- A1 Siliceous rock extraction and prehistoric lithic economies
- A2a The first peopling of Europe
- A2b Technological change during the Lower-Middle Pleistocene transition in Europe
- A2c What's happening now in Atapuerca? Latest research at the Sierra de Atapuerca sites
- A2d Contextualizing Schöningen and its implications for human evolution during the Middle Pleistocene
- A2e The Early and Middle Pleistocene succession in the Guadix-Baza Basin (Andalusia, southern Spain): geology, paleontology, archaeology
- A2f Pleistocene human dispersals: climate, ecology and social behavior
- A3b Transition from Lithic to Metal – appraisal on global changes
- A3c The emergence of warrior societies and its economic, social and environmental consequences
- A3e Objects of the dead, offerings from the living: interpreting finds in funerary contexts
- A3f 50 Years of Prähistorische Bronzefunde
- A4a The revolution of the sixties in Prehistory and Protohistory
- A4b The scientific value of 3D archaeology
- A4c Underwater Archaeology
- A5a The Final Palaeolithic of Northern Eurasia
- A5b From the Atlantic to beyond the Bug River – Finding and defining the Federmesser-Gruppen / Azilian on the North European Plain and adjacent areas
- A6a Human occupations in mountain environments: a comparative methodological perspective
- A6b The management of resources and territories in the Pyrenees from the earliest human occupation to the end of the Protohistory. A behavioral perspective
- A7b Emergence and consequences of technical innovations in America
- A7c Climate change and use of animals in South America during the Holocene
- A8a Lobbying for Archaeology (18TH- 21ST centuries). Innovative alliances in the establishment of archaeology
- A8b International relations in the history of archaeology
- A9a The origins of Upper Palaeolithic in Eurasia
- A9b The Study of the Environment and the Landscape in the Reconstruction of the Economic and Social Activities during the Upper Paleolithic. Methodological Approaches and Case of study

- A9c** The initial Cantabrian Magdalenian & the question of Magdalenian origins
- A9d** The Human settlement of Western Europe during the last glacial maximum
- A10** The Neolithic from the Sahara to the Southern Mediterranean Coast: a review of the most Recent Research
- A11a** The chronology of Palaeolithic cave art: new data, new debates
- A11b** Late Pleistocene cave art in its context
- A11c** New solutions for old problems: the use of new technologies for the documentation and conservation of prehistoric art
- A11d** Styles, techniques and graphic expression in rock art
- A11e** Public images, private readings: multi-perspective approaches to the post-Palaeolithic rock art
- A11f** The Role of Art in Prehistoric Societies
- A12** Detecting the Landscape(s) - Remote Sensing Techniques from Research to Heritage Management
- A13** Quality Management of Cultural Heritage: problems and good practices
- A14** The water as generator of networks
- A15a** Archaeological Heritage Policies and Management strategies
- A15b** Management and use of science data from preventive archaeology: quality control
- A15c** Cultural resources, management, public policy, people's awareness and sustainable development
- A15d** The educational activities of archeology and socialization of knowledge
- A15e** Museum networking in Glocal communities: experiences in sharing and cooperation towards peer awareness and target increase in Quaternary and Prehistory Museums
- A15** Education and dissemination strategies in museums and prehistoric Sites
- A16** Aegean-Mediterranean imports and influences in the graves from continental Europe – Bronze and Iron Ages
- A17a** Recent Trends and Aspects of Use-wear Analysis and their contribution to the Modernization of Archaeology
- A17b** Traceological research and experimental work
- A17c** Microscopic determination of hafting technology: use-wear and residues
- A18a** Redefining the Postpalaeolithic rock art in the world: Groups, diffusion areas, chronology and last methodological contributions
- A18b** Post-Palaeolithic fliform rock art in Western Europe
- A19** Bifacial tools in the Middle Palaeolithic of western Eurasia: typo-technological variability and spatio-temporal trends

# Index

- A20** The intellectual and spiritual expressions of non-literate peoples
- A21a** Neanderthals on their own terms: new perspectives for the study of Middle Paleolithic behaviour
- A21b** Technological change and behavioral variability in the MSA
- A21c** Movements in and Out for Africa: Assemblage variability and population dynamics in Northeast Africa and Southwest Asia during the MSA and Middle Paleolithic
- A21d** Chronostratigraphic data about the Middle to Upper Palaeolithic cultural change in Western Europe
- A22** Origins and evolution of Modern Humans Behaviour: a view from North Africa
- A24a** Recolonisation or new landscapes: adaptations and change in the Early Holocene
- A24b** Coastal adaptation: Assessing past resilient socio-ecological systems

PART 1 – PRESIDENT FRANÇOISE BOSTYN

ORAL

**1. RAW MATERIALS IN THE CANTABRIAN REGION: DIALECTICS BETWEEN QUARTZITE AND FLINT IN THE ARCHAEOLOGICAL RECORD**

*Prieto, Alejandro (Universidad del País Vasco)*

*alejandro.prieto@ehu.es*

*Arrizabalaga, Álvaro (Universidad del País Vasco)*

*alvaro.arrizabalaga@ehu.es*

*Yusta, Iñaki (Universidad del País Vasco) i.yusta@ehu.es*

The both qualitative and quantitative increase of studies on raw materials in the Cantabrian Region is changing the view on the management of the territory by prehistoric societies. Most of the studies about the lithological varieties in the archaeological and geological record focus on flint, a clastic rock of sedimentary origin. This is due to two reasons: On one hand, the preferential use of this stone by Palaeolithic societies and, on the other, the existence of a corpus of geoarchaeological studies on which allow to characterize this material. This situation has generated a biased picture about the management of raw materials by prehistoric groups, because quartzite, a metamorphic rock containing almost exclusively quartz, is the second type of stone more used in the Cantabrian Palaeolithic. This study is a reflection on the need of deeper knowledge about quartzite, as this will modify the current paradigm on territorial management by Palaeolithic societies.

The basis of this work is a selection of the most representative sites of the Palaeolithic along different areas and chronologies whose lithic tools have been studied at raw material level. The information about the main raw materials (flint and quartzite) has been broken down for each archaeological level and it has been chronologically and geographically contextualised. Finally, we reflect about the relationship between both raw materials and their geographical and chronological context through dual and dialectic understanding and dialectic reasoning.

The results of this work show general trends in the use of each type of raw material. In addition, they are a reflection about the chronological and geographical relationship between quartzite and flint based on the concepts coming from the catchment of these lithic resources. The most innovative results are the geographical relationship of quartzite with the Western Cantabrian Region and that of flint with the Eastern area, the chron-

ological analogy of quartzite with the earlier phases of Palaeolithic and flint with the more recent ones, and the association of the concepts of recurrent and occasional mobility with each type of lithic raw material.

This work offers a wide perspective on lithic resource exploitation by the societies who populated the Cantabrian Region during the Palaeolithic and demonstrate an unequal state of the art for each raw material. As a solution, we propose to intensify the methodological studies to characterize quartzite and its different types.

ORAL

**2. RAW MATERIAL CIRCULATION FROM SOUTH OF FRANCE TOWARDS NORTH-EASTERN OF IBERIAN PENINSULA THROUGHOUT PREHISTORY: EVIDENCES, LACKS AND HISTORICAL SIGNIFICATION**

*Xavier Terradas (CSIC-IMF, Barcelona) terradas@imf.csic.es*

*David Ortega (CSIC-IMF, Barcelona) ortega@imf.csic.es*

The North-east of the Iberian Peninsula is an area with a significant diversity in terms of availability of siliceous rocks for production of stone tools. These differences in the geographic representation of raw materials are also linked to other differences in their properties. Thus, some raw materials have disadvantages to be exploited by means of the application of certain knapping methods, especially with reference to blade production during Upper Palaeolithic and Neolithic times.

This context led to the search for alternative raw materials -especially in northern areas- more suitable for blade knapping. Most of these materials come from the north, from different parts of Southeast France -some of them several hundred kilometres away-, and their presence is profusely confirmed in the archaeological record of sites from NE Iberian, becoming often the more exploited rocks. Throughout the Upper Palaeolithic and Neolithic changes are observed in the provenance of raw materials, their morphology (as raw material, cores, blanks, tools, etc.), the intensity of their exploitation, and in its role within the subsistence activities of groups that used them.

We illustrate this process with examples provided by four concrete raw materials: Precambrian jasper from the Têt Basin, Oligo-Miocene flint native to the Narbonne-Sigean Basin, and two types of flint coming from the Provençal area (one Bedoulian, the other Oligocene). We have attempted to understand the scope of its distribu-

tion, which were the aims that led to their exploitation, as well as the activities in which they were incorporated within the social dynamics of societies from the North-east of the Iberian Peninsula.

ORAL

### 3. PALEOLITHIC CHERT MINES IN THE AVAS HILL OF MISKOLC IN NORD-EST HUNGARY

*Árpád, Ringer (University of Miskolc) bolringa@uni-miskolc.hu*

The first chert mine excavation on the Avas Hill of Miskolc, in NE Hungary, was conducted by Jenő Hillebrand, between 1928 and 1935. Hillebrand, originally, classified the phenomena to the Hungarian Solutrean. Later the dating became totally uncertain.

The first real Paleolithic chert mine were unearthed since 1988 at the part of the Avas called "Tzköves". These belong to both two transitional industries, Middle to Upper Paleolithic. The first is a Bohunician-like industry with Levallois technique and the second is similar to the Denticulate Mousterian.

The letter occurs also in Szeleta Cave at several levels. In 2004-2005 at the western part of "Tzköves" any others chert mine and workshops have been explored.

The interpretation of this chert mine objects exploited by fire-aided stopping and heat treatment, as well as that of the attached processing and camp sites are in progress. The heat-treated chert was used by some kind of prehistoric trade. The typical brown-grey striped, translucent, heat-treated chalcedony of Tzköves was found in many sites of Bükk Mountain.

ORAL

### 4. FLINT MINING, HANDICRAFT, AND THE NEOLITHIC REVOLUTION

*Lech, Jacek (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw) lech@iaepan.edu.pl*

Flint mining among the hunter-gatherer communities, in the later periods of the Palaeolithic and during the "Mesolithic prelude" (using the term coined by Graham Clark) is well documented. Its significance, and the spreading of various flint rocks and artefacts over great distances from the mines, clearly increased together with the in-

roduction of farming – the most important feature of the "Neolithic Revolution" according to V.G. Childe's classic concept. Only the Neolithic economy provided the basis for the rise of periodically functioning systems of developed underground flint mining and the, associated with it, high quality handicraft, long-distance distribution of flint and flint knapping products. The paper will try to point to the factors stimulating development of the most advanced forms of flint mining.

In prehistoric Europe at least several hundred mining fields were exploited, providing various flint rocks. The general conclusions arising from the study of those sites have a bearing on the theses presented in this paper. The Defensola A mine in Italy and the mines of the Danubian communities in Central and Western Europe will illustrate the influence of the "Neolithic Revolution" on the development of flint mining.

This will be followed by a discussion of the most advanced forms of flint mining, at Spiennes (Belgium), Krzemionki Opatowskie (Poland), Harrow Hill and Grimes Graves (England), which arose as a result of the cumulating of expertise and the work of late Neolithic communities, more populous and with a more developed food economy. Together with the advanced mining technology went improvements in handicrafts associated with flint knapping and working of other raw materials.

We have shown the relationship between systematic growth of food surpluses and the development of underground mining and high quality handicrafts based on the mined flint, but it seems that purely economic and technological explanations cover only some of the facts. It can be supposed that the most developed forms of flint mining, to which the "Neolithic Revolution" gave rise, were not only the effect of complex long-distance networks being established for the exchange of products of flint handicrafts, but of unknown myths and symbolic values, emotions and feelings associated with the origin of this raw material, its coming from the depths of the earth and remote regions. It was not only the matter of the raw material's "exotic" character, although this factor should not be underestimated. Especially in the case of deep underground mining, the Neolithic Universum – the *Weltanschauung* of the time – was equally important for the popularity and value of flint, as were purely economic and technological reasons.

Learning of the true factors, which decided about the establishing of the most developed and spectacular forms of underground exploitation, continues to be a difficult

problem for archaeology. It seems that certain opportunities now arise in this area, in connection with new, outstanding discoveries and wide-ranging comparative studies, utilizing social and cultural anthropology.

---

ORAL

## 5. FLINT MINING, HANDICRAFT, AND THE 'URBAN REVOLUTION'

*Zimmermann, Andreas (Institute for Prehistoric Archaeology, University of Cologne) a.zimmermann@uni-koeln.de*

More than 70 years ago, Gordon Childe proposed to distinguish four epochs divided by three revolutions: the "Neolithic revolution" with introduction of producing economy, the "Urban revolution" with division of work between craftsmen and farmers. While the older term "Industrial revolution" described an economy with high energy consumption – at the beginning mostly coal. One of the arguments for this periodization he found in the increase of population density. *"...in the economic sphere ... it will be possible to recognize radical and indeed revolutionary innovations, each followed by such increases in population that, were reliable statistics available, each would be reflected by a conspicuous kink in the population graph. These revolutions can accordingly be used to mark off ... stages in the historical process ..."* (Childe 1941 / edition of 1946, 22).

Within the last dozen of years, it was possible to work out reliable estimations of population-densities from hunter-gatherers onwards for Central Europe by a group of projects (LUCIFS, CRC 806). Because data and methods were homogenised it is possible to compare these estimations with each other. The results validate the hypothesis of Gordon Childe at least for this area. Therefore, the question arises: Why do population density increases dramatically during these revolutions while during each epoch only minor cyclical fluctuations are to be observed?

In this talk, factors contributing to the urban revolution will be analysed and handicraft is identified as probably the most important factor. Should Friedrich Engels be right when claiming division of labour as the relevant development? *„Die zweite große Teilung der Arbeit trat ein: Das Handwerk sonderte sich vom Ackerbau.“* (Engels 1884, edition from 1984, 188). Therefore, the importance of raw material procurement, mining, and artefacts production are discussed.

There is evidence that the economic sectors handicraft

and raw material procurement are not as important for the development of cities and states as long as they are not more accurately differentiated. Flint mining as well as Copper mining is practised already during subsistence oriented societies in Central Europe. Moreover, at the very beginning of the early Neolithic in western Germany already a division of work between different regions dependent on raw material availability as well as "trade" of specific kinds of flint is to be observed. There are even indications of different intensity of flint working in contemporary and neighbouring settlements.

Therefore, it is necessary to differentiate several sectors of handicraft, being either important or unimportant for the urban revolution. Mass products as tiles, stones for architecture, ceramics as well as textiles are economic sectors documenting existence of full time specialists necessary for state societies. While so called "elite consumption" is only a minor part of production already present in Chiefdoms according to Service (1971). However, part time specialists in less differentiated societies already carried out mining and even elaborate artefact production seasonally.

---

ORAL

## 6. BASALT AXE PRODUCTION SITES IN THE BAKONY MOUNTAINS

*Biró, Katalin T. (Hungarian National Museum) tbk@ace.hu*  
*Antoni, Judit – c/o alfred falchetto (HNM-NÖK Budapest)*  
*Wolf, Ern (HNM-NÖK Szombathely) wolferno2@gmail.com*

The Bakony Mountains is one of the prehistoric "industrial" centres of Hungary. Siliceous raw material exploitation sites are known and published from the area (Biró & Regenye 1995, 2003). Recent study on polished stone artefacts of the region resulted in the recognition of intensive artisan activity on Late Neolithic sites of the area in respect of local basalt resources.

So far, the best evidence is known from survey material from the sites of Pénezsgyőr, Zirc and Porva, from the collection of E. Wolf. The collected evidence involves large quantities of workshop evidence – half products, technological tool types and fabrication debris, various grinders and polishers.

Artefacts were identified by routine macroscopic methods and documented accordingly. Magnetic susceptibility (MS) data were equally registered. A few selected samples were subjected to standard petrographical

analysis.

The finds represent various polished stone tools and fabrication debris as well as tools of their production.

Similar evidence was observed and described in Hungary only on Late Neolithic sites of the Lengyel Culture at Aszód (Biró 1992) and Zengvárkony (Biró et al. 2003). An exceptional find assemblage of polished stone artefact half-products (Antoni 2012), probably also dated to the same period on the strength of the analogies of the survey material.

The utilisation of basalts of the region (Balaton Highlands and Little Hungarian Plain) has been the subject of petroarchaeological investigation in the context of polished stone raw material characterisation from Hungary (Füri et al. 2004, Szakmány 2009). The publication of the surface collected evidence of polished stone artefact workshops hopefully supports the systematic study of these important sites.

ORAL

## 7. PRODUCTION OF AXE BLADES AND EXPEDIENT TOOLS AT THE MIDDLE NEOLITHIC FLINT MINING SITE OF MESNIL-SAINT-LOUP (CHAMPAGNE, FRANCE)

*Hauzeur, Anne (Royal Belgian Institute of Natural Sciences, Paléotime) ahauzeur@yahoo.fr*  
*Collin, Jean-Philippe (Université Paris I, Université de Namur) collin.jeanphilippe@gmail.com*

Important and very dense extraction features have been excavated at Mesnil-Saint-Loup (Champagne) in 2010. This new mining site belongs to the « Pays d'Othe » mining complex of the Vanne valley, partly excavated 25 years ago. A preventive excavation at Mesnil was an opportunity to point out a production of axe blades as well as the making of expedient tools or « débitage » dated from the Middle Neolithic (3700-3650 cal BC).

The former set of tools (N = 380) is characterised by their high percentage of abandoned rough-outs, mainly at the first steps of their making off. Dimensions and morphology are extremely variable. Those observations could fit with the mechanical quality of the local flint which is often freeze-fractured but other arguments suggest the existence of learning/training exercises.

The other assemblage from Mesnil is the high amount

of knapped flint nodules (N = 1420) which have been poorly exploited. The alternative hypotheses of a real « débitage » or expedient tools is asked.

ORAL

## 8. APPLICATION OF REMOTE SENSING TECHNIQUES FOR THE LOCALISATION OF PREHISTORIC FLINT MINING EVIDENCES IN THE ARCHAEOLOGICAL COMPLEX OF TREVIÑO (BASQUE-CANTABRIAN BASIN, SPAIN)

*Tarriño Vinagre, Antonio (UPV/EHU) antonio.tarriño@gmail.com*  
*Orúe Beltrán de Heredia, Íñigo (UPV/EHU) innigo.orue@gmail.com*  
*Elorrieta Baigorri, Irantzu (UPV/EHU) i\_lobai@hotmail.com*  
*García-Rojas, Maite (UPV/EHU) maitensx@gmail.com*  
*Sánchez López de Lafuente, Aitor (UPV/EHU) aitor.sanchez@ehu.es*  
*Benito-Calvo, Alfonso (CENIEH) alfonso.benito@cenieh.es*  
*Junguitu Íñiguez de Heredia, Iosu (UPV/EHU) iosujun@gmail.com*

The prehistoric flint mining complex is located in the "Sierra de Araico" (South-Pyrenean Syncline) of the Western Pyrenees (Spain), situated in Treviño County (Burgos) and in the municipality of Berantevilla (Álava). In the last years investigations have been carried out for the detection of prehistoric mining activity, some of them dated from the Neolithic. Nonetheless, the vast extension of the Sierra has prevented, until the moment, from locating and delimiting all the vestiges associated to mining that exist there.

In this way, the objective of this work is to continue with the preliminary definition of the archaeological mining area by the localization of flint extraction structures.

For this aim, in this study we will use the obtained data from the remote sensors and the observation of the morphological and geomorphologic variables of the terrain. This will allow us to explore the area for the subsequent development of archaeological investigations in the new mining evidences that we find.

We propose the interpretation of the earth's surface by using the data obtained from the aerial photography, satellite images and Digital Terrain Models (DTM), derived from the LiDAR data (Light Detection and Ranging). The objective is to examine the structures that could be observed in the earth's surface and its relation with the

different types of exploited flints.

This methodology will allow the design of prospection works that will make possible to overcome the self difficulties of the extension of the archaeological complex—about 2,000 hectares—, providing a general vision of the areas subject to mining activity and of the geological characteristics of the South flank of the Miranda-Treviño syncline.

ORAL

### 9. RAW MATERIALS SUPPLY FROM REDEPOSITED SEDIMENTS OF QUATERNARY ORIGIN. A CASE STUDY FROM NORTH-EASTERN POLAND

*Budziszewsk, Janusz (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)*

*budziszewski.janusz@gmail.com*

*Szubski, Michał (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)*

*michal.szubski@gmail.com*

*Jakubczak, Michał (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)*

*michal.jakubczak87@gmail.com*

*Gruźdź, Witold (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)*

*wittold@gmail.com*

*Zalewski, Marek (State Archaeological Museum in Warsaw)*

*epoka.kamienia@pma.pl*

Most of the studies carried out in Poland on prehistoric flint mining were aimed at investigating sites where raw materials were extracted from the bedrock. Even though erratic flint dominates in lithic inventories from archaeological sites located in the Polish Plain it is still not well known how it was extracted. The main goal of our studies was to identify the flint mining sites in the quaternary deposits covering north-eastern Poland.

In 2013 we started with researches of flint mining sites in Knyszyńska (N-E Poland) with the use of airborne laser scanning (ASL). Digital Terrain Model of 34 km<sup>2</sup> was made on the neighbourhood of already known mining site "Krzemianki" and then we carried out field survey in the region densely covered with forest.

We discovered 3 concentrations of mining fields consisting of 11 sites which surface covers altogether 8 hectares. On the basis of the anthropomorphically changed relief of terrain on the mining field we can presume that the exploitation was taking place with the use of few methods. This may be due to the fact that this outcrop was visited in prehistory couple of times by different

mining groups. Unfortunately at this stage of project we were unable to collect enough of distinctive materials to specify chronology of these sites.

Our research is new evidence of flint mining carried out in the moraines of Warta glaciation. The surface dimension of mining exploitation of the erratic flint from quaternary deposits is surprisingly large. In this case the size of flint mines may be a result of poor quality of raw materials which caused more extensive extraction economy.

ORAL

### 10. WHY MAN DUG A FLINT - FROM EXTRACTION TO DISTRIBUTION. FAITH, ECONOMY AND SOCIAL RELATIONS: SOME REMARKS ABOUT THE FLINT-MINING ACTIVITY IN THE PREHISTORIC EUROPE.

*Boguszewski, Andrzej (Archaeological engineer INRAP and CEDARC associated member)*

*andrzej.boguszewski@inrap.fr*

The flint mining activity is practice in Europe already in the Late Paleolithic, the Mesolithic and the Early and Middle Neolithic time. However, it was in Chalcolithic when this activity grew in size and, in evidence oversteps the simple and pure economical activity. The flint-mines became more elaborated and the underground exploration system improved and extremely exhaustive. The hundred of thousands polished axes have produced and ... "this is the question" ... where this axes were go towards? Certainly, a lot of them were engaged for a common activity of every day, but the other seems to be reserved for quite other destination: gift, exchange, ritual, mark of prestige...

We want to look through the distribution of some finished axes and try to understand their intention.

A model for task subdivision and chain of operations at prehistoric chert quarries was developed in polydeformed, Cambrian/Ordovician, chert bearing carbonates of the Wallkill River Valley (LaPorta, 1990; 1994; 1996; 2004; 2009) and tested at several quarries in equivalent (tectonic cycle 1) rocks (LaPorta et al., 2010). Extreme deformation of tectonic cycle 1 rocks is expressed in quarry task subdivision. The quarry model exhibits a minimum of five spatially discrete task areas and an elongate chain of operation of comminution between each stage of refinement. Tectonic cycle 1 quarries reveal similar strategies of chert extraction and refinement toward a chain of operation and as many as 40 refinement steps are present at some quarries. Polyphase deformation renders tectonic cycle 1 quarries the most complex in the Appalachians. In order to apply the models to the second and third tectonic cycles, or other geological terrains such as the Hudson Valley quartz quarry districts, derivative models must be constructed after appropriate geological baseline data are gathered. That does not mean that no elements of quarry task subdivision and chain of operation are shared with Hudson Valley quartz quarries. The quartz quarries of the Hudson River Valley share some aspects of their extraction technologies with tectonic cycle 1 quarries to the west. Beaked hammers, large impact objects, milling instruments and curated elastic hammers are present at the quartz quarries as well. A central theme that runs through all quarries, irrespective of tectonic domain, is that rock is broken along planes of weakness/foliation. Similarities must exist, regardless of tectonic domain, if a model is valid and reliable. However, forced overprinting of tectonic cycle 1 models on unrelated geological terrains is a logical fallacy.

Use of lithic classifications such as chunk, block, shatter, waste flake, trim do not relate form of quarry debris to causative geological characteristics. Usage of such terms typically leads to the de-evaluation and eventual dismissal of quarry resources. Lack of causative understanding leads to misinterpretation, or failure to recognize, characteristics unique to extraction. One example in the first tectonic cycle is that Hertzian cones are rare to absent in the early/intermediate stages of quarry production. Hertzian cones are present in later stages of refinement when ore is comminuted to the microlithon free from tectonic weakness. Petrofabric explains why Hertzian cones are lacking in certain phases of the chain of operation, but are present in others. Astronomical numbers of excavated quarry

debris are ignored because the investigator assumes the absence of taxonomic cones is justification for classifying debris as naturally occurring or the result of freeze-thaw weathering processes. To have meaningful analysis of quarry debris, a petrofabric approach is necessary. Hudson Valley quartz quarries are analyzed using a petrofabric approach, which gives meaning to quarry/mine tailings despite their location outside of tectonic cycle 1. Hudson Valley quartz quarries contain many elements of the tectonic cycle 1 model; however, it is recognized that organization of quarries on the landscape varies due to geologic constraints, and resulting topographic expressions, which are measured accordingly

*de la Rasilla Vives, Marco (Universidad de Oviedo)*  
*mrasilla@uniovi.es*

Asturian palaeolithic sites contain siliceous raw materials such as flint, quartz, quartzite and sandstone which occur in several geological floors all along the region. Even though, flint presents a more detailed concentration of outcrops and most of them had gone unnoticed for the previous geological studies.

Current research has consisted of fieldwork, geomorphological studies, macroscopic classification of geo-archaeological samples and petrological and geochemical analysis. It has allowed us to attest the siliceous rocks available in the environment and to determine which of them have been procured. Furthermore, it has been possible to establish source areas and management patterns in several sites.

The procured flints are lidite (Ordovician), chert (Devonian), lidite, radiolarite, grey flint and chert (Carboniferous), jasper (Permo-Triassic), Piloña flint (Cretaceous and Paleogene) and Piedramuelle flint (Neogene). The quartzites more used in the sites are the fine-grained and microcrystalline ones, such as the Carboniferous

and Cretaceous quartzites that come from the conglomerates. Quartz and sandstone are less procured and need more studies. Given that they are more ubiquitous rocks than flint and quartzite.

Procurement of these rocks focuses on secondary outcrops such as fluvial terraces, alluvial and slope deposits, but for Piloña and Piedramuelle flints we have documented open air primary outcrops and workshops.

In the Mousterian and Aurignacian levels of the western sector of La Viña site the acquired rocks are quartzite, flint, quartz and sandstone. The most procured one in both cultural episodes is quartzite. Concerning this raw material, the main difference between Mousterian and Aurignacian resides in the use of local-semilocal Carboniferous and Cretaceous quartzites. During the Aurignacian the quartzite came mainly from local Carboniferous conglomerates, while flint procurement increased notably focused on bladelet production. The semilocal Piedramuelle flint predominates over other flint, but allochthonous Piloña flint has a notable presence.

In conclusion, current research shows an important proximity between source areas and archaeological sites as we can see in La Viña, where there is a preferential procurement of local quartzite and alternatively of semilocal and allochthonous flint. For the moment, flint is the only source in track record in the region. Whereas Piedramuelle flint is mainly procured in the Nalón basin, Piloña flint does it in the Sella basin and Carboniferous flint predominate in Las Cabras valley and in Cares-Devan basin.

*Genova (Italy) fabio.negrino@unige.it*  
*Scaramucci, Sem (Department of Physical, Earth and Environmental Sciences - R.U. Prehistory and Anthropology, University of Siena) semscara@yahoo.it*

The here presented project concerns radiolarite quarries/workshops exploited mainly during the Copper Age for the production of semi-worked pieces (preforms) used in the manufacture of leaf-shaped arrows, javelin points, daggers as well as other flat-retouched artefacts. This research focuses on the sites of La Pietra (Grosseto, Tuscany) and Ronco del Gatto (Parma, Emilia) and aims to reconstruct preforms production systems and to identify the circulation routes of these semi-worked products by analysing raw material samples and archaeological artefacts from the surrounding territories.

A study of the lithic assemblages from both sites by means of technological analysis is underway.

At the same time a detailed study of the outcrops object of quarrying activities is being carried out. This includes their mapping as well as detailed descriptions of the sedimentary series and in particular of the most exploited radiolaritic horizons and their possible large scale correlations. The data acquired from the geological sources, will be used as a basis for study and comparison with the archaeological artefacts. The latter will be studied by non-destructive methods (petrographic descriptions with direct observation through a stereomicroscope, possibly combined with geochemical analysis namely SEM-EDS, Raman).

Surveys carried out at La Pietra led to detect an area of more than 3 hectares covered with waste knapped material, fragments of lithic hammers and impressive traces of quarrying activity on a vertical cliff of the outcrop. During the past two years, a knapping area used for the manufacture of preforms was partially investigated. The preliminary technological study allowed to reconstruct the main stages of the transformation process of radiolarite slabs into preforms.

Comparable evidence has been reported at Ronco del Gatto, a locality similarly close to a radiolarite outcrop, about two hundreds kilometres north of La Pietra, in Emilia. Fieldworks carried out between 1997 and 2001 revealed several lithic workshops of different ages, dating from the Middle Palaeolithic to the Copper Age. To this latter period are attributable some workshops devoted to the production of artifacts with a flat blunted retouch as well as some sub-circular features, interpreted as radiolarite quarry fronts. The study of the lithic finds is un-

derway, but a preliminary analysis allowed to highlight many similarities with the *chaîne opératoire* of La Pietra. Similar and coeval radiolarite quarries are known in Eastern Liguria, at Valle Lagorara and Boschi di Liciorno (La Spezia). It is also important to stress that the use of jasper quarries was contemporary to that of copper mines, dated with radiocarbon methods to the same period. This is the case of the Monte Loreto mine (Genova, Liguria), less than ten kilometers away as the crow flies from the exploited radiolarite outcrops. The beginning of quarry activities in Liguria, Emilia and Tuscany must have played an important socio-economic role and a thorough study of this evidence would increase our knowledge of the processes that transformed the late Neolithic agro-pastoral communities in the more complex societies of the Metal Age.

**14. SYSTEMATIC CHARACTERIZATION OF PREBETIC CHERT FROM SERRETA AS PRIMARY RAW LITHIC MATERIAL IN MIDDLE PALAEOLITHIC SITES OF EL SALT AND ABRIC DEL PASTOR (ALICANTE, SPAIN)***Tarriño Vinagre, Antonio (UPV/EHU)**antonio.tarrinno@gmail.com**Tamayo Hernando, Aitana (ICV-CSIC) aitanath@icv.csic.es**Molina Hernández, Francisco Javier (Univ. La Laguna)**chergomw@gmail.com**Galván Saltos, Bertila (Univ. La Laguna)**bertilagalvan@telefonica.net*

lledian deposits of back-reef limestones (Early Eocene), in the Prebetic zone, SE of Spain, present significant silicifications. As a consequence of the presence of diagenetic chert, a subsequent deposit occurs in Oligocene conglomerates in the Alcoi region (Alicante).

These detritic deposits are revealed as the potentially more accessible and the more exploited along the Prehistory in the region, as evidenced by its presence in the archaeological sites and the large number of workshop areas found in this territory. The encountered industries correspond primarily to Middle Palaeolithic tools directly

associated to detritic deposits.

