suggested that iberia is a potential region for an independent horse domestication event; that the genetic types that proliferated following the retreat of the ice sheets were taken into the domestic genepool and spread throughout europe and beyond in prehistoric and later historic periods. However, the archaeological record in iberia is discontinuous, and evidence for early horse domestication in iberia that is based on rock art, is difficult to date accurately. Genetic research has been inconclusive, with the number of archaeological samples from iberia analysed at molecular level very low, particularly from the south, where horses are thought to have persisted. This has left population genetics patterns difficult to interpret, as they could be a result of modern and historic population movements. The influence of the wider mediterranean area within horse domestication is unknown even though the mediterranean was a major route for the spread of domestic species from the middle east. Furthermore, data from north africa is minimal and completely absent from any ancient dna study so far, therefore the genetic influence of north africa on horse populations from iberia or anywhere is completely unknown. This is the first comprehensive study of horse domestication in iberia and north africa that includes the ancient dna analysis of horses from a broad time

span, from the paleolithic to the present day, including pre and early domestication periods. The inclusion of ancient north african data is unique and gives us great new insights into these regions.

Ancient dna analysis: from all the sites sampled we successfully extracted dna from samples belonging to 10 different sites from iberia [ $n_{north}=7$ ,  $n_{south}=5$ ] and north africa: algeria [ $n=3$ ] and tunisia [ $n=4$ ]. The dna analysis followed previously published protocols and used a pcr based re-sequencing approach of the mitochondrial d-loop in order to allow the screening of a large number of individuals. Appropriate contamination control and authentication methods were followed. Modern dna analysis: mitochondrial d-loop was re-sequenced in a total of 200 living horses from iberia and na (morocco, algeria, tunisia) following previously published methods.

Phylogeny and biogeography: haplotypes were defined using bayesian mcmc clade credibility trees. A bayesian skyline was constructed from the combined trees in TRACER1.5. A continuous tree was constructed from the maximum credibility tree in SPREAD 1.0.4 and analysed in google earth. Population statistics were calculated and AMOVA performed using ARLEQUIN 3.11.

Here, we present the preliminary data resulting from the molecular analysis of archaeological and living horse populations. We compare iberian and north african populations with an extensive data set of eurasian horses that facilitate the integration of these results in a broad overview. We provide new insights into the potential founder populations of extant horses, the relationship of archaeological and present day genetic types and shed light on the process of horse domestication.

One of the most important and influential changes in human behaviour has been the change from small hunter-gathering/fishing bands to sedentary agrarian societies. This transition is generally characterised by the contrast between the two subsistence strategies and the accompanying cultural, technological and behavioural changes that occurred, and can be generalised (in Eurasia) as the Mesolithic-Neolithic transition. One of the characteristic features of this transition is how quickly the agrarian lifestyle spread and its impact on the demographic patterns of Europe; however, the nature of how it was spread remains open to debate. Ancient genomics applied to human skeletal remains from well-dated contexts allow us a precise understanding of population origins, genetic variation, migrations and admixture and comparisons between populations over time. Previous studies have shown close relationships between early Scandinavian and modern-day southern Europeans, as well as strong differences between hunter-gatherers and early farmers. However, with migration routes from the south and the modern mitochondrial DNA composition on the Iberian peninsula, the population history of southwestern Europe appears to have been different.

We sampled bone remains corresponding to 10 individuals excavated from El Portalón Cave. Radiocarbon dates were obtained for each sample. DNA was isolated using a conventional silica-based extraction method. DNA extracts were further converted into multiplexing illumina libraries and shotgun sequenced on a HiSeq platform.

Five of the 10 individuals analysed have not yielded sufficient coverage for genomic analysis. We present low coverage genomic sequences (average depth

between 0.2 and 1%) of five early Iberian farmers dated to between 4,000 and 5,000 years old, from El Portalón. These individuals display a similar pattern to that observed for central and northern European farmers and all show genetic similarities to modern-day southern Europeans, particularly to Sardinians, in contrast to the recently published 7,000 year old hunter-gatherer from near-by La Brana in Spain.

Our results are important to uncover the genetic origin of farming populations in the Iberian peninsula as well as the impact on demographic patterns. Moreover, these results will contribute to the clarification of the complete demographic picture of the neolithisation in Europe. This is an on-going study and we are currently increasing genome coverage and sample numbers to obtain a higher resolution of the patterns observed.

---

ORAL

## 12. UNRAVELING THE GENETIC HISTORY OF THE SPANISH WILD GOAT

*Ureña, Irene (Centro Mixto, Universidad Complutense de Madrid Instituto de Salud Carlos III de Evolución y Comportamiento Humanos.) iurena@isciii.es*

*Arsuaga, Juan Luis (Centro Mixto, Universidad Complutense de Madrid Instituto de Salud Carlos III de Evolución y Comportamiento Humanos.) jlarsuaga@isciii.es*

*Valdiosera, Cristina (Centro de Investigación Sobre la Evolución y Comportamiento Humanos, Universidad Complutense de Madrid Instituto de Salud Carlos III, 28029 Madrid, Spain) cvaldiosera@isciii.es*

The Iberian Wild goat (*Capra pyrenaica*, Schinz 1838) is an endemism of the Iberian Peninsula that has recently suffered the loss of two of its four subspecies. The taxonomic position of the genus *Capra* has opened an intense debate among researchers; this is due to the fact that its classification has been based mainly on morphological characters. It has been argued that horn morphology may not be an appropriate character for resolving its taxonomy. In addition, previous phylogenetic studies of the genus *Capra* are not in concordance with morphological studies. Based on paleontological studies, two independent migration waves of wild goats took place in Europe, the first one approximately 300 000 years ago involving the Alpine ibex followed by the Spanish ibex from the Caucasus round 80 000 years ago. However, according to molecular studies the origin of the Iberian wild goat and the Alpine ibex is the result of a single migration wave

of *Capra* into Europe followed by a vicariant speciation. Nonetheless, this hypothesis has been tested solely on modern data. Many goat species have suffered a drastic bottleneck in recent times due to exhaustive hunting and habitat fragmentation, hence it is likely that great part of their diversity has been lost. Therefore, ancient DNA studies are imperative in order to gain insight on their evolutionary genetic history.

A series of wild goat fossil remains from different sites and chronologies were sampled in Spain and southern France. We applied ancient DNA techniques in order to investigate the palaeogenetic history of the European wild goat. Firstly, we amplified 4 fragments of the cytochrome b gene that were further replicated and sequenced with standard methods in 19 samples from the site of Chaves in northern Spain. In addition, we recovered several regions of the same gene from 30 individuals by implementing an amplicon tagging method combined with high throughput sequencing. We performed phylogenetic analysis in a data set consisting on modern and ancient goat sequences. Finally, we calculated genetic diversity in samples dated from pre and post Neolithic.

Our preliminary phylogenetic analyses, based on the Sanger sequenced fragments, show a clear lack of genetic structure within the genus *Capra*, a pattern previously observed in other studies. The Iberian Wild goats and the Alpine Ibex group together showing a monophyletic origin for both species. These results are in concordance with the single wave migration theory of wild goats into Europe followed by allopatric speciation, however, more sequence data is required to confirm this observation. We report haplotypes that are not present in modern populations suggesting a higher genetic diversity in the past.

The mitochondrial genome in caprids is highly variable; therefore to increase resolution on their phylogenetic relationships, more sequencing will be needed to obtain complete genes or mitochondrial genomes. Haplotype loss is likely to have occurred with the arrival of domestic goats, habitat reduction due to expansion of human settlements and exhaustive hunting during the last century. This is an ongoing project and more data are still to be expected.

ORAL

**13. NEW APPROACHES TO THE GENETIC ANALYSIS OF ANCIENT GENOMES**

*Geigl, Eva-Maria (Institut Jacques Monod, UMR 7592 CNRS, University Paris Diderot, Paris, France) geigl.eva-maria@ijm.univ-paris-diderot.fr*

The analysis of ancient DNA preserved in archaeological remains, such as bones, teeth, and, exceptionally also hair and mummified tissue, has opened up a new dimension of archaeological research. Indeed, the analysis of single genetic markers as well as whole genomes enriches archaeology with a wealth of phylogenetic data on animals (including humans), plants and pathogens that add an enormous amount of information to the interpretation of the past. This concerns the evolution of humans, their demographic history, their pathologies, their social structures, but also the domestication of animals and plants, as well as the reconstruction of the dynamics of animal and plant populations revealing past climate changes.

The palaeogenome group of the Jacques Monod Institute develops research in most of the above mentioned areas in an attempt to enrich maximally archaeological research using both single marker and whole genome approaches. An important emphasis is put on methodological developments to push back the limits of ancient DNA research. In this talk, we shall give an overview about the research lines underway in our laboratory. In particular, we study the domestication of cattle and genotype extinct animals and past human populations.

ORAL

**14. GENETIC EVIDENCE FOR GENE FLOW AMONG LATE PLEISTOCENE HOMININS**

*Paabo, Svante (MPI-EVA) paabo@eva.mpg.de*

Over the past two decades, methods to retrieve DNA from ancient remains have progressed greatly. In cases where molecular preservation is exceptionally good and relatively small amounts of microbial DNA are present it is now possible to sequence complete genomes from Late Pleistocene hominin fossils. When whole-genome sequencing is not possible because too large amounts of microbial DNA are present, preselected parts of the genome can sometimes be isolated and sequenced. This has opened the possibility to compare genomes

not only between archaic and present-day humans but also increasingly among archaic hominins. I will review evidence that both Neandertals and a related Asian group, the Denisovans, have contributed DNA to present-day humans; that Neandertals have contributed DNA to Denisovans; and that another hominin that diverged earlier from the human lineage contributed DNA to Denisovans. I will also discuss how DNA from earlier hominins, particularly those discovered at Sima de los Huesos, may contribute to the emerging picture of the genetic interactions between different hominin groups.

FINAL DISCUSSION AND CLOSING REMARKS

# B55 Advances in Archaeological Palimpsest Dissection

*Organiser: Carolina Mallol and Cristo M. Hernández*

*Thursday, 4th (09:00 to 14:00)*

**1. DISSECTING PALIMPSESTS AT BAROZH 12: ONGOING RESEARCH AT A NEW MIDDLE PALAEO-LITHIC OPEN-AIR SITE ON THE EDGE OF THE ARARAT DEPRESSION, ARMENIA**

Glauberger, Phil (Middle East Technical University, Ankara, Turkey) [pglauber@metu.edu.tr](mailto:pglauber@metu.edu.tr)

Gasparyan, Boris (Institute of Archaeology and Ethnography, Armenian Academy of Sciences, Yerevan, Armenia)

Wilkinson, Keith (University of Winchester, Winchester, United Kingdom) [Wilkinson@winchester.ac.uk](mailto:Wilkinson@winchester.ac.uk)

Frahm, Ellery (University of Minnesota, Minneapolis MN, USA) [elleryfrahm@gmail.com](mailto:elleryfrahm@gmail.com)

Raczynski-Henk, Yannick (Ex-Situ Silex, Leiden, the Netherlands) [yannick@conserf.com](mailto:yannick@conserf.com)

Adler, Daniel (University of Connecticut, Storrs CT, USA) [daniel.adler@uconn.edu](mailto:daniel.adler@uconn.edu)

Field research at the Middle Palaeolithic site of Barozh 12 in western Armenia applies an array of integrated methods to investigate site formation processes and dissect archaeological palimpsests. On a plateau overlooking the Ararat Depression, obsidian artifacts were found densely concentrated and spread over a 100m x 200m surface area. Small scale test excavation revealed stratified, artifact rich sediments extending to a depth of roughly 1m. Preliminary stratigraphy suggests that fluvial and aeolian sedimentation and reworking, along with deflation and intermittent pedogenesis occurred amidst repeated hominin occupation of the locality. Excavation including a combination of geoarchaeological, chronometric, palaeo-environmental, and geochemical methods will be employed to investigate differential rates of sedimentation and artifact deposition, or 'time averaging', a primary mechanism of palimpsest formation. Geoarchaeological and palaeo-environmental methods will include micromorphology, mineralogy, grain-size, palynology, phytoliths, and starch grain analyses. Chronometric methods will involve optically stimulated luminescence dating of sediments, and uranium - thorium dating of pedogenic carbonates and carbonate crusts on artifacts to compare ages of sediment burial and weathering. A *terminus post quem* age will be acquired for the sequence through potassium/argon - argon/argon dating of basal tuff deposits. Results of obsidian raw material sourcing obtained using portable X-ray fluorescence (pXRF) on samples of artifacts from throughout the sequence indicate the use of local and distant sources. Alongside refitting studies, employing

pXRF as part of artifact analysis protocol will increase the resolution of on-site raw material exploitation and artifact manufacture episodes. These combined methods will assist in unraveling the palimpsests of behavioral evidence preserved at the locality.