The systematic prospection of both primary chert and archaeological one that was carried out from a geoarchaeological point of view, led as a result a direct correlation between the conglomerate outcrops and the existence of prehistoric workshop areas. The encountered chert possesses a wide macroscopic variability as a result of the geological evolution and thus, different structures within the nodule must be expected.

The microscopic texture of selected samples has been analyzed through the thin sections in petrographic microscope, whereas the mineralogical components and the presence of crystalline phases have been identified by means of X-ray diffraction (XRD). Thermogravimetric analysis has been used for the distinction among crystalline and non crystalline silica phases. The geochemical characterization has been carried out by means of both X-ray fluorescence (XRF) and Inductively Coupled Plasma (ICP-OES), allowing a quantitative determination of the chemical elements. The surface properties and the presence of undetectable pores with optical or electronical methods have been studied through nitrogen adsorption at 77 K. The physical characterization comprises the identification of the color, which was studied with visible-light spectrophotometry and the mechanical properties, obtained through microindentation test and three point flexural test.

The characterization of the chert samples allows the identification of a new type which has been revealed as essential raw material in the lithic industry, at least, of the Prebetic region. The systematic approach to the structure, composition and properties of these materials provides an unequivocal definition and description of the raw materials used as well as the alteration processes that have taken place.

The results obtained suggest that the large amount of amorphous or non crystalline silica present in the materials affect somehow their porosity and thus, the mechanical properties, which are more similar to a vitreous material rather than quartz or other crystalline phase of silicon oxide.

The comparative study of chert samples coming from two Middle Palaeolithic sites, El Salt and el Abric del Pastor, both of them in Alcoi (Alicante), indicate the preferential use of the same type of chert, the so called *Serreta* flint type. With this study, it has been also established a new systematic methodology for the characterization of the geological and archaeological specimens based on

the interpretation of analytical results that are applicable to a wide variability of materials.

### 15. DIRECT-ACCESS BEDROCK QUARTZ QUARRIES WITHIN MID- AND LOWER-HUDSON RIVER VALLEY, NEW YORK

*LaPorta, Philip (The Center for the Investigation of Native and Ancient Quarries and Pace University, Department of Chemistry and Physical Sciences) [plaporta@laportageol.com](mailto:plaporta@laportageol.com)*

*Minchak, Scott (The Center for the Investigation of Native and Ancient Quarries) [sminchak@laportageol.com](mailto:sminchak@laportageol.com)*

*Brewer-LaPorta, Margaret (The Center for the Investigation of Native and Ancient Quarries and Pace University, Department of Chemistry and Physical Sciences)*

*[mbrewer-laporta@laportageol.com](mailto:mbrewer-laporta@laportageol.com)*

A working assumption of archaeological studies (Brennan, 1977:427; Eisenberg, 1978:36; Latham, 1978[1958]:13; Ritchie, 1959:30) in the New York-New Jersey-Pennsylvania region is that quartz artifacts are derived from an expedient and technologically simple, bipolar crushing of glacially derived quartz cobbles. In some studies, weathered joint surfaces and foliation planes exposed during the lithic refinement process have been misinterpreted as cobble cortex instead of the internal fabric of the geological material. These misinterpretations have been embedded in archaeological research designs throughout the Hudson River Valley and require considerable revision.

Along the eastern side of the mid- to lower Hudson River Valley, a Paleozoic thrust fault exposes a linear belt of quartz outcrops on the modern-day erosional surface. This linear belt of quartz crops out intermittently for approximately 70 miles (110 km) from Sylvan Lake, NY southward toward Manhattan Island. Cropping out in this geological context are several types of quartz systems; Precambrian pegmatitic quartz (both simple and complex) and a plexus of Cambrian-Ordovician joint infillings (pneumatolitic, hydrothermal and metasomatic), pressure solution halos above quartzite beds, and metamorphosed quartz sand interbedded with marble. Field and hand sample observations elucidate clear to milky white, rose, and light to extremely dark gray/ black varieties of the quartz. Color is not specific to the formative setting of the quartz. However, each type of quartz can be differentiated utilizing environmental setting interpretation at the outcrop and correct use of the light transmitting petrographic microscope.

Geological mapping and archaeological excavation has revealed adits and evacuated conjugate joints associated with crushed and comminuted quartz and associated country rock. Workshops and associated subsistence sites are spatially proximal (range less than 30 feet (10 meters)) to the quarry face. Zones of extraction, processing and milling are spatially organized and archaeological excavations indicate maintenance of tailings debris. Present also are curated quarry tools and mining instruments fashioned from Cambrian Poughquag and Lowery metaquartzites, Lower Ordovician Cortlandt Complex ultramafics, and hornfelsic rocks created by intrusion of the Triassic Palisades Sill complex.

The close spatial relationship of direct-access quartz quarries, workshops and open-air subsistence sites with *Crassostrea virginica* shell middens points to the establishment of the marine pycnocline within the Lower Hudson River Valley. The establishment of the salt-water wedge ushers in stable *Crassostrea virginica* oyster mound accumulations and provided a reliable source of protein for prehistoric occupants. Examination of the shell middens reveals quartz flake debris derived from the bedrock quarries. The flake debris is interpreted as tools employed for the husking of shellfish. A cultural chronology constructed for this region reveals intermittent usage of the quartz and associated shell fisheries during the Paleo-Indian (12,000-9,000 B.P.); Early, Middle and Terminal Archaic (9,000-3,000 B.P.) into the Early Woodland (3,000-1,800 B.P.) periods. Diagnostic materials found in the related workshops indicate that quartz mining may have reached its acme of development during the Terminal Archaic/Transitional periods (4,300-3,000 B.P.). Lithic analysis of Early Woodland flake tool assemblages indicate that recycling of quartz from tailings piles may have continued through the Woodland Period after quarry face depletion

### 16. QUARRY INSTRUMENTS ASSOCIATED WITH DIRECT-ACCESS QUARTZ BEDROCK QUARRIES

*LaPorta, Philip (The Center for the Investigation of Native and Ancient Quarries and Pace University, Department of Chemistry and Physical Sciences) [plaporta@laportageol.com](mailto:plaporta@laportageol.com)*

*Minchak, Scott (The Center for the Investigation of Native and Ancient Quarries) [sminchak@laportageol.com](mailto:sminchak@laportageol.com)*

*Brewer-LaPorta, Margaret (The Center for the Investigation of Native and Ancient Quarries and Pace University, Department of Chemistry and Physical Sciences)*

*mbrewer-laporta@laportageol.com*

Success of prehistoric quarry endeavors is partially determined by the availability of elastic and very dense rock types that serve as raw materials for mining instruments. For direct-access quartz quarries of the Hudson River Valley, such raw materials are present in Wisconsin-age glacial till veneering the region. Petrologic/petrographic sampling of the till, and analysis of quarry tools/instruments excavated at quartz quarries, infer the following interpretations.

The Hudson Valley quartz quarry district not only varies along trend in terms of the type of quartz available and the country rock hosting it, but varies in raw materials used as mining instruments. In the northernmost trend, the quarry-tool assemblage consists of high percentages of metaquartzite, and lesser amounts of metasedimentary and metaigneous boulders/cobbles. Southward, the tool assemblage is metasedimentary and metaigneous rocks, as well as orthoquartzites. In the south-central sector of the district, basalt and hornfels were glacially eroded from the Palisades Sill. Ultramafic rocks eroded from the Cortland Complex were also present at quarries. In the southernmost extremity of the district, Palisades hornfels, Cortland mafics and smaller concentrations of ortho- and metaquartzites are mixed in the till. While considerable overlap in the tool/instrument raw materials occurs, there are also spatially discrete concentrations correlatable with percentage variations in local till. The variety of raw materials provides the prehistoric miner a wide assortment of materials of various strengths and elasticity to choose from.

In southern locations, there is greater variability in till petrology, allowing for a more robust tool kit and fuller development of local quarries. Caches of metaquartzite are found at southern quarries in all phases of quarry development. Metaquartzites are pecked and ground, are a variety of sizes, and fit specific morphological classes, some of which suggest hafting during use. These observations infer metaquartzite curation and recycling, with specific morphological classes prescribing varied functions at quarries and associated sites.

Metaigneous and metasedimentary tools are joint-bounded, exhibit glacial polish and are restricted to extractive zones as large blocks. Size and location constraints infer employment as impactors. Broken fragments may be recycled for use in other areas of the quarry, but missing is evidence of grinding and pecking and ubiquitous presence at the quarry. These materials appear to be expendable, in contrast to metaquartzite utili-

zation. Similar lack of curation and expendability is seen with hornfels located in milling and crushing areas. Orthoquartzites are present predominantly in workshops. These trends suggest preferential selection patterns and a cognizant application of the strength and size of material to perform certain tasks and functions.

Despite the abundance of till suitable for extraction needs, volcanic intrusives occurring throughout the region are also quarried for the production of mining instruments. These occur admixed with both curated and non-curated till components of the instrument assemblages. Volcanic hammerstone quarries are visible in all phases of extraction and processing, suggesting they have a different value. Hammers fashioned from quartz are also visible in the southernmost workshops. Chert hammers are uncommon, but present.

ORAL

## 17. OBSIDIAN PROVENANCE ANALYSIS IN ARCHAEOLOGY: A VIEW FROM WESTERN NORTH AMERICA

*Hughes, Richard (Geochemical Research Laboratory)  
rehughes@silcon.com*

Since the inception of instrument-based analyses in the middle 1960's, research conducted on silica-rich volcanic glass (obsidian) erupted in California and the Great Basin of western North America has played an important role in the overall development of worldwide provenance studies in archaeology. Early work in California and the Great Basin focused on chemical identifications of archaeologically-significant obsidian, which were then employed through artifact analysis to sketch the broad outlines of "exchange networks" in prehistory. Since these early days there has been growing sophistication in archaeological uses of provenance data, including more explicitly awareness of the interpretive differences attending views of obsidian "sources" as geochemical vs. spatial entities, and appreciation of the importance of segregating material by artifact class for analysis. This paper presents examples and illustrations of these issues, and relates them to more general problems, and potentials, associated with inferring the behavioral mechanisms responsible for observed artifact distributions in other types of siliceous rock.

*Hughes, Richard E. (Geochemical Research Laboratory; 20 Portola Green Circle, Portola Valley, CA 94028-7833 U.S.A.) rehughes@silcon.com*

*Segit, Tomasz (Warsaw University, Faculty of Geology, Institute of Geology) t.segit@uw.edu.pl*

One of the most important types of flint used in the Vistula river basin in prehistory were the so-called "chocolate flints" from Central Poland, exploited from the Palaeolithic to the beginning of the Iron Age. At present we know of 26 exploitation points of "chocolate flints," mostly mines. Several have been excavated.

Exploitation of "chocolate flints" was economically significant even after the Neolithic. In the Early Bronze Age this is supported by discoveries of flint mines and flint tools such as axe blades, sickles, daggers or arrowheads. The paper will present current problems with correctly determining the origin of "chocolate flint" from Central Poland and results of research into the geochemical and petrographic characteristics of this raw material. As well as remarks on the management of this raw material in the Neolithic and Bronze Ages. Differences between varieties of "chocolate flints" (mainly from different mines) are also discussed.

The term "chocolate flint" is imprecise, as considerable variations of this raw material can be found. Research into its occurrence and geology has an eighty-year history, but no complex petrographic-geochemical investigations have as yet been carried out.

The aim of research being conducted since 2012 is to explain the internal differences between chocolate flints and to determine their diagnostic features in relation to other siliceous rocks from Central Poland.

Samples have been collected from all the exploitation points of "chocolate flint," as well as samples of the basic siliceous rock occurring in Central Europe.

The samples have undergone geochemical examinations, especially as to the content of trace elements and organic material.

Tests have shown that colour variation, which has hitherto been the basic criterion for distinguishing "chocolate flint," is connected with the differing composition and distribution of organic compounds present in these rocks. We can observe a clear trend: the diminishing content of organic matter in lighter coloured flint. This is related to variations in the amount of organic matter in the environment in which the deposition of siliceous rocks took place. The other factor influencing the hydrocarbon content was the flint weathering processes.

The lack of a full geological and petrographic description of "chocolate flint" may result in considerable errors when reconstructing the economies of prehistoric communities, of which the most critical are erroneous descriptions of the raw material and inconclusive indications as to place of extraction. As a consequence, exchange networks may be reconstructed incorrectly and the role played in the economy by individual flint mines is not determined properly.

**Acknowledgements.** The investigations were funded by the National Science Centre in Poland (PRELUDIUM 2; UMO-2011/03/N/HS3/03973).

ORAL

**19. CHALCOLITHIC RAW MATERIAL ECONOMY IN THE LIGHT OF NEW DATA FROM MINING FIELD PRZYJAŹŃ IN RZECZKOWO (CENTRAL POLAND)**

*Budziszewski, Janusz (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)*

*budziszewski.janusz@gmail.com*

*Gruzdź, Witold (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw) wittold@gmail.com*

*Jakubczak, Michał (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)*

*michal.jakubczak87@gmail.com*

*Szubski, Michał (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw) michal.szubski@gmail.com*

The studies of chalcolithic production from chocolate flint are still not well investigated when it comes to the

production of blade “daggers”. These forms are usually made on long regular blanks and are found among inventories attributed to lubelsko-wołyńska culture. In our research we examine how these blades were extracted and produced.

During our survey carried out on chocolate flint outcrop in 2013 we discovered few new prehistoric extraction fields from which one, “Przyjaźń” in Rzeczkowo (Central Poland) was located on redeposited sediments of glacial origin. Flint nodules from this site were changed by post-depositional factors, which caused heavily patination of their colours. In such form they were picked up by prehistoric producers and used for blade production. We studied this collection with morphological analyses to access the technology and supported it with the comparison to experimentally made materials.

“Przyjaźń” is chocolate flint mine where raw material was extracted from quaternary sediments differently then we can observe on well know mines in the region. It is visible in fragmentary preserved relief of anthropomorphically changed surface of the site. Additionally, the specific type of colourful raw material, together with technology based on production of long blades with punch technique; presume us that the assemblages should be link with chalcolithic lubelsko-wołyńska culture.

Our hypothesis of raw material acquisition and flint distribution sheds new light on chalcolithic cultures in the region. Most probably the flints were extracted with use of simple methods and nodules were transported on long distances with only minimal preparation of precore. Occasionally, blades were produced on mining fields but it was linked with the early phases of reduction. Macro-lithic blades were made in settlements by highly qualify knappers.

ORAL

## 20. LITHIC PROCUREMENT STRATEGIES DURING THE MIDDLE NEOLITHIC IN NORTH-WESTERN FRANCE : THE CASE OF THE ‘CHASSEEN SEPTENTRIONAL’ CULTURE

*Bostyn, Françoise (Inrap – UMR 8215-Trajectoires, 11 rue des Champs, 59650 Villeneuve d’Ascq, France)  
francoise.bostyn@inrap.fr*

Several recent rescue excavations in the north-western France led to the discovery and the excavation of four news enclosure sites attributed to the ‘Chasseen septen-

trional’ culture. These sites have either simple palisaded ditches or bordered of one or several ring ditches. The studies of the lithic assemblages allow us to renew our knowledge of the raw material procurement strategies of these populations and point out the role of the flint mines in that organization. The ‘Chasseen septentrional’ settlements are located in a region where the Cretaceous substrate provide a large quantity of flint nodules of variable shape and size, most often exploited through small scale flint mines. These flint mines are specialized in the production of medium size blade axes. In parallel, we can observe the introduction of polished axes in metamorphic rocks. The distribution of finished products (blades and axes) coming from the specialized productions of the main flint mines of Spiennes (Belgium) and Jablines (Seine-et-Marne), which were exploited by people not belonging to the same cultural entity, seem to appear, given to the lithic assemblage of Villers-Carbonnel enclosure, in a second time. These changes in the raw material procurement strategies seem to have to be correlated with the development of multiple ditches enclosure sites.

ORAL

## 21. BETWEEN STANDARDISATION AND DIVERSIFICATION. SINGULAR SHAPE THE MINING TOOLS: WHAT THE REASON?

*Boguszewski, Andrzej (Archaeological engineer INRAP and CEDARC associated member) andrzej.boguszewski@inrap.fr*

When we study this exceptional phenomenon what is the flint extraction, we are still wonder about the choice done by the Neolithics to his tools. We can imagine that a mining tool-set was adapted to the technical constraints, to the local geology and to the environmental conditions. However, behind that, was-it also a cultural heritage reason in the preparation of this tool-set?

We made on review over 40 Neolithic and Chalcolithic flint mines and their tool-set, especially the antler, and we compare their shape and their degree of transformation. Some mines present a high standardization and almost a kind of “monotony”, while some other a riche technical and typological diversification. What is a sense or a significance of this difference? Where is their origin? In our paper, we discuss a different choice of the mining tools (stone, flint, bone and antler) in the Neolithic flint mines, and we will try to demonstrate the role of the non-technological influences into the mining system.

**22. WIERZBICA “ZELE” (POLAND): THE BRONZE AGE FLINT MINE IN THE LIGHT OF NEW EXCAVATIONS**

*Lech, Hanna (Autonomous Research Laboratory for Prehistoric Flint Mining, The Institute of Archaeology and Ethnology Polish Academy of Sciences) lech@iaepan.edu.pl*

*Lech, Jacek (Autonomous Research Laboratory for Prehistoric Flint Mining, The Institute of Archaeology and Ethnology Polish Academy of Sciences) lech@iaepan.edu.pl*

*Malecka-Kukawka, Jolanta (Laboratory of Traseology, Institute of Archaeology, Nicolaus Copernicus University, Torun) Jolanta.Malecka-Kukawka@umk.pl*

*Werra, Dagmara (Autonomous Research Laboratory for Prehistoric Flint Mining, The Institute of Archaeology and Ethnology Polish Academy of Sciences) werra@iaepan.edu.pl*

Wierzbica “ZeLe”, Radom district, in Central Poland, is an important flint mining site from the Bronze Age and Early Iron Age. The paper will present the latest studies. Excavations were carried out at the site in 1979-1988, 2012 and 2014, revealing 81 shafts, which were investigated in varying degrees. Over 8000 flint specimens from the “ZeLe” mine were classified according to a classification list. During the initial analysis, new categories of artefacts were distinguished, which had hitherto not been differentiated in the flint material from settlements and mining fields. Microscopic use-wear analysis was carried on selected artefacts from the mining field.

In early periods of the Bronze Age, the “ZeLe” flint played an important economic role. This is confirmed by numerous initial forms of axes and single roughouts of sickles and arrowheads. In the Late Bronze Age, flint had different uses. The deepest shafts, no. 19 and 28, dated to about 1000 cal BC, are connected with this phase. It seems that at this time flint and mining had more symbolic significance than economic. Flint mining became a spectacular example of cultivating old traditions for other purposes.

Use-wear analysis showed signs of mining work on some of the artefacts (eg. scraping clay off nodules). Other artefacts were used for work with organic material – scraping and drilling bones/antlers, cutting meat/skin, scraping and drilling wood. Tools with such traces had hitherto been found in the context of household clusters.

The analyses of flint material from “ZeLe” show that, during the Bronze Age, the significance of flint changed and

the period can be divided into two parts. In the early Bronze Age, flint and mining played an important part in the economy, while in the Late Bronze Age their symbolic meaning became more significant and economy took second place. This hypothesis requires further analysis. If confirmed, then the presence of flints in rituals will be proof of conservative ideologies persisting for a long time, into the Late Bronze and Early Iron Age.

It was shown that use-wear analysis of material from the mines provides important information about the behaviour of prehistoric miners, which is revealed through technological and morphologic analyses.

ORAL

**23. WHY UNDERSTANDING FLINT MINING IS ESSENTIAL TO UNDERSTANDING METALLURGY? AND VICE VERSA: A DEMOGRAPHIC EXPLANATION OF FLINT AND COPPER PRODUCTION VOLUMES**

*Edinburgh, Kevan (University College London) k.edinburgh@ucl.ac.uk*

*Shennan, Stephen (University College London) ioa-director@ucl.ac.uk*

The paper aims at explaining the actual performances of flint mining and earliest metallurgy in the European areas north of the Alps (6000 – 2000 calBC).

Radiocarbon dates from mining sites were summed, and the development of these <sup>14</sup>C probability densities over time was used as a proxy for extraction volumes.

It can be shown that the development of flint mining and metallurgy is strikingly correlated in time. Instead of interpreting this as an indication of direct interconnections (eg. in a shared market) flint mining and the exchange of copper will both be shown as being effects of / responses to changing population densities.

The positive as well as the negative growth of Neolithic populations – well visible in the demographic proxy (Shennan et al 2013) – caused mayor transformations in the economic networks regulating the flow of technology and raw materials. Radiocarbon modelling allows the quantification of extraction thus adding an important perspective to mining archaeology.

Barranco León and Fuente Nueva 3 (Orce, Andalusia, Spain) are well established as major archeological occurrences in the framework of Old Europe. Situated in southern Spain's Guadix-Baza depression, they provide an exceptionally rich and well dated record for the earliest human presence in Europe (1,4-1,3 Ma, respectively). Since 2008, renewed excavations and inter-disciplinary research conducted at the sites have considerably enlarged the artifact register, providing new lines of research in the fields of lithic technology and typology. Renewed interests focus on variability within the range of local raw material procurement patterns and also on the structural analysis of intra-site transmission of technological knowhow in the context of pioneering hominin groups in Europe. The context of the sites: on the shores of a paleo lake, and the evidence for the presence of other large carnivores, underline questions of expedience as an influence on techno-morphology in early stone toolkits. We propose an analysis of these themes, with an accent on updated information from these and other key sites situated in Europe and dating to the late Early Pleistocene.

Ongoing research at the Bois-de-Riquet site (Lézignan-la-Cèbe, l'Hérault, France) has significantly increased the archeological data available for this exceptional Lower Pleistocene occurrence. Since its discovery in the 1990's, the rich paleontological level situated within a basalt flowstone radiometrically dated to 1.57 Ma (archeostratigraphical unit: 'US2') has yielded a well preserved large and small mammal assemblage. New biochronological evaluations based on the entire faunal assemblage allow an age evaluation of around 1.3-1.2 Ma for this level (late-Early Pleistocene). A small lithic assemblage in basalt is attributed to anthropic intrusion. It includes some whole pebbles which are alien to the non-alluvial context of the infill. There are also a few small sized, non-modified flakes. The lithics have been analysed according to a strict selection protocol elaborated on the basis of a systematic experimental program. Microstratigraphical analysis of the deposits combined with updated geological interpretations of the site reveal that, at the time of the accumulation, a small opening existed within the thermal and textural boundary separating the basalt flowstone's base from its entablature. This shelter was situated within a low cliff juxtaposing a small river. It provided refuge to carnivores and, occasionally, hominins, who took advantage of the shelter and the nearby water source. Five different species of carnivores are identified at the site, including the large hyena *Pachycrocuta brevirostris*, as well as their coproliths, indicating the use of the cavity as a den. While the bone accumulation may be attributed to carnivores, the human presence already attested by a few stone artifacts is also suspected by the presence of cut marks on rare fossils. This paper synthesizes data from the ongoing interdisciplinary study of the Bois-de-Riquet site, an exceptional Lower Pleistocene occurrence in southern France.

ORAL

### 3. THE FIRST EUROPEAN PEOPLING AND THE ITALIAN CASE: PECULIARITIES AND OPPORTUNISM

Arzarello, Marta (Università degli Studi di Ferrara)  
marta.arzarello@unife.it

Peretto, Carlo (Università degli Studi di Ferrara)  
carlo.peretto@unife.it

de Weyer, Louis (Université Paris Ouest Nanterre La Défense)  
louis.deweyer@gmail.com

The Italian Peninsula attests an early human peopling by the presence of several sites such as Monte Poggiolo and Pirro Nord, the first one dated to about 1.0 My (by paleomagnetism and ESR) and the second one dated to 1.2-1.5 My (on biochronological basis and especially on the presence of *Allophaiomys ruffoi*).

The tecno-economical approach to the lithic industries has been used to highlight the technical behaviours, the choices related to raw materials and to make comparisons with other European sites that have the same chronology.

In these sites, the lithic production is generally characterized by short reduction sequences strongly adapted to the initial morphology of raw material (always flint cobbles or pebbles). The lithic production is mainly made by unipolar/orthogonal/multidirectional débitage but also the centripetal exploitation is attested and seems to have an important place inside the débitage economy. From a general point of view, these features are shared with the other contemporary European sites and with the African Mode 1, but some peculiarities can be underlined and these attest an extraordinary *savoir-faire* and capacity of adaptation to the raw material.

ORAL

### 4. THE FIRST EUROPEAN MODE 1 LITHIC INDUSTRY: VALLPARADÍS (BARCELONA, NORTH-EASTERN SPAIN)

García Garriga, Joan (Institut Català de Paleoecologia Humana i Evolució Social (IPHES) jgarc338@xtec.cat

Martínez Molina, Kenneth (Institut Català de Paleoecologia Humana i Evolució Social (IPHES) kmartine@xtec.cat

The Vallparadís site contains an abundant Epivillafranchian fauna and Mode 1 industry that has been dated to the upper limit of the Jaramillo subchron. The stone tool assemblage from Vallparadís covers the chronological vacuum between the pre-Jaramillo (Fuente Nueva 3,

Barranco León and Sima del Elefante TE9) and post-Jaramillo (Gran Dolina TD6) Iberian sites. The industries from these sites are associated to the Mode 1 technocomplex with a variability range.

The stone tools assemblage from Vallparadís has been analyzed by categories of artefacts and raw materials following the *chaîne opératoire* concept, discriminating technological issues related to configuration and exploitation processes.

At Vallparadís, lithic industry was obtained from short *chaînes opératoires* developed on small sized clasts and river pebbles on quartz, flint and lydite. Bipolar on an anvil knapping technique was used to core exploitation sequences, while a few cores were knapped with non orthogonal methods (unipolar and centripetal methods). The assemblage includes a significant amount of retouched tools, including notches, becs, scrapers and denticulates, and there are also a few denticulates associated with a distal notch and pointed tools.

Technological, taphonomical and archaeozoological data from the Iberian Early Pleistocene sites suggest that hominins share the same adaptive strategies. These early groups were able to maintain a continuous settlement in European ecosystems from 1.4–1.2 Ma up to the first half of the Middle Pleistocene (c. 0.6 Ma) and to expand into northern territories before the Jaramillo subchron. The adaptation of early hominins with Mode 1 technology to the different European ecosystems and climatic fluctuations probably retarded the expansion of new hominin groups with Mode 2 technology until the first half of the Middle Pleistocene.

Company, Julio (Laboratorio de Arqueología y Paleontología. IVC+R. CulturArts. Generalitat Valenciana)  
julio.company@uv.es

The archeological site *Alto de las Picarazas* (Chelva-Andilla, Valencia) is located on a small slope at 1,070 m above sea level, on the eastern extreme of the Iberian system. It was discovered in 2008 during the construction of the wind power station *Peñas de Dios II*.

The site is inside a cavity of tectonic origin, formed on a bank of limestone. The cave grew in size through karstic processes, developing in a sub-vertical direction as the bedrock dissolved. It is completely full of clay and carbonate colluvial sediments, and four stratigraphic levels have been identified.

With regard to information relating to biostratigraphy and paleomagnetism, two chronological periods are apparent: one in the Middle Pleistocene, associated with the presence of *Microtus (Iberomys) brecciensis* and *Allocrietus bursa*; and another (Level IV) in the Early Pleistocene with *Allophaiomys lavocatí*, *Allophaiomys nutiensis*, *Arvicola jacobus* and *Prolagus sp.*, signifying that this level dates back about 1.2 to 1.5 m years.

Level IV has also provided abundant remains of large mammals, especially indeterminate *Bovini* remains, *Equus sp.*, *Soergelia minor* and *Stephanorinus etruscus*, as well as a few examples of carnivores, particularly *Ursus etruscus*. A small group of lithic artifacts have also been recovered, made up mainly of flakes from limestone and siliceous materials.

The existence of this industry as well as bones marked with lithic tools, rabbit bones showing evidence of carnage and human teeth, and numerous charred bone remains indicate that *Homo sp* frequented the site in the oldest period of the sequence (Level IV), and that he consumed remains from a medium-sized bovine, deer and lagomorphs. This evidence provides conclusive proof of the presence of hominids in very early dates in the eastern Iberian Peninsula.

## 6. THE FIRST PEOPLING OF EUROPE VIA NORTH BLACK SEA CORRIDOR: DISCOVERY OF OLDOVA-NEAN IN THE DNIESTER VALLEY

Chepalyga, Andrey (Institute of Geography Russian Academy of Sciences) tchepalyga@mail.ru  
Anisyutkin, Nikolay (Institute of Material Culture History, Rus-

*sian Academy of Sciences) leonid.dictyoptera@gmail.com*

The problem of Oldovan pass ways from Africa into Europe cross Near East, last time is discussed. Previously proposed Anatolian - Balkan way southward of the Black Sea has not been confirmed by any oldovan sites. Reconstruction of Oldovan migration way from Africa to Europe via South Caucasus (Dmanisi) was proposed by E. Aguirre and E. Carbonell (2002).

New discoveries of oldovan pebble culture in the Dniester valley and in Crimea permit us to reconstruct new migration way northward of the Black Sea from Caucasus along the Taman peninsula and South Crimea coast to Europe. This new way **North Black Sea Corridor** (Chepalyga, 2013) is based on a chain of 17 Oldovan sites seem to be like **steppingstones** into Europe connected Asian oldovan area with European one. The best studied sites with oldovan culture tools were recovered and digged by N.K. Anisutkin and A.L. Chepalyga in 2010-2014 in Lower Dniester valley near the town Dubossary, Moldova (Dniester Republic). 5 sites related to VII (Kitskany) terrace (125 m asl.) sediments were recovered.

The multilayered site Bayraki is digged in Bayraki gully, east suburb of Dubossary town (N47°16'27" E29°11'10"). The terrace sediments section 10 m thickness subdivided by 10 lithological and 6 culture layers: two Achelean and four Oldovan. More than 1000 stone artefacts from chert, hard sandstones, quartzite were found in Bayraki (oldovan). Several hundred tools belong to heavy duty, light-duty, microtools including choppers, chop-pings, peaks, bill-hooks, end- and side- scrapers, borers, rabou, protoknives. This industry belongs to developed Oldovan culture Mode I. Some tools were effected by fire. Stone pavement from prepared lime stone plates, accompanied by tools in culture layer IV were digged. Using of this construction is unknown, possible it was animal skin preparation (bones absence and bill-hooks existence).

Mammals rest *Archdiscodon meridionalis tamanensis*, *Equus sussenbornensis* are typical for Tamanean complex (=Epivillafranchian). Mollusk fauna contains freshwater bivalves *Pseudosturia caudata*, *Crassiana crassoides* – index species for Kosnitsa complex (upper part of Lower Pleistocene).

Paleomagnetic studies recovered Matujama and Brunhes epochs as well as Jaramillo event 0.99-1.07 Ma. Oldovan culture layers (III-VI) are within Jaramillo event. This suggests the age of oldovan Bayraki site as 0.95-1.1 Ma. Ashelean layers I-II are in the base of Brunhes paleomagnetic epoch younger 0.78 Ma.

Just on Asia-Europe boundary in Taman peninsula was studied oldovan stratificated sites: Bogatyri, Rodniki, Kermek, Tsimbal (Schelinskiy, 2012). The westward pass-way continued on South Crimea coast where new Early Paleolithic, probably oldovan sites Echki-Dag, Artek, Gaspra, Ai-Petry, Blue bay, Cape Majachny (Zuk, 1995, Stepanchuk, 2006) were recovered. This was the narrowest part of the North Black Sea Corridor 10-15 km width named as **South Crimea Pass**. Further to the west migration way can passed on NW Black Sea shelf (dried during Gurian Sea basin) up to the Dniester river valley and upstream to Dubossary, where are Bayraki and other Oldovan sites on Dniester valley: Kretceshti, Moch-Gori, Napadovo, Luka Vrublevetskaya (total 7 sites). These oldovan sites are as likely steppingstones from Asia into Europe and further just to Atapuerca.

ORAL

## 7. EARLY PALEOLITHIC OF KOROLEVO: TYPOLOGICAL ANALYSIS.

*Kulakovska, Larissa (Institute of Archaeology NASU)  
larissa.kulakovska@gmail.com*

The Korolevo Paleolithic site located on two terraces "Gostry Verkh" (120 m) and "Beyvar" (100 m) of the right bank of Tisza River. In the main geological profile (12 m) 7 paleosoils distinguished (K-III – K-IX) (Haesaerts, Koulikovska, 2006, fig.2). In the sequence of 10 archaeological Levels two lowest ones were determined as Lower Paleolithic (Kulakovska, 2001, Kulakovska, Usik, 2011). It should be stressed that in Transcarpathian sediments there are no organic finds.

AH VII was found in the small pebble alluvium layer under Brunhes-Matuyama-Brunhes boundary (MIS 23/25). For the artifact production the local volcanic raw material andesite (vitrophyric dacite (Racz, 2013)), quartz and quartzite were used. The main in situ collection of Level VII (33 artifacts) included cores, flakes, choppers and fragment of the bifacial tool. Primary flaking presented by simple unidirectional, parallel methods. Additionally one artifact can be determined as polyhedron, which probably is result of the way of reduction "without hammer". This industry belongs to so-called Mode I (fig.1,B) (Kulakovska et al., 2010).

Cultural Level VI was found in the upper part of inter-Mindel paleosol K-VII (after P.Haesaerts, 2006) (around 550 000 years ago). The lithic collection contains more

than 5000 pieces. Apart from main raw material (andesite = vitrophyric dacite) quartzite, quartz, flint, slate were used for reduction. The primary flaking characterized by exploitation of simple unidirectional, parallel and rare radial methods. Polyhedron kinds of artifacts are present too. In the tool-kit the next tool-types are present: simple, transversal and diagonal scrapers with steeped retouch; denticulates, etc.. A few samples with bifacial retouch by shape and the way of treatment are quite similar to "Keilmesser" of Micoquen techno-complex. The industry of Level VI can be attributed to Mode 1 too (Kulakovska et al, 2010) (fig.1,A).

The new investigations of Lower Paleolithic stratified sites and detailed analysis of lithic industries made some adjustments to established understanding of this period. The typology of Lower Paleolithic industries demonstrated quite wide variability and quite "developed" level of the tools manufacture, which can be change opinion about expected "archaism" (Derevyanko, 2009). The tool collection of Level VI of the Korolevo site supports this opinion. In contradistinction to typology the primary flaking demonstrated monotonic examples of reduction and simple technology. In this context it possible to talk about reduction "without hammer", simple unidirectional and parallel exploitation of cores with flat working surface. The technology of centripetal reduction of non-Levallois flat cores is not developed yet (Kulakovska, Usik, 2010).

For the Middle Paleolithic the methods of primary flaking are more variable and technologically more complex. It can be marked the appearance of Levallois Methods, widespread centripetal Methods, parallel and convergent methods and other variants. Thus, the first trace of presence of humans for the time of MIS 23/25 in Tisz?-Danube basin marked by Mode 1 type industry of AH VII Korolevo I site. The next wave of human occupation (600-500 ???) represented by Mode 1 industry of AH VI Korolevo I site.

---

ORAL

## 8. EARLY PLEISTOCENE ADAPTATIONS IN THE LEVANT: A VIEW FROM BIZAT RUHAMA, ISRAEL.

Zaidner, Yossi (Zinman Institute of Archaeology, University of Haifa; Institute of Archaeology, The Hebrew University of Jerusalem) [yzaidner@research.haifa.ac.il](mailto:yzaidner@research.haifa.ac.il)

The site of Bizat Ruhama, located on the southern coastal plain of Israel, at the fringe of the Negev desert, yielded

several lithic and faunal assemblages in primary anthropogenic context and is dated to the Matuyama paleomagnetic chron (1.96-0.78 Ma), based on paleomagnetic and faunal evidence. The results of the current study at the site reveal a spatially extensive single-horizon open-air occurrence with indications for fast burial and good preservation of the original site features. According to geological and faunal evidence Bizat Ruhama hominins inhabited inter-dune depression in an open homogeneous semi-arid environment. The faunal assemblage was accumulated primarily by anthropogenic agents, preserving signs of hominin butchery. Altogether, the results point to short-term hominin occupations and suggest that animal carcasses were processed in situ along with knapping activities.

The lithic technology is characterized by using both free-hand and bipolar techniques for reduction of small pebbles in order to obtain flakes. Core-tools are virtually absent and intentionally retouched tools are probably very few. The lithic assemblage shows clear evidence for systematic secondary knapping of flakes. The probable aim of the flake knapping was to maximize raw material exploitation by producing a large number of small, thin and sharp flakes. The flakes were knapped using a bipolar technique. Similar techniques of flake reduction possibly occur in some of the Early Pleistocene sites in Europe. The Early Pleistocene site at Bizat Ruhama contributes to our understanding of the range of Eurasian habitats exploited by early hominins, and the behavioral adaptations and technological skills of the earliest Eurasians.

---

ORAL

## 9. THE HOMINID COLONIZATION OF EUROPE IN THE CONTEXT OF MULTISTAGE PUNCTUATED DISPERSALS INTO THE CIRCUM-MEDITERRANEAN AND EURASIA

Rolland, Nicolas (Universidad Victoria, Canada) [prehistory@shaw.ca](mailto:prehistory@shaw.ca)

Palaeoanthropological spatiotemporal distribution patterns indicate that Europe was colonized during the Early Pleistocene from two independent converging trails from eastern and southwestern directions. These integrated within a wider framework, which encompassed a series of multidirectional dispersal and peopling events from separate staging posts around the Circum-Mediterranean and throughout Eurasia, ultimately originating in Subsaharan Africa. Their time trajectory highlights a

multistage, 'punctuated' configuration, which suggests a succession of adaptively stable peopling phases alternating with renewed dispersals from these staging posts. These observations require addressing their reticulate and multivariate causal interrelationships: identifying optimal colonization habitats; implications for colonization logistics of a single polymorphous early Homo species; the bearing of biocultural hominization antecedents on the model of 'pioneering' populations expansions; the behavioural ecological dynamics between incoming hominids for habituation with unfamiliar large Palaearctic mammalian prey species during the Epi-Villafranchian and Galerian Events; the respective roles of social canids analogs in prey species habituation, and of long-lived core aspects of hominid socio-spatial and ecological organization for interpreting this punctuated stasis/dispersals sequence.

POSTER

POSTER

**10. MODELING HUMAN SETTLEMENT, FAUNA AND FLORA DYNAMICS IN EUROPE DURING THE MID-PLEISTOCENE REVOLUTION (1.2 TO 0.5 MA).**

*Rodríguez, Jesús (CENIEH) [jesus.rodriguez@cenieh.es](mailto:jesus.rodriguez@cenieh.es)*

*Mateos, Ana (CENIEH) [ana.mateos@cenieh.es](mailto:ana.mateos@cenieh.es)*

*Palombo, María Rita (Dipartimento di Scienze della Terra, Università di Roma "La Sapienza")*

*[mariarita.palombo@uniroma1.it](mailto:mariarita.palombo@uniroma1.it)*

*Hertler, Christine (Senckenberg Forschungsinstitut)*

*[christine.hertler@senckenberg.de](mailto:christine.hertler@senckenberg.de)*

We introduce here a new international project supported by the INQUA Humans and Biosphere Commission (HaBComm) focused on the Mid-Pleistocene Revolution. This project intends to be a "pilot project" intended to be developed into an International Focus Group in the 2015-2019 INQUA inter-congress period.

The so called Mid-Pleistocene Revolution (c. 1.2-0.5 Ma) was a major environmental crisis driven by changes in orbital forcing which increased the amplitude of climatic oscillations. Changes in climate drastically affected vegetation in complex ways and led to a significant renewal of mammalian faunal paleo-communities. Human groups with Oldowan technology were present in southern Europe shortly before the Jaramillo subchron and in Britain shortly after the Matuyama/Brunhes boundary. However, evidence of human presence during the 0.7-0.5 Ma period is remarkably scarce, leading some authors to

propose a depopulation of the continent in this period and a subsequent recolonization by other groups with a new material culture: the Acheulean.

The aim of this project is to bring together researchers with experience in the study of the archaeological evidence on the colonization of Europe in the Early and Middle Pleistocene, specialists who may provide primary data on the potential constraints to human settlement (palaeoclimate, mammalian faunas, palaeoflora, palaeogeography, quantitative palaeoecology, sedimentology and palaeosoils...) and specialists in mathematical modeling. The main goals of this project are as follows: (i) archaeologists will develop hypotheses about the patterns of human occupation and cultural change in relation to the main environmental constraints of this period and (ii) palaeontologists, palynologists, palaeoclimatologists, geologists, and palaeogeographers will provide the primary data to test these constraints; (iii) these conceptual models will be turned into mathematical models, and this will be made possible with the participation of mathematicians, biogeographers and engineers with experience in the modeling of complex systems using different methodological approaches (like stochastic, differential, or agent-based models). Members of the project are not expected to have previous skills on research fields other than their own. This initiative is intended as a forum where specialists may share their expertise and join efforts to build up new approaches to address the key question of understanding the way environmental change influenced the human occupation of Europe in the Early and Middle Pleistocene.

## 1. THE EARLY PALEOLITHIC SITE OF KERMEK IN THE WESTERN CISCAUCASIA (RUSSIA)

*Shchelinsky, Viacheslav (Institute of Material Culture History, Russian Academy of Sciences) shchelinsky@yandex.ru*  
*Gurova, Maria (National Institute of Archaeology, Bulgarian Academy of Sciences) gurovam@yahoo.fr*

The site of Kermek is located in the south of European Russia in the southern Azov Sea region, on the northern shore of the Taman Peninsula, near the village of Peresyp'. The site was discovered in 2008 by V.E. Shchelinsky during a survey of the Early Pleistocene deposits exposed in the coastal cliff of the Azov Sea. The sequence hosts the important palaeontological localities of Tizdar 1 and 2. The archaeological site is preserved *in situ* and has a clear geological context. The bed containing stone artefacts belongs to the sedimentary sequence of the Late Kujalnik regional stage of the Black Sea marine scale. In the studied section, these deposits are characterized by reversed magnetization, a fauna of fresh- and brackish water molluscs, including the index fossil *Dreissena theodori*, and a small mammal fauna with *Allophaiomys deucalion*.

The deposits are dated to the late Gelasian or earliest Calabrian stage between c. 2.1-1.77 Ma. The stone industry of the site includes some 300 objects characterized by:

- the exclusive use of local stone raw material (silicified dolomite in the form of platy fragments of different sizes);
- archaic technology of the primary stone flaking, based on use of the unprepared core-like stone fragments (cores with 1-2 and more platforms, with few removals);
- the debitage includes deliberately made large flakes;
- abundant deliberately produced tools (choppers, chopper-like massive sidescrapers, picks, sidescrapers made on flakes and stone fragments, endscrapers, thorned tools, beak-shaped tools, etc.)
- some of the artefacts show well preserved use-wear traces.

The stone industry of Kermek represents a specific Tamanian variant of the Oldowan. Characteristic of this early industry is the presence of deliberately made large flakes and complex tools, such as picks. Kermek is currently the oldest-known Oldowan site in western Asia

outside the Caucasus, located at the southern boundary of Europe.

ORAL

## 2. STRUCTURAL CONTINUITY AND TECHNOLOGICAL CHANGE IN EARLY AND MIDDLE PLEISTOCENE TOOLKITS

*Carbonell, Eudald (IPHES-URV-IVPP) eudald.carbonell@urv.cat*  
*Barsky, Deborah (IPHES-URV) dbarsky@iphes.cat*  
*Sala, Robert (URV-IPHES) robert.sala@urv.cat*  
*Celiberti, Vincenzo (CERPT-UVPD) vceliberti@hotmail.com*

A structural foundation has been laid down to interpret early stone industries using a four-phase, branching evolutionary model: *Homogeneity*, *Variability*, *Diversity* and *Multiplicity*. *Homogeneity* hypothetically predates the first recognizable industries in Africa, at a time when stones were used but there was no controlled knapping. The *Variability* phase bears witness to hominins innovating and testing unidirectional and orthogonal knapping strategies. In Africa and Eurasia, this phase invariably precedes the appearance of shaped tools in assemblages with largely divergent timeframes. The present contribution defines *Diversity*, a phase characterized by standardized shaped tools and innovative stone reduction methods. Presently, flake-core assemblages without configured tools are united under the denomination 'Oldowan' or 'Mode 1' and assemblages containing handaxes, picks and/or cleavers are called 'Acheulian' or 'Mode 2'. The model exposed here does not suggest to replace existing nomenclature, but rather to adapt an alternative approach to the ways we conceive of techno-typological change. On a structural level, it could explain why analogous developments occurred diachronically in different areas of the globe where contact between populations was unlikely. This *Diversity* phase testifies to the enhanced techno-functional capacities developed by hominins to access resources in competition with other carnivores. This would, in turn, have expanded their free-time to further improve their toolkits and widen their range of activities. This process intensified exchange between an ever more complex lifestyle and enlarged cognitive capacities and, ultimately, provided a driving force leading to *Multiplicity*; the fourth and final phase of our model explaining change in early human technology.

Cueva Negra overlooking the R. Quípar, a R. Segura tributary, is an upland rock-shelter 75 km N of the Mediterranean coast and 110 W of the Segura river-mouth. It contains undisturbed sediment 5m deep assigned by magnetostratigraphy to >0.78 Ma (Matuyama magnetochron). Optically stimulated

sediment luminescence implies >0.5 Ma and mammalian biochronology (notably, of Arvicolid rodents) indicates <1-0.7 Ma. Remains include hominin teeth, an Acheulian limestone handaxe, and small chert, limestone or quartzite artifacts, knapped on site, often by bipolar reduction or repetitive centripetal flaking of small discoidal cores. Retouched artifacts include small irregular chert fragments, resembling chert at an adjacent conglomerate outcrop according to laser-ablation inductively-coupled plasma mass-spectrometry of 19 lanthanide and other crustal trace elements, though some chert was likely procured ~25 km away (one radiolarite artifact from ~40 km). Mammals, birds (including waterfowl), reptiles, amphibians and fish corroborate pollen typical of mild (MIS-21?), damp, fluvio-lacustrine environments. Evidence of fire in a deep, sealed layer includes thermally-altered, lustreless chert, with pot-lid fractures and conjoined splintering caused by thermal shock; charred burnt bone, and white calcined fragments showing conjoined lengthwise long-bone spalling typical of circumferential shrinkage after thermal volatilization of organic components. Taphonomical analysis and electron microscopy of bone fragments attribute discolouration to burning, not to post-depositional mineral staining. Sediment geochemistry and thin-section micromorphology suggest combustion; Fourier Transform infrared spectroscopy and electron spin resonance analysis of chert and bone imply firing temperatures 550-600°C. Fire ~0.8 Ma supported hominin cognitive versatility, techno-manual dexterity, and palaeoeconomic extractive behaviour in long-vanished Western European palaeoecological and palaeobiogeographical contexts.

Vallverdú, Josep (IPHES-URV) jvallverdu@iphes.cat

Excavations at the Barranc de La Boella (Tarragona, Catalonia, Spain) since 2007 have opened three localities with rich archaeopaleontological assemblages: La Mina, El Forn and Centre de Convencions.

Paleontology, paleomagnetism and cosmogenic analyses have yielded dates close to 1 my, being La Mina the oldest site and El Forn and Centre de Convencions the younger. The mammal taxa identified in the three localities are *Mammuthus meridionalis*, *Hippopotamus antiquus*, *Stephanorhinus cf. hundsheimensis*, *Equus sp.*, *Ursus sp.*, *Miomys savini* and *Victoriamys chalinei*.

The lithic assemblage from La Mina is formed by percussive pebbles, choppers, chopping-tools, cores, simple flakes and few retouched flakes, and has been ascribed to an Oldowan technology. The lithic assemblage from El Forn and Centre de Convencions are mostly formed by similar tools than La Mina, but they stand out because of the presence of two large cutting tools: one pick and one cleaver made on schist. These Acheulean forms appear in association to a set of flint flakes finely flaked, among which some denticulates and notches are present. Furthermore, at Centre de Convencions the lithic assemblage, that includes several refitting groups, is closely related to the remains of an elephant, in a clear buthcery context.

These evidences may point to Barranc de La Boella as one of the older Early Acheulean sites in Europe. The study of the variability of the three localities in the same environmental conditions may contribute to the knowledge about the appearance of the Acheulean in Europe, and its relation of continuity or discontinuity with the Mode 1 or Oldowan.

The site of La Cansaladeta is located in a narrow passage dug out by the Francolí river in the prelittoral range that connects the Tarragona coastal plain with the central Catalan depression. The archaeological deposit lays on top of a +40-45m fluvial terrace, at the foot of a partially dismantled rock shelter.

The archaeological works initiated at the site in 1999 brought to light a rich Middle Pleistocene stratigraphic succession containing 10 archaeological levels. Although the site's archaeological record is mainly composed of lithic artefacts, faunal remains as well as fire evidences are available.

Here we present the description of the sedimentary succession of the site, the available chronological framework (including Luminiscence, ESR/Useries datings and biostratigraphical information), the characteristics of the lithotechnical and faunal assemblages, as well as the first interpretation of the human occupations at the site.

Lower levels date back to the Early Middle Pleistocene, and the upper ones show an age of c. 300 ka. Three main occupation phases have been differentiated. The oldest levels appear in a paleosol formed on a clayey layer that contains also some limestone fragments detached from the shelter's wall and roof. During the second phase, low energy fluvial sediments coming from lateral river floods were deposited and sealed the archaeological levels. After a transitional phase, the upper levels appear totally included in colluvial slope sediments.

The rich technological record is made up with several local raw materials, especially chert but also hornfels, quartzite, quartz and other residual rocks. Knapping sequences seem to be autochthonous, as all the elements and size-categories of the reduction sequence are present, and refits are common. Although the technological features observed along the sequence are not very diagnostic, in the lower levels there is a significant presence of some Acheulean forms among the large shaped tools, accompanied by a restricted variability among the small retouched tools (mostly

denticulates) and a virtually absence of prepared cores.

The faunal assemblage is scarce and appears strongly weathered. In fact, only the levels included in the two lower sedimentary phases have provided fruitful information, especially from a biochronological point of view.

Although neither combustion areas nor structures related to fire have been documented to date, its damage has been repeatedly recorded on either lithic and faunal remains, what seems to point to its systematic use along the sequence.

The new data provided by the ongoing excavations at the La Cansaladeta site considerably helps the early human settlement of northeast Iberia to be reconstructed. In fact, combining these data with those coming from el Barranc de la Boella, a site located very close in the same Francolí basin, we can draw a new scenario on the early human presence in the region and on the diffusion of the Acheulean.

---

*Hardy, Bruce (Kenyon College) hardyb@kenyon.edu*  
*Bahain, Jean-Jacques (MNHN) bahain@mnhn.fr*  
*Falguères, Christophe (MNHN-CNRS) falguere@mnhn.fr*

The lower unit of la Noira, located in the Center of France, has yielded an assemblage composed of Large Cutting Tools (LCTs), cores and flakes. ESR dates (655 ± 55 ka) and technical characteristics suggest that it is among the oldest evidence of the Acheulean in Western Europe. Since 2011, new excavations of the level have been undertaken.

The aim of the communication is to provide new data on the excavations of the workshop and replace the lithic assemblage in the European technological framework. More than 30 m<sup>2</sup> have been opened and the site yields artefacts from workshops. Hominins found millstone slabs in huge quantity along the river. We can describe

the modes of knapping on these slabs, crude bifacial tools, flaking of small and large flakes, cores. Cores, flakes and crude LCTs are dispersed among the fragments of slabs.

Numerous slabs show few invasive removals or are broken by hard direct percussion. Associated with these possible crude cores, there small and large flakes, cores. Flakes are few retouched. Large flakes are not used for the shaping. Most of the LCTs are crude tools, some of which are broken. One is a completely worked biface. A preliminary study of the microscopic traces attest butchery and wood working.

Hominins were present at the beginning of a Lower Middle Pleistocene glacial-interglacial cycle, before a pleniglacial period (MIS 16). The site is contemporaneous of sites with LCTs such as Arago levels P-Q or Notarchirico, or sites without LCTs such as Pakefield or Isernia. Technological comparison will allow us discussing on the diversity of strategies in Europe at 800-500 ka and the hypothesis of punctual arrivals of new traditions as soon as 700 ka.

---

ORAL

## 7. LA GRANDE VALLÉE, A NEW EVIDENCE ON THE DISCUSSION OF THE APPEARANCE OF BIFACIAL TECHNOLOGY IN EUROPE

*Emilie Claud (INRAP; UMR5199, CNRS) emilie.claud@inrap.fr*

*Jérôme Primault (DRAC Poitou-Charentes; UMR7041, CNRS)*

*jerome.primault@cluture.gouv.fr*

As noticed by organisers of this session, the archaeological evidence dating between 0,8 and 0,5 Mya in Europe is scarce but recent discoveries suggest that the Acheulian or Mode 2 started to appear around this time. In this context, every new evidence and site dating from this time period are welcomed additions to debate about the modalities of the appearance of Mode2 in Europe. In this communication, we will present recent data coming from a new excavation, La Grande Vallée, and its contribution to the knowledge of technological change during the Lower-Middle Pleistocene transition in Europe.

La Grande Vallée is situated at the borders of the 'Bassin

Parisien' and 'Bassin Aquitain', between the extensions of the 'Massif Central' and the 'Massif Armoricain'. Located in the northern part of the Seuil du Poitou, the site occupies a key-space between southern and northern Europe. Discovered in 1995, the site was recently excavated from 2006 to 2008, by an interdisciplinary team.

Within three meters depth, five archaeological layers were discovered, delivering more than 18 500 lithic artifacts. Archaeological and pedostratigraphic results as well as thermoluminescence dating on burnt flint converge on an age for the lithic assemblages around 500 ka for the two oldest layers (U5i, U5g) and 400 ka for the three youngest layers (U5e, U5c, U5a). Attributable to the technological Mode 2, the wealth of lithic assemblages of La Grande Vallée permit us to study a series of sites during a scarcely documented period in Europe. Huge slabs of Upper Turonian flint were exploited by hominids to produce huge flakes. These huge flakes were used as tools or blanks for bifacial shaping. Handaxes have also been produced by direct shaping of Upper Turonian slabs. Technological studies show a large typological variety with morpho-functional concepts of relatively stabilized tools as well as specialized and repeated 'chaînes opératoires'.

All these recent data from La Grande Vallée will be presented and placed in the debate as a new evidence in the discussion of the appearance of bifacial technology (mode 2) in Europe.

*Rocca, Roxane (Université Paris Ouest Nanterre La Défense UMR 7041 - ArScAn - équipe AnTET) roxane.rocca@gmail.com*

The site of Ficoncella, in northern Latium (Italy), provides the opportunity to investigate the modalities of a short occupation in a fluvial context during Lower Palaeolithic. Geological investigations, radio-isotopic dating and tephrochronological analyses indicate that the human activity took place on a riverbank during the sea-level high-stand of the marine isotope stage 13 (MIS 13; ca. 500-490 ka)

This period represent a key moment in the Italian Lower Palaeolithic, at the crossroad between the youngest mode 1 sites, (Monte Poggiolo) and the first acheulean one (Venosa). Furthermore, Ficoncella is located in Central Italy, known for its richness of Lower Palaeolithic occupations belonging to those two wide techno-complexes (Ceprano, Campo Verde, Castel di Guido, Torre in Pietra, La Polledrara).

The lithic assemblage, obtain after three fieldworks missions, was analysed using firstly a classical technological approach. This classical techno-productional analysis has been combined with a techno-functional approach. Refitting analysis and RMU (Raw Material Unit) approach represent an important step of the methodology applied. It's a useful tool for understanding the lithic industry and the spatial distribution of the material. The goal of this method is to understand the functional potential of a tool thanks to the chronology of the removals, the technical consequences of each removal on the blank (angles, surfaces morphology, etc). This approach will be combined with a use wear analysis to go further in the understanding of the site function and interactions with the fauna.

The first results obtain after three fieldwork missions, allows us to reconsider the variability of technical and maybe subsistence strategy during the Lower Palaeolithic. The geological and taphonomical data indicate that the finds where accumulated in a short time range. The lithic industry, very small in size, shows a very original reduction sequence. The good preservation status allowed us to makes a first use wear analysis. The hypothesis that Ficoncella could be an occasional butchery site is supported by the presence of a partially preserved carcass of *Palaeoloxodon antiquus*.

To conclude, the material of Ficoncella contains some extremely interesting information. The technological

features are both very original and well integrated in the Lower Palaeolithic variability. The absence of handaxes still now is not so surprising given the technical trends known in Italy and Southern Europe this chronological range. The technical abilities, evidences by the precision of gesture in core preparation, flaking and retouch are remarkable. This may help renew our image of the lithic industries without handaxes too often ignored.

ORAL

## 9. STILL, SOME DIFFICULTIES: THE EARLIEST OCCUPATION OF EUROPE AS SEEN FROM THE LEVANT

*Sharon, Gonen (Tel Hai College) gonen@telhai.ac.il*

Recent excavations and research have resulted in a wealth of new data from Early Pleistocene sites in Europe. Yet, a critical review of the published findings in light of evidence from the Levant poses some difficulties in accepting the interpretation of this data. A look from the east raises the following issues:

Chronology: the Early Pleistocene sites in the Iberian Peninsula yield a solid chronology; however, this cannot be claimed for most of the sites beyond the Pyrenees. These sites are dated either by means of stratigraphic correlations or by less well-established dating methods. Technology: Early Pleistocene Levantine (and African) assemblages are Early Acheulian (or Developed Oldowan) in nature, the type site being 'Ubeydiya. While non-biface assemblages do exist in the Levant (Bitzat Ruchama) the absence of the early Acheulian from Western Europe should be explained.

Nature of sites: The Levantine sites (again, similar to African sites) are large in area, with long chronological sequences and a wealth of stratified, in situ lithic tools. Such sites are also present in Western Europe, beginning with the Middle Pleistocene. The question remains as to why we do not find large scale, rich sites from the Early Pleistocene.

The eastern gap: Early sites are reported from the Levant and the Caucasus. Some preliminary reports are starting to come from Turkey, but we still await solid evidence for Early Pleistocene sites in Eastern Europe (admittedly, even evidence for the Acheulian is still rare).

These important questions remain to be answered by researchers studying the earliest occupation of Europe.

POSTER

POSTER

### 10. LITHIC MATERIALS IN HIGH FLUVIAL TERRACES OF THE RIVERS CINCA-ALCANANDRE (N SECTOR OF THE EBRO BASIN)

*Montes, Lourdes (Universidad de Zaragoza)*

*lmontes@unizar.es*

*Domingo, Rafael (Universidad de Zaragoza)*

*rdomingo@unizar.es*

*Rodríguez-Ochoa, Rafael (Universitat de Lleida)*

*rrodriguez@macs.udl.cat*

*Utrilla, Pilar (Universidad de Zaragoza) utrilla@unizar.es*

*Peña-Monné, José Luis (Universidad de Zaragoza)*

*jlpena@unizar.es*

*Sampietro-Vattuone, María Marta (Univ. Nacional de Tucumán-CONICET) sampietro@tucbbs.com.ar*

The findings of Palaeolithic tools linked to Quaternary accumulations in the Ebro Basin are very scarce, with some exceptions such as the Najerilla valley ensembles (La Rioja). Recently, we have localised some materials on the higher fluvial terrace levels from the interfluvial Alcanadre – Cinca – Noguera Ribagorzana (Level Qt1). Today these reliefs are platforms and isolated hills, around 200 m above the main rivers. They are composed of gravels that come from the Pyrenean and Pre-Pyrenean ranges and show in the top the development of petrocalcic horizons (*caliches*), that can reach a thickness of up to 2-5 m such as in Saso de las Fitas (Alcanadre river) and in Sierra de San Quílez (Cinca river). The palaeomagnetism and the development degree of the petrocalcic horizons could date these two high terraces in 0.9-1 million years. The prehistoric materials found at those terraces are scarce but significant: in las Fitas we have found some cores and pebbles that have been knapped to simple morphologies, either uni- or bifacial, on quartzite and similar rocks; in San Quílez there are some archaic handaxes and a trihedral piece knapped on flint. As they were on top of both terraces, they must be younger than them, without any further precision.

A third quaternary formation between the courses of the Cinca and the Noguera Ribagorzana, Mina de Olriols, shows a different disposition. It is an alluvial fan - terrace deposited by a lateral stream. Its position, altitude and lesser development of petrocalcic horizons could locate it topographically in Middle Pleistocene levels. It could be related to the Cinca river's terraces Qt5 to Qt6 (178/151 ky to 98 ky respectively). This deposit holds some stratified remains, obtained from a section left by

a quarry exploitation: a 0-type cleaver made on black basalt and some scarce bone splinters.

The soil study and the analysis of the eolized pieces will help us to precise the chronology of the prehistoric remains from Saso de las Fitas and Sierra de San Quílez. As for Mina de Olriols, we seek to assess the chronology of the geological strata by means of an OSL dating, in order to confirm or discard the relationship between this area and the dated quaternary terraces.

*roxane.rocca@gmail.com*

The Cimitero di Atella site (Basilicata, Southern Italy) was discovered in 1990 and examined for more than 20 years by an *équipe* of Università di Firenze directed by Prof. Borzatti von Löwenstern. Thanks to geological and geomorphologic studies on the area, located a few kilometres far from the Venosa basin sites (Loreto and Notarchirico), and to the typological classification of the lithic industry, a chronology around 600-550 ka (OIS 15) has been proposed for this site. Moreover, the presence of "bifaces" has led authors to refer this techno-complex to the Lower Acheulean. Despite of problems related to the absence of direct radiometric dates, after this new study Atella site can be taken into account in the large debate on the first peopling of Europe.

This work is based on data obtained in a graduation thesis about the lithic industry found in Atella levels F, considered as colluviums and excavated on about 12m<sup>2</sup>, which has been analysed through a technological approach, never applied on these materials until today. Then, retouched tools have been studied by a techno-functional approach, reasoning about transformative and prehensile parts on each tool. Materials were affected by strong taphonomic events of both mechanical and chemical nature, so it was possible to analyse only a sample of 666 pieces.

The technological categories found are cores, flakes, small tools, large tools and retouch flakes.

Retouched flakes and natural fragments have been divided into small and large tools on dimensional basis, even if large tools category approximately corresponds to the "bifaces" individuated by Borzatti and colleagues. Actually the *façonnage* of these tools affects almost exclusively only one of the blank surfaces. Small tools are made both on natural fragments and *débitage* flakes and, whatever is the nature of the support, they share some common features: small dimension, important thickness and a flat ventral surface used as a striking platform for retouch.

Comparing Atella lithic industry with others, with or without bifaces/handaxes, we found analogies first in production strategies and then in recurrences individuated on small tools confection. Large unifacial tools, on the other hand, hardly find comparisons with other Italian or European sites.

In conclusion, we assert on one part the great scientific potential of the area, on the other part the necessity of continuing survey researches in the Atella basin, enlarging the excavated area of Cimitero di Atella site levels F, and restudying several old lithic collections discovered in the area (for example, Loreto in the Venosa Basin) applying this new technological approach, with the intent of a better comparison among these techno-complexes.