ORAL

**2. OCCUPATIONAL EVENTS IN BOLOMOR CAVE (VALENCIA, SPAIN): ARCHEOSTRATIGRAPHIC ANALYSIS OF LEVELS I TO XII (100 - 200 KYA)**

Sañudo, Pablo (Universitat Rovira i Virgili (URV) [pablo.sañudo@bolomor.com](mailto:pablo.sañudo@bolomor.com)

Fernández Peris, Josep (Servei d'Investigació Prehistòrica (SIP) [josep.fernandez@bolomor.com](mailto:josep.fernandez@bolomor.com)

The study of human occupations in Paleolithic assemblages has an important goal in the definition of time and space in which human activities were developed.

Archaeological remains belonging to different occupational events appear normally overlapped in a same stratigraphic unit forming an occupational palimpsest. The separation of these occupational events, which can often be a challenge, is the basis for the analysis of the organizational behavior of the human groups that inhabited the site. In this sense, archeostratigraphic analysis establishes the diachronic relationship between cultural deposits by delimitating continuous sterile layers, allowing us to separate these occupational events, as first stage from establishing another complementary analysis with the aim of reconstructing the occupational patterns and social behavior of these human groups.

The site of Bolomor cave is located in the eastern Mediterranean coast of Spain, approximately 100 m above sea level, over the Valldigna Valley (Valencia, Spain). The stratigraphic sequence, with a maximum thickness of 14 m, has been dated by AAR and TL between MIS 5e and MIS 9 (100 kya to 350 kya). According to sedimentological studies, the stratigraphic sequence has been divided into seventeen levels. Human presence is practically continuous along the stratigraphic sequence of the site, originating a rich archaeological assemblage, formed by lithic and faunal material, human remains and some of the oldest evidences of fire use.

Mining labors developed in the 1930s of the 20th century destroyed the central area of the site and divide the remaining stratigraphic deposit into three areas, named

west, north and east. Archeostratigraphic analysis has been developed over the middle upper sequence, between levels I and XII (MIS 5e – 6), completely excavated in west and north areas. Both areas have been analyzed from several longitudinal and crosssectional profiles of 25 cm thickness, for searching thin sterile layers that proves the existence of inoccupation events along the archaeological sequence of the cavity.

The analysis exposed in this work reveals the existence of at least 22 occupational units along the middle upper stratigraphic sequence of Bolomor Cave (levels I to XII), that supposes the repeated use of the cave as campament for different human groups during a long period of 100 kya.

The Oscurusciuto rock shelter (Ginosa - prov. of Taranto) is one of the key-sites for the study of Neanderthal groups in Southern Italy. As part of its rich sequence, the stratigraphic unit 13 is presented here together

with the hearths found therein. This SU represents the sedimentological interface between the underlying tephra layer (SU 14: almost sterile, identified with the Mount Epomeo Green Tuff, dated to about 55 kyrs BP) and the overlying sand layer (SU 11 rich in anthropic remains). The presence and location of hearths, together with the horizontal distribution of the finds, has allowed to recognize an articulated structuring of the rock shelter divided into different activity areas. At the same time, this evidence revealed the palimpsest nature of this layer, defined as the sum of natural depositional processes and of a series of depositional anthropogenic events repeated over the course of time according to a virtually constant scheme, but with slight spatial dislocations.

The integrated analysis with the GIS Science/Tools of the relationship between the Raw Material Units, the refitting/conjoint, the hearths and the above mentioned activity areas have allowed to dissect the fundamental components of this palimpsest.

Using an high-resolution temporal perspective it was possible to identify single events and to formulate hypotheses on the minimum number of occupations occurred in this SU. At the same time, this temporal perspective has allowed to identify a possible correlation between these occupations.

Therefore, the results show the importance of using integrated research methods in order to identify short anthropic occupations within each single palimpsest.

### 4. PALIMPSEST: FROM SITE FORMATION PROCESSES TO HUMAN BEHAVIORS.

*Martinez-Moreno, Jorge (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria ) jorge.martinez@uab.cat*

*Mora, Rafael (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria ) rafael.mora@uab.cat*

*Roda Gilabert, Xavier (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria ) javier.roda@uab.cat*

*Roy, Miquel (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria ) miquel.roy@uab.cat*

The opposition between dynamic / static has articulated the notion of palimpsest, that is the core concept to understand human activities in the past. However, despite the importance of these implications, this discussion started in the 70s, and it is not yet widely applied in Paleoanthropology.

Lastly, we assist to a growing interest to analyze site formation processes. From this perspective, we have developed theoretical and methodological approach for the study of palimpsests.

We will expose the application of geo-statistical techniques concerning on Roca dels Bous and Cova Gran de Santa Linya, as examples of palimpsests with a limited resolution. We prioritize vertical dispersion analysis against the horizontal distribution of artifacts. These simple techniques warn that these deposits are palimpsests with a limited spatio / temporal resolution. However, these techniques permit to make inferences related with site formation processes and from these results we can get essential human behaviors.

Archaeological assemblages recovered in natural deposits are affected by dynamic processes that make difficult to establish the association between artifacts. These techniques advertise that burial and conservation are complex processes. Despite these difficulties, the context allows building inferences concerning on the behavior of human groups in the past.

ORAL

**5. ASSEMBLAGE FORMATION AT EL SALT SU X (ALICANTE, SPAIN). DEFINING TEMPORAL FRAMEWORKS FOR THE STUDY OF HUMAN BEHAVIOR CONCEALED IN MIDDLE PALAEOLITHIC PALIMPSESTS**

*Machado Gutiérrez, Jorge (Universidad de La Laguna) jorgemachado85@gmail.com*  
*Pérez Luis, Leopoldo (Universidad de La Laguna e IPHES) leoperezluis@gmail.com*

Isolating and sequencing lithic, faunal and combustion assemblages according to their corresponding depositional events is a required procedure in the dissection of Palaeolithic palimpsests in order to approach past human behavior. Such behavior may manifest a single instantaneous action or a specific set of related activities performed during one or more occupation episodes. In our view, the lack of temporal correlation among the remains we rely on to infer such activities from archaeological palimpsests represents an important methodological problem. The main effect of this problem is the inability to delimit minimal units of analysis from which to interpret behavioral dynamics of Neanderthal groups (i.e. ideally, assemblages representing a single occupation episode). With the aim

to face this problem, we present preliminary results of an empirical case of palimpsest dissection at the Middle Palaeolithic site of El Salt, Alicante, Spain. First, we isolated lithic and faunal remains and a single combustion structure corresponding to a potentially synchronic assemblage within SU X, using archaeostratigraphic methods. Then, tanking this material as our minimal unit of analysis (Archaeostratigraphic Unit 3), we explored its internal temporal dimension through a Raw Material Units (RMU) approach, lithic refitting and zooarchaeological data. Preliminary results show spatial relationships between specific areas of the site and the presence of different time-averaged technical behaviors, which suggest that Archaeostratigraphic Unit 3 was formed by the superposition of several short duration human occupation episodes.

**6. HEARTHES AND RABBIT BONES IN THE MIDDLE PALAEOLITHIC: NEW EXPERIMENTAL APPROACH TO IDENTIFY INTENTIONAL AND UNINTENTIONAL THERMAL ALTERATION OF BONE AND ITS APPLICATION TO PALIMPSEST DISSECTION**

*Pérez Luis, Leopoldo J. (Sociedades Cazadoras-Recolectoras Research group (Universidad de La Laguna, Tenerife) and Instituto Catalán de Paleoecología y Evolución Social (IPHES, Tarragona) leoperezluis@gmail.com*

Burnt bones are ubiquitous in Upper Pleistocene archaeological sites and they are usually associated to anthropogenic origin. Here we present the results of experiments that show how anthropogenic and non-anthropogenic bone can be unintentionally, postdepositionally affected by fire. Distinguishing between intentional and non-intentional alteration of bone is a key to excavate and interpret burnt faunal remains correctly, as well as constituting an aid to archaeological palimpsest dissection.

For our experiment we used only rabbit (*Oryctolagus cuniculus*) bones, whose presence in Pleistocene deposits is linked to different biogenic agents. We buried fresh and dry rabbit bones variable depths (2,5 to 7,5 cm) and made 8 simple combustion structures over them. Fire duration varied: 2 h. (2 fires), 4 h. (2 fires), 6 h. (2 fires) and 8 h. (2 fires). After cooling, all the bones was excavated and grouped according to depth. For each specimen, we describe color, structural modifications

and anatomical element type. Our experimental assemblage we compared to archaeological burnt rabbit bone stratigraphically associated with six combustion structures from Middle Palaeolithic Unit X of El Salt (Alcoi, Alicante).

We observed that rabbit bones buried at the same depth had a similar response to combustion and that their transformation was determined by their nature (fresh or dry). Fresh bone is more affected than dry bone. We also observed the occurrence of more than one color in a single bone, a feature previously interpreted as consequence of burning bone with meat attached to it. None of the buried bones calcined, while all of those in direct contact with flames were. Finally, we observed that different combustion time caused different proportion of modification in the color and structure of the bones. Short duration fire (2 h.) showed very little modification, while long duration fires (8 h.) modified practically all bones.

This experimental allows us to say that buried unburnt bone can be thermally altered by fire made above it. Thus, not all of the burnt bone in an archaeological assemblage is unquestionably anthropogenic or associated to anthropogenic combustion activity. For this reason, studies investigating the relationship between fire and bone in Prehistory, should be accompanied by taphonomic analyses (marks from different agents) and spatial analyses (3D positions of bone element in relation to hearths). This kind of observations are fundamental towards accurate excavation and interpretation of faunal assemblages. From an interdisciplinary perspective, this type of work contributes to the dissection of archaeological palimpsests, in order to identify specific human occupations approach historical explanations our archaeological sites.

POSTER

## 7. VIRTUAL PALIMPSESTS: THE USE OF MOBILE DEVICES TO VISUALISE THE ARCHAEOLOGICAL RECORD.

*Dragos, Gheorghiu (NUA Bucharest) gheorghiu\_dragos@yahoo.com*  
*Livia, Stefan (ITC Bucharest) livia.stefan@itc.ro*

To help archaeologists and the public more easily visualize the stratigraphy of archaeological sites, we propose the use of IT and mobile devices to achieve a palimpsest dissection. Specifically, we developed a web

application for mobile devices that identifies locations of interest (LOIs) on a map and allows the visualization of the historical information, superimposed over the live image of the site and in chronological order; this, in turn, makes explicit the archaeological layers.

The approach utilized is based on the following: a) rigorous measurements of geographic positions (latitude, longitude coordinates) of the archaeological excavations; b) digital photographs of the artifacts, displaying only the contour; c) assignment of chronological values to each artifact; d) storage of the information in a database. For a user in the proximity of the LOIs, the application displays his position and the distance to the LOIs on a map.

By selecting an archaeological location, the application displays the images of each artifact, superimposed in an axonometric vertical and in chronological order, from the oldest to the newest layer of dwelling.

The application is developed with Augmented Reality and HTML5 as IT technologies and can be accessed from smartphones and Tablet PC with Android or iOS scanning a QR barcode.

We consider that the proposed application will prove useful in helping archaeologists, researchers and other interested users, discover various historical sites, as well as access and visualize the archaeological information in an intuitive and integral manner. The Augmented Reality displays the virtual information superimposed on the real view.

POSTER

## 8. IN-SITU OR REWORKED? MICROMORPHOLOGICAL EVIDENCE FOR MIXING PROCESSES IN SHELTER SEQUENCES OF THE IBERIAN PENINSULA AND NORTHERN MOROCCO

*Kehl, Martin (Institute of Geography, University of Cologne) kehl@uni-koeln.de*  
*Linstädter, Jörg (Institute of Prehistoric Archaeology) joerg.linstaedter@uni-koeln.de*  
*Weniger, Gerd-Christian (Neanderthal Museum) weniger@neanderthal.de*

The formation of palimpsests involves phases of strongly reduced sediment accumulation, partial sediment erosion or sediment mixing by bioturbation, cryoturbation, peloturbation or processes of mass

movement along a slope. Humans may also cause mixing by differential trampling, raking out of fire residues or dung and levelling of dwelling floors. Generally, mixing processes cause problems in age determination of archaeological sequences resulting in age inversion or unexpectedly young ages. Micromorphology provides an important tool to identify mixing processes and clarify site formation in order to set up more reliable (chrono-) stratigraphic frameworks of shelter deposits. In addition, the first step to identify and disentangle Palimpsests is to evaluate mixing processes.

In the framework of the CRC 806 „Our way to Europe“, we investigated several Middle to Upper Palaeolithic rock shelter sequences. We found a set of micromorphological features which indicate in-situ archaeological levels while others give strong evidence for reworking or mixing. In-situ preserved archaeological layers often show subhorizontal orientation of elongated rock fragments, an increased degree of compaction, remnants of surface seals, signs of trampling and internal layering. Reworked deposits may show rolled aggregates and concretions, a low degree of compaction and lack of surface features. Internal layering is lacking. The poster will discuss these feature sets considering case studies in cave and rock shelter sequences in Spain (Las Palomas de Teba, Ardales, Arbreda) and Northern Morocco (Ifri Oudadane, Ifri N'Ammar). Overall, it was found that micromorphology considerably improved our understanding on processes of reworking. Micro features indicating reworking should be taken as evidence for the presence of a palimpsest.