The Sierra de Atapuerca is a carbonated gentle anticlinal ridge belonging to the NW extreme of the Iberian Chain (North-Central Spain, Burgos), which has been isolated (at least from the Oligocene) by subhorizontal continental endoreic sediments of the NE Duero Cenozoic Basin. The shift to exoreic conditions in the Duero Basin caused the onset of a downcutting staircase model, which caused the development of the Atapuerca multi-level cave system, containing several sites from the Early Pleistocene. In this work, we carry out the palaeogeographical reconstruction of the SW flank of the Sierra de Atapuerca, where these archaeo-palaeoanthropological sites are located.

These works are based on detailed geomorphological, geological and stratigraphical analysis, combined with GPS and 3D LiDAR data, and GIS and finite elements modelling. This work combines the reconstruction of Pleistocene base levels, the analysis of valley longitudinal profiles, the study of slope retreatment, the reconstruction of cave morphologies, and the reconstruction of post-depositional deformation features shown by the site sediments

These reconstructions have provided the landscape and karstic palaeogeographical habitats during the Pleistocene hominid occupation of the Sierra de Atapuerca.

Electrical Resistivity Tomography (ERT) carried out in the Sierra de Atapuerca sites (Ortega et al., 2010; Bermejo et al., 2013) has revealed its ability to characterizing the sub-surface geometry, which allows future archaeological planning strategies. This work is specially focused on the Torcas area in which the Gran Dolina, Galería Complex and Sima del Elefante sites, discovered by the railway trench, are located. These sites preserve archaeo-palaeoanthropological sedimentary infills dating back to the Early and Middle Pleistocene. The surveying was based on the elaboration of several ERT sections on the Trinchera area and in these sites' slope. This geophysical survey is aimed to identifying the extension and continuity of passages in the Trinchera multilevel cave system. The result of this exploration, together with previous geophysical, topographic, archaeological, geological and geomorphological data, shows a larger complexity of the karstic system than previously thought. The data confirms the presence of ancient cave entrances filled with sediments which relate to the upper cave level, and the existence of endokarstic morphologies belonging to the intermediate and lower karst level.

In the cave entrance deposits of the Trinchera del Ferrocarril (Sierra de Atapuerca) there are sediments derived from soils and paleosoils. Paleosol studies provide observations to characterize paleoclimates, rates of sedimentation or fix hierarchies on stratigraphic discontinuities, among others. In this contribution, we present the description and classification of soil-horizons through field and microscopic features in order to propose a preliminary soil stratigraphy of the Middle Pleistocene lithostratigraphical units of the Elefante, Galeria and Gran Dolina sites. The description of soil-horizon forming processes is based on the association of relict features and are distinguished from disturbed and inherited (re-sedimented) pedological features.

The indirect evidences available about paleoclimates and climate change in the Middle Pleistocene record of the Trinchera del Ferrocarril are mainly based on the abundant biostratigraphic record. This biostratigraphic record illustrates the dominance of temperate habitats according to the stable ecological composition of the mammalian record. The climatic-related significance and temporal span of the soil-forming processes can be added to the evidences devoted to interpret the Paleocology in the Sierra de Atapuerca project.

Trinchera del Ferrocarril soil-horizons of Middle Pleistocene age can be grouped according to the dominant nature and number of phases in the soil forming processes recognized. Sediments derived from upslope soils recorded in the lithostratigraphic units can be characterised by their mineral composition and colour as yellow calcitic, red-yellowish carbonated and brown carbonaceous. The calcitic and carbonated sediments shows monophased pedological features of carbonatation and criogenic soil forming processes. Also, carbonated sediments may contain polyphased carbonatation and cryptocrystalline enrichments and depletions. Carbonaceous sediments contain monophased carbonatation and iron depletion.

During the Middle Pleistocene, the cave entrances of the Trinchera del Ferrocarril are located in the karstified middle slope of the Sierra de Atapuerca. The cave entrance depositional environment is a product of short

episodes of sedimentation, when sediment gravity flows and gravitational collapses on high slope surfaces occur, separated by large episodes of no deposition or erosion. This depositional environment, similar to colluvial or debris flow dominated alluvial fan sedimentary model, point out to the habitat stability suggested by biostratigraphic assemblages. The habitat stability in the cave entrance deposits Trinchera del Ferrocarril is likely related to sedimentary dominance of the red-yellowish carbonated sediments (terra rossa). However, petrographic and micromorphological observations allowed us to distinguish different kinds of soil horizons in order to systematize a local paleoclimatic evolution in the cave entrance setting. The ability to trace chronostratigraphic correlations between cave entrance soil stratigraphies helps us to suggest a regional biome for the paleoclimatic interpretation. Also, the temporal scale of the depositional recurrence may be considered in the chronological frame of the marine isotopic stages and other paleoclimatic events (stadials and interstadials, Bond cycles, etc.).

ORAL

#### 4. THE BISON FROM ATAPUERCA SIMA DEL ELEFANTE LEVEL TE9 AND THE DISPERSAL HUMANS AND BISONS TO WESTERN EUROPE

*van der Made, Jan (Museo Nacional de Ciencias Naturales, CSIC, Madrid) mcnjv538@mncn.csic.es*

The possible reasons for the first human dispersal to Europe have been the subject of intensive debate and research. A possible relationship between climatic change on the one hand and human and faunal dispersal, in particular bisons, on the other has been suggested fifteen years ago (Carbonell et al, 1999). Since that time, early human remains or indications of human presence have been found in a number of localities, localities have been dated more precisely, and early bison remains have been identified. All this applies to Atapuerca TE9.

More precisely worded the "bison hypothesis" is as follows. Humans and bisons may have been present in western Asia or eastern Europe, but their westward expansion was limited by a wooded environment in central Europe. When glacial cyclicity started to develop at the end of the Early Pleistocene, open environments (called mammoth steppe) expanded periodically into central and western Europe. After a cold phase, temperatures rose and a short period with warm open landscapes existed before forests were restored. Bisons may

have used the opening of the landscape immediately, while humans may have dispersed during such a short period with prevailing warm open landscapes.

Here the new data are discussed in relationship to the "bison hypothesis". The bison remains from Atapuerca TE9 will be presented. Bison evolution and systematics will be discussed using simple biometrics. The ages of the localities with the earliest human and bison presence will be discussed.

According to the morphology of the skulls and horn cores, robusticity of the metapodials and size trends, there are three to four groups or lineages of bison in western Europe. The two first lineages to appear are the one of *Bison menneri* - *B. voigtstedtensis* and *Bison degiulii* - *B. schoetensacki*. The bison from Atapuerca TE9 belongs to the first lineage.

The appearance of the first two lineages of bison in Western Europe appears to have coincided with the first appearance of humans there, and indeed, several of the earliest localities recording early humans, also record early bisons.

The ages of the first localities that record human and bison presence are relatively close to the ages of major climatic changes, which lead to the well known glacial cycles.

The results are consistent with the "bison hypothesis".

The main aim of this communication is to present the technological strategies documented in Sima del Elefante site and its relevance in the European context. Sima del Elefante is a cave with a stratigraphic sequence 25 m thick and 15 wide. The exposed section has been divided into 16 lithostratigraphic units (TE7 to TE21), dating from the end of the Lower Pleistocene to the Late Middle Pleistocene.

We describe the most outstanding features of the lithic tools found in Sima del Elefante. The lithic assemblage found in the Lower Pleistocene levels up to 2013 field-work season contains 86 artefacts, and the Middle Pleistocene levels have yielded 41 artefacts.

Neither pebble tools nor Large Cutting Tools (LCT) have been recovered from the Lower Pleistocene levels. On the basis of its technological features, the lithic assemblage from the lower sequence of Sima del Elefante can be assigned to the Mode 1 technocomplex. The lithic collection from the Middle Pleistocene levels is defined by the presence of medium to large-sized implements, including several LCT, and longitudinal and centripetal reduction sequences. These types of lithic components are usually associated with the Mode 2 technocomplex. Sima del Elefante has two main values for the study of human evolution. On the one hand, the lower levels (TE7-TE14) are an essential reference to know the early stages of the colonization of Europe. The TE9c level has provided stone tools (Mode 1), faunal remains and human fossils, dated to 1.22 My. On the other hand, this is one of the few European sites with a stratigraphic sequence including remains of human occupations during the end of the Lower Pleistocene and the Late Middle Pleistocene (Units TE18-TE19). This allows us to compare the technological and paleo-economic strategies carried out by different species of hominins during two key phases of the occupation of Europe.

The Sima del Elefante site is a major cave infill with a stratigraphic succession 25 m thick and 15 wide. The lower levels of the cave (TE7 to TE16) show a reverse polarity magnetization direction attributed to the Matuyama Chron. Subunit TE9c was dated to  $1.22 \pm 0.16$  Ma years old by the cosmogenic nuclides. TE9c is a complex sedimentary deposit composed by subangular blocks and a clayey matrix. This deposit shows plastic deformations and few fissures. During the excavation it was impossible to define different archaeopaleontological levels within TE9c. However, the morphology of the sedimentary deposit and its fossil content indicate that there are different moments and processes of accumulation.

In this level we recovered a human mandible and a phalanx (*Homo* sp.) apparently associated to a Mode 1 lithic assemblage and faunal remains with anthropogenic processing marks, mainly on Cervidae and large bovid bones.

The main aim is to show the archaeological and paleoecological features of TE9c, so the scenario of the first hominins occupations at Sierra de Atapuerca.

We analyzed level 9 from several disciplines: geomorphology, paleoecology, taphonomy and archaeology.

After the anatomic, taxonomic and taphonomic analyses of the fossil remains recovered in this site, we can observe that the animals recovered from TE9c can be classified in three groups: small animal (mainly birds and lagomorphs), small-medium size carnivores (*Vulpes* cf. *alopeoides*, *Canis* cf. *mosbachensis*, *Lynx* *issiodorensis* ssp. *Pannonictis* cf. *nestii*) and medium-large ungulates (*Equus* *altidens*, *Eucladoceros* *giulii*, *Sus* sp. *Bison* cf. *voigtstedtensis*; *Dama* "nestii" *vallonnetensis*). In the most of the cases, the remains of small animals and carnivores have been recovered in anatomical connection or semi-connection. While in the case of large herbivores, only in a case we recovered a part of an animal (*Bison* sp.) in anatomical semi-connection.

A total of 33 lithic remains, mainly in chert, have been discovered and assigned to Mode 1 technology. These

artefacts have been recovered through the sedimentary deposit, but the absence of refitting does not allow us to confirm that these pieces correspond to the same moment in time.

We consider that there are several events of accumulation and that the origin of each one of the accumulations seems related to the characteristics of each group of fossil remains recovered from this level.

---

*Kahlke, Ralf-Dietrich (Senckenberg Research Institute, Research Station of Quaternary Palaeontology, Am Jakobskirchhof 4, D-99423 Weimar, Germany) rdkahlke@senckenberg.de*

After the 600 ka long Late Villafranchian period of consistent temperature variations 1.8-1.2 Ma BP, a new regime of global climatic evolution developed. Between 1.2 and 0.9 Ma BB the frequency of the global  $\delta^{18}\text{O}$  record became less stable and its amplitudes increased significantly. This interval can be seen as a transitional time, linking the span of 41 ka climate periodicity with the following 100 ka one. Its progressing environmental instability created the ecological preconditions for a ground-breaking faunal turnover in Eurasia. In many groups of larger mammals new forms arose, which replaced preceding Villafranchian elements. Throughout the entire western Palaeartic renewed mammal communities evolved and inhabited a growing variety of habitats. The distinctive character of the resulting faunas of the 1.2-0.9 Ma stretch supports the idea of introducing a separate biochron, the Epivillafranchian. However, extended large mammal records from this period of time remain still rare in Europe.

After the 600 ka long Late Villafranchian period of consistent temperature variations 1.8-1.2 Ma BP, a new regime of global climatic evolution developed. Between 1.2 and 0.9 Ma BB the frequency of the global  $\delta^{18}\text{O}$  record

became less stable and its amplitudes increased significantly (Raymo and Nisancioglu, 2003, fig. 1; Lisiecki and Raymo, 2005, fig. 4). This interval can be seen as a transitional time, linking the span of 41 ka climate periodicity with the following 100 ka one. Its progressing environmental instability created the ecological preconditions for a ground-breaking faunal turnover in Eurasia. In many groups of larger mammals new forms arose, which replaced preceding Villafranchian elements. Throughout the entire western Palaeartic renewed mammal communities evolved and inhabited a growing variety of habitats (Kahlke et al., 2011). The distinctive character of the resulting faunas of the 1.2-0.9 Ma stretch supports the idea of introducing a separate biochron, the Epivillafranchian (Kahlke, 2007) However, extended large mammal records from this period of time remain still rare in Europe (review in Kahlke, 2006).

Untermassfeld shows a combination of cranial traits: some of them are also observed in *U. arctos* and are considered primitive, while others are shared with *U. deningeri*- *U. spelaeus*, and are interpreted as derived towards the speloid lineage. The derived condition of the palate thickness observed in Untermassfeld and the speloid lineage is shared with the cranial remains of *Ursus dolinensis*, from Sierra de Atapuerca (Gran Dolina -TDW4-5).

As a result of our analysis based in cranial traits, we conclude that bears from Untermassfeld and Atapuerca – Trinchera Dolina 4 (TDW4) might represent the ancient stock from which the cave bear arose.

### 8. PHYLOGENETIC POSITION OF THE GRAN DOLINA-TD6 HOMININS IN THE CONTEXT OF THE HUMAN EVOLUTION IN EUROPE

*Bermúdez de Castro, José María (CENIEH,) josemaria.bermudezdecastro@cenieh.es*

*Martinón-Torres, María (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) maria.martinon@cenieh.es*

The so-called "Aurora Archaeostratigraphic Set" of the TD6 level of the Gran Dolina cave site in Sierra de Atapuerca, northern Spain has yielded about 150 human fossil remains, attributed to *Homo antecessor* (Bermúdez de Castro et al., 1997, Science 276), and dated to the MIS 21 or MIS 25. Our aim is to present a brief analysis of the main features of this sample and to discuss the phylogenetic

position of this hominin assemblage in the framework of the evolutionary scenario of the settlement of Europe.

The TD6 human fossils exhibit a particular mosaic of primitive and derived features for the Homo clade that reinforces the taxonomic identity of H. antecessor. Some dental features are primitive regarding the Homo clade, whereas other are derived and shared with Pleistocene Eurasian hominins. The mandibles show a primitive structural pattern shared with other African and Asian specimens. However, they have lost the massive aspect characteristic of most Homo African mandibles, and present some progressive features also shared with Middle Pleistocene African and, particularly, Asian specimens. None of the mandibular features considered apomorphic in the European Middle and Late Pleistocene hominins are present in the TD6 mandibles (perhaps except the great development of the medial pterygoid tubercle).

In spite that the TD6 hominins are nearly one million years old, it can be stated that they show a clear tendency towards what might be called "modernity". In fact, their brain size was higher than 1000 cubic centimeters and the postcranial skeleton shares most of the features with European Middle and Late Pleistocene hominins, including modern humans. The stature estimations reveal that TD6 hominins were tall, about 175 centimetres. The pattern of dental development is definitively modern, whereas the very complete face ATD6-69 (adolescent) represents the earliest occurrence of a modern face in the fossil record. The remodeling pattern of this specimen is also similar to that of modern humans.

The TD6 hominins also exhibit some postcranial and dental features that are shared with Neanderthals and the European Middle Pleistocene hominins. Obviously, these features cannot be considered as Neandertal apomorphies, but traits that appeared in an old hominin population and were inherited by both H. antecessor and H. neanderthalensis.

Since we no longer support our previous hypothesis about the phylogenetic position of H. antecessor as the last common ancestor of the Neandertals and modern humans, it is necessary to reconcile the present evidence with an alternative hypothesis. We propose a cladogenetic event of the genus Homo, previous to the chronology of H. antecessor, from which gradual branching of hominin lineages (species) would have occurred throughout time. This cladogenesis would have been characterized, among other features, by a cranial size increase and the appearance of a derived modern-

like face morphology. This means that we need to revise the Eurasian fossil record with a different perspective. H. antecessor would represent a side branch confined to Western Europe. Interbreeding between individuals of Homo antecessor and those of other branches of the same cladogenesis, which colonized Europe in later times, cannot be ruled out.

ORAL

## 9. MORPHOLOGICAL COMPARISON OF THE PLEISTOCENE HOMININ LOWER MOLARS FROM ATAPUERCA SITES BY MEANS OF MICROCT.

*Martínez de Pinillos, Marina (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) mari-nampg@hotmail.com*

*Martinón-Torres, María (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) maria.martinon@cenieh.es*

*Martín-Francés, Laura (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) laura.martin-frances@fa.cenieh.es*

*Bermúdez de Castro, José María (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) jose-maria.bermudezdecastro@cenieh.es*

Since the Atapuerca fossils are the most representative remains to understand the evolution of the genus Homo in Europe during the Early and Middle Pleistocene, the study of their dentition is becoming increasingly important. Several discoveries (Bermúdez de Castro and Martínón-Torres, 2013; Martínón-Torres et al., 2007a; Meyer et al., 2014) propose that the human occupation of Europe during the Pleistocene depended upon the non-linear recruitment of populations from the central area of dispersals of Eurasia. Morphological comparisons between those populations will provide new and valuable information to investigate the evolutionary scenario of the first European settlement.

The aim of this study is to explore the affinities between extant and extinct human population in Europe. For this purpose, and knowing that the expression of trigonid and talonid crest pattern seems to be of significant taxonomic and phylogenetic value (Bailey, 2002; Martínez de Pinillos et al., 2014; Martínón-Torres et al., 2014), we present a comparative study of these traits at the outer enamel surface (OES) and enamel dentine junction (EDJ) for H. antecessor, H. heidelbergensis (Sima de los Huesos samples), H. neanderthalensis and H. sapiens by means of microtomography (microCT).

Our results reveals that despite of the wider variability of trigonid crests types at the EDJ compared to the OES, the correlation in the morphology of the inner and the outer surface of the lower molars is high. Furthermore and in accordance with previous works (e.g. Bermúdez de Castro et al., 2003; Martínón-Torres et al., 2013), we highlight a more primitive dental conformation in Gran Dolina TD6 hominins in comparison with more derived features in the European Middle Pleistocene hominins from Sima de los Huesos.

To the light of our microCT study, we present some evolutionary interpretations of the relationship among the Early and Middle Pleistocene hominins of Europe, where the divergence of the features -primitive or derived- is considered regarding to *H. sapiens* and *H. neanderthalensis* trigonid and talonid crest expression.

### 10. CROWN FORMATION TIMES IN HOMO ANTECESSOR MOLARS (GRAN DOLINA-TD6, SIERRA DE ATAPUERCA, SPAIN)

*Modesto-Mata, Mario (Centro Nacional de Investigación sobre la Evolución Humana (CENIEH) / Equipo de Investigación Primeros Pobladores de Extremadura) paleomariomm@gmail.com*

*Bermúdez de Castro, José María (Centro Nacional de Investigación sobre la Evolución Humana (CENIEH) josemaria.bermudezdecastro@cenieh.es*

*Dean, Chris (Department of Anatomy and Developmental Biology UCL) chris.dean@ucl.ac.uk*

*Martínón-Torres, María (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) maria.martinon@cenieh.es*

Human remains from Atapuerca-Gran Dolina TD6 level represent at least 11 individuals that are dated to approximately 0.9 million years. These fossils were recovered in different seasons since 1994 and were the base to name a new human species, *Homo antecessor*. There are several publications regarding the morphological features of this hominin, including teeth. However, information available about *Homo antecessor* dental development is scarce, and those studies did not employed histological variables. Here, we studied the crown formation times of *Homo antecessor* lower molars. Our results are compared with molar crown formation times in other hominin species and great apes obtained from the literature. We studied seven *Homo antecessor* molars that are as-

signed to three individuals: two lower molars (one M1 and one M3) and five upper molars (three M1, one M2 and one M3). Environmental scanning electron microscope (ESEM) was used to estimate the imbricational enamel formation time and microtomography (microCT) was used to estimate the appositional enamel formation time.

Crown formation times of *Homo antecessor* molars fit within the variability of other hominin species.

Molar crown formation times are relatively stable throughout hominid evolution at least from the last common ancestor with chimpanzees, regardless dental morphological differences. Thus, differences in the eruption times might be mostly based on differences in the root extension rates.

## ORAL

### 11. THE UNGULATES FROM GRAN DOLINA LEVEL TD8 AT ATAPUERCA: EVOLUTION, BIOSTRATIGRAPHY, BIOGEOGRAPHY

*van der Made, Jan (Museo Nacional de Ciencias Naturales, CSIC, Madrid) mcnjv538@mncn.csic.es*

*Rosell, Jordi (IPHES/URV) jordi.rosell@urv.cat*

*Blasco, Ruth (The Gibraltar Museum) rblascolopez@gmail.com*

The locality of Gran Dolina at Atapuerca records the Early-Middle Pleistocene boundary, an extraordinary sequence of fossiliferous levels straddling this boundary, archaeological levels and the level TD6, which yielded over a hundred remains of *Homo antecessor*. These levels are dated by an array of dating techniques and palaeomagnetism situates the Brunhes-Matuyama boundary in the top of level TD7. Level TD8 is the first Middle Pleistocene fossiliferous level.

Ongoing research results in increased data on the ungulates that lived around the Early-Middle Pleistocene transition and new hypotheses on their evolution. Here we present the ungulate association of TD8 in this context and compare it to those of other localities of more or less similar age. The TD8 ungulates are similar to those of lower levels at Gran Dolina, but differ from those from many other European early Middle Pleistocene localities. TD8 is peculiar in retaining a species of the giant deer genus *Eucladoceros* and a small rhinoceros. Such a small rhinoceros is common in the late Early Pleistocene and some believe it to be related to *Stephanorhinus etruscus*,

while others believe it to be related to *S. hundsheimensis*. The persistence of these forms suggests that TD8 is older than the localities with which it is compared. If that is the case, it is the oldest Middle Pleistocene ungulate fauna. Alternatively, it is a geographic difference and relict forms persisted longer in Spain.

The Sierra de Atapuerca sites offer a series of chronological sequences whose correlation allows the paleoenvironmental and cultural evolution during the Early and Middle Pleistocene to be reconstructed. Previous work in these sites showed the difficulties in identifying clear cut-off points separating entirely different environmental episodes along the sequence, which lacks evidences of extremely harsh conditions. Another difficulty was relating the paleo-environmental changes with the cultural ones.

Here we present a multiproxy analysis focused on the Middle Pleistocene unit TD10 of Gran Dolina site, which is the richest archaeological unit being excavated in Atapuerca. Our main goal is to describe in detail the 3m thick stratigraphic succession of TD10, and to situate the most significant geological, geochronological, paleoenvironmental, palaeontological and archaeological information recovered up to now in the most representative profiles.

The main purposes of such a multidisciplinary presentation are to identify specific micro-scale environmental variations through the TD10 sedimentary unit, and to assess how they are reflected in the archaeo-palaeontological record.

A total of twelve "sample units" (layers) have been individualised in the TD10 succession, from top to bottom: four in sub-unit TD10.1, four in TD10.2, two in TD10.3 and two in TD10.4. One extra control point was taken in level TD9, just to record the differences between these apparently so diverse units.

Each of these points has been specifically sampled, and data coming from different fields of study is taken into account separately. Data sources broadly include geology (sedimentology, stratigraphic features, soil micro-morphology observations and geochronology), environment (pollen, small and large fossil vertebrate remains) and archaeology (behavioural data coming from technological and zooarchaeological studies).

A first step in the study involves combination of these

proxy data to characterise each of the control points, which will lead us to define hypothetically synchronic and homogeneous associations. This will allow us to draw preliminary hypotheses, which intent to correlate environmental and cultural data for these homogeneous layers.

A second step involves an analysis of the evolution of the archaeological and palaeontological assemblages from the sucession of TD10, taking into account the evolutionary trends of all those features considered significant, both for environmental and cultural aspects.

The excavation and sampling strategy is demonstrated to be fruitful to characterise specific layers in the TD10 sequence. It allows a better description of both environmental and cultural aspects than previous studies, which were based on larger units of analysis.

The comparison of the different synchronic associations, which have been observed, is useful from an evolutionary perspective. In its turn, the diachronic framework proved to be useful to properly contextualise some of the archaeological issues of TD10 already published.

In general terms, we can conclude than environmental constraints hardly explain by themselves the identified cultural changes. However, the combined information for each selected layer furnished crucial data to contextualise and to improve the characterisation of the varied subsistence strategies of the hominins who left their archaeological evidence in TD10 during the late Acheulean.

Determining the paleoecology and paleoenvironments at fossil localities provides a context in which specific hypotheses can be made about how particular taxa survived and evolved over time. For example, the assumption that Neanderthals consumed predominantly meat derived from large game is supported by the abundance of ungulate bones associated with the Mousterian lithic industry. This idea is reinforced by microwear and stable isotope analyses that identify Neanderthals as dependent on a high protein diet derived mainly from large and medium-sized herbivores. Conversely, other researchers argue that these humans consumed a more varied diet including smaller game, plants, and marine resources. Exploring the paleoenvironment and availability of resources on the landscape would permit a specific test between these different paleodietary proposals (i.e., protein-dominated vs. varied diet) for Neanderthals. This particular study aims to determine the paleoecological conditions present in northern Iberia during the Middle Pleistocene with the ultimate goal of resolving the resources available to the populations of humans within the Neanderthal lineage living there.

Data for this study was obtained from stable isotope analyses of tooth enamel from large mammals (Bison, Cervus, Equus, Panthera) coming from level TD10 of Gran Dolina (Sierra de Atapuerca, Burgos, Spain). TD10 is a layer dated to between  $379 \pm 57$  ka and  $418 \pm 63$  ka (MIS 11) and shows evidence of humans from the Neanderthal lineage on the landscape. Some of the analyzed remains were consumed by humans and therefore can help decipher the subsistence strategies developed by homi-

nids in the European Middle Pleistocene. Two sampling techniques were utilized in this study: most specimens were bulk sampled which provides an average value for diet and habitat use while the tooth was growing. Three samples of bison were serially sampled, taking multiple samples perpendicular to the growth axis of the tooth, which provides finer detail into diet and habitat use.

The results obtained from our samples indicate a habitat dominated by C3 plants. The bovid samples had the highest  $\delta^{13}\text{C}$  values indicating eating in open habitats. The mean  $\delta^{13}\text{C}$  values for *Cervus* and *Equus* are the same, suggesting that horses and red deer overlap in diet/habitat use. For  $\delta^{18}\text{O}$  values, no significant differences were observed among the studied taxa. The values from TD10 are very similar to data from a previous study that included specimens from Atapuerca Faunal Unit 6. The serial samples of the three bison teeth reveal little carbon isotope variation over the time when the tooth was mineralizing. The bison also show the most positive carbon isotope values among the sampled herbivores within TD 10. The isotope values that we find support the idea that there were open habitats as well as more wooded or forested habitats as a Mediterranean habitat would show, as was suggested for this layer from previous studies based on faunal and pollen analysis.

#### **14. THE FACIES UTRILLAS QUARTZITE VARIETY: FROM A PETROGRAPHIC CHARACTERIZATION TO A FUNCTIONAL ANALYSIS DESIGN. THE EXAMPLE OF GRAN DOLINA SITE, TD10 LEVEL (SIERRA DE ATAPUERCA, BURGOS, SPAIN)**

*Pedergrnana, Antonella (IPHES/URV) apedergrnana@iphes.cat*  
*García-Antón, M.Dolores (URV/IPHES) lgarciaanton@iphes.cat*

The convergence between lithic use-wear and petrographic analyses is an example of the fruitful interaction of different disciplines in order to obtain a more confident interpretation of the archaeological record. Normally, functional analysis is performed showing any or very less regard about the various lithic raw materials specific characteristics. In our opinion, in order to provide a more suitable interpretation of the archaeological use-wear evidence, each rock type should be treated individually underlining the most accurate parameters for describing surface modifications.

Thus, this overall research initiative has been undertaken

with the effort to evaluate the role of lithic raw material variability within the use-wear formation processes, focusing specifically on a number of lithological varieties generally labeled as quartzite (from the very well metamorphosed types to quartz-arenites). With this concern, quartzite varieties coming from TD10 level of Gran Dolina site (Sierra de Atapuerca, Burgos) will be described from a petrographic point of view. Physical differences will be described in terms of chemical composition, grains size, fabric, metamorphism degree, presence or absence of cement, etc... In this work we will focus on the facies Utrillas (FU), which is one of the most representative varieties within the TD10 level quartzite assemblage. Showing the characters of a meta-quartzite, it presents more regular petrographic features than other varieties. The two FU types are also documented in detail through SEM observations. Sequential experiments are done in order to understand use-wear formation processes and to evaluate which petrographic features might influence them.

The obtained results of the experimental observations in the light of the petrographic descriptions provided us with a possible theoretical formulation about quartzite surface modifications due to use, valid at a wide-ranging scale. A general model about use-wear on quartzite tools will be subsequently obtained by applying this analysis pattern to the other quartzite varieties present in the TD10 level assemblage.

#### **15. QUARTZ AND QUARTZITE REFITS OF GRAN DOLINA SITE (SIERRA OF ATAPUERCA, BURGOS): CONNECTING THE LITHIC ARTEFACTS IN TD10.1 LEVEL**

*López-Ortega, Esther (IPHES, URV) elopez@iphes.cat*  
*Bargalló, Amèlia (IPHES, URV) ameliabarg@gmail.com*  
*de Lombera-Hermida, Arturo (IPHES, URV, GEPN-USC) artu-  
lomb@gmail.com*  
*Mosquera, Marina (IPHES, URV) mmosquera@iphes.cat*  
*Ollé, Andreu (IPHES, URV) aolle@iphes.cat*  
*Rodríguez, Xosé Pedro (IPHES, URV) xprodriguez@iphes.cat*

The preliminary results of lithic refits in the NW sector of Gran Dolina TD10.1 level have shown the existence of short, medium and long connection distances between the artefacts and hence the possibility of identifying activities areas in the site. Continuing this study, the new work presented here, takes into account the entire lithic assemblage recovered from the total surface of TD10.1 (more than 95 m<sup>2</sup>).

The current study is focused on refits of quartz and quartzite artefacts. Even though they are secondary raw materials in the tool production, mainly based on flint, the identification and association of these pieces to different raw material units (RMU) have widely increased the number and the type of refits including both short and long distance connections. The aim of this analysis is to identify different reduction strategies of these raw materials and a distinct spatial distribution of production, transport and use processes that affects them.

The spatial distribution of the artefacts, the projection of RMU-s and the refits present within each RMU indicate about the existence of several accumulations, some of them related to knapping activities, as well as the final use and discard of the items. From the technological point of view, the refits studied support the reduction strategies previously published and provide information about fragmented and complete knapping sequences, which allows inferring intra-site and inter-site patterns of mobility. This information will be completed by use-wear analysis and taphonomic studies, thus inferring more specifically where different activities at the site took place.

The results obtained, along with other taphonomic studies, allow assessing the resolution of the archaeological assemblages, in particular their potential horizontal and vertical movement and the potential time-spans that they represent. The diachronic study through the sequence of TD10.1 allows us to understand the evolution of the different occupational and spatial patterns developed by the hominids in the cave.

ajrh78@gmail.com*

*Palmira Saladié (IPHES/URV) psaladie@iphes.cat*

*Carbonell, Eudald (URV, IPHES, IVPP) ecarbonell@iphes.cat*

Gran Dolina site is being large scale excavated since 1996. Between 2003 and 2013, it has recovered more than 66,000 faunal and 13,000 lithic remains from TD10.2 sublevel (c.400kyr). In this communication we present the results obtained from the zooarchaeological and taphonomic analysis of the former.

Anatomical and taxonomic composition, mortality profiles and surface damages modification has allowed us to reconstruct the taphonomic history of the assemblage and establish the origin of the accumulation.

The TD10.2 sublevel it's a bison bonebed that represents several events of mass communal hunting in which several bison were slaughtered to be exploited intensively by the hominines that occupy the cave.

The hemispheres of the human brain are asymmetrical, both functionally and structurally, thus avoiding a duplication of neural circuits costs (Levy 1977), and reducing interference between different functions (Galaburda et al., 1978). The division of labor between the two hemispheres is known as lateralization (Kalat, 2004), and it is recognized that various higher cognitive functions are lateralized (Hutsler & Galuske, 2003).

The most common structural asymmetry is known as petalia, the extension of one hemisphere beyond the other (Gilissen, 2001), and is related to the individual's handedness (Geschwind & Levitsky, 1968; LeMay, 1976; Chiarello et al., 2009). In humans, the common pattern is the extension of the right frontal and left occipital hemispheres (Chui & Damasio, 1980; LeMay, 1984; Toga & Thompson, 2003) which corresponds to right handedness (90% of the present-day human population). The

other 10% corresponds to left handedness with a reversed pattern.

The best known functional asymmetry is Broca's area (Brodmann areas 44, 45 and 47), located in the left hemisphere (Geschwind & Levitsky, 1968; Zilles et al., 1996; Kalat, 2004). This is an important neuroanatomical region related to language, but Foundas (1998) noted that there is a significant asymmetry of area 45 in the left hemisphere in both right- and left-handed individuals. In contrast, there is a clear left asymmetry of area 44 in right-handed individuals, and a right asymmetry of this area in left-handed individuals. Foundas (1998) concluded that the use of hands therefore is positively correlated with the asymmetry in area 44.

Petalias have been quantified on the endocasts from human specimens from the Sima de los Huesos site, using the method from LeMay (1982). The results have been matched to handedness. Additionally, Broca's and Brodmann areas have been isolated in each endocast from Sima de los Huesos, and the development of areas 44 and 45 also has been related to handedness. Results were combined to define the possible handedness in every specimen.

Handedness was inferred in a previous cultural dental wear analysis concluding a preferential direction of the labial striation in each dental specimen (Lozano et al., 2008).

Correlation between the orientation of anterior dental striations and particular brain asymmetries was examined in six crania with associated dentitions to examine possible handedness.

The combination of results from the analysis of petalias and Broca's area has resulted in a variety of patterns of brain laterality in the Sima de los Huesos collection. Additionally, handedness was correlated with brain laterality in five of six specimens.

Only one specimen was the exception, because brain laterality does not correspond to right handedness, but the preferential dental striation pattern is right oblique, related to the use of right hand.

One cranial-dental specimen shows a contrary pattern between handedness and brain asymmetries. This specimen therefore used the non-preferential hand for some tasks leaving marks on the anterior teeth, maybe due by any physical problem in the left hand or maybe possible to learning by imitation using the non-preferential hand.

ORAL

## 18. THE LATEST MEGACEROIDES SOLILHACUS FROM EUROPE AT GALERÍA, ATAPUERCA?

*van der Made, Jan (Museo Nacional de Ciencias Naturales, CSIC, Madrid) mcnjv538@mncn.csic.es*

*Cáceres, Isabel (Àrea de Prehistòria, Universitat Rovira i Virgili (URV), Avinguda de Catalunya 35, 43002 Tarragona, Spain - IPHES, Institut Català de Paleoecologia Humana i Evolució Social, C/Escorxador s/n, 43003 Tarragona, Spain) icaceres@iphes.cat*

*Ortega, Ana Isabel (CENIEH, Centro Nacional de Investigación sobre la Evolución Humana, Paseo Sierra de Atapuerca 3, 09002 Burgos, Spain - GEE, Grupo Espeleológico Edelweiss, Diputación Provincial de Burgos, Paseo del Espolón 34, 09001 Burgos, Spain) anaisabel.ortega60@gmail.com*

Giant deer were a common elements in the environment of early humans and in fact, most of the time, there was more than one species. A particular species is indicated with the name *Megaceroides solilhacus*, while also other names, such as *Praemegaceros* or *Megaloceros verticornis* are applied. This was a large species, which has been considered to be typical for the Cromerian or early Middle Pleistocene and even to be anterior to the glaciations known as Elsterian or Anglian. This species or the lineage to which it belongs is present in various levels at Atapuerca. The latest record at Atapuerca is in level TG10a of Galería.

New ESR dates for this level (Falguères et al., 2013) suggest that this may by far be the youngest *Megaceroides* known from Europe. These dates suggests ages around 250 ka and TG10a being correlative of stage 8. Though other dating techniques (TL and IRSL) suggest significantly older ages, the possibility of such very young ages are interesting from a biogeographic point of view.

Deer of this genus are known from Europe, the Middle East and from North Africa. The North African species *Megaceroides algericus* is mostly or only known from the late Pleistocene and has a wide array of derived features. Though there is some discussion on its origins, it seems likely that it is a descendant of *M. solilhacus*. There is however, a long temporal gap between the latest *M. solilhacus* and the earliest *M. algericus*. The latest *Megaceroides* from Eurasia is from Petralona in Greece, Azokh in Nagorno-Karabakh and from Atapuerca TG10a, which could bridge the gap between the Eurasian and African records. The appearance of *Megaceroides* in North Africa seems to be part of a Late Pleistocene increase of the presence of Eurasian species in North Africa.

Faunal exchange between Africa and Eurasia shows an overall decreasing trend during past four million years, which is probably related to an increasing aridity in North Africa and the Middle East. Human dispersal out of Africa seems to have coincided with some moments of more intense faunal exchange. Whether this is a mere coincidence, or not, remains to be seen, but the dispersal of *Homo sapiens* out of Africa coincided more or less with a renewed dispersal of Eurasian mammals, including *Megaceroides*, into North Africa.

Galería Complex is an archaeological site located at Trinchera del Ferrocarril (Sierra de Atapuerca, Burgos) characterized by a significant Middle Pleistocene human occupation. The systematic excavation includes the areas known as Galería (with the Sinkhole of TN, excavated between 1980-1995) and Cueva de los Zarpazos (excavated between 2002 and 2010). This deposit has a sequence of five stratigraphic units and a soil, with an important archaeological and palaeontological record 500 to 200 ka years old. This site has been related with the hominin fossils found at Sima de los Huesos site and the archaeological sequences of the level TD10 of Gran Dolina site.

New archaeological interventions started in 2010 with the main objective of checking the previous information about the occupations in Galería and extending the archaeological, taphonomical, sedimentological and palynological knowledge about the environmental conditions of these occupations. This paper presents the updated type stratigraphic sequence of Galería site, which includes a synthetic relation of the different sections with the geological and archaeological units. This type sequence intends to be a reference for fieldwork reviewing progresses and for the future research, as well as support the archaeological palimpsest character of the GSU subunits of TG11 level.

The new excavations have provided more than 970 faunal remains and 56 lithic artifacts. The lithics were made basically on Neogene chert and the faunal assemblage is represented mainly by axial and cranial elements of cervid and equid individuals. The overall dynamics observed seem to be the same than those identified in the former interventions, this is, that the humans and carnivores vied for the existing animals resources. We emphasize that the new works have uncovered evidences of human occupation in the GIV unit, traditionally considered sterile.

ORAL

## 20. THE EMERGENCE AND DEVELOPMENT OF THE ACHEULEAN IN ATAPUERCA: THE GALERÍA SITE (C. 500-250KA)

*García-Medrano, Paula (IPHES/URV) pgarciamedrano@gmail.com*

*Cáceres, Isabel (URV/IPHES) icaceres@iphes.cat*

*Ortega, Ana Isabel (CENIEH, GEE) anaisabel.ortega60@gmail.com*

*Ollé, Andreu (IPHES/URV) aolle@iphes.cat*

*Eudald Carbonell (URV-IPHES-IVPP) ecarbonell@iphes.cat*

Galería is one of the main sites of the Trinchera del Ferrocarril (Atapuerca), together with Gran Dolina and Sima del Elefante. This site has a long well dated sequence from 500Ka to 250Ka, which have let us to make a diachronic study of the technology. At the lower levels of Galería, we have documented the first vestiges of Acheulean in Atapuerca. This is characterized by the use of quartzite cobbles to shape Large Tools (mainly handaxes and cleavers) and by the exploitation of large flakes of Neogene chert. As a consequence of the maintenance of the same occupational patterns and the same "toolkit", the technology of Galería has kept an image of technological stability

through the Middle Pleistocene. Nevertheless, we have isolated technological characteristics which reflect technological changes through time.

In addition, we have made a synchronic study of the occupations. The most part of the knapping sequences are made outside the cave and the operative chains are very fragmented, as a consequence of short and sporadic occupations, for the only purpose of obtaining the animals that had fallen into the cave through a natural trap created by the TN shaft, in successful competition with carnivores. In spite of this, through the refits we have characterized not only the spatial distribution of the activities but the knapping sequences developed inside the cave. This two areas, (outside – inside) mean different knap strategies.

The Galería excavations were developed during the 80s and 90s. These were recently restarted at the upper levels of the sequence. This has allowed us to make a synthesis of the ancient dates and plan the whole set of new questions to solve with the new interventions.

1. Is there any change in the occupational pattern at the end of the sequence?
2. Which is the real degree of technological activity inside the cave?
3. Is it possible to consolidate the technological features documented through the Galería's sequence?

ORAL

## 21. MAPPING WITH GIS THE PREHISTORIC SITES AROUND SIERRA DE ATAPUERCA (BURGOS). THE GENERAL SPATIAL DISTRIBUTION OF THE HOLOCENE

*Marcos Sáiz, Francisco Javier (Área de Prehistoria. Universidad de Burgos) fjaviermarcos@hotmail.com*

In recent decades, the area around Sierra de Atapuerca has been the subject of several archaeological interventions (excavations and surveys), both by the Research Projects and Management or Emergency Archaeology. The most significant advance for the archaeological knowledge of this territory, in terms of sites discovered, has been carried out, precisely, by researchers of University of Burgos, Department of Prehistory (Atapuerca Research Team).

In fact, since 1999 to 2007 we have developed a Research Project focused to the analysis of the evolution of prehis-

toric settlement around Sierra de Atapuerca during the Holocene. The fieldwork was based in 10 archaeological surveys, 8 with a full coverage intensive systematic method over 314 Km<sup>2</sup> (10 Km radius of Cueva Mayor), and 2 intensive systematic surveys over the sites.

The purpose of this communication is to present, over this territory, an update cartography until 2014 with all archaeological sites of the Holocene: surveys sites, excavations sites, caves and megalithic structures. Furthermore, we discuss about the mapping techniques with GIS and geospatial databases applied to archaeological surveys, we evaluate the megalithic structures and the settlements excavated in other digs, and we make an assessment of the relevance and contributions of the different archaeological interventions. In this work, we must underline the successful results generated, with a general spatial distribution of the Holocene with more than 200 sites.

GIS and the general spatial distribution of the Holocene with more than 200 sites (caves, sites and megalithic structures), suggest that the territory around Sierra de Atapuerca is one of the North Meseta regions more intensely exploited.

The horse has played an important role in the prehistoric societies along the time. During the Paleolithic the horse was frequently hunted and consumed by man. In the Iberian Peninsula, the horse was a common element at the end of the Late Pleistocene, after which there was a long period during the Early Holocene when sites containing horse remains were very rare. It was not until the Chalcolithic or Bell Beaker culture when more equine remains were found in certain regions.

The horse was exploited for various reasons in the Iberian Peninsula during the Bronze Age. In some cases, horses were used for their meat. They were also used as pack or draft animals, and only after they fulfilled this purpose, were eventually consumed. Another possible purpose of horse exploitation could be to obtain milk. Nonetheless, no evidence has been found at any site in Iberia that indicates mare's milk consumption.

Lastly, during the Bronze Age, horses could have been considered goods that represented prestige. The possession and consumption of horses could have served to distinguish between different social classes living in settlements in that period. This is difficult to verify with the zooarchaeological record.

In this study, an exceptional consumption of horse remains in Early Bronze Age is documented. These remains were discovered during the sixth excavation campaign of the El Portalón site directed by J. M. Apellániz in 1979. The material consists of 103 bones and teeth, belonging to a minimum number of six individuals of *Equus* sp., recovered in a thin stratigraphic interval (around 70 centimeters) and a 2 m<sup>2</sup> of area (called Horse stratigraphic unit: HSU). It is dated c. 2000 yr cal B.C.

The mortality profile (three of the six individuals were slaughtered before reaching four years of age), butchery marks (on 27.18% of the bone remains), thermal alteration and the percussion marks suggest horse meat as an important resource for the inhabitants from the Bronze Age of El Portalón. This is unusual among other Iberian sites where ovicaprines, bovids and suids provide the majority of the meat. The high percentage of equid remains identified in the HSU (43% of total NISP) makes this place one of few Holocene Iberian sites (with Cerro de La Encina and the phase III of Pic del Corbs) where the horse is the most abundant species.

The mentioned evidences and the low representation of the equid remains in the other levels of the whole site's stratigraphic sequence bring forward the exceptional character of equid consumption represented in this site,

and, together with other contextual evidences, suggest that this accumulation of horse remains could be the result of a feast.

The main goal of this work is to introduce the archaeological characteristics of a collective burial excavated in

the level 7/8 from "El Portalón de Cueva Mayor" site (Sierra de Atapuerca, Burgos). The radiocarbon dating for this funerary level, obtained from seed, faunal and human remains, indicates dates of  $4350 \pm 30$  BP. This, together with the typology of cultural material places this burial in the pre-Bell Beaker pottery Chalcolithic period of the Spanish North Plateau (between 4600 and 3950 BP).

The level 7/8 represents a tumular structure in which several burials were performed. Over 93 human remains have been recovered from this level, belonging to a minimum number of 11 individuals, four adults and seven subadults. Because these burials were disturbed by later chalcolithic dweller, in most cases, it is not possible to establish a clear association among the human remains and the cultural materials (grave goods) found in this level. Therefore the funerary ritual related to these human remains is hard to describe.

Fortunately, during 2012 field season, an intact burial with a complete human subadult skeleton was recovered from this level. The burial was clearly associated to both, cultural and faunal remains. Our study shows that the level 7/8 from El Portalón fits well with the pattern of the Chalcolithic funerary world that is defined by the collective character of the burials and by the no spatial coincidence of them and habitat areas.

This extraordinary discovery provides an important source of knowledge regarding the funerary behaviour during this prehistoric period in the Spanish North Plateau.

Since several decades ago, the conventional pollen analysis has been supplemented with information provided by Non Pollen Palynomorphs (NPP). Generally, the taxa included in this group are microalgae, fungi, insects and arachnid's chitinous remains, plant debris and other organic palynomorphs with an undetermined origin. Most of them have limited dispersal, which implies that their presence can only be inferred predominantly local environmental issues. Thus, although they cannot contribute to the reconstruction of palaeoenvironmental conditions, are valuable tools to characterize the original layers, as well as local environmental features that influence the deposits formation processes.

The pollen results of the Trinchera sites (Trinchera Elefante, Gran Dolina and Galeria), at Atapuerca, always have been statistically not much representative. The different attempts have been demonstrate important taphonomical biases related with the low preservation of pollinical records. There are also other palaeobotanical evidences, such as charcoal and seeds that are poorly represented. These data provide punctual information on taxa presence but do not represent a continuous vegetal record. The input of the NPP results to the incomplete data of the traditional palaeobotanical disciplines could contribute to complete the loose of information, at least in respect of the local environmental condition of the caves. The NPP can provide us information about the presence of decay organic matter accumulations, erosion processes or about moisture conditions, contributing to the understanding of biological, physical or chemical dynamics that resulted in the different sedimentary sequences that cover almost 1, 5 million years.

Bennàsar, Maria (IPHES-URV, Tarragona) bennasar.ma-

ria1@gmail.com

Blain, Hughes-Alexandre (IPHES-URV, Tarragona) hablain@iphes.cat

There are a number of *Sorex* (Mammalia; Soricidae) species from the Pleistocene of Europe which are intermediate in size between *S. minutus* and *S. araneus*. Among them we have *S. hundsheimensis*, *S. casimiri*, *S. prealpinus*, *S. bor*, *S. subaraneus* and *S. runtonensis*. Our aim here is to characterize and allocate some 170 *Sorex* specimens from Sima del Elefante (Sierra de Atapuerca, Burgos, Spain) to one of these taxa.

The specimens were obtained by concentrating sediment after a process of washing and sieving the sedimentary materials from the excavation of the Sima del Elefante site between 1996 and 2010. The sample is composed of isolated mandibles, maxillae and teeth that are either loose or in situ. Detailed morphological comparisons and morphometric analysis were performed.

The previous analyses allow us to discard all candidates for the identity of the Sima del Elefante items, with the exception of *S. subaraneus* and *S. runtonensis*. Some morphological features enabling this attribution are the high cusped fourth lower premolar with a strong buccal cingulum, the lower molars with a mesially stretched paraconid and high rear cusp curved distally, the thick buccal cingulum and the well-developed talon of the upper incisor, the squarish shape of the upper first and second molars and their poorly expanded hypoconal flange, the deep external temporal fossa of the mandible with a small spicule very close to the tip of the coronoid process, and the high and triangular internal temporal fossa with a shallow part extending to the tip.

The first record of the *Sorex runtonensis*-*subaraneus* group in the Iberian Peninsula comes from the Lower Red Unit (levels TE7-14) of the Sima del Elefante, which is dated to ca. 1.1-1.5 Ma. These two species, *S. runtonensis* and *S. subaraneus*, are very close in size, shape and appearance, their distinction being very subtle and, in many cases, not reliable. Their broad range of morphological and morphometric variation mostly overlaps when considering all the valid records throughout Europe.

*Alcázar de Velasco, Almudena (UCM-ISCI) huellasdelaetoli@yahoo.es*

Beavers are large rodents that are present in Eurasia since the Oligocene. They are specialized mammals with concrete ecological preferences, so this group presents a great interest for paleoecological reconstructions. The extant European beaver, *Castor fiber* lives in semiaquatic habitats, therefore semiaquatic preferences are attributed to the fossil remains of *C. fiber* as well. The oldest record of *Castor* in Spain, *Castor* sp., is from the Ruscinian of the Guadix-Baza basin, when the wet conditions increased after the aridity maximum of the Turolian. Then it disappears again during the end of the Pliocene, with several aridity peaks such as recorded in i.e. the Zújar section, and never reappears again in Southern Spain.

Then, the beavers reappear again only in the north of the Iberian Peninsula, at the end of the Early Pleistocene, in the localities of Atapuerca. In view of the very complete fossil record from the paleontological localities from the south of Spain, such as Fonelas-1, the Guadix-Baza and the Granada basins, among others, we interpret that the absence of *Castoridae* in the south of Spain is real, and not due to a bias.

We study several cranial, mandibular fragments, isolated teeth, and postcranial fossil remains of beavers present in the Early Pleistocene and late Pleistocene layers of the cave-sites of the Sierra de Atapuerca karst complex. The localities with beaver remains are, from older to young levels, the Lower red levels of Sima del Elefante (TELRU), the Gran Dolina levels TD3/4, TD5, TD6, Galería de las Estatuas, and the Bronze levels of Portalón.

We have studied near 50 specimens of *Castor* from the Atapuerca localities. They reveal the presence of beavers in Atapuerca during the end of the Early Pleistocene and the Upper Pleistocene—Holocene. The beaver does not appear in the Middle Pleistocene layers from Atapuerca such as TD10, Galería, or upper red unit of the Sima del Elefante.

The morphometric analysis of the fossils shows that the *Castor* remains from the different Pleistocene localities of Atapuerca are similar in size and morphology, having small differences in size, of little significance from the point of view of the taxonomy. They are too similar in size and morphology to the skeletal remains of fossil and extant *Castor fiber* compared from the literature and from several institutional collections as well.

The beaver remains found in Atapuerca are scarce, though present in four of the localities of the karst complex of the Sierra de Atapuerca. They are attributed to the species *Castor fiber*, because they are nearly identical to the extant species in size and morphology.

We can thus conclude that the species *Castor fiber* is present in Spain since the early Pleistocene. It was living in aquatic environments, as their extant relatives. Other proxies such as stratigraphy and sedimentology, fossils of small rodents, insectivores, anurans, and aves, show that the early Pleistocene levels of Sima del Elefante and Gran Dolina were formed under humid conditions, and that running water or ponds were near the entrances of the caves.

---

## POSTER

### 4. FIRST REPORT OF THE BIRDS (AVES) FROM THE LEVEL TE7 OF SIMA DEL ELEFANTE (EARLY PLEISTOCENE) OF ATAPUERCA (SPAIN)

*Núñez-Lahuerta, Carmen (Aragosaurus-IUCA, Departamento de Ciencias de la Tierra. Facultad de Ciencias, Universidad de Zaragoza) carmenn1989@gmail.com*

*Cuenca-Bescós, Gloria (Aragosaurus-IUCA, Departamento de Ciencias de la Tierra. Facultad de Ciencias, Universidad de Zaragoza) cuencag@unizar.es*

The sites of the Sierra de Atapuerca (Burgos, Spain) are known due to its complete quaternary record, both stratigraphic and paleontologic. The record comprises the cave filling sediments in a karst system, developed in carbonate rocks. The Sima del Elefante site is divided in three units, according to its geological features: the lower red unit TELRU (early Pleistocene), the middle white unit, and the upper red unit (TEURU) (Middle Pleistocene). In this work we present the first results of the study of the bird association from the lower level of the TELRU, TE7, that belong to the *Allophaiomys lavocati* biozone, aged 1.5-1.1 Ma (Cuenca-Bescós et al., 2013).

Unlike in other papers published about the Aves of the

Sima del Elefante (Rosas et al., 2001), all the specimens studied were obtained by concentrating the sediment with the process of washing and sieving the sedimentary materials acquired from excavations of Sima del Elefante. These processes are simultaneous to the Atapuerca excavation campaign, that started in 1996, and about 12-15 tones of sediments are processed each campaign. The product is a concentrate consisting of calcareous fragments from the cave walls, fossil remains of small vertebrates and fragments of large vertebrates. The concentrates are packed and labelled, indicating the campaign year, the site and stratigraphic level from which it came, the grid unit, and the depth. The bird remains are separated from the other groups using a binocular magnifying glass in the laboratory of the University of Zaragoza, and they are photographed with a digital camera attached to the binocular magnifier, then, they are recorded in the data base and provisionally stored in the laboratory. The specimens studied are kept in the Natural Sciences Museum of the University of Zaragoza. The systematic analysis were done using the general nomenclature after Baumel (1983); the identification keys used are Janossy (1982), Tomek & Bochenski (2000; 2009) and Bochenski & Tomek (2009). The reference collection was the Natural Sciences Museum of the University of Zaragoza collection.

Nine avian taxa have been identified in the preliminary study of the fossil assemblage: Anseriformes indet., Falconiformes indet., Galliformes indet., Passeridae indet., Motacilla sp., Turdus sp., Corvidae indet., Corvus monedula, Corvus frugilegus.

The first Aves analysis of the lower level of the TELRU shows nine different avian taxa, but the big amount and variety of the fossils points to a high number of taxa that will be identified in the future, during the next steps of this investigation. Also paleoecological analysis must be done, because there's no reports available yet concerning paleoecological studies of the small vertebrate assemblage.

*Carbonell, Eudald (URV, IPHES, IVPP) ecarbonell@iphes.cat*

Gran Dolina site is one of the most important Pleistocene archaeological sites in Europe. It has three important archaeo-paleontological layers: TD10, TD6 and TD4, where high densities of anthropogenic bones and lithic remains have been found. In this site, a new hominid has been defined, Homo antecessor. The relevance of this site makes a good definition of the sedimentary process essential for a fine understanding of the archaeological remains. Gran Dolina belong to Torcas multi-level karst system, being a conduct of the middle level cutted by a Railway Trench of XIX century. This level was opened to outside during Lower Pleistocene beginning its infill of sediments that carried on archaeological and palaeontological remains. These sediments have been divided into 11 lito-stratigraphic units defined by major unconformities. By field works and sedimentary, mineralogical and chemical analyses, a revised stratigraphic section and new sedimentary data is showed.

19 sedimentary facies have been distinguished. Each sedimentary facies have been characterized by particle size analysis. Allochthonous facies are differentiated in sediment gravity flow facies and fluvial facies. Gravity deposits have been classified by their clasts/matrix ratio, dividing them in debris fall, debris flow and mud flow. Fluvial facies were sub-divided in channel, floodplain and decantation facies using their particle size and their stratigraphic position. Autochthonous facies were differentiated in speleothem, breakdown, phosphatic accumulation, weathering detritus and autochthonous fluvial.

Analyses reveal a relative homogeneity in the mineralogy and chemistry of Gran Dolina sediments. This can be indicate that allochthonous sediment have the same source (Sierra de Atapuerca), so chemical and mineralogical variations are due to others reasons like environment change or biological activity.

Through these works we have elaborated a detailed sedimentary facies map, which synthesize the processes and environmental changes during the cavity infilling.

Food resource availability strongly influences the survival opportunities of all organisms and it is considered that meat was a relevant food resource for Homo populations during Early and Middle Pleistocene. The availability of resources, the intensity of competition with other secondary consumers and the ability to access meat and fat resources conditioned human presence in Europe in this time period. Mathematical modelling of palaeocommunity trophic dynamics is a powerful tool for investigating food resource availability and intraguild competition.

We selected for this study the richer Early and Middle Pleistocene faunal assemblages from Sierra de Atapuerca. Only assemblages with nine primary consumer and three secondary consumer species were included. Available resources for secondary consumers were obtained from a mathematical model based on Leslie Matrices. The model is developed under two premises: populations should be stable and net reproduction rate is equal to one. This model determines the age structures that make the populations of primary consumers stable, the average biomass that can be sustainably extracted in the long term, and its distribution in body size categories. In a second step, the distribution of resources among secondary consumers is also modeled and sustainable densities for each carnivore are estimated. Expected densities for secondary consumers are estimated from allometric equations. The ratio sustainable density/expected density is taken as a measure of the degree of fulfilment of the secondary consumers requirements.

The faunal assemblage with the highest human fossil

abundances is in TD6 1-2 level from Gran Dolina site, which coincides with the lowest competition intensity among secondary consumers. The single assemblage from Atapuerca dated to the early Middle Pleistocene TD8 level of Gran Dolina site presents higher competition intensity than the Early Pleistocene assemblages and lack evidence of human presence. Nevertheless, there are several assemblages with evidence of human presence at Atapuerca after 0.5 Ma, and some of them exhibit competition intensity values similar for TD8.

Firstly, this model allows estimating food resource availability for the guild of secondary consumers and comparison of competition intensity between different faunal assemblages. Secondly, our results support an environment rich in trophic resources for secondary consumers at Sierra de Atapuerca during the late Early and early Middle Pleistocene. Competition intensity was higher during the early Middle Pleistocene than during the late Early Pleistocene. This results evidence that humans were able to successfully exploit the Atapuerca ecosystems even a moderately high levels of intraguild competition.

POSTER

**7. THE PREPARATION AND CONSERVATION TREATMENTS OF THE HOMO ANTECESSOR FOSSILS**

*López-Polín, Lucía (IPHES) lucia.lopezpolin@iphes.cat*

*Bermúdez de Castro, José María (CENIEH,) josemaria.bermudezdecastro@cenieh.es*

*Carbonell, Eudald (URV, IPHES, IVPP) ecarbonell@iphes.cat*

We report the preparation and conservation work carried out on the human fossils from level TD6 (Gran Dolina) recovered in excavations from 2003 to 2007. Many of them, after excavation, were partially covered or even almost completely included in a compact and hard sediment strongly adhered to the surface, and they required a series of preparation work, without which in many cases, their study would not have been possible. The treatments made were technically simple (mechanical cleaning, consolidation, reconstruction), but they were developed under a strict methodology of conservation whose aim has been to recover and preserve the archaeological information.

Besides the obvious retrieval of information itself, insofar as the fossils were uncovered, reassembled and strengthened, the preparation work of the Homo antecessor fossils has served to establish some criteria that we hope will help to settle the intervention methodol-

ogy designed to treat similar material. Briefly, these proposed criteria consist of adapting the interventions to the needs of the research without contravening the conservation fundamental principles, such as the respect for the integrity of the material, the minimal intervention and the reversibility of products and treatments used. A key aspect in the work here reported is detailed documentation of the whole process, recording both the products and techniques used in interventions, as well as the fossils in the different phases of the treatment (before, during, after treatment). The documentation allows understanding the decisions made about treatment and also to undo the treatment in the future (e.g. to remove consolidants or glues). Additionally, the documentation also helps to retrieve more information, which may be available only before or during the reconstruction of the fossils (e.g. detailed images of the fracture planes before reassembling a fossil); it also helps to interpret part of the changes originated by the treatment (e.g. distinguish between marks caused by the preparation work and traits of taphonomic interest).

With this work we aim to show that the result of the preparation and conservation (hands on) treatments is not the simple recovery of a fossil (to have a clean and reconstructed specimen) but to recover and to save all the information available during all the treatment.

recent humans and their environment, allows us to reconstruct the relationship between the paleolithic hunter-gatherers, their ecosystems and resources availability. We present here a new approach to the catchment of lithic raw material and the gathering of vegetable resources. A bioenergetic point of view has been increasingly used to address key issues in Palaeobiology and Palaeocology. Currently, we have designed two experimental studies: the first one, focused on quartzite catchment from the Trinchera Dolina site; the second one, focused on collection of plant resources conducted by lactating women in the area of Sierra de Atapuerca.

The experimental designs were carried out with a sample of 20 subjects in vivo, 10 men and 10 women. Several protocols have been applied to the participants in the Bioenergy Laboratory at CENIEH and at Sierra de Atapuerca. Protocols of Anthropometric, Bioelectrical Impedance and Indirect Ventilatory Calorimetry have been performed in the bioenergy. Height, weight, other body parameters, body composition and resting metabolic rate were measured in each participant. The activities of material procurement were recreated at Sierra de Atapuerca, monitoring the subjects with a calorimetry mobile device along a set of established itineraries. The route for quartzite catchment run from the Trinchera Dolina site to the closer outcrop while a couple of routes were selected for vegetable gathering: a steep ground walk, and a smooth ground walk. The female participants walked the vegetable gathering routes twice: one to simulate they were carrying a baby, and other one unloaded.

Several variables related to energy expenditure and body composition were obtained for each subject: Total Energy Expenditure, Resting Metabolic Rate, Fat Free Mass, Fat Mass, etc. All these data are useful to quantify the energy cost of each activity corrected by anthropometric measurements. These results have been compared between different physiological conditions.

This experimental project opens new possibilities to correlate different body parameters with energy expenditure and, therefore, to estimate energy expenditure in hominin fossil populations with different body proportions and compositions. Estimation of energy requirements of the human population inhabiting the Sierra de Atapuerca during the Middle Pleistocene, based on their body parameters allow us to reconstruct the energetic costs during two daily tasks in a more reliable way. This research line will improve our understanding of the energetic efficiency of extinct populations.

The study of different aspects of the interaction between

*Bermúdez de Castro, José María (Centro Nacional de Investigación sobre la Evolución Humana, CENIEH, Burgos) jose-maria.bermudezdecastro@cenieh.es*

The study of dental remains is a wealthy and stable source of information about phylogenetic relationships between extinct hominin species. Metric dental features are a reliable indicator of the underlying genotype of the individual/species under study. Since the last systematic metric analysis of the Atapuerca-Sima de los Huesos (SH) lower molars (Bermúdez de Castro and Nicolás, *Am. J. Phys. Anthropol.*, 1995) the sample has substantially increased, so an updated assessment is necessary. Lower molars were the most abundant dental remains present in Sima de los Huesos, and first lower molars ( $M_1$ ) are the most stable teeth within the lower molar series.