ORAL

### 9. FINDING SINGLE-PERIOD SITES TO STUDY: AVOIDING PALIMPSEST SITES IN THE RAGANELLO BASIN.

van Leusen, Martijn (Groningen Institute of Archaeology) p.m.van.leusen@rug.nl

A 'palimpsest' is a Medieval manuscript on vellum that has been erased and over-written; archaeologists use this term as a metaphor to describe archaeological sites as a composite of features and remains from several periods - later ones overlapping with and often erasing earlier ones. This is rightly presented as a problem: untangling complex chronostratigraphies and dealing with increasingly 'gappy' data as one goes back further in time is a work garnering diminishing returns. But what if the Medieval scribe had reams of paper instead of a limited supply of vellum? In this paper the author, who has extensive experience in survey projects in central and

southern Italy, will argue that many problems associated with the excavation of palimpsest sites can be avoided by a two-step approach in which the selection of the site to be excavated follows on a wider (microregional) geoarchaeological survey. This approach is illustrated by examples from the author's recent 'Rural Life in Protohistoric Italy' project (2010-2015), in which single-phase and multiphase protohistoric site classes could be defined on the basis of the composition of surveyed assemblages and topographic characteristics of the site. Representative examples from these classes have been further investigated to define what a 'typical' single-period rural protohistoric site looks like; this information can then be used to reassess nearby excavated examples of multiperiod palimpsest sites. It will be argued that this research strategy, though initially more laborious, will resolve many interpretation problems that continue to plague excavators of palimpsest sites.

ORAL

### 10. ASSESSING SYNCHRONIES IN NEANDERTHAL OCCUPATIONS FROM ARCHAEO-MAGNETIC ANALYSES. A CASE STUDY OF MIDDLE PALAEO-LITHIC COMBUSTION STRUCTURES FROM LEVEL O AT ABRIC ROMANÍ ROCK-SHELTER (CAPELLADES, SPAIN).

Carrancho Alonso, Ángel (Área de Prehistoria, Dept. Ciencias Históricas y Geografía, Universidad de Burgos, Edificio+D+I, Plaza Misael Bañuelos s/n, 09001 Burgos, Spain) acarrancho@ubu.es

Villalaín, Juan José (Dpto. Física, Universidad de Burgos, Escuela Politécnica Superior, Avda. Cantabria s/n, 09006 Burgos, Spain) villa@ubu.es

Vallverdú, Josep (IPHES, Institut Català de Paleoecologia Humana i Evolució Social, C/Marcel·lí Domingo s/n, Campus Sescelades (EdificiW3), 43007 Tarragona, Spain / Área de Prehistoria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain.) jvallverdu@iphes.cat  
Carbonell, Eudald (IPHES, Institut Català de Paleoecologia Humana i Evolució Social, C/Marcel·lí Domingo s/n, Campus Sescelades (EdificiW3), 43007 Tarragona, Spain / Área de Prehistoria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain.) eudald.carbonell@urv.cat

The Abric Romaní (Capellades, Barcelona, NE of Spain) is a wide rock-shelter with a 20 m deep stratigraphic sequence dated by more than forty U-Series and <sup>14</sup>C (AMS) data between 39 and 70 ky BP (Bischoff *et al.*, 1988; 1994). This is a travertine deposit where thousands of lithic artefacts, bones, archaeobotanical remains, and even

wood implements (Carbonell & Castro Curiel 1992) have been recovered. However, the site is particularly known by the large number of combustion structures (hearths) documented in its stratigraphy. These are characterised by a well-preserved thermo-altered substrate beneath a charcoal-rich thin facies interpreted as hearth related archaeological assemblages. Currently, the Abric Romani is the Middle-Palaeolithic archaeological site with one of the most complete and continuous prehistoric fire record of the world. Here we report the archaeomagnetic and rock-magnetic results obtained from the study of several hearths sampled at level O (~ 55 ky BP).

The sampled combustion structures appeared exposed as a more or less continuous surface of 2-3 meters of length, black colour, irregular geometry and variable thickness. Archaeological information is unable to differentiate if they correspond to a single or multiple burning events and if so, determine if these are widely separated in time. The main goal of this study is to determine possible synchronies or diachronies among these burnt features from the analysis of their archaeomagnetic directions. The natural remanent magnetization (NRM) of 50 oriented specimens from three hearths was stepwise demagnetized by alternating field or thermal demagnetization in order to determine the characteristic remanent magnetization (ChRM) direction. All analyses were carried out at the laboratory of Palaeomagnetism of Burgos University (Spain). Three mean archaeomagnetic directions contained within the  $\alpha$ -95 (confidence angle) of the others hearths studied were obtained at level O. The mean directions obtained are statistically indistinguishable among them strongly indicating a "synchronic" record of the geomagnetic field or at least, that they were produced very close in time. These observations agree well with archaeological observations. Considering the age of these materials it is not possible to compare the obtained directions with any paleosecular variation record. However, we have interpreted the archaeomagnetic directions in terms of temporal scale of Neanderthals' occupations to evaluate if they were close in time or not. Furthermore, a complete set of rock-magnetic experiments has been performed in order to reconstruct the technological (palaeotemperatures) and environmental (kind of atmosphere) conditions undergone in the production of these combustion structures. We discuss the potential and limits of archaeomagnetism to reconstruct spatial congruence of fire use at Palaeolithic sites.

ORAL

## 11. IDENTIFICATION OF WOOD ASH IN ARCHAEOLOGICAL DEPOSITS USING SOIL MICROMORPHOLOGY AND INFRARED MICROSPECTROSCOPY.

*Thibodeau, Megan (Simon Fraser University) mthibode@sfu.ca*  
*Berna, Francesco (Simon Fraser University) francesco\_berna@sfu.ca*

Soil Micromorphology is one of the most useful and valuable tools to untangle the complicated palimpsest left behind by human activity. One important part of human behaviour is the control of fire and soil micromorphology allows for the identification of microscopic wood ash and interpretation of its depositional and taphonomic processes. However, distinguishing wood ash from other types of calcified plant materials can be challenging due to the petrographic similarities among pyrogenic, pedogenic, and geogenic micritic calcite. This paper illustrates the potential of integrating soil micromorphology and Fourier-Transform infrared microspectroscopy (FTIR-m) to identify pyrogenic calcite and characterize its context and origin at a microscopic scale.

Recent studies have demonstrated that infrared spectroscopy can distinguish between geogenic, pedogenic, and pyrogenic calcite based on the variance in atomic order in each polymorph from different formation processes. However, this approach has not been integrated with micromorphological analysis of materials in thin section. This research analyses known samples of calcite forms to determine whether the differences in formation processes are reflected in the FTIR-m spectra and applies the results to several Paleolithic contexts.

Here, we illustrate the application of this integrated analytical approach in several Paleolithic contexts. Preliminary results suggest that this combined approach has the potential to distinguish wood ash from other calcite types within the archaeological record on a microscopic scale.

Understanding the archaeological record requires both the ability to characterize its composition and interpret what processes produced, transported, and modified the materials. Soil micromorphology and FTIR-m are both powerful techniques to approach these questions.

ORAL

**12. PUZZLE OUT A PALIMPSEST: TESTING AN INTERDISCIPLINARY STUDY IN THE LEVEL O OF ABRIC ROMANÍ.**

*Bargalló, Amèlia (IPHES URV) ameliabarg@gmail.com  
Gabucio, Maria Joana (IPHES URV) mj.gabucio@gmail.com  
Rivals, Florent (ICREA IPHES) florent.rivals@icrea.es*

Cultural deposits, especially those accumulated in caves and rock shelters, are usually the result of several occupational events in the same space, forming palimpsests. In addition, the materials of these occupational events are usually deposited with remains of natural origins and may be altered, partially destroyed or reworked because of the process of superimposition. Abric Romaní (Capellades, Barcelona) is a Middle Palaeolithic archaeological site dated between 40 to 70 ka BP. The archaeological levels are excavated on a large surface (around 300 m<sup>2</sup>) and the spatial location of archaeological remains is carefully recorded. Most of the sequence is formed by precipitation of carbonates forming well-bedded travertine layers (high sedimentary rate: 0.46 mm/yr). The conservation of some archaeological evidences like hearths and wood implements in this sedimentary context is good.

The level O is dated to 54.6±0.4 kyr by U-series. The excavations from 2004 to 2012 have provided more than 40.000 remains including lithics (23.393), fauna (9.299), charcoals (3.524), wood imprints (109), and combustion structures (63). The excavated surface of level O reaches 278 m<sup>2</sup>. Here we focussed on a particular area, located in the north-eastern corner of the site. This work is based on the study of lithic and faunal remains of this area, with the aim to dissect palimpsest to the finest possible units. For this we used different methods and techniques such as the archaeostrigraphy, intra-site spatial archaeology, zooarchaeology, tooth microwear, taphonomy, lithic technology, and faunal and lithic refits.

These methods allowed to identify two archaeolevels in this area (Oa and Ob). In Oa, the area is 31 m<sup>2</sup> and there are a maximum of three accumulations, two of them related to two combustion structures. This area corresponds to a domestic area where we identified different activities: stone knapping, anthropogenical bone breakage products, cutmarks and burned bones. This domestic area is placed in the central part of this archaeolevel. All data indicate that the assemblage corresponds to a low-intensity campsite.

In Ob the area is 27 m<sup>2</sup> and we have distinguished two accumulations of archaeological remains distributed in fifteen combustion structures. The faunal remains are indicating that roasting, defleshing and bone breakage by percussion occurred *in situ*. Through the study of lithic remains we identified knapping stone tools *in situ*, and the recycling into other artefacts. All this indicates that this area corresponds to various domestic areas. The refitting of lithic and taphonomy evidence an overlapping of several successive events. One of these events was synchronic to other areas of the rock shelter, as indicated by refits (lithic and faunal remains), tooth microwear, anatomical and taxonomical identification. Our results have shown that combining different methods it is possible to obtain high resolution data for dissecting the palimpsest, but even having distinguished these finer units, we still work with palimpsest. However, the study of these finer units permits to work with time scales which are closer to the ethnographic time facilitating, therefore, our further ethno-archaeological interpretation of the Neanderthal occupations at Abric Romaní.

ORAL

**13. ARCHAEOLOGICAL STRATIGRAPHY IN LOWER PALAEOOLITHIC SITES: INTERPRETING ASSEMBLAGE FORMATION.**

*Rosana Obregón (rosana.obregon@cenieh.es)*

La aplicación del método arqueostratigráfico a yacimientos del paleolítico inferior se revela como una herramienta eficaz para poder separar los materiales acumulados durante largos periodos de tiempo en un único estrato geológico. A través de la identificación de los vacíos arqueológicos, los materiales que forman un enorme palimpsesto de pueden individualizar al menos en micropalimpsestos. Se ha aplicado esta metodología a dos yacimientos de cronología y características muy diferentes, tales como Gran Dolina nivel 10 de Atapuerca, y SHK de Olduvai, con lo que se ha podido trabajar con un patrón de acumulación en cueva y otro al aire libre. Estos estudios han demostrado que este método aporta datos importantes sobre la intensidad de los asentamientos humanos, pero también de los posteriores eventos naturales que afectaron a la definitiva acumulación de sus restos.

ORAL

**14. IS THIS YOURS? SPATIAL ANALYSIS OF TWO BURIALS FROM THE MESOLITHIC SHELLMIDDEN OF CABEÇO DA AMOREIRA (MUGE, PORTUGAL)**

*Goncalves, Celia (Universidade do Algarve) cmgoncalves@ualg.pt*  
*Cascalheira, Joao (Universidade do Algarve) jmcascalheira@ualg.pt*  
*Bicho, Nuno (Universidade do Algarve) nbicho@ualg.pt*

All over the world shellmiddens are known for their great potential in the preservation of high-resolution archaeological records. Nevertheless, site formation processes associated with shellmiddens and their inherent complexity have always been one of the major obstacles to the interpretation of the settlement dynamics that led often to the use of these sites not only as middens but also as burial and residential spaces. This complexity becomes very clear when we look at the lar matrix-to-artifact ratio of such sites. In fact, these deposits are mostly composed of cultural material (e.g. shells and fire-cracked rocks) deposited through spatially confined processes that are the source of very significant horizontal and stratigraphic variations.

New archaeological work conducted since 2008 in the mesolithic shellmidden of Cabeço da Amoreira have been providing very relevant data on site formation processes, function, and even aspects related to the social peculiarities of the last hunter-gatherer communities of Central Portugal.