For this study we excluded  $M_1$  with a wear degree higher than 3 (Molnar, *Am. J. Phys. Anthropol.*, 1971). Thus, the analysed sample results in 26 SH  $M_1$ s, assigned to 19 individuals. SH was compared to a large sample of Contemporary Homo sapiens (N=253) held at the Anthropological Museum of the University of Coimbra (Portugal), Early Homo sapiens (N=7), Homo neanderthalensis (N=6), Homo heidelbergensis (N=2), Homo antecessor (N=2), Early Homo from Africa (N=3) and Early Homo from Asia (N=5) specimens. For each specimen we measured the total crown area and the absolute and relative area of each of the main cusps. The areas were measured with Ushikata X-PLAN360d planimeter over scaled high quality photographs of the teeth. Statistical comparison of the differences among groups, Principal Component Analysis and Linear Correlations between absolute and relative cusp areas were applied using PAST 2.17 and SPSS Statistics software.

SH  $M_1$ s are, in absolute terms, as small as contemporary Homo sapiens and they do not differ significantly from Early Homo sapiens. Furthermore, there are significant differences between the  $M_1$  cusp areas of Early Homo taxa in general and those of later Homo species. SH  $M_1$

protoconid relative area is the largest of all the studied groups. In the Principal Component Analysis (PCA) for the cusps absolute areas we found an area exclusively occupied by contemporary Homo sapiens and SH populations, whereas Homo antecessor falls closer to earlier Homo taxa. In contrast, in the PCA for the cusp relative areas, 4 out of 6 Neanderthal specimens falls within SH variability. Contemporary Homo sapiens presents a wide range of variation that encloses both Neanderthal and SH distributions among other groups.

From a metric aspect,  $M_1$ s are notably stable, although it is possible to find some differences between the larger specimens of Early Homo and the smaller  $M_1$ s in later Homo taxa groups. The highest relative area of the protoconid in SH concurs with the highest area of the homologous cusp in the upper molar series (Martinón-Torres et al., *J. Anat.*, 2013). The reduction in the total crown and absolute cusps areas in both SH and contemporary Homo sapiens suggests a likely case of parallelism. Although in absolute terms neanderthal molars are larger than those of SH, regarding the relative cusp areas SH and Neanderthals are similar. An exploration of other dental classes would be necessary to investigate the processes behind the dental reduction in the genus Homo.

POSTER

**10. SKULL MORPHOLOGY OF THE URSUS DENINGERI FROM SIMA DE LOS HUESOS AND THE CAVE BEARS LINEAGE: A GEOMETRIC MORPHOMETRIC ANALYSIS.**

*Santos, Elena (Centro Mixto UCM-ISCIH de Evolución y Comportamiento Humano. Monforte de Lemos 5. 28029 Madrid. Spain / Laboratorio de Evolución Humana. Universidad de Burgos, 099001 Burgos, Spain) esureta@ubu.es*

*Carretero, José Miguel (Laboratorio de Evolución Humana. Universidad de Burgos, 099001 Burgos, Spain) jmcarre@ubu.es*

The cave bears lineage is an extinct bear clade with a continuous presence during the European Pleistocene. Within this lineage, Ursus deningeri von Reichenau, 1904 is the species which lived through the Middle Pleisto-

cene, evolving into *Ursus spelaeus* Rosenmüller, 1784, the typical representative for the Late Pleistocene. Further study of the craniodental and postcranial remains led to the subdivision of cave bears into two chronospecies: *U. deningeri* and *U. Spelaeus*.

Two complete skulls of *Ursus deningeri*, one recovered from the Middle Pleistocene site of Sima de los Huesos in Sierra de Atapuerca (Spain), and the other one from Petralona (Chalkidiki, Greece), were reconstructed with computed tomography. The cranial morphology of *U. deningeri* was analysed using geometric morphometrics and compared to extinct and extant Ursidae (*Ursus* cf. *dolinensis*, *Ursus spelaeus*, brown, and American and Asiatic black bears). The purpose of this work was to explore the variation in skull morphology between these different taxa.

Landmarks for 2D digitalization of the cranium were chosen to reflect the skull morphology profile and general shape of the cranium. Skulls of extants Ursidae and the fossil remains of *U. cf. dolinensis* and *U. spelaeus* were digitalized with computed tomography. Generalized Procrustes superimposition was performed on the coordinates and allometry corrected for using pooled regression analysis. Principal Component Analysis (PCA) was conducted and interpreted about the skull morphology. PCA differentiates between genera in Ursidae. The position of the *U. deningeri* and *U. cf. dolinensis* in morphospace is between brown and cave bears.

This study allows establishing that genera of the *Ursus* can be differentiated based on cranial shape. Combined studies with computed tomography and geometric morphometrics of endocranial remains will provide important new evidence which can inform about biochronological studies. The resulting analysis supports an ancestor-descendant relationship for the ursids included in the cave bear phylogenetic lineage (*U. cf. dolinensis*, *U. deningeri* and *U. spelaeus*).

Crown formation times can be assessed by adding the imbricational and the appositional enamel formation times, so it can be estimated based entirely on the enamel. Previous research in the last decades have focused in the imbricational enamel because it is relatively easier to count long-period lines (perikymata) on its surface and establish formation times. Some authors have studied the variability of the total number of perikymata in different modern human populations, as well as the rate of enamel extension by dividing the crown height in ten deciles and counting the perikymata in each of the deciles. These authors have found that some modern human populations show a significantly lower number of perikymata, but little is known about the variability of these traits in modern humans. Our aim is to add new data on this topic and discuss imbricational enamel formation time variability in modern humans.

The sample analysed consists in 23 incisors from three different populations: a Calcolithic and a Bronze Age populations from the Atapuerca-Mirador Cave, and a presumably Bronze Age population from Maltravieso Cave. Perikymata were count by obtaining several images using an environmental scanning electron microscope (ESEM).

## POSTER

### **11. PERIKYMATA NUMBER AND IMBRICATIONAL ENAMEL FORMATION TIMES IN THE INCISORS OF THREE ARCHAEOLOGICAL MODERN HUMAN POPULATIONS FROM MALTRAVIESO CAVE (CÁCERES) AND MIRADOR CAVE (BURGOS)**

*Modesto-Mata, Mario (Centro Nacional de Investigación sobre la Evolución Humana (CENIEH) / Equipo de Investigación Primeros Pobladores de Extremadura) paleomari-*

The perikymata number and imbricational enamel formation times of the incisors from these three archaeological populations are closer to the European and Inuit values rather than to South African values.

The results obtained in our study support the intrapopulation homogeneity of the European and Inuit populations for the perikymata number. However, more information from other African samples is needed to test whether the low number of perikymata is exclusive to the South African group or can be generalized to the whole African continent.

POSTER

**12. ANOTHER WAY TO ANALYZE THE RAW MATERIAL IN GRAN DOLINA AND GALERÍA (SIERRA DE ATAPUERCA, BURGOS, SPAIN) FROM EXPERIMENTAL ARCHEOLOGY**

*Terradillos-Bernal, Marcos (Área de Prehistoria. Universidad de Burgos/Fundación Atapuerca) mterraddillos@hotmail.com*  
*Rodríguez-Álvarez, Xosé-Pedro (Universitat Rovira i Virgili/ Institut Català de Paleoecologia Humana i Evolució Social) josepedro.rodriguez@urv.cat*

This poster analyses the qualities of the raw materials used in Gran Dolina and Galería and their influence in the development of knapping process. Combining technological analysis and experimental archaeology has proven to be an excellent tool for the understanding the different interpretation of the qualities of raw materials and their relation with the development of the gestures, methods and techniques.

An extensive range of analyses have been conducted on the lithic artefacts recovered from the Sierra de Atapuerca, but in this case we have complemented these analyses with the development of a complex program of experimental knapping that analyses the influence of the qualities of the raw materials in the technological behaviour.

Through this methodological approach we have analyzed the basic characteristics of a large range of raw materials in this environment, their influence in the different processes of knapping and the bases of the selection of each raw material.

Mode 1 of TD6 emphasizes the selection of Palaeozoic materials with thick formats on which an orthogonal knapping is applied, although we can see an important difference with the rest of the Lower Pleistocene European sites

of Mode 1, like the preferential selection of the Cretaceous chert. In Mode 2 of Galería the selection of large and flat blanks of sandstone and Neogene chert for the production of handaxes stands out. Finally, in the transitional assemblages (Mode 2–Mode 3) of TD10-1 and TD10-2 the selection of Neogene chert predominates, which allowed a knapping intensification and the production of a great proportion of flakes with more cutting edge.

The development of an extensive experimental program applied to the study of the lithic technology of Gran Dolina and Galería has allowed us to draw some general conclusions, and has provided answers to some of the specific questions raised by the technological studies.

---

POSTER

**13. A TECHNOLOGICAL ANALYSIS OF THE CUTTING EDGE AND WEIGHT OF ARTEFACTS. THE CASE OF THE LOWER AND MIDDLE PALAEOLITHIC OF THE SIERRA DE ATAPUERCA (BURGOS, SPAIN)**

*Terradillos-Bernal, Marcos (Área de Prehistoria. Universidad de Burgos - Fundación Atapuerca) mterraddillos@hotmail.com*  
*Rodríguez-Álvarez, Xosé-Pedro (Area de Prehistoria, Universitat Rovira i Virgili (URV). Tarragona- IPHES, Institut Català de Paleoecologia Humana i Evolució Social. Tarragona. Spain) josepedro.rodriguez@urv.cat*

This poster analyses the relationship between the weight and cutting edge of lithic artefacts from the main Lower Palaeolithic sites of the Sierra de Atapuerca. The weight and cutting edge of a tool determine its cutting ability and the amount of force it is capable of, making them extremely important aspects of study to further our understanding of the potential capacity for human intervention in the environment. We explain that the quantitative and qualitative technological analysis of these two aspects is of fundamental importance in determining the potential of lithic assemblages.

These are the two basic features which influence the potential capacity for the use of a tool. Studying the cutting edge is relevant because it is the part of the object that comes into direct contact with the materials being worked on, while the weight affects the force of the instrument.

The aim of this study is to develop a way to analyse cutting edge productivity and the mass of the knapped stones in order to determine whether there is a relation-

ship between length of cutting edge, the quality of raw materials and the distance from the source of supply. This productivity must be related to the function and length of occupation of the site. We believe that studying the features of cutting edges in relation to the weight of lithic artefacts, together with the management of raw materials and the potential function and duration of occupations, makes it possible to progress in our understanding of the palaeoeconomy and technology of the Palaeolithic.

## 1. OVERVIEW OF THE CURRENT EXCAVATIONS IN SCHÖNINGEN

*Conard, Nicholas (University of Tübingen)*  
*nicholas.conard@uni-tuebingen.de*  
*Serangeli, Jordi (University of Tübingen)*  
*jordi.serangeli@uni-tuebingen.de*

Since 2008 researchers from the University of Tübingen and the Heritage Office of Lower Saxony have conducted a new series of excavations and analyses at the late Lower Paleolithic locality of Schöningen. This complex locality that formed in lakeside deposits during the terrestrial equivalent of MIS 9 includes multiple sites dating to ca. 300 ka BP. Since completing a number of rescue excavations near the active portion of the lignite mine in Schöningen, ongoing fieldwork has focused on the well-known Spear Horizon with its well preserved wooden implements and skeletons of dozens of butchered horses. This paper presents the newest results from these excavations and discusses their implications for our understanding of the technological and social-economic behavior of the hominins who inhabited and used the landscape around the paleo-lake of Schöningen. Using these observations we can begin to reconstruct the settlement dynamics of the hominins who occupied this part of the northern European Plain during the late Middle Pleistocene.

## 2. THE CHRONOSTRATIGRAPHY AND ENVIRONMENTAL DEVELOPMENT OF THE MIDDLE PLEISTOCENE SEQUENCE OF SCHÖNINGEN

*Richter, Daniel (MPI Evolutionary Anthropology)*  
*drichter@eva.mpg.de*  
*Urban, Brigitte (LEUPHANA University of Lüneburg)*  
*brigitte.urban@leuphana.de*

The Quaternary sequence of Open Lignite Mine Schöningen represents one of the longest terrestrial records in Europe and has the potential to provide unique insight into Middle Pleistocene environmental and climatic changes and the correlation of terrestrial records to the Marine Isotope Stage system (MIS). Schöningen is famous for the oldest weapons which could have been used for long range hunting – the well-known Schöning-

gen wooden spears. However, formation processes and nature of the sediment trap containing this record, as well as the chronostratigraphic position are debated, including the age of the spears.

Extensive palynological work provides a relative framework for the age of the stratigraphical succession at Schöningen, including the definition of unique interglacial pollen assemblages which are difficult to be placed in the European chronostratigraphical framework. Chronometric dating is therefore needed to provide anchor points. First results are available from U-series dating of peat formation of the Reinsdorf Interglacial of Schöningen site 13 II-2 underlying the archaeological horizon of level 13 II-4 with an age of around 300 ka and from luminescence dating, notably TL ages on heated flint from the oldest human occupation at the site of Schöningen 13 I-1. The dating results provide a nominal age range between MIS 10 and MIS 7 for that layer and by inference of proxy data the human occupation at Schöningen 13 II must have taken place during/around MIS 9.

This work forms the basis of a new project to provide a chronostratigraphical framework for Schöningen, funded by the Ministry of Science and Culture (PRO\*Niedersachsen) of the state of Lower Saxony, which will be based on the dating of the entire sequence with multiple chronometric techniques and refined high resolution palynological and sedimentological studies. We will present first luminescence age results and new palynological data from the project.

## 3. A GEOARCHAEOLOGICAL VIEW ON SITE FORMATION AND HUMAN BEHAVIOR AT SCHÖNINGEN

*Stahlschmidt, Mareike C. (Institute for Archaeological Sciences, University of Tuebingen)*  
*mareike.stahlschmidt@uni-tuebingen.de*  
*Miller, Christopher E. (Institute for Archaeological Sciences, University of Tuebingen)*  
*christopher.miller@uni-tuebingen.de*

Geoarchaeological research at Schöningen is focused on describing and evaluating the depositional contexts at Schöningen 13 II-4, Schöningen 13 II-4 Upper Berm and Schöningen 12 II-4. We performed geoarchaeological field analyses and micromorphological analyses to investigate the formation of the find-bearing layers and the obtained data were then used to re-evaluate concepts and ideas about human behavior during the Lower Paleolithic.

Previous researchers (Thieme, 2005; Voormolen, 2008; Lang *et al.*, 2012) suggested, that human activity at Schöningen took place on a surface on the dry lake shore during times of low water levels and that the archaeological assemblage was embedded *in situ* with rising lake level. The micromorphological analyses of the find-bearing layers revealed no evidence for drying events, and instead demonstrated a subaqueous deposition of the associated sediment. Consequently, possible site formation models other than an *in situ* preservation of the archaeological assemblage are discussed, including human disposal of materials into the lake, humans hunting or caching on lake-ice, and geogenic relocations of the artifacts by wave action or slumping.

#### 4. ON THE EVIDENCE FOR USE OF FIRE AT SCHÖNINGEN

Miller, Christopher E. (Institute for Archaeological Sciences, University of Tübingen) [christopher.miller@uni-tuebingen.de](mailto:christopher.miller@uni-tuebingen.de)  
Stahlschmidt, Mareike (Institute for Archaeological Sciences, University of Tübingen)  
[mareike.stahlschmidt@uni-tuebingen.de](mailto:mareike.stahlschmidt@uni-tuebingen.de)

Since its discovery in 1994, the site of Schöningen 13 II-4 has been at the center of discussions on the use and control of fire by Middle Pleistocene hominins in Northern Europe. Among the remains of butchered horses, wooden hunting spears, and other lithic and organic implements, excavators uncovered four circular areas exhibiting potential fire reddening of the sediment. These areas were tentatively identified as the remains of hearths. Following their discovery, the hearths at Schöningen have been widely cited as evidence for human control of fire in the Middle Pleistocene of Northern Europe. Here we present a multidisciplinary study of these reddened features to investigate their origin and formation. Our results show that the reddened areas are the result of natural redoximorphic processes in the sediment, rather than human control of fire. We also discuss other possible lines of evidence for human use of fire at Schöningen, including possibly burnt wooden artifacts.

#### 5. PLANT RESOURCES AND THEIR USE. INDICATIONS FROM BOTANICAL MACRO-REMAINS OF MIDDLE PLEISTOCENE SCHÖNINGEN (GERMANY)

Bigga, Gerlinde (University of Tübingen)

[gerlinde.bigga@uni-tuebingen.de](mailto:gerlinde.bigga@uni-tuebingen.de)

In Palaeolithic contexts organic remains are rarely preserved. Plant remains are thus underrepresented in contrast to animal bones. But the absence of organic remains does not mean that plants have not been used for dietary purposes and raw material. An optimal foraging strategy includes a varying amount of vegetable food, as we can see from ethnobotanical studies. The hunter-gatherer societies illustrate the importance of plants for subsistence purposes, even under subarctic conditions. The sediments in Schöningen contain abundant botanical macro-remains, which offer the opportunity to reconstruct the local vegetation and work out the usefulness for human purposes.

Several hundred wood fragments and 38 sediment samples from different archaeological horizons were available for analysis. The sediments were water screened for botanical macro-remains. A reference collection helped identifying species, wood species identification was possible through thin sectioning.

The reconstructed local vegetation includes more than 21.000 diaspores of aquatic plants, lake shore vegetation, and adjacent shrubs and trees of an elder fen wood. The taxa list from the "Horse Butchery Site" (Schöningen 13II-4) includes a broad spectrum of usable species and provides important sources of food, raw material, medicine and firewood. Young shoots, leaves, berries, fruits and nuts from many different edible plants are available from spring to autumn. During winter the lake shore vegetation reveals a hidden food source in the form of underground storage organs (USOs: roots, rhizomes, tubers). They are rich in starch and can be eaten raw, cooked, dried for later use or grind into flour.

In Schöningen we have evidence for plant use as raw material, such as the spears, the roasting spit, the digging stick and the wooden handles show (Thieme 1997, 1999, 2007). This means *Homo heidelbergensis* was aware of the plant resources and were capable of exploiting them. Indications of plant use for other subsistence purposes is still lacking in the Lower Palaeolithic record and neither the site of Schöningen could shed light into the darkness. Theoretically starch is an excellent source of energy, thus USOs were rarely left unexploited. Special knowledge or sophisticated tools are not necessary to dig them up in the muddy lake shore sediments. Plants are waiting immobile until someone gathers them, so effort and risk are low. As an indication, that this resource was exploited, we have a wooden tool from Schöningen 13II-4, interpreted as a digging stick by its form and wear

patterns. Even when direct evidence is missing, the exploitation of these resources seems inevitable.

ORAL

## 6. HUMAN BEHAVIOURAL STRATEGIES IN INTERGLACIAL ENVIRONMENTS: THE CASE STUDY OF THE 13 II-4 SITE AT SCHÖNINGEN

*Turner, Elaine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) turner@rgzm.de*

*Gaudzinski-Windheuser, Sabine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) gaudzinski@rgzm.de*

*García-Moreno, Alejandro (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) garcia@rgzm.de*

*Hutson, Jarod (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) hutson@rgzm.de*

*Villaluenga, Aritza (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) villaluenga@rgzm.de*

A major success story of human evolution is our ability to adapt and survive in various environments. In fact, the relationship between changing environmental circumstance and the development of human behaviour is as old as humanity itself. Despite the causal connection between environmental change and the development of human behaviour being often cited, there is still little real understanding of what processes might be involved. Recently, the MONREPOS Archaeological Research Centre has begun to address these issues through a major core-research project "Human Behavioural Strategies In Interglacial Environments", where we attempt to decipher the complex relationship of human behaviour and climatic change by analysing and comparing specific case studies and high resolution archives. One of these archives is the 13 II-4 "Spear Horizon" site at Schöningen.

Interglacial environments were specifically chosen for our research since they offer very favourable conditions of preservation for well datable archaeological sources and high resolution ecological data. In these contexts, Schöningen holds a unique position. We employ an overall research strategy which guarantees a systematic and methodologically comparable treatment of the subject. At Schöningen we are focussing on a holistic understanding of the site with a detailed and comprehensive analysis of the finds currently being undertaken

in order to extract the maximum information on the archaeozoological, taphonomical and spatial aspects of the assemblage. Our aim is to identify patterns of Middle Pleistocene hominin subsistence behaviours around this lakeshore environment.

The large lake at Schöningen was frequently visited by ungulates, a situation that was known to the Middle Pleistocene hunter groups and was repeatedly exploited by them. In particular, herds of horses died and were dispatched at the edge of the lake. The preliminary archaeozoological evidence points to a systematic butchery of many horse carcasses. GIS applications will later enable us to expand these results in terms of use of space on a local, intrasite scale, as well as in the wider landscape around this lakeshore environment.

The 13 II-4 "Spear Horizon" site at Schöningen presents a unique opportunity to assess hominin behavioural strategies during a Middle Pleistocene warm phase. The results of the Schöningen analysis can be compared with those from other warm stage sites currently being investigated by MONREPOS, which cover a period of several hundred thousand years from the Middle Pleistocene until the beginning of our present interglacial.

ORAL

## 7. AN ARCHAEOZOOLOGICAL AND TAPHONOMIC PERSPECTIVE OF HOMININ BEHAVIOUR AT THE SCHÖNINGEN 13II-4 ?SPEAR HORIZON?

*Hutson, Jarod (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) hutson@rgzm.de*

*Villaluenga, Aritza (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) villaluenga@rgzm.de*

*García-Moreno, Alejandro (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) garcia@rgzm.de*

*Turner, Elaine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) turner@rgzm.de*

*Gaudzinski-Windheuser, Sabine (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) gaudzinski@rgzm.de*

The "Spear Horizon" is the most well-known of the Schöningen localities, yet the underlying social and economic behaviours of Middle Pleistocene hominins reflected in the archaeological record at this important site are rela-

tively unexplored beyond the elementary associations between the wooden implements, butchered horse bones, and lithic artefacts.

To provide a context for such behaviours, the Monrepos Archaeological Research Centre and Museum for Human Behavioural Evolution has begun a comprehensive archaeozoological and taphonomic analysis of the entire large mammalian faunal assemblage from the Schöningen 13II-4 Spear Horizon, and here we present preliminary results of that research.

Our objective in this presentation, and that of our entire project, is to demonstrate that the site represents much more than a novel accumulation of spears, bones, and stones, but rather provides a unique opportunity to study Middle Pleistocene hominin behaviour in great detail. Building from multi-proxy studies to chronicle animal life histories across the landscape, we use archaeozoological and taphonomic traces of hunting strategies and butchery practices to reconstruct how Middle Pleistocene hominins viewed and used the wider lakeshore environment.

This holistic approach offers critical insight for interpreting the entire Schöningen complex of sites and a further piece of the incomplete record of Middle Pleistocene adaptation and hominin behavioural evolution, in general.

ics, faunal and wooden remains, among them the well-known spears. However, the processes involved in the formation of this site remain unknown, and the former interpretation of the site as the result of a single hunting event has been challenged by ongoing research.

As part of a comprehensive research project piloted by the Monrepos Archaeological Research Centre and Museum for Human Behavioural Evolution, an analysis of the spatial distribution of faunal remains from the "Spear horizon" has been initiated in conjunction with the ongoing zooarchaeological and taphonomical analyses. Through the application of a Geographic Information System, the aim of this spatial analysis is to clarify the taphonomic processes involved in site formation, as well as to identify tangible patterns in the distribution of faunal remains.

This will enable us to understand hominin behavior in terms of use of space, both on a micro-scale (intrasite) as well as in the wider landscape around this lakeshore environment.

The study of hominin spatial behavior from a holistic perspective is a key issue in understanding human evolution and adaptation to interglacial environments.

*[pascale.richter.boehner@nld.niedersachsen.de](mailto:pascale.richter.boehner@nld.niedersachsen.de)*

*Schoch, Werner H. (Labor für Quartäre Hölzer, Unterrutstrasse 17, CH-8135 Langnau a.A.) [www.woodanatomy.eu](http://www.woodanatomy.eu)*

About 20 years ago first sensational wooden objects were found at the Palaeolithic site of Schöningen 13II-4 in lower Saxony, Germany. In the subsequent years eight wooden spears and a wooden lance were identified in a find layer with many faunal remains at a former lake shore which can be assigned to the end of the interglacial period of OIS 9 dated to c. 300.000 years ago. The last years the GIS-based analysis of the spears and the

find layer made progress and for the first time it is possible now to better understand the find situation in general and the context of the wooden weapons in special. The talk will present results of this analysis and discuss aspects of taphonomy, preservation conditions, time depth, role of human agents and the spears context. The spears and their context argue for repeated hunts at the site and this is in accordance with the evidence of other disciplines.

### 10. NORTHERN EUROPEAN EVIDENCE CITED FOR MIDDLE PLEISTOCENE SPEAR USE

*Milks, Annemieke (UCL) a.milks@ucl.ac.uk*  
*Pope, Matt (UCL) m.pope@ucl.ac.uk*

The evidence for hunting amongst hominin groups in northwestern Europe has emerged as a key archaeological research question over the past century. Predation might be envisaged as a necessary adaptation to more seasonal climates of the region and, significantly, it provides three early and clear archaeological signatures that suggest the possible manufacture and use of hunting weaponry: a wooden implement from Clacton-on-Sea dated to MIS 11, the GTP17 horse scapula with a possible impact fracture from Boxgrove dated to MIS 13, and the collection of wooden spears from Schöningen in Germany.

The two Clacton and Boxgrove artefacts, both from northern Europe, have been used to argue in favour of the possibility that hunting with simple wooden spear technologies emerged as a hominin capability in the early Middle Pleistocene. In 1911 the broken tip of a wooden implement was found in a freshwater deposit outcropping on the West Cliff in Clacton-on-Sea, Essex, dating to MIS 11. This humanly modified yew branch, known as the 'Clacton spear point', was subjected to various lines of analysis in the 1970s and still remains the oldest known wooden tool, but has yet to be conclusively identified as a hunting weapon through these studies. The site of Boxgrove in West Sussex provides complementary evidence from the collection of butchered *Equus ferus* remains at the GTP17 locality. Here a fragment of a scapula bearing a damaged edge with a semi-circular plan, has a cross sectional profile suggested to be consistent with impact from a sharp wooden projectile: a possibility that has yet to be tested through systematic experimental analysis. Given the significant evidence for apparent spear manufacture from Schöning-

en that emerged in the 1990s, it is now imperative to bring these earlier objects under closer scrutiny. It would now be useful to establish, with a greater degree of certainty, the evolutionary history of weapon manufacture and use in the European Middle Pleistocene to help us assess the nature of hominin predation behaviour during the period.

Consequently, it is now timely to develop new and robust research approaches to the Clacton spear point and the Boxgrove horse scapula. Alongside this, it is also important that experimental approaches examining the performance and potential lethality of simple wooden spears are developed further. This paper presents an analytical programme initiated this year at UCL's Institute of Archaeology in response to these research questions. This research will not only address the performance of wooden spears but also use the data collected to re-address the overall morphology and specific features of the Clacton and Boxgrove objects. It outlines why existing interpretations of the Clacton spear point and the Boxgrove scapula fall short of fully demonstrating Middle Pleistocene hunting with wooden spears. This paper is primarily intended to provoke discussion of current analytical and interpretational challenges we face in the study of these rare but important objects, and presents aspects of proposed and on-going research for debate and scrutiny?.

ORAL

### 11. THE COMPLEXITY BEHIND SIMPLE APPEARANCE: THE WOODEN TOOLS OF SCHÖNINGEN

*Haidle, Miriam Noël (Research Project "The Role of Culture in Early Expansions of Humans" ROCEEH, Senckenberg Research Institute and University of Tübingen, Germany) miriam.haidle@uni-tuebingen.de*

The use of wood as raw material for tool production is neither uniquely human, nor cognitively demanding. Wooden artifacts are rare in the Paleolithic record due to specific preservation conditions. The site of Schöningen situated in a lignite area opens a window to the range of wooden tools in the late Lower Paleolithic.

To assess the specificity of the use of spears, throwing sticks, and clamp shafts the processes of their production have been reconstructed and coded in cognigrams and effective chains. These show the different attention foci (raw materials, tools), actions, and effects of foci on other foci.

The coding in a systematic way allows identifying the concepts behind the tools and comparing it to other tools of other raw materials. It is thus possible to point to the range of conceptual and cognitive foundations behind a rare class of artifacts.

*T.van.Kolfschoten@arch.leidenuniv.nl*

*Bocherens, Hervé (Department of Geosciences, Biogeology, University of Tübingen) herve.bocherens@uni-tuebingen.de*

Stable isotopes in fossil bones and teeth provide information on the habitat and diet of extinct mammals. This approach has been used for the fauna of the Middle Pleistocene site of Schöningen dated to about 300,000 years ago.

Carbon and nitrogen stable isotopes from collagen of exceptionally well-preserved bones of Schöningen were used to decipher the ecological preferences of various herbivorous taxa, including Elephantidae (*Palaeoloxodon antiquus*), Rhinocerotidae (*Stephanorhinus* sp.), Equidae (*Equus mosbachensis*), Cervidae (*Cervus elaphus* and *Megaloceros giganteus*), and Bovidae (*Bison*, *Bos/Bison* and *Bubalus*).

More than half of the tested specimens yielded collagen with chemical composition (%C, %N, C/N) within the range of collagen from fresh bone. The carbon isotopic values indicate a range of dense forest to open habitats. The vegetation consumed by the herbivores from the famous spear horizon originates from open environments. During the climatic Reinsdorf Interglacial optimum, the landscape seems to have been relatively open as well, but certainly included parts that were forested. The results also indicate some niche partitioning; different herbivore species used different plant resources.

For instance, the horses seem to have been predominantly browsers, while the straight-tusked elephants were feeding chiefly on grass. By comparison with other interglacial mammalian faunas from Central Europe for which carbon isotopes were investigated, the landscape in Schöningen appears as a mosaic of patches of dense forest combined with large open areas, in a similar way as during other Pleistocene interglacials. Large herbivores were foraging mainly out of the forested areas, in contrast with the pre-Neolithic Holocene period, during which the surviving large herbivores dwelled essentially in densely forested areas.

These results provide valuable insight on the palaeoenvironmental setting in which the Middle Pleistocene hominins operated in Schöningen. Despite a high proportion of tree species in the vegetation, the landscape was still relatively open, probably due to the impact of megaherbivores (elephants, rhinoceros) that led to the maintenance of open pasture areas beneficial to a high and diverse biomass of herbivores.

## 13. HORSE PALAEODIET AND ACCUMULATION PROCESSES AT SCHÖNINGEN 13 II-4: A MULTI-PROXY ANALYSIS COMBINING MESOWEAR, MICROWEAR, AND STABLE ISOTOPES

*Rivals, Florent (ICREA, Institut Català de Paleoecologia Humana i Evolució Social (IPHES) frivals@iphes.cat*

*Julien, Marie-Anne (University of Southampton)*

*m.a.julien@gmail.com*

The Schöningen site became particularly famous with the discovery of well preserved wooden spears at the 13 II-4 locality. The stratigraphical and the biostratigraphical records of Schöningen 13 II-4 indicate a correlation with the Marine Isotope Stage (MIS) 9 and an age of about 300 ka B.P. Among the archaeological remains (including the wooden spears), the site yielded a rich and well-preserved bone assemblage consisting mainly of large mammal remains. At Schöningen 13 II-4 the main large mammal species is the horse (*Equus mosbachensis*), and part of this horse assemblage is known to be the result of hominid hunting activities, and possibly from a single mass-kill event. We tested the hypothesis that the assemblage from Schöningen 13 II-4 is the result of a single hunting event. The study is based on the inter-individual variability dietary traits of the horses.

We used an approach combining tooth microwear (microscopic scars produced by the interaction of food items on the occlusal surface of the teeth), mesowear (cusp relief and shape), and stable isotopic analyses. The application of tooth wear and stable isotopic analyses on archaeological assemblages offers, besides the classical identification of ungulates dietary behavior, the possibility to disentangle between single or multiple depositional events.

The paleodiet of the horses from Schöningen 13 II-4 was characterized through tooth meso- and microwear analyses as browse-dominated mixed feeders. Stable isotopic analysis of enamel carbonate points as well to an unselective dietary behavior, with intermittent grazing and browsing. Schöningen horses fed in a mosaic-like vegetation habitat, composed of woodland patches interspersed with open areas, or in an open vegetation with dispersed trees and bushes.

Microwear patterns in herbivorous ungulates provide a signal used to identify differences between samples of animals accumulated during a single season and those that were accumulated over an entire year or longer periods. The coefficient of variation calculated on the micro-scratches values at Schöningen 13 II-4 indicates a high variability, significantly different from localities with short occupations. The oxygen and carbon isotopic intra-tooth analysis was performed on different individuals from Schöningen 13 II-4. The inter-individual variability is similar to the variability recorded for horses from multi-layered localities and the intra-tooth isotopic variations are different enough to suggest that the horses did not live together during the formation time of their crown, likely resulting from different seasonality of death.

The results from the two methods are concordant and suggest that the assemblage from Schöningen 13 II-4 cannot be the result of a single event, but is the consequence of an accumulation during multiple events, likely in various seasons of the year.

The two methods used in this study lead to consistent results concerning the feeding behavior and the process of formation of the horse assemblage. Combining independent proxies such as tooth wear and isotopic analysis allows here a fine scale reconstruction of animal behavior and a better understanding of the processes of fossil faunal accumulation.

*britt.starkovich@uni-tuebingen.de*

*Verheijen, Ivo (Leiden University)*

*theskullcollector@hotmail.com*

The Middle Pleistocene archaeological site of Schöningen 13 II-4 became famous by the discovery of the oldest, complete wooden spear in the world. Over the last 20 years, the site yielded the remnants of at least 10 wooden spears, a throwing stick, 20 to 30 stone tools, about 1500 smaller flakes and thousands of bones with a variety of hominin butchery marks. The majority of these bones were concentrated in an area containing more or less complete carcasses of 20-25 horses. The archaeological layer is also known as the "Spear horizon".

In 2011, a new archaeological area was discovered at the site Schöningen, nearly 50m south of the site 13 II-4. Based on a similar stratigraphical sequence and archaeological assemblage, the archaeological layer at this new excavation was interpreted as a continuation of the Spear Horizon. Therefore, this area is referred to as "Spear Horizon South". In October 2012, the first find of *Homotherium latidens* was made from this area, a serrated lower 3rd incisor. In 2013, ongoing excavation produced more *Homotherium* remains, including another incisor, two carnassials, a humerus, a scapula and a rib. By combining archaeological, archaeozoological, isotopic and microwear analysis, more insight will be gained on the life and possibly the death of this individual.

The numerous stone artifacts of Schöningen 13 II-4 show a clear lower Paleolithic concept. The layers of this site are dated to approximately 300 Ka, which correlates with MIS 9. Therefore, this discovery is among the youngest records of *Homotherium latidens* in Europe. An astragalus from the Mealhada cave in Portugal comes from

an old excavation and has been questionably dated to the Riss-Würm interglacial. The well-known *Homotherium* remains from the Late Pleistocene site of Kents cavern in England were recently studied using geochemical analysis. The results show that they were probably transported to Kents Cavern and buried there during the Upper Paleolithic. In 2000, a mandible of a *Homotherium* was dredged up by fishermen from the bottom of the North Sea. It has been dated using <sup>14</sup>C dating to 28,000 years BP, but this date has been questioned due to the lack of stratigraphic context. In 1956 a canine was discovered at Steinheim an der Murr, which has been dated between the end of the Holsteinian and the beginning of the Saalian glaciation. This *Homotherium* might have the same age as the remains from Schöningen, but the documentation of the stratigraphic position of canine from Steinheim is very modest. Therefore the remains of the saber-toothed cat from Schöningen are considered to be the youngest finds from a recently excavated, well-documented site with stratigraphic and chronologically well-analyzed layers.

In Schöningen 13 II-4 we have the opportunity to analyze possible relationships and interaction between the Early Paleolithic hominins and saber-toothed cats. It is probable that new finds from the same individual will be discovered in future, since only a section of the new area has been excavated so far.

### 15. ORDER, DISORDER, MEAT SHARING, AND LOGISTICS. MIDDLE PLEISTOCENE BUTCHERY PATTERNS AT SCHÖNINGEN (GERMANY)

*Starkovich, Britt (University of Tübingen)*

*britt.starkovich@uni-tuebingen.de*

*Conard, Nicholas (University of Tübingen)*

*nicholas.conard@uni-tuebingen.de*

This paper presents the results of an ongoing analysis of the faunal remains from the "Spear horizon south" (13II-4 layer) at the Lower Paleolithic site of Schöningen. Though the focus of this presentation is on the new excavation area, comparisons are drawn with previously presented data (i.e., van Kolfschoten 2014; Voormolen 2008). Taxonomic data indicate that, as with the main excavation area, hominins primarily hunted large Pleistocene equids (*Equus mosbachensis*), which were likely attracted to the lake shore or a nearby stream to drink. The representation of equid body parts from both areas is quite even, suggesting that elements were not trans-

ported away from the site by either hominins or carnivores. A major focus of this study is hominin butchery of the faunas. Cut and butchery marks are common, and are often arranged somewhat haphazardly on the bones. This observation prompted an investigation of the relative "orderly" or "disorderly" nature of the cuts. Following Stiner and colleagues (2009; 2011), cut mark angles were measured and compared between adjacent cuts on each individual bone. Presumably, a single hominin defleshing one bone would produce multiple parallel, or "orderly" marks, while multiple hominins or several butchery events would result in scattered, non-parallel, or "disorderly" cuts. Like previous research, we found that cut mark angles on Schöningen long bones tend to be less "orderly" than similar data from Middle and Upper Paleolithic sites. Stiner and colleagues interpret this as less standardization in meat provisioning and greater access to carcasses by multiple hominins. Cut mark angles on Schöningen long bones are even less "orderly" than data from the Lower Paleolithic site of Qesem Cave. In addition to social explanations regarding meat provisioning, this might also reflect the logistics of butchering a large amount of meat from one or multiple ungulate carcasses over the course of hours or days. Indeed, axial elements such as ribs and vertebrae have more "orderly" cuts than long bones, reflecting the physical practicalities of orienting one's body in relation to a large carcass during butchery. Overall, hunting and butchery evidence from the "Spear horizon south" indicates that Lower Paleolithic hominins at Schöningen were intelligent, cooperative hunters that understood the behaviors of prey species on the landscape, and hunted socially to procure and butcher large game. Butchery strategies differ from later and contemporary hominins, which may provide insight into evolving social structures in the Paleolithic, as well as reflecting behaviors at a different kind of site.

### 16. RESIDUE AND MICROWEAR ANALYSES OF THE STONE ARTEFACTS FROM SCHÖNINGEN

*Rots, Veerle (University of Liège) veerle.rots@ulg.ac.be*

*Hardy, Bruce (Kenyon College) hardyb@kenyon.edu*

Stone artefacts from Schöningen 12 and 13 were examined microscopically to identify residues, wear and manufacturing traces in order to clarify their possible anthropogenic origins and their function.

We present evidence showing that the stone tools were used for working wood and hide, and for cutting

meat. The results from the use-wear and residue analysis proved complementary in several instances. Suggestive though uncertain evidence of hafting was observed on a few pieces. This could be particularly interesting given the identification of wooden hafts at the locality. The results of this analysis demonstrate the potential of these techniques for Lower Palaeolithic sites such as Schöningen.

(C. Pasda, 2012, 37ff) and the geological setting of the site (L. Fiedler, 2012).

The assemblage of Schöningen 13 I is a good case example to highlight the possibilities and limits of studying ephemeral lower Palaeolithic sites.

**17. EARLIEST HUMAN TRACES IN LOWER SAXONY ?  
STONE TOOLS FROM THE SITE SCHOENINGEN 13 I**

*Felix, Hillgruber K. (Lower Saxony State Office for Cultural Heritage) felix.hillgruber@nld.niedersachsen.de*

The lower Palaeolithic site of Schoeningen is one of the most important Stone Age sites in Germany, providing the earliest reliable evidence for human occupation in northern Germany. During the last 20 years various Middle Pleistocene find locations were unearthed in the open cast mine. Of special importance is Schoeningen 13 I which is located a few hundred meters north of Schöningen 13 II, where the famous wooden spears were found. At Schöningen 13 I H. Thieme documented, a middle Pleistocene sequence which can probably be attributed to the earliest part of OIS 9 (Holsteinian) which is older than the "spear horizon". During three months of work 120 m<sup>2</sup> were excavated (H. Thieme 2007, 212). The low density scatter of finds included a small number of probable stone tools, especially notched and carinated pieces. The number of typologically unambiguous tools is very low. In addition a large number of burnt flints might indicate the early use of fire.

A first chronometric TL-date is assigning the layer at least to OIS 9 (D. Richter & H. Thieme 2012, 171-182). In order to verify and quantify the human impact at this site a systematic study of the flint assemblage was started. Inventories from the Lower Palaeolithic in many cases yield objects ranging from obvious non-artefacts to man-made tools. In between a wide range of lithic chunks, thermal flakes and naturally chipped stones appear. In contrast to the spear horizon, where no natural admixture of flint stones is present, the sediments of 13 I included coarse grain particles like gravel and larger stones. The separation of the natural pieces and man-made tools can be difficult and the criteria for the acceptance of true artefacts may vary considerably depending on the scientist

The central sector of the Guadix Basin (Betic Cordillera, Spain) is a key area for unravelling the evolution and migration routes of early hominins and associated fauna into Europe from Africa and Asia. Its importance stems from the presence of continuous sedimentation over the last 4 million years and the excellent preservation of a large number of archaeological and palaeontological sites from this time range in its fluvio-lacustrine facies. A number of detailed stratigraphical, sedimentological, petrological and geochemical studies have been carried out in the area, with the aim of characterising the palaeoenvironmental evolution of the Guadix Basin over the last 4 Ma.

The nature of the sediments in the Guadix Basin, mainly fine grained fluvial sediments and all types of continental carbonates, has prevented the preservation of palaeoenvironmental proxies such as pollen, beetles and chironomids. However, the geochemistry of the abundant continental carbonates outcropping in the area has proved crucial in reconstructing the environments in which early hominins and vertebrate faunas of Asian, European and African origin lived during the Plio-Pleistocene in southern Spain.

The Pleistocene sites appear in the Axial System facies, a high sinuosity fluvial system that developed wetlands in its floodplain. Our interest is focused on the palustrine

carbonates forming the ponds and wetlands. From the Early Pleistocene to the Middle Pleistocene, a pronounced change is observed in the carbonate beds, from isolated, periodically-desiccated shallow ponds in the floodplain to extensive wetlands in the central valley, resulting in vertically stacked palustrine limestones showing a lower edaphisation degree. This drastic change in the sedimentary style and lithology is related to lower sedimentation rates, to the redistribution of the three drainage systems and to the flatter topography coinciding with the change between genetic units V and VI.

After field and petrographical studies, samples of the palustrine carbonates were analyzed, using a VG PRISM series 2 mass spectrometer by analyzing CO<sub>2</sub> liberated from sample reaction with phosphoric acid at 90° C. Internal (RHBNC-PRISM) and external (NBS-19, LSVEC) standards were analyzed every 8 samples.

The results include a range of values for δ<sup>13</sup>C and δ<sup>18</sup>O which coincide with the expected isotopic values for palustrine carbonates. The low correlation between the isotopic values for the Pleistocene carbonates indicates that the water bodies in which the carbonates were deposited experienced free water circulation, and therefore, evaporation was not the main factor driving isotopic fractionation. This lack of correlation, even in the small Early Pleistocene ponds, means that there would be a fairly continuous water supply for the animals and the early hominins living in the Guadix-Baza Depression throughout the Early and Middle Pleistocene.

A number of studies examine salinity changes in the water in the Baza Basin and comment on the presence of hot springs. The present study reveals for the first time that even when the lakes in the Baza area became more saline and potentially non-potable for fauna and hominins, the Guadix Basin remained a key focal point for access to freshwater, enabling survival in an otherwise hostile environment.

In this paper a detailed description of the archeological and paleontological levels D 1, D 2 and E of the Barranco León section (Guadix-Baza Basin, SE Spain) is presented. Sedimentological and paleontological analysis based on small vertebrates provide new significant data regarding the chronology of the site and its paleoenvironmental and paleoclimatic evolution. The microvertebrate analysis includes rodents, insectivores, squamate reptiles, amphibians and fishes.

According to this analysis, an age close to 1.4 Ma is assumed after numerical and biochronological proxies, close in age to the site of Sima del Elefante in Atapuerca (Spain). From an environmental and climatic point of view, the mean annual temperature at the time of deposition was significantly higher than 13 °C, with prevalent humid conditions. However, although most of the species were inhabitants of water edges, an open landscape was present in the vicinity of the lake. Across the D1-E profile, a trend towards open dry conditions is recorded.

Palmqvist, Paul (Departamento de Geología y Ecología, Universidad de Málaga, Campus de Teatinos, 29071 ? Málaga, Spain) ppb@uma.es

Since the discovery of site of Venta Micena in 1976, and after nearly four decades of continuous survey and research at the region of Orce (Guadix-Baza Basin, Andalusia, southeastern Spain), with 350 m<sup>2</sup> systematically excavated at this site, 140 m<sup>2</sup> at Barranco León, and 106 m<sup>2</sup> at Fuente Nueva-3, this region has provided one of the most important Early Pleistocene collections of large mammals from the European continent, with more than 25,000 fossil specimens housed at the Palacio de los Segura-Museo de Prehistoria y Paleontología de Orce.

The mammal lists from Venta Micena, Barranco León and Fuente Nueva-3 show typical pre-Jaramillo, Late Villafranchian assemblages, with a chronology for Venta Micena of ca. 1.5 Ma, ca. 1.4 Ma for Barranco León, and ca. 1.2-1.3 Ma for Fuente Nueva-3.

The best-known site is Venta Micena (VM), placed in the biozone of *Allophaiomys ruffoi*, with a typical faunal list of the middle Late Villafranchian, marked by the presence of *Soergelia minor*, a small sized, mesodont bovid that is also recorded at the site of Dmanisi. By the moment, no evidence of human presence has been found at Venta Micena, but most of the recorded species from this site are also present in assemblages with human remains and/or lithic tools from other sites of Europe and Western Asia.

The sites of Barranco León (level D) (BL) and Fuente Nueva 3 (FN3) are situated in the biozone of *Allophaiomys* aff. *lavocati*. Although they are stratigraphically positioned above Venta Micena, they are also placed below the Jaramillo normal subchron (1.07 Ma). Both sites are marked by a record of human presence, and by the absence of *Soergelia*. Their assemblages provide evidence of an important event, the arrival of a large hypsodont Caprini, *Ammotragus europaeus*, which survives until the Jaramillo event at the site of Vallonnet in southern France. There is also evidence of the arrival of a new large stenohippid horse, *Equus sussenbornensis*, detected at Barranco León, which survives until the end of the Early Pleistocene. Both species are typical grazers that inhabited open plain environments, which suggests a

process of aridification during the latest Villafranchian, previous to the arrival in Europe of the classical Galerian species. These are especially characterized by the presence of *Sus* (gr. *scrofa*), which earliest records in Europe are at the site of Sima del Elefante of Atapuerca, level TE9, dated ca. 1.2 by cosmogenic nuclides, and in Untermaassfeld (Germany) and Vallparadís Estació layer EVT10 (Catalonia, Spain), which are both placed in the Jaramillo normal subchron.

In summary, on the basis of the data analyzed we can affirm that the arrival of humans into Western Europe pre-dates clearly the Jaramillo subchron (ca. 1.07 Ma).

Martínez-Navarro, Bienvenido (IPHES, Institut Català de Paleoecologia Humana i Evolució Social (IPHES), 43007, Tarragona, Spain. /Àrea de Prehistoria, Universitat Rovira i Virgili (URV), 43002, Tarragona, Spain./ ICREA, Barcelona, Spain) bienvenido@iphes.cat

The Late Villafranchian site of Venta Micena, in the north-east of the Guadix-Baza Basin, preserves a huge number of large mammal remains. Paleoecological study of this assemblage, based on combined taphonomic, biomechanical, ecomorphological and biogeochemical approaches, has provided compelling evidence on the environmental context inhabited by the first human populations that dispersed in Western Europe. The nearby sites of Barranco León and Fuente Nueva-3 document patterns of anthropic activity for these early human populations (Oldowan tool assemblages and cut marks on bones).

Taphonomic study of the main excavation quarry of Venta Micena has shown that most herbivore remains come from carcasses of ungulate prey selectively hunted by hypercarnivores (coursers *Homotherium latidens* and *Lycaon lycaonoides*; ambushers *Megantereon whitei* and *Panthera gombaszoegensis*). Evidence of prey selection includes the finding for ungulate species of a direct relationship between the percentage of juveniles with deciduous teeth and the body mass estimated for adults; U-shaped, attritional mortality profiles deduced from tooth wearing classes; and arthropathies and bone exostoses in the postcranial skeleton, which would handicap these individuals to escape from predators.

Major taphonomic biases of the assemblage include the kleptoparasitism of ungulate carcasses by the giant hyenas (*Pachycrocuta brevirostris*), which had a body mass

in excess of 120 kg; the transport of ungulate prey as whole carcasses or anatomical parts, depending on the size of the species scavenged; and the selective fracturing of bones by the hyenas as a function of their marrow contents and mineral density.

Biomechanical analyses of *P. brevirostris* remains have shown the bone-crushing adaptations of this hyena, which had a mandible more resistant to vertical bending in the region behind the premolars than any living hyaenid.

Ecomorphological inferences on the Venta Micena ungulates were derived from values of hypsodonty and relative length of the premolar tooth row. Biogeochemical analyses included stable isotope ratios (carbon, nitrogen and oxygen) and relative abundances of trace elements (strontium and zinc) measured in bone collagen and hydroxylapatite. These proxies were used for estimating the feeding and habitat preferences of ungulate species, which allowed to classify them as grazers in open plain (*Equus altidens*, *Hemitragus* cf. *albus*, *Bison* sp., *Praeovibos* sp., *Hippopotamus antiquus*), mixed feeders (*Hemibos* aff. *gracilis*, *Soergelia minor*, *Metacervocerus rhenanus* and *Mammuthus meridionalis*) and browsers in forest (*Stephanorhinus* aff. *hundsheimensis* and *Praemegaceros* cf. *verticornis*). The comparison of the abundance of these ecological categories with those present in modern African and Indomalayan communities showed that the fauna of Venta Micena inhabited a mixed environment with a predominance of open plains and tree patches in the surroundings of a lake fed by hydrothermal waters, similar to the Rift Valley in East Africa. Contribution of thermal springs resulted in a mild environment, with a permanent water sheet in the lake that favored the presence of drought intolerant megaherbivores and a high level of organic productivity due to the saline contents of these waters. Unexpectedly high values of nitrogen isotopes in the hippos indicate that this species did not graze on terrestrial grasses, as do modern hippos, but fed exclusively on aquatic vegetation.

## 5. THE LITHIC ASSEMBLAGES FROM BARRANCO LEÓN AND FUENTE NUEVA 3: A NEW VIEW OF OLD STONES

Barsky, Deborah (IPHES-URV) [dbarsky@iphes.cat](mailto:dbarsky@iphes.cat)  
Sala, Robert (URV-IPHES) [robert.sala@urv.cat](mailto:robert.sala@urv.cat)

Toro, Isidro (Museo Arqueológico de Granada) [toromoya-no@hotmail.com](mailto:toromoya-no@hotmail.com)

The archeological sites of Barranco León and Fuente Nueva 3 (Orce, Andalusia, Spain) are representative of the considerable advancements made in recent years in the study of Oldowan stone industries and the context of their occurrence in Western Europe. The sites, dated to 1.4-1.3 Ma, are amongst the first to have been globally accepted to provide indisputable evidence for a hominin presence in Western Europe well over one million years ago. Since their discovery, these two sites continue to provide the most complete and numerically significant lithic sample known to date in this area of the world. Furthermore, the exceptional preservation of lithics and faunal remains in a lake basin context provides an opportunity- rarely documented for this chronology, to study the lithics in association with the remains of large to medium-sized herbivores and carnivores. New discoveries and applied methodologies have increased the dataset of first industries, widening the range of morpho-technological descriptions and opening up new pathways to discerning the behavioral and cognitive features of their artisans. Ongoing excavations have recently enlarged the lithic sample from each of these two key Oldowan occurrences, continuously widening perspectives for inter and intra site investigations. This paper provides a technological analysis of the main features of these industries, highlighting new data obtained during the last years of fieldwork and lithic studies. Recent advancements include: a re-appraisal of the behavioral aspects of hominin raw material collection and use, progress in the study of the role of the limestone macro-tools, as well as a new vision of some of the specificities of the industries, such as *pièces esquillées*, heavy-duty scrapers and polyhedral morpho-types. Finally, some subtle differences distinguishing these two, largely analogous assemblages, will be examined.

Lithic tools from Barranco León site (1.4 my) provide information about the oldest known European Mode 1 assemblages. The site is located in Guadix-Baza Basin (Andalusia, Spain). We have related our raw materials results and morphological analysis in order to know the occupation models and mobility patterns of the hominids intra and extra site.

The analyzed lithic assemblage was recovered at 2005, 2010 and 2011 fieldwork seasons.

On the one hand only the lithic assemblage made in flint have been analysed for the raw material study. The study of the lithic raw materials has been carried out using microscopic and petrographic analysis to describe the flint characteristics as well as to locate the raw material catchment areas.

On the other hand it has been made a morphotechnic analysis using the Logical Analytical System to define the technology.

The main raw materials used are flint and limestone. Using the petrographic analysis it has been possible to define a calcedonic bioclastic flint with oolites which we are called "Orce Jurassic Flint". Primary flint sources belong to the same unit of oolitic limestone and are assigned to Dogger period (Jurassic).

This flint is irregular in shape and very breakable, due to the presence of fractured joints in its primary formation. This flint appears in a secondary conglomeratic deposit

too, situated 720 metres from the site. The average dimension of the flint does not exceed 50 mm in these deposits. Raw materials size is important to define the knapping strategies. A percentage of 58% of the lithic assemblage is made in this flint. We therefore propose the conglomeratic secondary deposit as the main raw material supply area.

The analyzed lithic assemblage presents small and non cortical flint cutting tools in contrast with large-sized limestone percussion tools. The presence of retouched flakes is not numerically significant. However a few flakes present a non standardized retouch and a double patina that seems to mean the use of discarded flakes to be re-knapped and re-used.

The technique used to reduce the nodule was direct hammer percussion and bipolar on an anvil technique. Knapping strategies were adapted to raw material constraints and the initial nodule morphologies. Unidirectional-unifacial and orthogonal methods predominate as opportunistic techniques. Usually, the *Chaîne Opératoire* is brief and incomplete. Nevertheless the artifacts were knapped, used and discarded at the same place. The aim of the acquisition of the local flint was to produce flakes with cutting edges and without a standardized morphology.

The hominids used the raw materials immediately available on the secondary deposits. The technological features of the lithic assemblage associated with faunal remains that presents cut marks, allow us to interpret the occupation model of Barranco León as a butchery site, where it has been carried out an opportunistic exploitation of animal carcasses, with a sporadic but repeated occupation.

The Early Pleistocene (Late Villafranchian) sites of Orce, placed in the northeastern sector of the Guadix-Baza Basin (Granada, southeastern Spain), are key to the study of the first human settlements in the European subcontinent. Evidence of human presence and anthropic activity has been found in two sites, Barranco León and Fuente Nueva-3. Carnivoran modifications identified in these sites, together with Venta Micena, were mostly originated by the giant, short-faced hyena *Pachycrocuta brevirostris*.

A deciduous tooth of *Homo* sp. has been identified recently in the site of Barranco León, with a chronology of ~1.4 ma. In addition, a huge assemblage of Oldowan (i.e., Mode 1) tools, abundant cut-marks on large mammal bones resulting from disarticulation and defleshing activities, and percussion marks that evidence bone fracturing for accessing marrow contents have been identified in this site, as well as in Fuente Nueva-3, a nearby locality with a slightly younger chronology.

In this sedimentary basin, the hominins inhabited a mild environment rich in vegetation, that provided all resources necessary for their living, including the presence of a lake with a permanent water sheet fed by thermal springs and abundant ungulate carcasses. However, these animal resources were also focus of attention for the scavenging carnivores, particularly *P. brevirostris*.

Taphonomic study of the huge assemblage of large mammals preserved in the site of Venta Micena has shown the behavior of this hyena, which followed specific patterns of bone consumption for each anatomical element of the ungulate skeleton. This model has been extrapolated to the other two sites, where carnivores are

less represented, Fuente Nueva-3 and Barranco León. Comparative taphonomic analyses of the three assemblages shows that, apart from other carnivores of smaller body size, *P. brevirostris* was the main collecting and modifying agency of bones in Venta Micena. In contrast, anthropic activity predominates in both Barranco León and Fuente Nueva-3 (mainly in the lower archaeological level), which suggest a secondary access of carnivores to these areas.

However, the upper archaeological level of Fuente Nueva-3, which has provided ~150 coprolites and several tooth remains of *P. brevirostris*, is an exception to the pattern of competitive exclusion depicted above for hominins and scavenging carnivores. Taphonomic analysis of ungulate postcranial remains preserved in this level has shown increased carnivoran activity, thus evidencing an intense competition for ungulate carcasses between *Homo* and *Pachycrocuta*. Systematic excavations during the year 2001 unearthed a partial skeleton of *Mammuthus meridionalis*, in which the limbs and cranium were absent. Surrounding the bone remains, which are mostly in anatomical connection, there are 34 dark-colored coprolites, rich in organic matter, and 17 flint flakes. This finding allows discussing on a competition event for hominins and hyenas, although there is no evidence of direct confrontation between them. Instead, the most parsimonious interpretation points to a sequence of carcass consumption in which hominins had primary access to this elephant, dismembered its limbs and transported them to a safer place, while the hyenas arrived later and exploited in further depth the resources linked to the axial skeleton.

Barranco León and Fuente Nueva 3 are amongst the oldest archeological sites of Europe. They are especially significant because of their anthropological, lithic and faunal remains, as well as the characteristics of their occupation models. The aim of this paper is to present the preliminary results from the spatial analysis realized in of both sites from 2010 and obtained using innovative scientific techniques.

The spatial analysis of the artifacts from both sites has been carried out by applying different technical components and software systems, developed with the aim of improving the excavations and laboratory work. This methodology provides reliable information and creates a unified platform to access specific data. The use of a Robotic Total Station has allowed us to identify the precise location of each artifact and to individualize each archeological level.

More than 1 million years ago, the Orce environment was characterized by the existence of a large lake, located in the eastern sector of the Guadix basin, as well as by the presence of a fluvial system composed by a large river and its affluents, which extended through the western sector of the basin. The region was characterized by a savannah landscape, with abundant large herbivores, and also numerous carnivores that left their prey, previously exploited, to other scavengers. Hominins, also present in the landscape, took advantage of the abundant water

sources and the wide variety of wildlife resources. They exploited the animal carcasses, establishing small, opportunistic occupations on the shores of the lake.

Thanks to the spatial analysis, the zooarchaeological, taphonomical and technological studies in both sites, we may characterize these sites as sporadic occupations occurring either within the sites themselves, or in some nearby location. In both cases, we may observe an opportunistic or marginal intervention center. The sites are short-term occupations, characterized by relatively simple spatial organization and sparse artifact accumulations, as well as by short lithic operative chains and fragmentary bone remains showing a differential use of certain anatomical parts and / or bones in the final stages of consumption.

The Orce sites (Barranco León, Fuente Nueva-3, and Venta Micena) in the Guadix-Baza Basin (southern Iberian Peninsula, Andalusia, Spain) are exceptional Early Pleistocene locations in Europe. These sites are found in fluvio-lacustrine deposits which are very rich in paleontological remains. Moreover, Barranco León and Fuente Nueva-3 have yielded archaeological materials with abundant lithic tools associated with large mammals, as well as a human decidual tooth from Barranco León Level D, being the earliest evidences for the early human presence in Western Europe. The Orce localities provide extraordinary well-preserved large fossil mammals, which give remarkable data for paleobiological studies (taxonomy, biochronology, taphonomy, paleoecology, etc.). In addition, these paleontological levels provide interesting information to understand the fossil preservation processes in the context of lacustrine-open air sites. The field work at Orce is conducted by a multidisciplinary team, where conservators are directly involved and play an important role. In this study we present the preservation of the large mammal remains, explain the techniques applied to conserve them, and show the obtained results during the last four years period at the Orce sites research.

The principal problems for fossil preservation are due to weathering, diagenetical processes and the big dimensions of some large mammal, that difficult the excavation and delay the extraction of the fossils. Besides all, another important added difficulty, which is directly linked to the others, is the extreme climatic condition in the Orce region, with important variations of temperature (T) and relative humidity (RH) between day and night during the field work seasons. These changes seem to affect the structure of the fossil bones and their preservation while stay exposed during the excavation procedures. We have used a data logger to record variations in T and RH during the field work to know if climatic changes are really producing damage in the bones, and have applied three dimensional surface scanning to record the conservation state of the *in situ* remains before to extract them from the site. These techniques provide us interesting information on the preservation of the fossils and allows us to perform a methodology to protect them while they are kept *in situ* between one field season to another.

## 1. DOPAMINERGIC SYSTEMS EXPANSION AND THE ADVENT OF HOMO ERECTUS

*DeLouize, Alicia M. (University of Colorado, Colorado Springs) Alicia.davis@ucdenver.edu*

*Coolidge, Frederick L. (University of Colorado, Colorado Springs) fcoolidg@uccs.edu*

It is well accepted that a grade shift occurred in hominin evolution approximately 1.9 million years ago with the appearance of *Homo erectus*. With the challenges of complete terrestrial life, new cognitive abilities were selected for that allowed this species to thrive for the next million and a half years. It has also long been recognized that there was a change in diet with the advent of *Homo erectus*, that is, a greater reliance on meat. However, the relationship between additional meat and the cognitive abilities of *Homo erectus* has mostly remained unclear.

The present paper proposes that an increase in dietary meat protein and fats may have led to an increase in dopamine and dopaminergic systems, a critical chemical neurotransmitter in the brain. This purported change in dopaminergic systems may have played a key role in many of the traits and abilities exhibited by *Homo erectus* at that time, including increases in body and brain size, dispersion, and a greater aptitude for spatial and social cognitions.

*Rook, Lorenzo (Dipartimento di Science della Terra, Università degli Studi di Firenze) lorenzo.rook@unifi.it -*

*lrook@geo.unifi.it*

The main subject of this work is to study the ecological relationships, the (co)variation and evolutionary trends, and the geographical dispersal patterns of the large omnivorous mammal taxa - pigs, bears, monkeys, and hominins - as represented in a number of Early Pleistocene fossil assemblages from eastern Africa, the Levantine Corridor, the Caucasus, and southern Europe, chronologically spanning from ca. 1.8 to 1.0 Ma. The main question of the research relies upon two basic broad assumptions: (i) the dispersal patterns of the omnivorous species within and out of Africa are primarily and intimately related to climatic, thus to paleoecological determinants; (ii) within mammal fossil series, dental morphology and micro-wear analysis are helpful tools for comparatively assessing evolutionary changes, biogeographic habitats, and dietary habits.