This paper will focus on the analysis of spatial distribution of different categories of artifacts from the top layers of the shellmidden where two human burials were discovered. The use of GIS software was essential for the analysis of quantitative and qualitative data, allowing the establishment of intrasite spatial relationships. Distributions, densities, and correlations of artifacts to the human burials allowed an insight into the processes involved before and after the deposition of the bodies.

ORAL

**15. COMBUSTION STRUCTURES AS PALIMPSEST OF NEOLITHIC-CHALCOLITHIC OCCUPATION OF CAVES AND ROCKSHELTERS IN NORTHERN IBERIA: A MICROSTRATIGRAPHICAL APPROACH**

*Polo Díaz, Ana (Departamento de Geografía, Prehistoria y Arqueología, Euskal Herriko Unibertsitatea, Francisco Tomas y Valiente s/n, 01006 Vitoria-Gasteiz, Spain) anapolo-diaz@gmail.com*  
*Fernández Eraso, Javier (a Departamento de Geografía, Prehistoria y Arqueología, Euskal Herriko Unibertsitatea, Francisco Tomas y Valiente s/n, 01006 Vitoria-Gasteiz, Spain) javier.fernandez@ehu.es*  
*Simpson, Ian (Biological and Environmental Sciences. University of Stirling) i.a.simpson@stir.ac.uk*

Combustion residues are one of the principal indicators of anthropogenic activity during Prehistory.

Human use of caves and rockshelters during the Neolithic and Chalcolithic can be traced by the study of thermally altered detrital accumulations of animal waste, palaeobotanical residues and burial deposits preserved in the archaeological record. However, relevant questions remain unsolved regarding both the use of the space and the intensity and rhythms of the occupation patterns of these contexts and how burnt sediments can contribute to clarify these issues.

Microstratigraphy is a fundamental tool for the reconstruction of the formation processes of combustion residues from anthropogenic origin. Particularly micromorphology can provide significant information regarding fuel choice and management of burnt residues over time as indicators of activities carried out at the site and settlement patterns.

Results of micromorphological and macroscopic analysis of combusted accumulations documented in Neolithic-Chalcolithic cave and rockshelter deposits from Northern Iberia are presented. Data obtained support evidence of recurrent penning of herbivores, domestic areas and manipulation of human remains through fire.

Some key questions regarding the occupation patterns of these sites are discussed:

What is the actual correlation between the frequency of combustion structures/residues documented in penning areas within caves and rockshelters and the frequency of the sites used as a pen?

Are single combustion structures documented in burial pits, containing burnt remains of different individuals, evidence of single collective *burial and burning* episodes? or could they be the result of occasional burning events of body remains which were accumulated over hundreds of years?

Assessment of high-resolution data provided by the analysis of combustion residues from the point of view of the *palimpsest effect* allows to address the role of sedimentary parameters regarding the use and the occupation patterns of the sites studied in the analysis of social behaviours and management of natural resources of prehistoric groups in the transition to farming societies in Northern Iberia.

**1. RETOUCHE TOOLS MADE OF CALLISTA CHIONE VALVE: AN ADAPTATION OF NEANDERTHALS ON THE MEDITERRANEAN SEA SHORE. THE REPRESENTATIVE CASE OF GROTTA DEL CAVALLO (SOUTHEAST ITALY).**

*Romagnoli, Francesca (Università degli Studi di Firenze) f.romagnoli2@gmail.com*

*Baena, Javier (Universidad Autónoma de Madrid) javier.baena@uam.es*

*Sarti, Lucia (Università degli Studi di Siena) lucia.sarti@unisi.it*

Neanderthal retouched tools made of marine shells have been reported in several sites in southern peninsular Europe (Italy and Greece). At present, the chronology of this evidence is inferred by environmental markers such as faunal associations and sedimentary data. The absence of absolute chronometric data does not allow proposing solid inference on contemporaneity between sites.

These tools were first identified in the late 1950s. During the last 50 years they have been the object of only a few analyses, always with a typological approach, and the literature lacks detailed descriptions.

After a general overview of these tools, we present here new data from Grotta del Cavallo. The site is located on the Ionian coast of Salento peninsula and preserves one of the most important Italian Middle Palaeolithic deposits covering a chronology from MIS 5 to MIS 3. Retouched shells were found in layer L (MIS 5a / MIS 4). The *Callista chione* assemblage is composed of 126 retouched elements, with shiny appearance and retouched cutting edges clearly readable.

We have focused the research on the reconstruction of the productive sequence, from the finding of the valve

to the discard of the tools. The approach used has been multidisciplinary, combining taxonomy, taphonomy, morphotechnical analysis, techno-functional analysis of the cutting edge and experimental archaeology.

Fishes or marine mammals were not identified in the faunal assemblage. Other marine shells were found, but only *Callista chione* were retouched. The valves were collected on the beach after the death of the mollusc and were retouched with high technical control when entire, using a stone hammer. The retouch was convex and localised on the natural edge of the valve, on the internal surface of the shell.

The results suggest that the exploitation of the shells was finalised to the production of tools and was not related to subsistence activities. They were part of the economic strategies of a group highly mobile. The experimentation and comparison between lithic and shell tools suggests that they were artefacts integrated in the cultural tradition, realised with a technical gesture that is almost the same of quina and semi-quina flint retouch.

The detailed analysis of shell tools may contribute to the understanding of the role played by shell as raw material in the European Middle Palaeolithic and to the debate on the technical behaviour and the adaptation to the environment of Neanderthals.

ORAL

**2. INVESTIGATING THE SEASONAL FACTOR IN NEANDERTHAL SHELLFISH GATHERING USING OXYGEN ISOTOPE ANALYSES OF SHELL REMAINS**

*Douka, Katerina (University of Oxford) katerina.douka@rlaha.ox.ac.uk*

A scheduled round of activities allows modern hunter-gatherers to take advantage of the seasonal appearance of resources and often their mobility patterns coincide with anticipated seasonal abundance and the presence of optimally available resources.

Most prehistorians would agree that Neanderthal subsistence strategy was equally influenced by seasonal fluctuations in prey and plant availability. The limited data of the seasonal cycle of Neanderthals come mainly from the study of mammalian teeth cementum increment, sex ratios and the seasonal growth or reproductive conditions of their prey.

In addition to terrestrial plants and animals, however, Ne-

Neanderthals exploited aquatic resources. In this contribution, we investigate in particular the role marine shellfish may have played in the seasonal procurement strategies of Neanderthals. By using oxygen isotope and growth increment analyses, the season-at-death of a number of molluscan shells from Mousterian contexts in Iberia is assessed allowing a seasonal date to be obtained for the specific Neanderthal coastal occupations.

### 3. THE USE OF COASTAL LANDSCAPES AND THE EMERGENCE OF MODERN HUMANS IN SOUTHERN IBERIA

*Bicho, Nuno (ICArEHB - Universidade do Algarve) nunofbicho@gmail.com*

*Castela, Guilherme (FE - Universidade do Algarve) gcastela@ualg.pt*

*Gonçalves, Célia (ICArEHB - Universidade do Algarve) ceelinmag@gmail.com*

This paper focuses on the importance of prehistoric coastal adaptations for European Pleistocene human evolution. We will discuss aspects related to history, including the so-called coastal paradox and various archaeological and ethnographical biases of the study of the use of coastal resources as well the conceptual definitions of coastal adaptation, the systematic use of coastal resources, and the application of those concepts to the study of early Humans in Southern Iberia.

We also focus on coastal exploitation by hunter-gatherer-fisher human groups in Southern Iberia and the regional ecological niches. The phenomenon of Upwelling is described in detail followed by a discussion on its relation to an optimum biomass context in southern Iberia and the possible impact on the economical and dietary adaptations by Neanderthals and the first anatomically modern Humans in the region.

We will also describe some of the early sites, including Bajondillo, Nerja in Spain, Gorham's and Vanguard caves in Gibraltar, and Vale Boi, Mira Nascente and Praia Rei Cortiço in Portugal with coastal resources in the Iberian margin.

We will analyse and define variables indicating exploitation of coastal resources and will propose a model for the definition of episodic and systematic use of coastal ecological contexts, including the presence of fish, marine mammals, molluscs, maritime birds. This statistical model will help to define the earliest systematic use of

coastal resources in southern Iberia.

Shellfish are a rich source of micronutrients and habitual exploitation of these marine resources contributes to healthy balanced diets. Nutritional Ecology Theory suggests that such diets should result in healthier populations and shorter inter-birth intervals, which, in turn, should favour demographic increase (e.g. Hockett & Haws 2003, 2009). These factors may have contributed to the success of modern humans dispersing into Eurasia between 50 and 40 ka BP. Here we present new data on the mollusc assemblage from Ksâr 'Akil, which throw light on Upper Palaeolithic coastal adaptations.

Ksâr 'Akil is a key site in the eastern Mediterranean, well-known for its vast Initial/Early Upper Palaeolithic deposits associated with remains of modern humans (e.g. Ewing 1947). This site provides a unique opportunity to study the antiquity of Upper Palaeolithic shellfish exploitation, as well as trends in this subsistence practice throughout that period. In this study we combine zooarchaeological and isotopic analyses to assess the role of marine molluscs in human diets.

The intertidal rocky shore gastropods from Ksâr 'Akil (*Patella caerulea*, *Patella rustica*, *Patella ulyssiponensis*, *Phorcus turbinatus* and *Phorcus articulatus*) were collected for consumption and transported to the site by its occupants. The earliest evidence for the consumption of marine molluscs at Ksâr 'Akil comes from the Initial Upper Palaeolithic at approximately 44 ka cal BP (layer XXII). Tidal resources became a regular component of the diet

by the Early Upper Palaeolithic (around 43-41 ka cal BP), when small quantities of shellfish were habitually gathered. Oxygen isotope data suggest that the exploitation of *Phorcus turbinatus* took place throughout the year with a focus on the colder months.

In summary, our investigations indicate that although shellfish represented a minor source of protein they were a stable source of essential nutrients not readily available in terrestrial foods.

ORAL

### 5. LATE PLEISTOCENE TO HOLOCENE SHELLFISH EXPLOITATION AT HAUA FTEAH, LIBYA FROM THE STABLE ISOTOPE ANALYSIS OF PHORCUS TURBINATUS AND PATELLA CAERULEA SHELLS

*Prendergast, Amy (University of Mainz) aprender@uni-mainz.de*  
*Rhiannon, Stevens (University of Cambridge) res57@cam.ac.uk*  
*O'Connell, Tamsin (University of Cambridge) tco21@cam.ac.uk*  
*Barker, Graeme (University of Cambridge) gb314@cam.ac.uk*

The seasonal pattern of shellfish foraging at the archaeological site of Haua Fteah in the Gebel Akhdar, Libya was investigated from the Neolithic to the Epipalaeolithic via oxygen isotope analyses of the topshell *Phorcus turbinatus* and the limpet *Patella caerulea*. To validate both species as faithful year-round palaeoenvironmental recorders, the intra-annual variability of  $\delta^{18}\text{O}$  in modern shells and sea water were analysed and correlated with measured sea surface temperature (SST). Both species were found to be good candidates for seasonal shellfish foraging studies as they preserve a full annual SST cycle in their shell  $\delta^{18}\text{O}$  with minimal growth cessation. Analysis of the archaeological specimens showed that mollusc exploitation during the Neolithic (c. 7.7 to 6.2 ka) and Mesolithic (locally known as the Capsian c. 12.3 to 9.3 ka) was restricted to autumn and winter. Other archaeological evidence from these archaeological units show that hunting activities occurred during the warmer months. Therefore, the timing of Holocene shellfish exploitation in the Gebel Akhdar may have been influenced by the seasonal availability of other resources and possibly used as a dietary supplement when foods in the Mediterranean were less abundant. During the Epipalaeolithic (locally known as the Oranian, c. 16.1 to 13.1 ka), shellfish were foraged year-round. This compliments other evidence from the archaeological record that show that this period was more intensively occupied than previous and

subsequent units. This finding is significant as the Epipalaeolithic was the coldest and driest phase of the last glacial cycle in the Gebel Akhdar and it adds weight to the theory that the Gebel Akhdar may have served as a refugium for humans in north Africa during times of global climatic extremes.

ORAL

### 6. FOOD AND ORNAMENTS: CHANGING PATTERNS OF EXPLOITATION OF MARINE MOLLUSCAN RESOURCES AT FRANCHTHI CAVE (ARGOLID, GREECE) DURING THE UPPER PALAEO-LITHIC AND THE MESOLITHIC (36,000-9,000 BP).

*Perlès, Catherine (Université Paris Ouest) catherine.perles@mae.u-paris10.fr*

The long Upper Palaeolithic and Mesolithic sequence of Franchthi Cave is often quoted for the increasing importance through time of marine resources exploitation. Fish species characteristic of a brackish-water lagoon, such as sea bream, eel and gray were regularly captured since at least the Late Upper Palaeolithic, and fishing culminated with an episode of intense tuna fishing in the Upper Mesolithic. Marine molluscs, which will be the focus of this presentation, were collected even earlier and constitute the bulk of the ornaments ever since the Aurignacian occupations. Edible marine molluscs only appear in some quantity much later, during the Late Epigravettian (ca. 11,000 cal BC), and continue to be exploited until the end of the Mesolithic (ca 7,000 cal BC).

The progressive introduction of marine resources in the diet has been related to the growing proximity of the coast as the sea level rise, or as a compensation for the decline of large game resources. However, it will be argued here that the dietary contribution of marine resources in general, and marine molluscs in particular, remained low and very selective. Different habitats such as rocky substrates, sandy beaches and marshes or lagoons were exploited ornamental and food resources, but in both cases the range is restricted. For instance, *Cyclope neritea* was collected alive in brackish lagoons, but *Cerastoderma glaucum*, which lives in the same environment, was neglected. More generally, the edible bivalves that will be largely exploited during the Neolithic - *C. glaucum*, *Ruditapes decussatus*, *Donax trunculus*, *Donacilla cornea*, are very rare in the Palaeolithic and Mesolithic deposits. Among the gastropods, *Patella* sp. and *Osilinus* ssp. are only regularly present in the Late Palaeolithic. *Atriplex trunculus* is occasionally present in the Mesolithic. *Cerithium vulgatum* is the most abundant

gastropod, but its use as food or bait remains uncertain. Whether or not *C. vulgatum* was eaten, the number of edible marine molluscs in each unit remains in any case lower than the number of ornamental specimens, and far lower than the number of land snails. The contribution of marine molluscs to the diet during the Palaeolithic and the Mesolithic remained marginal, and, especially during the Mesolithic, ornamental species appear to have been the main focus of molluscan coastal exploitation.

Molluscs have traditionally been considered as marginal resources for Upper Palaeolithic societies. However, in recent years, new data have emerged to demonstrate that their importance for human utilization was probably greater than previously thought. The assessment of archaeological shells has generally been carried out from a nutritional or ornamental perspective, but not from the technological potential that these resources might have.

In this paper, use wear analysis combining low and high magnification microscopy, and chemical analysis using Scanning Electron Microscope (SEM), were performed

on shells from the Solutrean and Magdalenian levels of Altamira cave (northern Spain).

Results showed that 57 shells were used as tools for processing the red pigments (ochre) used in the artistic representations on the cave walls. The identification of shell tools in these levels of Altamira cave represents a new example of utilization of marine resources during the Upper Paleolithic. It also provides new perspectives regarding the painting techniques on cave walls and insights into their production by hunter-gatherers during this period.

Finally the technological use of shells demonstrates that marine resources were of greater importance to Upper Palaeolithic hunter-gatherers, and that their utility was more diverse, than previously understood.

The frequency of mollusks, shellfish, fish, seabirds, and marine mammal remains from archaeological sites along the Atlantic coast of Northern Spain attests to the relatively intense exploitation of marine resources during the Upper Palaeolithic, Epipalaeolithic, and Mesolithic. The main function of coastal resources seems to have been food supply for societies, although they were also used for both technical and symbolic purposes. Numerous studies show that an increased role of marine resources in human diet is associated with low residential mobility and limited home ranges (Kelly 1995; Binford 2001). Our investigation aims to investigate if such changes in diet and mobility correlate with changes in the exploitation of marine resources for symbolic purposes, in particular marine shell bead manufacture.

We performed a diachronic analysis of shell accumulations from an Epipalaeolithic (Praileaitz I) and two Mesolithic (El Mazo, El Toral III) sites located in the Vasco-Cantabrian and Asturian regions.

Following a method based on taphonomic, morphometric, and microscopic analyses of modern and archaeological shell reference collections, we identified shell bead taxonomic diversity and reconstructed the way in which shells were accumulated, transformed into beads and used.

Results show that the shell accumulation at the Epipalaeolithic site of Praileaitz I represents discarded raw material considered unsuitable for the manufacture of personal ornaments. The lack of other archaeological remains associated with the shells supports a brief occupation of the cave and the existence of highly specialized task-specific sites connected to bead manufacture during the Epipalaeolithic. Exportation of raw material suitable to be transformed into beads outside the cave also shows the segmentation of the bead manufacturing in both time and space.

In contrast, analysis of shell beads at the two Mesolithic sites (El Mazo, El Toral III) indicates that all the stages of bead manufacture are represented in the accumulation: unmodified raw material, beads broken by manufacturing process and finished beads. This indicates that shells were collected, sorted and transformed into beads at these sites. Use-wear on some of the shell beads shows that part of them were re-introduced in the sites and accidentally lost by the inhabitants of the cave.

The variety of remains associated with the beads, including shells for consumption, lithic and faunal remains and hearths/ash lenses, indicates a relatively long term oc-

cupation of the sites where various activities related to technical, economic and symbolic purposes were conducted.

We conclude that the observed differences may reflect a switch from a logistic mobility to a more residential mobility with the onset of the Holocene, which involved a change in the way and location in which shell beads were sorted, modified and assembled. Future research will have to determine if the absence of short-time task-specific sites in archaeological contexts with intense exploitation of marine resources is significant or depends on the low archaeological visibility of short-lived occupations.

---

ORAL

### **9.DOES THE DIVERSITY OF THE FAUNAL REMAINS MAKE THE DURATION OF MESOLITHIC SHELL-MIDDENS?**

*Dupont, Catherine (CNRS CReAAH UMR6566) catherine.dupont@univ-rennes1.fr*

The Late Mesolithic is clearly marked, on an Atlantic scale, by a more important preservation of shell middens than it was during the previous periods. This visible increase of archaeological sites is widely dependent on geomorphologic contexts in which one sites formed. The consequence of this fact means that the actual distribution of archaeological sites is widely linked to the nearby marine environments that were present during the functioning of the prehistoric settlements. The stabilization of the coastline is not irrelevant to the increase of the archaeological witnesses. In spite of this multiplication, certain Atlantic zones of the facade are sterile in Mesolithic shell middens. Are these hiatuses connected to zones of desertification of the coastline by Mesolithic? Furthermore, the community of the European archaeologists also focused on this final phase of the Mesolithic because it can be the beginning of the stabilization of the residence of human groups.

The data of the old excavations coupled with those of new searches allow to discuss hiatuses in the distribution of archaeological sites. Thanks to a database which lists all the faunal components Mesolithic shell middens, we can think, at the same time, about the geographical distribution of these sites where shells and other wild resources were consumed on the European Atlantic facade scale. This database also allows to work on the diversity of consumed animals by the populations which spent a lot of

time on the coastline. Furthermore, the development of new disciplines, such as the archaeomalacology makes possible to dissect in detail the exploited resources, to confront them with the available environments but also to try to reconstitute the human behavior through the selected species, their biotopes and their sizes.

If global phenomena are observed on the European Atlantic facade scale, the return to case studies can turn out precious to understand better the diversity of the human behavior. So, from study of French and Portuguese cases we wish to discuss the diversity of the faunal remains discovered on Mesolithic sites. Is this diversity proportional to the volumes of the shell middens and to the times of residence of the coastal populations? In spite of the numerous biases connected at the same time to the degrees of preservation of archaeological sites, to the diversity of the techniques of excavation, to the existence of specialists capable of taking into account artefacts we shall try to know what hides behind the variability of the diversity of the faunal remains exploited by coastal Mesolithic people.

ORAL

#### 10. EL COLLADO SHELL MIDDEN AND THE EXPLOITATION PATTERNS OF LITTORAL RESOURCES DURING THE MESOLITHIC IN EASTERN IBERIAN PENINSULA

*Fernández-López de Pablo, Javier (Institut Català de Paleocologia Humana i Evolució Social (IPHES) jfernandez@iphes.cat  
Gabriel, Sonia (Laboratório de Arqueociências, Direcção Geral de Património Cultural (Lisbon, Portugal) gabriel.sonia@gmail.com*

The 1980s excavations by J. Aparicio in the El Collado, a large open air Mesolithic site on the coast of Eastern Spain, revealed a sequence of human occupations consisting on a large shell midden and 14 human burials dated during the Mesolithic period.

Human palaeodietary reconstructions based on bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  isotope ratios, identified a variable contribution of marine proteins, ranging from fully terrestrial diets to a maximum input of 25% (García-Guixé et al., 2006). Most subsequent research on Mediterranean coastal and dietary adaptations refers to the site's funerary record and palaeodietary study, but the composition and chronology of its shell midden has remained unstudied. This work reports the first series of AMS radiocarbon dates on the shell midden stratigraphy along the

systematic taphonomic study, taxonomic identification and quantification and morphometric analyses of shellfish and fish bone assemblages.

Results indicate mixed marine-terrestrial molluscs composition of the shell midden. The edible land snail *Sphincterochila candidissima* and the marine bivalve *Cerastoderma glaucum* are the best represented species throughout the archaeological sequence. The pattern of intertidal resource exploitation is clearly dominated by coastal lagoon as well as inhabiting mud and sand flats bivalves (*C. glaucum*, *Glycymeris violacescens*, *Ruditapes decussatus*) and gastropods (*Cerithium vulgatum*, *Hexaplex trunculus*). The presence of rocky shore intertidal species is minimal, mostly related with the manufacture of *Columbella rustica* pierced shell ornaments. On the other hand, fish bone assemblages are overwhelmingly dominated by the gilthead sea bream (*Sparus aurata*) which often occurs in brackish water coastal lagoons.

ORAL

#### 11. SHELLFISH PROCUREMENT PATTERNS AND ENVIRONMENTAL CONDITIONS DERIVED FROM OXYGEN STABLE ISOTOPES ON PHORCUS LINEATUS FROM THE MESOLITHIC SHELL MIDDEN SITE OF EL MAZO (ASTURIAS, NORTHERN SPAIN).

*Gutiérrez-Zugasti, Igor (IIIPC-Universidad de Cantabria) igorgutierrez.zugasti@gmail.com*

*García-Escárzaga, Asier (IIIPC-Universidad de Cantabria) asierge@hotmail.com*

*Martín-Chivelet, Javier (Universidad Complutense de Madrid) martinch@uclm.es*

*González Morales, Manuel R. (IIIPC-Universidad de Cantabria) moralesm@unican.es*

One of the main features of the Mesolithic on the Atlantic facade is the significant procurement of coastal resources. Among these, intertidal resources played an important role in the last hunter-fisher-gatherer societies as it is showed by the formation of huge middens containing large amounts of molluscs, echinoderms and crustaceans. A crucial issue for the interpretation of these deposits is to determine the chronological significance of foraging, as it can provide important information on subsistence strategies and settlement patterns. Previous research on mollusc carbonate shells has shown that oxygen isotope ratios ( $\delta^{18}\text{O}$ ) are mainly dependent on

sea surface temperature (SST), allowing the determination of past environmental conditions and the season of capture of the shells. However, calibration of the past isotopic data and its variability must be performed through the study of modern samples.

The topshell *Phorcus lineatus* daCosta, 1778 is one of the most abundant species in Mesolithic shell middens in northern Spain. Oxygen isotope ratios were analyzed on carbonate samples from modern *P. lineatus* shells collected fortnightly at Langre beach and also on water samples collected with the same periodicity and at the same location. Then, sequential samples from archaeological shells were analyzed to determine environmental conditions and the seasonal patterns of resource procurement at the initial occupations (c. 9 ka) of El Mazo shell midden site (Asturias, northern Spain).

Results showed a high correlation between  $\delta^{18}\text{O}$  values from modern shells and instrumental data on sea surface temperatures. The analysis of growth patterns also showed minimum growth cessation through the year. Data on  $\delta^{18}\text{O}$  from water samples helped to corroborate that the shells grew in fully marine conditions, with no significant influence of freshwater. Archaeological samples exhibited a seasonal pattern of exploitation with collection focused in late autumn and winter, while sea surface temperatures inferred from  $\delta^{18}\text{O}$  values were found to be similar to today.

Oxygen isotope ratios showed that *P. lineatus* provide accurate data on past sea surface temperatures in northern Spain and also on the season of capture of the shells. Collection of *P. lineatus* at El Mazo shell midden site was carried out seasonally (late autumn and winter), in agreement with data from previous research in the area but in contrast with seasonal information coming from studies on *Patella* at other Mesolithic sites, which showed collection throughout the year. Sea surface temperatures derived from isotopic data and information from other palaeoenvironmental proxies revealed that early Holocene environmental conditions at the region were similar to current conditions.

ORAL

## 12. EARLY-MIDDLE HOLOCENE COASTAL EXPLOITATION IN CENTRAL MEDITERRANEAN: A NEW INSIGHT FROM GROTTA D'ORIENTE AND CALA MANCINA

*Colonese, Andre (BioArCh, Department of Archaeology, University of York (UK) andre@palaeo.eu*

*Landini, Walter (Dipartimento di Scienze della Terra, Università di Pisa (Italy) landini@dst.unipi.it*

*Lo Vetto, Domenico (Dipartimento di Storia, Archeologia, Geografia, Arte e Spettacolo, Università degli Studi di Firenze (Italy) domenico.lovetto@unifi.it.*

*Martini, Fabio (Dipartimento di Storia, Archeologia, Geografia, Arte e Spettacolo, Università degli Studi di Firenze (Italy) fabio.martini@unifi.it*

The Mediterranean Sea has one of the most nutrient-poor surface waters in the world, which is thought to have imposed ecological limits to the exploitation of marine organisms by hunter-gatherers. Recent archaeological excavations at Grotta d'Oriente (Favignana Island, Trapani) and Cala Mancina (San Vito lo Capo, Trapani) have provided new archaeozoological evidence of fishing and shellfish harvesting during the Mesolithic, offering a novel insight into the role of marine resources to human groups in central Mediterranean at the beginning of the Holocene.

We performed archaeozoological and morphometric analysis on intertidal faunal remains (mollusc, fish) from Mesolithic deposits of Grotta d'Oriente (Favignana Island, Trapani) and Cala Mancina (San Vito lo Capo, Trapani). Results were compared with available data from other coastal sites in Sicily and Southern Italy

Results indicate that at both Grotta d'Oriente and Cala Mancina Mesolithic peoples exploited prevalent species inhabiting the intertidal rocky shore. Species inhabiting mud and sandflats as well as coastal lagoons and large shallow inlets and bays (*Cerithium vulgatum*, *Bittium* cf. *reticulatum*, *Potamides conicus*, *Truncatella subcylindrica*) were also found at Grotta d'Oriente. Some of these species (*Bittium* cf. *reticulatum*, *Potamides conicus*) had their shells fragmented or eroded, suggesting that they may have been transported to the deposit accidentally. Mesolithic coastal exploitation at Grotta d'Oriente and Cala Mancina appears to have been influenced by rising sea levels between ~10 and ~7 cal ka BP.

ORAL

In this paper we present the preliminary results obtained from the study of the bivalves recovered during the archaeological excavations in Vestíbulo chamber of Nerja Cave (Málaga, South of Spain) made by Professor Francisco Jordá Cerdá between 1983 and 1987, excluding the materials already published of the C-4 test unit, which were studied using a different methodology. These excavations recovered the archaeological record of the sequence from the Gravettian to the Neolithic. The molluscs remains of the Vestíbulo of Nerja Cave record constitute an extraordinary collection, composed of more than 136.000 specimens that corresponding to more than 78 kg weight. In this work we only study the marine bivalves (Jordá et al. 2010).

The studied material was recovered directly during the excavation and from screened sediments. To identify the molluscs to species, as well as for information on habitat and distribution, we consulted a variety of bibliographic references on both marine molluscs and continental ones. We followed also the online systems such as the Check List of European Marine Mollusca (CLEMAM), NatureServe, Hardy's Internet Guide to Marine Gastropods and Fauna Ibérica. All the data were recorded in a database containing the following fields: location data, list of taxa recognized in every excavation unit, recognized elements of every taxon and ecological characteristics of

every taxon. The malacological collection of Vestíbulo is placed in the Provincial Museum of Malaga.

The bivalve remains of the Vestíbulo of Nerja Cave are more than 124.000 specimens that corresponding to more than 65 kg weight. More than 115.000 of these specimens (59 kg) derived from the Epimagdalenian shell midden (Jordá et al. 2011). 36 taxa of bivalve were identified which can be highlighted *Glycymeris glycymeris*, *Mitylus edulis*, *Lithophaga lithophaga*, *Modiolus adriaticus*, *M. barbatus*, *Chlamys varia*, *Pecten maximus*, *P. jacobus*, *Spondylus* sp., *Ostrea edulis*, *Bornia sebetia*, *Acanthocardia tuberculata*, *Cerastoderma edule*, *C. glaucum*, *Laevicardium norvegicum*, *Cardidae* indet., *Macra stultorum*, *Solen marginatus*, *Venus verrucosa* and *Tapes decussatus*.

The archaeological record of Nerja Cave is distinguished by the abundant presence of human gathered marine and continental molluscs with a high presence of bivalves. Marine bivalves were consumed from Solutrean and Magdalenian-Epimagdalenian through Mesolithic and Ancient Neolithic, with development during the Younger Dryas of an important shell midden. Besides, some taxa were introduced in the cave accidentally.

**14. SIEVING AND SORTING: HOW POST-EXCAVATION STRATEGIES CAN INFLUENCE RESULTS.**

*Juanola, Laura (Universitat Autònoma de Barcelona) laura\_333333@hotmail.com*

*Franch, Anna (Universitat Autònoma de Barcelona) Anna.FranchB@e-campus.uab.cat*

*Hardy, Karen (ICREA at Universitat Autònoma de Barcelona) khardy@icrea.cat*

Post-excavation can be considered as the poor relation of archaeological work. Repetitive, slow and often dull, it is arguably at its most challenging when it involves shell middens. Here, after wet sieving, everything needs to be sifted out from the predominant background of minute fragments of broken shell which normally represent over 99% of all remaining material.

During the course of post-excavation of material from two multi-period shell middens from the Isle of Skye, Scotland, a range of different sieve sizes and long-term sorting strategies, were used to compare retrieval of minute material, principally, very small fish bone.

Here, we highlight the methods used, and the results of the relative proportions and types of material recovered, as well as the difference outlooks for the future understanding of food procurement strategies at these sites, in the different time periods.

There was significant diversity in the quantity of small material recovered.

**15. MAARITIME: AMINO ACID RACEMISATION DATING OF THE MEDITERRANEAN RIM**

*Demarchi, Beatrice (University of York) [beatrice@palaeo.eu](mailto:beatrice@palaeo.eu)  
Penkman, Kirsty (University of York) [kirsty.penkman@york.ac.uk](mailto:kirsty.penkman@york.ac.uk)*

Amino acid racemisation (AAR) geochronology is one of the few techniques which combine great temporal depth with the ability to directly date archaeological shell remains. As these represent the direct evidence of activities carried out by humans in the past (e.g. the early exploitation of marine resources), establishing an accurate geochronology for archaeological molluscs and other biominerals is an important step for our understanding of human evolution.

Here we present results from the project mAARiTIME, which focuses on key Mediterranean sites spanning the last 100 ka and beyond. By applying a closed-system method of AAR dating, we are building stratigraphic frameworks, which combined with new independent geochronology aim to provide reliable dating control for the Mediterranean. Closed-system tests are performed to assess the suitability of different marine taxa, and then the AAR data from sub-fossil shells used to build pilot chronological frameworks for southern Europe and northern Africa.

**1. A NOTE ON THE TECHNOLOGICAL STRATEGIES OF BLANK PRODUCTION ADOPTED BY THE MIDDLE PLEISTOCENE HOMINIDS OF CHAMBAL BASIN, INDIA**

*Abbas, Riza (Indian Rock Art Research Centre) rizaabbas@yahoo.co.in*

Based on large cutting tool (LCT) technology of Early Acheulian, new ingenious techniques of predetermined blank production such as Levallois and Kombewa method was introduced and perfected during the Late Acheulian period. These technological shifts were acquired globally and possibly points towards changes in behavioral and cognitive patterns of Hominids. In India, such technological changes and strategies have been noticed in number of Middle Pleistocene assemblages. Recently, various Late Acheulian assemblages of the Chambal basin have given evidences of use multiple blank production strategies such as Levallois, Kombewa and incipient blade technology by the Middle Pleistocene hominids of the Basin

**2. FORMATION PROCESSES AT THE ACHEULEAN SITE OF LALITPUR, NORTH CENTRAL INDIA**

*Agarwal, Neetu (Universitat Rovira i Virgili, Tarragona, Spain) neetu1501@gmail.com*  
*Mishra, Sheila (Deccan College Postgraduate & Research Institute, Pune) sheila.mishra@gmail.com*

Lalitpur is an important Acheulean site in the Bundelkhand Gneissic Complex on the margins of the Peninsular craton and the Gangetic alluvial plains discovered and excavated in the late 1950s and early 1960s (Singh 1965, IAR 1961-62, 1962-63).

During recent restudy of the site it was realized that an understanding of the formation processes is critical to enable interpretations of hominin behavior particularly for surface and near surface sites belonging to Lower to Middle Pleistocene. Therefore, geoarchaeological investigations were undertaken in the region around the Acheulean site of Lalitpur to understand the geomorphic processes shaping the past landscape. Sedimentological nature of the deposits, site stratigraphy, coarse clast

analysis and taphonomic condition of the artefacts was used to assess the depositional and post-depositional history of the site and understand the context of occurrence. GIS was also used as a tool to understand the fluvial dynamics and geotectonic context.

The work has helped to establish that it is not a surface site, but that the artefacts are only recently getting eroded from a previously buried context. Moreover, the site has not been subject to any fluvial dynamics. The major processes active at the site are low energy erosional processes like weathering and small scale slope processes like surface wash, thereby establishing good context and integrity of the assemblage. Artefact taphonomy also rules out long term exposure and repeated or multiple occupation. This work highlights the importance of studying formation processes and it also suggests that 'surface sites' can be quite informative and should not be ignored.

ORAL

**3. THE ACHEULEAN IN THE UPPER JIRA RIVER, WESTERN ODISHA, INDIA.**

*Behera, Pradeep (Sambalpur University) pkbehra@rediffmail.com*  
*Behera, Neena (Sambalpur University) neenat1@gmail.com*

The Acheulean, characterised by the appearance of *Homo erectus* with increased cognitive and adaptive abilities, standardized tool-making by employing large-flake blanks and first migration of human population out of Africa, is often regarded as representing technological stasis and homogeneity over a huge geographical domain spreading across Africa and Eurasia. It also represents the longest lasting (~1.7 Ma – 250 K) cultural phase in human history. Cultural remains of this phase are fairly widespread in South Asia and have been reported from diverse physiographic regions. Our understanding of various aspects of this cultural stage has greatly expanded during the last twenty years. Not only several new sites in primary/semi-primary contexts have been brought to light and excavated, but research problems have shifted and the quality of information gathered has also improved. Recent dates obtained from the Acheulean levels at Attirampakkam by palaeomagnetic measurements and cosmogenic nuclide dating methods have pushed back the antiquity of this cultural stage in India to about 1.5 Ma. Although Acheulean artefacts have been reported from a large number of localities in the state of Odisha since the forties of the last century, majority of these are from

secondary contexts. Our recent investigations in the upper course of the river Jira, a tributary of the river Mahanadi, in the district Baragarh, western Odisha, have brought to light a number of localities bearing Acheulean artefacts in semi-primary/primary contexts, away from fluvial network. The assemblages recovered from this region include varying proportion of handaxes, cleavers, cores, spheroids, polyhedrons and a variety of tools made on flakes. While a couple of sites bear unmistakable evidence for quarry activities and production of large-flake blanks, at most of the localities large-flake blanks and/or semi-finished as well as finished bifaces were procured from the nearby raw material sources for use. Trial pits taken at one of the localities revealed sub-angular/sub-rounded pebbly-cobbly gravel in a lateritic matrix as the sedimentary context of the surface Acheulean assemblages. Technomorphologically, most of these assemblages exhibit Late Acheulean character, while presence of an earlier phase cannot be ruled out. The present paper is an attempt to highlight the results of our recent investigations in the upper Jira river valley of Odisha.

#### ORAL

#### 4. MIDDLE PLEISTOCENE ACHEULEAN IN THE GUADALQUIVIR RIVER: ARCHAEOLOGICAL SITES WITH ABSOLUTE CHRONOLOGY BETWEEN 400-100 KY BP

*Caro Gómez, José Antonio (Universidad de Córdoba) jacaro@uco.es*

*Díaz del Olmo, Fernando (Universidad de Sevilla) delolmo@us.es*

*Borja Barrera, César (Universidad de Sevilla) cesarborja@us.es*

*Recio Espejo, José Manuel (Universidad de Córdoba) bv1reesj@uco.es*

The Low Guadalquivir sequence, with a wide chronological development (>1,5 My), has a system of 14 alluvial terrace levels (from T1 at +210-200 m. to T14 +8-6 m.).

From T5 (+139-130 m.) to T13 (+14-13 m.) there are Palaeolithic records, that is, from the early Middle Pleistocene to Upper Pleistocene.

The aim of this paper is to analyze the called "Regional Full Acheulean" from the archaeological sites in Guadalquivir River's alluvial terrace levels which have absolute dating: T9 (+75-73 m.), T10 (+55-45 m.), T11 (+40-35 m.) and T12 (+29-26 m.).

It is used a geoarchaeological methodology carrying out the following techniques: prospection and archaeological excavation, geomorphological, sedimentological, stratigraphical and technotopological for lithic industries. From the point of view of the geochronological analysis they have been applied two dating of sediments techniques: Optically Stimulated Luminescence (OSL) to a polymineral of fine-grained (2-10 microns) and U/Th to carbonated facies ( $^{234}\text{U}/^{238}\text{U}$  according to the isotopic rapport  $^{230}\text{Th}/^{234}\text{U}$  age dating).

The Acheulean sequence of the Guadalquivir River is defined by the introduction of the earlier macrolithic elements in high terraces complex (T6 to T9). where will be configured the technological model of industrial series. In the final (T-9) sequence it is taken place a technological change with the increase and a better technical making of macrolithic set, as well as a shy standardization of tools on flake. In the archaeological site of Graneros (T9) it is obtained a chronology of >350 ky (U/Th) for the older sediments (carbonated) and 224 ky and 126 ky (OSL) for sandy channel bars, in their higher levels.

On T10 and T11 levels the "Regional Full Acheulean" culminates, being an increase of handaxes index and a diversity of lithic types. In Tarazona III (T11) archaeological site it is found a chronology from 138-104 ky (OSL) with Acheulean industries at the bottom levels and Middle Palaeolithic ones on the top. On T12 lowest levels the Acheulean series show rounded pieces, although in the highest, they are without rounded and even with more evolutionary characteristics. The stratigraphical sandy profile of Algabarrilla (T12) archaeological site provides a chronology between 206 ky and 170 ky (OSL).

According to technological and geochronological aspects, the Palaeolithic evolutionary process in the Guadalquivir River is defined by:

- 1) From T5, undefined industries
- 2) An homogeneous technological complex of Acheulean character in highest alluvial terraces (T6 to T9), chronologically before to 300 ky, which will keep a constant basic features (T9 to T11) (Full Acheulean), gradually varying in the time.
- 3) At the end of Middle Pleistocene (under 120 ky) turned up into lately lithic sets called "Transitional Final Acheulean" and Middle Palaeolithic technocomplexes.

**5. GEOMORPHOLOGICAL INVESTIGATIONS OF DENSE CLUSTERS OF ACHEULIAN ARTEFACTS AT TIKODA, DISTRICT NARWAR, MADHYA PRADESH, INDIA**

*Deo, Sushama (Department Of Archaeology, Deccan College, Pune) sushamadeo@yahoo.co.in*  
*Ota, Simadri (Archaeological Survey Of India, Bhopal) simadriota@gmail.com*

Raisen hill complex is reported to be one of the richest concentration of Acheulian artefacts (Jacobson 1975) and described as surface sites. On the contrary our recent investigations of the Acheulian localities near Tikoda village confirm that Acheulian artefacts are eroding out of more than 10 meter thick sedimentary context. Large numbers of Acheulian artefacts were found in clusters within a 2 sq km area forming a definite geographical unit.

Geologically, the area is covered by Protorozoic Vindhyan sandstone and Cretaceous-Eocene Deccan Trap rocks. Geomorphologically, the Narwar hill complex forms a water divide between two major river systems the Betwa (a tributary of the Chambal river that joins the river Yamuna) to the north and the Narmada to the south. The 'V' shaped valley is a distinctive feature of the study area. It is enclosed by low-lying Narwar-Tikoda ridge on one side; the other side opens into a broad river valley. The 'V' shaped valley floor has preserved a thick sedimentary deposit and gives appearance of badland topography. The average elevation of this valley floor ranges from 465 to 440 m ASL. Seasonal streamlets drain the valley and erode the thick sediments.

Our detailed field investigation has shown following salient features:

Regolith consists of ferricretes, Vertisols, locally derived ferruginous gravel, silty-sandy loess-like sediments.

The area is characterized by locally developed landscape on pediment surface with depressions.

These depressions are filled with fluvio-lacustral and fluvial deposit.

On the whole there is no major break in deposition as indicated by absence of distinct fossil soils.

Low energy river system prevailed during the Acheulian times.

ORAL

**6. ADAPTATION, DETERMINISM, INNOVATION, DIFFUSION, CONVERGENCE? ACHEULIAN VARIABILITY AND MINERAL ENVIRONMENT**

*Gaillard, Claire (Muséum national d'Histoire naturelle, UMR 7194, Paris) gaillacl@mnhn.fr*  
*Agarwal, Neetu (University Rovira i Virgili, Tarragona) neetu1501@gmail.com*  
*Mishra, Sheila (Deccan College, Pune) sheila.m, ishraq@gmail.com*

The link between raw material and shape of the Acheulian bifacial tools has been abundantly discussed. In the western Europe morphological variations of the large cutting tools (LCTs) have been related either to raw material, to resharpening / reshaping or to cultural constraints. Besides, the production of large flake in many of the African and Asian Acheulian sites has been shown not to depend on the nature and shape of the raw material. However the shape of handaxes is used to propose models of cultural diffusion and human population dispersal.

Comparison of assemblages from different geological frameworks, focussing on those where LCTs are rather simply shaped and apparently not much resharpened nor reshaped, will help assessing the variability of Acheulian assemblages, up to East Asia, in relation to their mineral context.

Away from the Cretaceous and Paleogene basins of western Europe, where flint is necessarily preferred, the variety of knappable rocks offers a large range of possibilities. The selection of a particular rock type depends on its quality, shape, accessibility, etc. but it is also contingent upon the knapper's requirement, energy, mental template, technical habits and possible social constraints.

In Asia and Africa most of the knappable rocks available to the Acheulian craftsmen are to be cut from outcrops or collected from screes in the form of slabs or chunks or from rivers as cobbles and pebbles. Right from the first evidence of stone tool manufacture it is clear that the raw material is carefully selected. This improves in the Acheulian when compared to the Oldowan as it is admitted that transportation of raw materials as well as finished tools increases.

Depending on the investment in shaping the bifacial tools, the mode of blank procurement and the

selection of particular forms will influence the final tool morphology to various degrees. The balance between "large flake based" and nodule based tools in relation to the available raw material allows assessing the weight of the tradition versus that of adaptation to the mineral environment.

The technical behaviour answers to survival need according to cultural traditions and raw material contingences. The latter imply adaptation and reactivity in case of change and the former require stability for the consistency of human groups. To understand this behaviour, its evolution and its implication for Acheulian populations demands to consider at least the mineral environment together with the finished products.

ORAL

## 7. DISCOID TECHNOLOGY: A KEY TO TRACE THE EMERGENCE OF THE ACHEULEAN AT MELKA KUNTURE (UPPER AWASH, ETHIOPIA)

*Gallotti, Rosalia (Université Bordeaux 1, UMR 5199 PACEA-PPP) rosaliagallotti@yahoo.it*

*Mussi, Margherita (Università di Roma Sapienza - Dipartimento di Scienze dell'Antichità) margherita.mussi@uniroma1.it*

In 1971, Mary Leakey established at Olduvai the distinctive characters of the Oldowan and Acheulean industries, introducing the terminology and descriptive criteria needed to define them. Following the methodological approach developed in Europe by F. Bordes, she used a typological classification of lithic assemblages. Notably, she defined "discoids" as bifacially flaked tools with a working edge along the whole circumference. Over more than 30 years, Leakey's typological definition was retained as the reference one when dealing with the earliest archaeological record of East Africa.

Since 1971, however, after that discoid technology was recognized in late Pliocene/Lower Pleistocene complexes, Leakey's "discoids" were silently moved into the category of cores. Notwithstanding much attention devoted in recent years to the technical criteria employed in small débitage in East African complexes, descriptions of discoid flaking procedure(s) generally lack in technical definition. Furthermore, the technological analysis does not take into account the theoretical discussion and analytical details developed in the last 20 years in the study of European Middle Paleolithic assemblages.

The aim of this paper is to present a systematic techno-economic account of the discoid débitage in the Lower and Middle Pleistocene industries (1.7-1.0 Ma) of the Melka Kunture region. This includes a systematic survey of raw material composition in the (paleo)channel system, to define volcanic facies, size and shape of the original matrixes in coarse alluviums.

Our analysis shows that 1) since 1.5 Ma discoid technology was used in the Ethiopian highlands both for small-medium flake production and for the extraction of large flakes to be turned into large cutting tools (LCTs); 2) in older sites the centripetal exploitation does not document a full management of the débitage convexities and of the core volume, but aims at the proper solution in the exploitation of (sub)spherical cobbles; 3) the knappers were able both to transform the original matrix shape and to select morphologically ideal cobbles in order to apply criteria required by discoid débitage; 4) discoid small débitage is based on reduction sequences longer than those documented for other methods; 5) discoid débitage coexists with unifacial centripetal prepared exploitation (UCPE), both in small débitage and in LCT chaînes opératoires. UCPE bears some of the technical criteria successively developed by the Levallois technology, suggesting that the co-existence of discoid and Levallois technologies in more recent contexts could come from these Lower Pleistocene assemblages; 6) discoid small débitage becomes dominant in the middle Acheulean and is replaced by Kombewa method for LCT production.

These technical behaviours are shared by other penecontemporaneous East African assemblages, with our without LCTs. This common background is relevant in cultural terms and notably provides a key to trace the emergence of the Acheulean in East Africa.

## 8. AN ACHEULEAN LANDSCAPE IN THE ARABIAN DESERT

*Groucutt, Huw (University of Oxford) huw.groucutt@rlaha.ox.ac.uk*

*Shipton, Ceri (University of Queensland) c.shipton@uq.edu.au*

*Jennings, Richard (University of Oxford) richard.jennings@rlaha.ox.ac.uk*

*Petraglia, Michael (University of Oxford) michael.petraglia@rlaha.ox.ac.uk*

The Lower Palaeolithic record of Arabia is poorly known, but available insights hint at its importance for understanding hominin behaviour and dispersals.

Our recent survey in the Dawadmi area of central Saudi Arabia has revealed a rich Lower Palaeolithic record, with sites distributed across a large area. In part of the area we surveyed there is an extensive landscape of Acheulean localities. This landscape is stable with very little sediment aggradation, slope movement, or channel migration. Acheulean artefacts are thus in primary contexts allowing for reconstructions of landscape-use. Systematic surveys over an 8 x 5 km area around the site of 206-76 were undertaken in January and February 2014.

Three main locality types were identified: workshop sites at the base of andesite dykes; off-sites where individual isolated artefacts occurred across the landscape; and sites alongside fluvial channels (wadis), to which artefacts were imported. Analysis of artefact typology indicates that bifaces were preferentially transported away from workshop sites and discarded either at off-sites or wadi sites. Excavation at the site of 206-76 revealed a ~2m deep Acheulean sequence with an occupation floor at the base. This demonstrates the potential for stratified Lower Palaeolithic sites in Arabia. Technological analysis of the Dawadmi material indicates a preference for the use of the bifacial concept in all aspects of lithic reduction and tool production.

Our findings demonstrate the major potential of the Arabian archaeological record to cast light on the Lower Palaeolithic in various ways, including the landscape and excavated site contexts described in this paper.

ORAL

## 9. EAST ASIAN ACHEULEAN: TOWARD A SYNTHESIS OF ITS ATTRIBUTE AND EMERGENCE

*Hao Li (University of the Witwatersrand) wits\_ivpp@hotmail.com*

*Kuman, Kathleen (University of the Witwatersrand) Kathleen.Kuman@wits.ac.za*

The presence of Acheulean tool types (e.g. handaxes, cleavers) in East Asia has recently attracted considerable attention. They challenge the long lasting concept that the Early Palaeolithic in East Asia is characterized only by Mode 1 technology, and they reflect the diversity and complexity of Palaeolithic culture in this stage.

However, there is no consensus on how to explain this technological phenomenon. Do they represent a true Acheulean technology in East Asia, or are they merely Acheulean-like? Did they arise from indigenous development of Mode 1 types or did they result from the migration of new cultural groups into East Asia? Owing to the extensive variability observed in the Western Acheulean, the authors consider that the emergence of an East Asian Acheulean and its attributes should be multifactorial and complex, and it requires an in-depth understanding of the interrelated aspects and feedback loops during the process.

We propose a synthetically hypothetical framework to answer questions of East Asian Acheulean. This refers to a detailed study of the technological, behavioral, cognitive, biological, palaeoecological, chronological, etc. evidence available for the East Asian LCT sites. In addition, a scientific-realistic logic will be used in the study to verify or reject the hypotheses proposed earlier. For better demonstrating the approach, we will present a case study of LCT sites in Danjiangkou Reservoir Region (central China), which is not yet well known to Western scholars.

The research into LCT sites in Danjiangkou Reservoir Region would in fact support the existence of the true Acheulean techno-complex in East Asia, which explicitly shows the diversity and complexity of the Early Palaeolithic in this vast region. However, because of the relatively limited materials available, the authors suggest that it is still premature to decide on the original mechanism of East Asian Acheulean.

The synthetical hypothetical framework constructed here is a system-based solution that tries to present the most holistic view (combining technology, behavior, cognition, ecology, biology, chronology, etc.) to answer the emergence of East Asian Acheulean and its attributes.

ORAL

## 10. EXPERIMENTAL STUDIES IN REPLICATING EARLY PLEISTOCENE ACHEULIAN TECHNOLOGY AT ATTIRAMPAKKAM, INDIA

*Kumar, Akhilesh (Sharma Centre for Heritage Education) akhilarchaeo@gmail.com*

*Pappu, Shanti (Sharma Centre for Heritage Education and Deccan College) pappu.shanti@gmail.com*

Excavations at the site of Attirampakkam, along the southeast coast of India, resulted in estimating the

chronology of Acheulian assemblages (Layers 6 to 8) to range in age from >1.07 Ma to around 1.8 Ma (weighted mean age estimate at around  $1.51 \pm 0.07$  Ma). Here, we examine the Early Pleistocene Acheulian *chaîne opératoire* at this site, based on both analysis of the assemblage as also experimental knapping. Experimental studies were initiated using quartzites, in order to investigate diverse technological strategies used in the manufacture of bifaces and other large and small tools. We discuss here, results of these studies in terms of: a) diversity of core reduction strategies; b) techniques used in the manufacture of handaxes and cleavers; c) issues related to retouch and resharpening of tools; d) nature of the waste products produced. We situate results in the context of analysis of the Early Pleistocene Acheulian assemblage from various trenches excavated at the site. We discuss implications in terms of hominin cognition and behaviour. Finally, we situate results in the light of studies conducted by us elsewhere in the Kortallaiyar and Arani river basins in this region, and from published literature.

ORAL

## 11. THE ACHEULIAN IN THE INDIAN SUBCONTINENT: REMOVING MISUNDERSTANDINGS ROOTED IN THE MOVIUS LINE PARADIGM

*Mishra, Sheila (Deccan College) sheila.mishra@gmail.com*

The Indian Acheulian played an important role in the Movius Line paradigm of two contemporary Lower Palaeolithic cultures, representing separate evolutionary trajectories in the Lower Pleistocene (Movius, 1948). This paradigm has long been superseded in Africa and Europe but still plays an important role in sidelining the Asian Palaeolithic record, including the Indian subcontinent, from any important role in human evolutionary developments. In this presentation continuing misunderstandings of the Indian Palaeolithic record rooted in the outdated Movius line paradigm are outlined and the role of the Indian Subcontinent in crucial developments in hominin evolution suggested. The major new findings are:--

The Indian representative of the Chopper-chopping tool tradition, the Soanian, actually dates to the Late Pleistocene and does not belong to the Lower Palaeolithic at all. It is more closely related to similar late Pleistocene "pebble tool" assemblages of SE Asia. It is contemporary to the Indian microblade technology and not the Indian Acheulian

Acheulian artefacts found in over a dozen localities in areas where Late Siwalik sediments outcrop in India, Nepal and Pakistan, most probably derive from them therefore belong to the Lower Pleistocene

Artefacts from the Indonesian site of Ngebung can be attributed to the Acheulian and *Homo erectus* in Java most probably had Acheulian technology

The only Lower Palaeolithic stone tool technology in the Indian Subcontinent and adjacent Sundaland was Acheulian

The Indian Acheulian is comparable in age to the African Acheulian

ORAL

## 12. EVOLUTION AND CULTURAL IMPLICATIONS OF ACHEULEAN FLAKE CLEAVERS

*Mourre, Vincent (Inrap, UMR 5608) vincent.mourre@inrap.fr*

Flake cleavers are massive stone tools made from large flakes and characterized by wide and unretouched cutting-edges. The cutting-edges result frequently from the intersection of the flakes lower surface and one or more previous flake negatives but sometimes the upper surface of the cutting-edge can be natural. Flake cleavers were recognized since the end of the 19<sup>th</sup> century as typically Acheulean tools. Cleavers were identified in 1928 by M.C. Burkitt in Southern Africa a few years after their European counterpart were named "*hachereaux*" by H. Breuil. In 1956, thanks to the study of more than 600 North African flake cleavers, J. Tixier proposed an analysis and a typology which remain valid until today.

This contribution will expose the results of a systematic technological analysis of flake cleavers series from Sub-Saharan Africa, North Africa and southern Europe. This study and an overview of the related literature demonstrate that environmental constraints are insufficient to explain the realization of flake cleavers during Acheulean times and that cultural factors are therefore involved. Flake cleavers analysis also highlights the evolution of predetermination within the Lower and Middle Pleistocene industries and thus enhances the definition of Acheulean itself.

ORAL

**13. IN SMALL THINGS REMEMBERED: ACHEULIAN SMALL TOOL ASSEMBLAGES AT SHISHAN MARSH (JORDAN)**

*Nowell, April (University of Victoria) anowell@uvic.ca*  
*Stueber, Daniel (University of Victoria) dstuber@aol.com*  
*Ames, Christopher (UC Berkeley) cjhames@google.com*  
*Cordova, Carlos (Oklahoma State University) carlos.cordova@okstate.edu*  
*Pokines, James (Boston University) jamespokines@gmail.com*

In his classic book *In Small Things Forgotten*, American archaeologist James Deetz reminds us that the past can be understood most fully by studying the small things so often forgotten or overlooked by archaeologists. While Deetz was referring to the historic past, his observations are equally applicable to prehistory in general and the Acheulian, in particular. Over the past century, prehistorians studying Acheulian assemblages have focused their energies largely on the now iconic handaxe arguing that its highly recognizable, symmetrical, tear drop shape can be a window onto the origins and evolution of modern cognition, sociality, language, teaching, skill acquisition, and even symbolic behavior. This focus on the handaxe, and by extension big game hunting, has been at the expense of Acheulian small tool and microlithic assemblages and their associated tasks. These assemblages, comprised of utilized flakes, tools and cores less than 2-3 cm in length, are known from sites in many parts of the world including Poland, Germany, Hungary, Israel, the Czech Republic, Slovakia, China, East and South Africa and now Jordan. A comprehensive study of the assemblages may challenge our definitions of what constitutes the "Acheulian" and alter our understanding of Lower Paleolithic subsistence practices, craft production and technical knowledge. In this paper, we present a detailed study of the small tool and microlithic assemblages from the Shishan Marsh site, a newly excavated Acheulian paleomarch site in Azraq, northeast Jordan and explore the role these assemblages played in hominin survival in a shifting paleodesert environment.

**14. ACHEULIAN CULTURE OF JONK RIVER BASIN, IN HIGHLAND OF ODISHA AND CHHATTISGARH**

*Padhan, Tosabanta (Deccan College Post Graduate & Research Institute, Pune, India) tpadhan@gmail.com*

The research was carried out in the Jonk river basin, one of the major tributaries of the upper Mahanadi in the western highland of Odisha and eastern Chhattisgarh of India. Field investigations over five seasons (2007-2012) resulted discovery of 15 Acheulian sites in different geological context. The stone tool assemblages from all the sites have been studied in detail including their dimensions and technological attributes. Besides this attempt also been made for the reconstruction of lithic reduction sequence, raw material procurement strategy and settlement pattern and site formation processes. The Acheulian tools types in Jonk comprise of handaxes, cleavers, scrapers, cores, giant cores, polyhedrons, pointed flakes, irregularly flaked pebbles, and a variety of hammer stones. The distribution of Acheulian sites in the region illustrates colonisations of upland area and most of the sites were found on the foothills and few are found close to river bank. Uses of five different kinds of locally available raw materials have been observed for the manufacturing Acheulian tools in the study area. This study has helped to understand the regional archaeological structures, prehistoric strategies and their adaptation to the local Quaternary landscapes after observing the different types of lithic assemblages and associated sedimentary contexts.

**15. THE ACHEULIAN AND BEGINNINGS OF HUMAN CULTURIFICATION**

*Paddayya, Katragadda (Deccan College, Pune) k.paddayya@gmail.com*

Tylorian definition of culture encompasses the whole range of products, tangible or otherwise, emanating from man's mental and corporeal activity.. This paper pleads that we need to rise above the oft-repeated definition of the Acheulian as a mere technological tradition. Surely, the use of natural flakes with sharp edges and then purposely knocking of such flakes from raw blocks of stone was a major departure, and archaeologists are yet to track down the record of this stage. Sooner or later, flaking a part of the periphery of rounded or angular blocks from one or both sides came up, leading to production of half-tools we commonly call choppers. But it is in the Acheulian that true culturification of natural objects takes place, and bifaces comprising both handaxes and cleavers have now moved from the fold of nature into the realm of culture. Their manufacturing processes and shapes are now firmly entrapped in human minds,

as suggested by the phrase mental templates.. As pointed out by the anthropologist Thomas Wynn, this has been facilitated by the emergence of Piagetian cognitive operations like symmetry of space, reversibility, whole-part relations, etc. Humankind indeed set itself on the path of creating artifacts.

Add to this innovative field the Acheulian groups' tendency to occupy carefully chosen basin-like landscape settings and restrict their nomadism within these confines, careful selection of raw materials for making stone artifacts, and adapt their foraging in tune with the seasonally shifting water sources and plant and animal foods. Noteworthy too are the use of wood and bone for shaping tools and weapons and use of natural ochres for application on body. Sociality, group living and transmission of skills to the younger ones are some of the other dimensions of this culturification, whose understanding has been sidelined by our long-standing preoccupation with stone tool collections.

## 16. ACHEULIAN LANDSCAPES ALONG THE SOUTH-EAST COAST OF INDIA

*Pappu, Shanti (Deccan College & Sharma Centre for Heritage Education) pappu.shanti@gmail.com*  
*Akhilesh, Kumar (Sharma Centre for Heritage Education) akhilarchaeo@gmail.com*

Northern Tamil Nadu, along the southeast coast of India, is well known since 1863, for its Acheulian site complexes. Research by the Sharma Centre for Heritage Education, has resulted in the study of more than 40 Acheulian site complexes, details of which are presented here. Of these, Attirampakkam, was excavated, producing an Early Pleistocene age ranging from >1.07 Ma to around 1.8 Ma (weighted mean age estimate at around  $1.51 \pm 0.07$  Ma), for horizons in Layers 6 to 8. We present here an overview of the nature of Acheulian sites in this region, focusing on the chronology, stratigraphic context, and lithic assemblages. We discuss in detail the Early Pleistocene Acheulian *chaîne opératoire* at Attirampakkam, situate this site in the regional Acheulian context, and address issues related to long term stasis and change within the Acheulian. We situate these studies in the perspective of debates on Acheulian cognition, long-term technological and behavioural changes, and issues related to dispersals both in India and elsewhere in the world. We question prevalent notions on technological

and typological criteria for defining Early versus Late Acheulian in the Indian context, and examine the validity of current terminology in the study of Acheulian lithics.

## 17. ACHEULEAN INDUSTRIES IN THE UPPER JIRA RIVER VALLEY, DISTRICT BARGARH, ODISHA: A PRELIMINARY REPORT ON RECENT INVESTIGATIONS

*Thakur, Neena (P.G. Department Of History, Sambalpur University, Burla, Odisha) neena1662@rediffmail.com*  
*Behera, Pradeep (P.G. Department Of History, Sambalpur University, Burla, Odisha) pkbehra@rediffmail.com*

The Acheulean, characterised by the appearance of *Homo erectus* with increased cognitive and adaptive abilities, standardized tool-making by employing large-flake blanks and first migration of human population out of Africa, is often regarded as representing technological stasis and homogeneity over a huge geographical domain spreading across Africa and Eurasia. It also represents the longest lasting (~1.7 My – 250 Ky) cultural phase in human history. Cultural remains of this phase are fairly widespread in South Asia in general and India in particular. Recent dates obtained from the Acheulean levels at Attirampakkam by palaeomagnetic measurements and cosmogenic nuclide dating methods have pushed back the antiquity of this cultural stage in India to about 1.5 My. Although Acheulean artefacts have been reported from a large number of localities in the state of Odisha since the forties of the last century, majority of these are from secondary contexts and mostly includes sporadic finds.

We conducted investigations in the upper course of the river Jira, a tributary of the river Mahanadi, in the district Bargarh, western Odisha. These investigations have brought to light a number of localities bearing Acheulean artefacts in semi-primary/primary contexts, away from fluvial network. At some localities trial pits were taken to understand the sedimentary context.

The assemblages were studied using a combination of *chaîne opératoire* approach and attribute analysis which helped reveal technological characteristics of the assemblage.

The assemblages recovered from this region include varying proportion of handaxes, cleavers, cores, spheroids, polyhedrons and a variety of tools made on flakes. While a couple of sites bear unmistakable evidence for quarry

activities and production of large-flake blanks, at most of the localities large-flake blanks and/or semi-finished as well as finished bifaces were procured from the nearby raw material sources for use. Trial pits taken at one of the localities revealed sub-angular/sub-rounded pebbly-cobbly gravel in a lateritic matrix as the sedimentary context of the surface Acheulean assemblages.

Techno-morphologically, most of the assemblages exhibit Late Acheulean character, while presence of an earlier phase cannot be ruled out. The present paper is an attempt to highlight the results of our recent investigations in the upper Jira river valley of Odisha.