The study provides critical information to the ongoing debate on the dispersal and adaptive hominin patterns during the Early Pleistocene in different eco-geographic contexts related to other large mammal taxa similarly relying upon a wide spectrum of resources, and thus acting as direct potential competitors together with large carnivores (Canids, Hyaenids). The methodologies include systematics, microwear analysis (extinct and extant species), statistical applications and inclusion of stable isotopes data.

ORAL

## 3. TESTING THE MOVIOUS LINE WITH AGENT-BASED MODELLING

*Romanowska, Iza (Institute for Complex Systems Simulation Centre for the Archaeology of Human Origins University of Southampton, UK) I.Romanowska@soton.ac.uk*

The Movius Line controversy is one of the most persistent research themes in Early Palaeolithic Archaeology. A number of hypotheses have been put forward to explain the pattern of the spatial distribution of Mode 1 and Mode 2 industries. It has been suggested (Lycett & Von Cramon-Taubadel 2008; Lycett & Norton 2010) that in areas further away from the origins of the first 'Out of Africa' dispersal the population density was lower than in the zones closer to Eastern Africa. As a result, smaller and less well connected human groups could not sustain the sophisticated technological knowledge necessary to produce Mode 2 implements and reverted to simpler knapping strategies i.e. Mode 1.

An Agent-based model was developed to test the above hypothesis. It consists of an paleoenvironmental reconstruction of the Old World coupled with a dynamic simulation of the sea level fluctuations in which large areas of dry land would occasionally (on a geological time scale) become submerged and reappear due to climatic changes, acting as an 'environmental pump' driving human movement.

The goal of this study is to compare population density in the Acheulean and Oldowan regions throughout the simulation to evaluate if the proposed demographic disparity between the two regions is plausible. If, under a wide sweep of parameters informed on contemporary hunter-gatherer but also mammalian data, the model will show no differences between the Mode 1 and Mode 2 areas in terms of population density then the aforementioned hypothesis can be rejected.

ORAL

#### **4. THE ENVIRONMENT OF EARLY HUMANS IN SOUTHERN CAUCASUS - HIGH-RESOLUTION RECONSTRUCTION OF CLIMATE AND VEGETATION IN ARMENIA AT THE MATUYAMA/JARAMILLO REVERSAL**

*Bruch, Angela (ROCEEH Research Centre) [abruch@senckenberg.de](mailto:abruch@senckenberg.de)*

*Gabrielyan, Ivan (Armenian National Academy of Sciences) [ivangabrielyan@yahoo.com](mailto:ivangabrielyan@yahoo.com)*

*Scharrer, Steffen (ROCEEH Research Centre) [steffen.scharrer@senckenberg.de](mailto:steffen.scharrer@senckenberg.de)*

The Southern Caucasus is the area of earliest human occupation in Eurasia, proven by findings of *Homo* fossils in Georgia with an age of ca. 1.8 Ma. The pace and causes of the early human colonization, in one or several migratory waves from Africa into new environments of the Eurasian continent during the Early Pleistocene, are still a matter of debate. However, climate change is considered a major driving factor of hominin evolution and dispersal patterns. In fact directly or indirectly by its severe influence on vegetation, physiography of landscape, and animal distribution, climate modulates the availability of resources.

Lake sediments from Sisian Formation, Vorotan River Basin, southern Armenia, provide detailed information on environmental changes during late Early Pleistocene. Based on magnetostratigraphic and radiometric dating,

the exposed part of the succession covers a stratigraphic age from ca. 1.3 to 0.9 Ma and includes the Jaramillo subchron. Due to the precise age control high-resolution pollen analysis was conducted at the Matuyama/Jaramillo reversal spanning from 1.12 to 1.035 Ma (MIS 33 - MIS 30) with a mean resolution of ca. 250 years per samples.

Results document a clear vegetation response on orbitally forced climatic changes with open vegetation during the less pronounced cycles MIS 33/34, the expansion of broadleaved deciduous forests during the cooling phase of the very warm and humid MIS 31, and the expansion of needleleaved forests during the long, cool and humid MIS 30. Furthermore, the age of the numerous macro floral assemblages could be constrained to warm and humid parts of the climatic phases, most of them connected to MIS 31 confirming the dominance of mosaic vegetation at that time.

Plant species compositions show strong relations to Euxinian and Hyrcanian forests occurring today at the coasts of the Black Sea and Caspian Sea, respectively, which must have been expanded considerably during warmer and more humid periods of the Early Pleistocene. Climate quantifications show substantially warmer and 50-100% more humid conditions for most pronounced interglacials. Based on those results we extrapolate the maximum extend of forests and mosaic landscapes in Southern Caucasus for different climatic phases during Early Pleistocene as a prerequisite for the reconstruction of early human environments in this region.

Medin, Tsegai (Institut Català de Paleoecologia Humana i Evolució Social-IPHES, C/ Marcel·lí Domingo s/n, Edifici W3, Campus Sescelades, 43007 Tarragona, Spain; National Museum of Eritrea, P.O. Box 5284, Asmara, Eritrea) eldatse@gmail.com

Palmqvist, Paul (Departamento de Geología y Ecología, Universidad de Málaga, Campus de Teatinos, 29071 ? Málaga, Spain) ppb@uma.es

Research during more than 25 years of this team working on Early and Middle Pleistocene fossil collections of large mammals around Europe, Asia and Africa, with special interest in the Ibero-Mediterranean sites of the Guadix-Baza, Besalú-Banyoles, Vallès-Penedès and Francolí Basins, has helped to build up new biochronological and paleoecological issues on the faunal and human dispersals from Subtropical Africa into the middle latitudes of Eurasia.

The first, well-recorded evidence of human dispersal into Eurasia was found at the site of Dmanisi, in the Caucasian region, dated ca. 1.8 Ma. Five skulls and thirty-five postcranial human remains, together with a large collection of Oldowan lithic artifacts corroborate these findings. This site is also characterized by the record of a few but very significant species of African origin, like the saber-toothed cat *Megantereon whitei*, an ambush predator that inhabited mixed habitats, with powerfully developed forelimbs, elongated and non-crenulated upper canines, and a short mandible with reduced precarnassial cheek teeth. It was well-adapted to hunt medium-to-large sized ungulates, but its masticatory structure only allowed it to eat the softer parts of its prey, leaving most of the carcass intact for scavengers, especially for the starring of the ecosystem, the giant, short-faced hyena *Pachycrocuta brevirostris*, but probably also for hominins. Later, *M. whitei* and *P. brevirostris* are common inhabitants of Europe and Asia during the late Early Pleistocene.

Another important African immigrant recorded in the Late Villafranchian is the giant hippo *Hippopotamus antiquus*, which is a sister species, if not the same, of *Hippopotamus gorgops*, with a mean body mass estimated in 3200 kg. Although it is cited at the site of Coste San Giacomo in Italy, around 2.0 Ma, it becomes a common species in the ecosystems of southern and central Europe since 1.5 Ma, as recorded at Venta Micena in the Guadix-Baza Basin and many other sites. Apart from its

enormous size, it shows anatomical adaptations in the skull and the postcranial to the aquatic environment, with more elevated orbital and nasal cavities, a narrower and more elongated muzzle, and shorter distal limb segments than in the extant, less aquatic and more amphibious species *Hippopotamus amphibius*. There is only evidence for the arrival of one African origin species during the latest Early Pleistocene in Europe, the giant cercopithecoid monkey *Theropithecus cf. oswaldi*, which is found at the site of Cueva Victoria, southeastern Spain (ca. 1.0 Ma).

The discussion of other African origin species during the latest Early Pleistocene into Europe, such as *Panthera fossilis*, *Panthera pardus*, *Crocuta crocuta*, *Hyaena hyaena*, or *Elephas (Palaeoloxodon) antiquus*, still remains open, but it is clear that all of these species are well known and become common in the continent during the early Middle Pleistocene, when the developed Acheulian culture arrived and colonized most of the subcontinent. This dispersal was also accompanied by the arrival of the large Bovini *Bos primigenius*, evolved from the latest African Early Pleistocene form *Bos buiaensis* (found at Buia, Eritrea), which also evolved from the giant African buffalo *Peloroavis oldowayensis*.

ORAL

## 6. THE ACHEULIAN OF GESHER BENOT YA'AQOV: CLIMATE, CULTURE AND SOCIAL BEHAVIOR

Goren-Inbar, Naama (Institute of Archaeology, The Hebrew University of Jerusalem) goren@cc.huji.ac.il

The excavations at the Acheulian site of Gesher Benot Ya'aqov (GBY) provide unprecedented multidisciplinary research opportunities and have consistently yielded unique data that are relevant to issues of climate, culture and social behavior. Along a stratigraphic-temporal record beginning at 1.1 Ma, a Mediterranean landscape rich in floral and faunal taxa of different biogeographic origins prevailed in the Upper Jordan Valley of the Levantine corridor. The sites at GBY (over 15 rich superimposed cultural entities located on the edge of paleo-Lake Hula) are present along the entire stratigraphic record and furnish insights into Acheulian technology and cognition over a time trajectory. They have yielded an unprecedented archive of different behavioral patterns that shed light, among others, on the mechanisms and character of human dispersals.

ORAL

## 7. PALEOLITHIC OCCUPATIONS OF KUZFINDIK VALLEY AND PLEISTOCENE HUMAN DISPERSALS IN NW ANATOLIA

*Dinçer, Berkay (Istanbul University) berkaydincer@gmail.com*

*Türkcan, Ali Umut (Anadolu University) aturkcan@anadolu.edu.tr*

*Erikan, Ferhat (Anadolu University) ferikan1988@gmail.com*

Anatolia (Asian part of Turkey) is accepted to be one of the main Out of Africa hominin dispersal routes in the Pleistocene. Despite its crucial role as a route, research in Anatolia is very limited and this large peninsula remains as a *terra incognita* for the Paleolithic archaeology. Excavated Paleolithic sites are very few in number and located in separate geographical areas.

Kuzfindik Valley in northwestern Anatolia was subject to systematical archaeological surveys and 8 Paleolithic open-air sites were revealed. Due to its location on the southeast-northwest oriented natural land-routes within Anatolia, the Paleolithic sites in Kuzfindik Valley may help understanding the early hominin dispersals.

Techno-typological analyses of nearly 300 lithics collected from eight different open-air sites.

ORAL

## 8. ON CULTURE AND GENETICS: SOME OBSERVATIONS ON THE FIRST INHABITANTS OF ANATOLIA

*Gil Fuensanta, Jesús (UAM - Spain) jesus.gil@uam.es*

*James, Ariel José (UAM - Spain) arieljose.james@gmail.com*

*Mederos Martín, Alfredo (UAM - Spain) alfredo.mederos@uam.es*

*Boynikoglu, Ediz (Trakya Üniversitesi, Turkey) boynik@gmail.com*

Recently there have been several issues for discussion on the idea that culture and genetics are intertwined. This theory considers that there are cultural and genetic elements throughout evolution. An example of support appears to be based on neurological evidence that moral cognition occurs in the frontal lobe (cf. Joshua Greene Cognitive Laboratory at Harvard).

The influence of social rules of a given culture cannot be removed entirely from the picture, but from a logical point of view it cannot be an element of our universal genetic programming.

The hereby research presented in Burgos contains some personal observations that depart from fieldwork conducted primarily in Eastern Thrace (West Turkey) and also Northern Mesopotamia (Euphrates and Tigris region) on some characteristics of a cultural horizon of the Middle Paleolithic industries within the framework of the Tilbes Archaeological rescue Project.

On the other hand, the climate although seems not to be the "prime mover" in many cases for the researched area, it can act as a trigger or important conditioning.

ORAL

## 9. REGIONAL HUMAN CORRIDOR AND VARIABILITY OF THE MIDDLE PALAEOLITHIC LITHIC ASSEMBLAGES DURING THE UPPER PLEISTOCENE IN THE GUADALQUIVIR-GUADAIRA RIVER VALLEYS (SOUTHERN SPAIN)

*Díaz del Olmo Fernando (Universidad de Sevilla) delolmo@us.es*

*Caro, José Antonio (Universidad de Sevilla) jacaro@uco.es*

*Borja, César (Universidad de Sevilla) cesarborja@us.es*

*Recio, José Manuel (Universidad de Córdoba) bv1reesj@uco.es*

The lithic industries of the Middle Paleolithic in the Guadalquivir River valley (South of Spain) have been studied in relation to their geomorphological units and stratigraphic position. Based on the raw materials these pebble industries are gathered in two general kinds: quartzites, from the North; and flint, from the South. The biggest extension of the Guadalquivir's alluvial terraces are spreading over its left river catchment, that is toward the South, because of the stream network from the Subbetic dissect the piedmont of liaison between the Subbetic and the Guadalquivir Basin as well as its alluvial terraces system.

The Middle Palaeolithic archaeological sites network in the Guadalquivir's affluent valleys by the left, with the two kinds of raw materials, allows us to reconstruct fluvial geographical areas of human circulation and raw material provisioning (*Regional Human Corridor*, RHC). Focusing the study on the Guadaira River, Guadalquivir's affluent by the left, twenty archaeological sites has been recognized in Sierra de Esparteros piedmont (link Subbetic-Guadalquivir Basin) and in the alluvial terraces system. It is about a regional geoarchaeological context with high technotypological variability in the sites, chronostratigraphically dating from MIS6.

They are studied 20 geoarchaeological sites (28 assemblages) with industries of the Middle Palaeolithic in the Guadalquivir-Guadaira (G-G)'s alluvial sediments and in piemont's karstic fillings (Sierra de Esparteros). The methods applied are: geomorphological map, absolute dating (OSL and U/Th), technotipological analysis and use-wear analysis of the lithic industries (binocular microscope and SEM).

The geomorphological *continuum* established between the Guadaira River and its connection with the Guadalquivir's alluvial terraces shows that these archaeological sites constitute a fluvial RHC since late MIS6 with two leading stages:

1) A short time, transit Middle-Upper Pleistocene (MIS6/MIS5) (>129 ky and under 104 ky), with predominance of industries in quartzites (notches, scrappers and pebble tools).

2) A long time (under 110 ky, and even of 50 ky), made up by lithic assemblages in quartzites and flints with high diversity of flakes tools, with presence of Levallois technique and handaxes testimonies.

The technotipological analysis of the industries shows three RHC kinds of activities: provisioning and distribution of raw materials, knapping and anthropic activities, which imply the use of industry (workshop and settlement of character regular, occasional and indeterminate):

- The connection G-G means a model of alluvial and multifunctional character RHC during the Middle Palaeolithic with two noticeable stages.

- The G-G RHC allows the anthropic circulation and explains the provisioning area of flint and quartzite.

- The technotipological variability is seen in the maintenance of Acheulean characters, increase in the use of flint and intensification of high complexity knapping techniques (Levallois, thorougher retouchings and diversification of tools on flakes).

**Acknowledgements:** GeoCroQ Project (HAR2011-23798).

ORAL

## 10. NEANDERTHAL LIFEWAYS IN NORTH-WEST EUROPE: THE CHALLENGE OF THE EEMIAN FOREST

*Bringmans, Patrick M.M.A. (The 'Veldwezelt-Hezerwater' Neanderthal Research Centre - Belgium) Patrick.Bringmans@*

*hotmail.com*

*de Warrimont, Jean-Pierre (Archeologische Vereniging Limburg - The Netherlands) warri009@planet.nl*

*Pierre M. Vermeersch (Catholic University Leuven - Belgium)*

*Pierre.Vermeersch@ees.kuleuven.be*

*Schirmer, Wolfgang (Heinrich-Heine-Universität Düsseldorf - Germany) schirmer@uni-duesseldorf.de*

The 'Eemian' interglacial (Marine Isotope Stage [MIS] 5e) seems to represent an exceptionally warm period. It has been argued by Clive Gamble (1986) that the 'Eemian' probably represented a hostile ecological niche to Neanderthals, because the majority of the biomass was stored in non-edible form. In spite of these claims, Roebroeks *et al.* (1992) refuted the basis of Gamble's model by stating, that Neanderthals were present in North-West Europe during the Eemian interglacial with deciduous forests. However, this latter hypothesis seems inconsistent with the lack of observational evidence to support it.

New data from the 'Lower Sites' at Veldwezelt-Hezerwater (Bringmans 2006) show that the incipient soil horizons there seem to represent late Late Saalian phases of pedogenesis under boreal conditions just prior to the MIS 6/5e transition. The pedostratigraphical position provides a firm basis to conclude that these soil horizons represent the terrestrial equivalent of the late Late Saalian 'Zeifen Interstadial' (MIS 6.01). It seems that many of the so-called 'Eemian' Neanderthals sites in North-West Europe should be dated to the MIS 6/5e transition and not to the 'Eemian' itself.

On the other hand, it appears that the remaining 'Eemian' sites should actually be dated to the early part of the 'Eemian', because analysis shows high percentages of herbaceous *taxa*, which suggests that the forest was relatively open. For instance, both Neumark-Nord (Germany) and Caours (France) were occupied during the 'Eemian' by Neanderthals. However, there is evidence that supports a major time lag of 5,000 years between the onset of the 'Eemian in the south' and the 'Eemian in the north' of Europe (Sier 2013). The evidence uncovered at Neumark-Nord shows that the Neanderthals were present there during the *Corylus*-phase (120,000 BP), which was more open compared to the later stages of the Eemian (Gaudzinski *et al.* 2013). No traces of Neanderthal presence were recovered from sediments deposited during the later *Carpinus*-phase of the Eemian when a closed canopy forest prevailed. New investigations at Caours (Antoine *et al.* 2006) have allowed the discovery of several Middle Palaeolithic layers with interglacial large mammal remains, which can also be dated to the early Eemian. However, the oldest Middle Palaeolithic layers

at Caours exhibit late-glacial characteristics, which we claim should also be dated to the late Late Saalian Zeifen Interstadial (MIS 6.01).

The 'Eemian' climax forests in North-west Europe appear to have been deserted by Neanderthals, because they were less suitable places for food collecting. It is however possible, that river valleys were ecologically more diverse. Although the palaeo-environmental data suggest dense forests at some of these 'Eemian' sites, the faunal remains are actually a mix of closed forest species (e.g., deer) and open country species (e.g., horse). So, although some of the palaeo-environmental data seem to point to climax forests, the sites themselves represent open swatches such as lake and river shores. The 'Eemian' would then become a generic term that only refers to a vague ecological mosaic, rather than to a specific environment.

*Moyà-Solà, Salvador (ICREA & Institut Català de Paleontologia Miquel Crusafont, UAB) salvador.moya@icp.cat*

The oldest evidence of hominin presence in the Iberian Peninsula comes from three localities (Barranco León,

Fuente Nueva 3 and Sima del Elefante) from the latest Early Pleistocene. In Iberia, this time interval was characterized by warm temperatures, with landscapes dominated by open dry grasslands and several wooded areas. Several authors suggested that the paleoenvironmental conditions most favorable for the dispersal of hominins across Europe would correspond to open landscapes, similar to the African environments in which early *Homo* had evolved. The Iberian Peninsula apparently displayed these kind of environments, although other factors might have conditioned the survival of these early *Homo* populations. In particular, taphonomic studies carried out in the Orce localities suggest that large carnivorans, such as *Pachycrocuta brevirostris*, were responsible of an intense bone modification activity during the late Early Pleistocene. Evidences of early *Homo* modification are also recorded, although the analysis of available data has thus far suggested a primary access to the carcasses by humans only under occasional circumstances. In fact, several scholars established a parallelism between the composition of the carnivore guild and the impact of hominin activities in the record. Thus, in the localities with Villafranchian carnivorans, hominin activities have a much scarcer impact than in the localities with Galerian carnivorans.

Shortly after the record of the Guardix-Baza Basin, a global climatic event, known as *Mid-Pleistocene Revolution* and elapsing from 1.25 Ma to 0.7 Ma, started in the Northern Hemisphere. During this time interval, the previous low-amplitude, 41 ka obliquity-forced climate cycles were progressively replaced by high-amplitude, 100 ka cycles. The latter implied a transition towards a strongly non-linear forced climate system, and were accompanied by a substantial increase in global ice volume at 0.94 Ma. These climatic changes, had a profound effect on the biota and the physical landscape—and, as a consequence, probably also in the interaction of European early *Homo* with the environment.

There are only a few European localities that record this time interval of great climatic shifts and therefore enable to study the impact of the latter on the taphocenoses. The Vallparadís Section (Vallès-Penedès Basin) chronologically well-constrained and ranging from 1.2 to 0.6 Ma, records during the MPR the same carnivore guild as the Orce localities, at last until 0.83 Ma. This evidence suggests that, in the Iberian Peninsula, the carnivore guild remained stable during most of the MPR, thus probably constituting a persisting limiting factor for the subsistence and dispersal early *Homo* populations. This is further supported by the taphonomical evidence provided by the bone remains from the various layers

of the Vallparadís section, which show that the distribution of skeletal elements and their preservation closely resemble those documented from the Early Pleistocene site of Venta Micena, which has been attributed to the activity of *Pachyrocuta brevirostris*.

The reported evidence reinforces the idea that large carnivores were an important limiting factor for hominin dispersal and subsistence throughout the whole second half of the Early Pleistocene, including the latest portion of this stage, when climatic conditions became unstable.

ORAL

## 12. PLEISTOCENE HUMAN DISPERSAL ABOVE 55° NORTHERN LATITUDE: EVIDENCE OF ABSENCE OR ABSENCE OF EVIDENCE?

Nielsen, Trine Kellberg (Aarhus University) farktnielsen@cas.au.dk

The early dispersal into and colonisation of Europe has been the focus of an increasing amount of research. The relatively recent discoveries of evidence supporting the so-called "long chronology" (Roebroeks 2006) (including such famous sites as Atapuerca (c. 42°N) in Spain and Dmanisi (c. 41°N) in Georgia) has certainly encouraged this development. Evidence from Britain (e.g. Happisburgh, Boxgrove, Pakefield) even supports an early colonisation of high northern latitudes around 52°.

To what degree these occupations represent continuous habitation or local extinction-events is difficult to unambiguously ascertain due to the relatively poor time resolution (Hublin & Roebroeks 2009). Despite these obvious chronological challenges, the current site data available does seem to suggest that north-western Europe up to 55°N was colonised by at least 800.000 BP and thereafter subjected to a series of occupations. However no uncontested sites have, as of yet, been recognised above 55°N latitude. This signal may be an outcome of the major advances of the Scandinavian ice sheet causing poor preservation and mixed stratigraphic conditions in the area of impact. Perhaps these glaciotechtonic activities were even powerful enough to completely cover the tracks of Neanderthals reaching these northern hunting grounds during intermediate periods of favourable conditions. As population density seems to decrease along the northern gradient, sites becoming more scattered in the landscape in the North, one could argue that if such northern expeditions did occur, the impact and possible debris-accumulation for archaeologists to find today is minimal

even without the destructive power of the glaciers.

However, there is of course another possible explanation – that this absence indicates actual adaptive constraints among the early inhabitants of Europe. In this scenario 55°N latitude would constitute the 'maximum northern range' of a species that, at many other occasions, have proved highly successful in adapting to a wide variety of environments. Understanding the dynamics of such an 'adaptive boundary' thus becomes essential, especially the climatic, ecological, and social factors controlling it.

In this paper the archaeological data available in proximity to 55°N latitude (with a focus on Germany above the Elbe River basin and southern Scandinavia) will be discussed in conjunction with the ecological evidence present for the same region. Since a majority of the lithic finds from the area have very low (to non-existing) chronological affiliation, it can be challenging to achieve a satisfactory resolution when trying to accurately model the distribution and successfully explain the variables controlling it. Despite this, the development of a methodological approach based on eco-cultural niche modelling (Banks et al 2006) will be attempted and evaluated.

ORAL

## 13. PALEOLITHIC PERIOD IN SEYMAREH VALLEY, CENTRAL ZAGROS, WESTERN IRAN: SOME OBSERVATION

Zeynivand, Mohsen (Department of Archaeology, Islamic Azad University, central Tehran Branch) zeynivand@gmail.com

Mazaheri, Khoda karam (Department of Archaeology, Islamic Azad University, Ilam Branch) Kh.Mazaheri@yahoo.com

Bahramiyan, Saeid (Department of Archaeology University of Tarbiat Modares, Tehran, Iran) Bahramiyan.saeid@gmail.com

Seymareh Valley is referred to central sector of Dareh Shahr township of Ilam Province at the extreme south of Pish-kuh in central Zagros and western Iran. Prehistoric sites of the region resurveyed in 2010 and for the first time, an evidence of presence of Hunter-Gathering groups is discovered. The Seymareh valley has importance from two aspects; the first, it is one of the folded Zagros's lateral valleys that was original location of human movement in the region and due to laying between the lowlands of southwest of Iranian plateau and central Zagros Highland is considered as intermediate zone. Second, it has a remarkable environment due to

the climate conditions and being of Seymareh River and Kabir-Kuh Mountain. In addition, the significant and interest Information from Paleolithic periods was found at the Hulailan and Kuran Buzan Valley and from northern part of the Susiana plain, respectively at north and south of the Seymareh valley. These evidences and potential environment of Seymareh valley itself may to be representing somewhat the possibility of communities Pleistocene's presence in the Valley.

But the most important natural event was major Seymareh landslide that has remarkable impact on Landscape and environment and also difficulty in identification of prehistoric sites as by falling Anticline of southeastern part of Kabir-Kuh, length of 16 Km., its debris have been spread to limited area about 20Km in the southeastern of Seymareh Valley, and by blocking the course of Seymareh and Kashkan Rivers, makes a natural dam. This huge natural event caused formation of a great Lake behind this dam and major parts of Seymareh was drown which results accumulation of alluviums and deposits at the valley floor with about 40m thickness. However, the Seymareh landslide have been remarkable impact on Structure of the Seymareh valley in the early Holocene and limited the ability to identify of possible sites, duo to the alluvium, before this event, It was rather optimistic that the evidences of remains belonging to Paleolithic periods was identified in altitudes laying higher from the alluvium of the Valley floor and on rocky outcrop located in the valley floor. In fact this assemblage is the first known evidences relating to this period at the Valley. The most of lithic artifacts collected from this open sites and rock shelters is made on flake and no traces of blade and microliths. Except to a few flakes and Cores, the rest of findings have not the known Characteristics of Zagros industry. Such assemblages was identified from the Folded Zagros, included Pol-Dokhtar, Baba Zeid, several parts of Kuhdasht and Locales at Islamabad plain, before this time.

The Notable point about the assemblage of the rock shelters is lack of remarkable open sites in the valley floor. It seems evident that the lack of Paleolithic remains at the valley floor is influenced by geological factors and sedimentation factors.

#### 14. THE NORTHEASTERN MEDITERRANEAN AND THE ORIGINS OF SEAFARING

*Papoulia, Christina (University of Crete) christina\_papoulia@hotmail.com*

By focusing on the lithic evidence from the islands of the Aegean and Ionian Seas this paper discusses the arguments for early Palaeolithic sea-crossings. Based on the geomorphology and the proposed sea-level reconstructions, the recently published lithic collections together with new, under study data from the Inner Ionian Sea Archipelago are presented and the possible sea-routes are proposed. Were the early hominins which occupied the northeastern Mediterranean during the Lower and the Middle Palaeolithic cognitively, socially and technically competent for such an innovative and challenging task? The evidence at hand cannot but imply -at least- Neanderthal presence on certain islands of the Mediterranean.

#### 15. EXAMINING THE ROLE OF CLIMATE, ECOLOGY AND ADAPTATION IN MODELS OF HUMAN DISPERSALS INTO THE AMERICA

*Schurr, Theodore G. (Department of Anthropology, University of Pennsylvania) tgschurr@sas.upenn.edu*

The peopling of the Americas has long been viewed as a case study in human migration and adaptation. Colonizing groups entered regions uninhabited by other human populations at the end of the Pleistocene and then lived in relative isolation from other Eurasian groups for many millennia before the arrival of Europeans in the 15<sup>th</sup> century CE. They entered the New World during the last glacial maximum, either through coastal and/or interior routes, from the Beringian landmass, and then rapidly dispersed through the American continents. However, the timing, points of dispersal and number of population expansions that occurred during this period remain unresolved, particularly in light of new genomic data from Siberia and Native American populations. While genetic data have clearly delineated founding lineages in these populations and are forcing a rethinking of migration scenarios, they are often not considered in the context of the environmental and climatic conditions of the Late Pleistocene period, which would have shaped potential settlement areas in Eurasia, dispersal routes in and out of Siberia, and biological and cultural adaptation that ancestral Native American populations would have undergone prior to entering the Americas.

This paper will review the paleoclimatological and paleoenvironmental records for Siberia and the Americas and attempt to situate the current genetic data from indigenous Siberian and Native American populations in

this context to assess the validity of different migration scenarios for the Americas and characterize the demographic and adaptive features of the human groups living during the LGM.

## 16. HUMAN BEHAVIORAL ECOLOGY AND THE PLEISTOCENE COLONIZATION OF NORTH AMERICA

*Daniel S. Amick (Loyola University Chicago) damick@luc.edu*

*Matthew J. Root (Rain Shadow Research and Washington State University, Pullman) rainshadow@completebbs.com*

Colonization of North America by anatomically modern humans appears to have followed the Last Glacial Maximum. Current evidence suggests migration from Northeast Asia using coastal routes followed by the eventual colonization of the interior including the notably sophisticated adaptations known as Clovis. Multiple migrations likely occurred resulting in considerable complexity to this early archaeological record. These early migrants encountered and sometimes hunted now extinct species, but the degree to which they caused those extinctions remains debatable.

Substantial and geologically rapid environmental change during this interval presented humans with new challenges and opportunities which seem to have resulted in a unique set of adaptive strategies that resulted in the rapid settlement of a vast continent. Those behaviors are often characterized as large-scale mobility, regionalization of subsistence and settlement patterns, advanced systems of resource and technological knowledge, rapid responses to different resources and their shifting spatial and seasonal configurations, the use of functional and symbolic forms of artifact caching, and maintaining social ties through periodic aggregation and down-the-line exchange.

Evidence of such swift colonization presents a range of problems for understanding the human behavioral ecology of these hunter-gatherers. Understanding how humans succeeded in this exceptional accomplishment have been advanced by considerations of landscape learning, cultural transmission, and demographic modeling.

*Solís, Óscar R. (Postgraduate Student Universidad Rovira i Virgili (URV), Tarragona, Spain; Scholarship Holder Fundación Atapuerca, Burgos, Spain) zolhiz@yahoo.com.mx*

Over the past seven years, an archaeo-paleontological research has been carried out in the Barranca del Muerto site, located in souther Sierra Madre, Santiago Chazumba, Oaxaca, Mexico (18° 11'44"N latitude and 17° 40'15"W longitude, at an altitude of 1,774 m., in a semi-desert environment with desert scrub).

The excavation works are part of the larger project "Biodiversidad y Sociedades cazadoras recolectoras del Cuaternario de México" co-directed by the Instituto Nacional de Antropología e Historia de México and the Institut de Paleoeologia Humana i Evolució Social de Tarragona (Spain). The project's main goal is the study of the hunter-gatherers and their relationships with the fauna and the rock art.

We have undertaken four fieldwork seasons and all materials were recorded by coordinates X, Y, Z. There have been sampling of pollen seriations for its study (to be conducted in the laboratories of ENAH and IPHES) and several osteological materials have been analyzed through the electronic microscope in search of cut Mark. Few other materials were sent to Beta Analytic laboratories for C14 analysis.

The number of animal species discovered includes both megaherbivores (giant sloth, gomphothere and gliptodont, among others), and mesoherbivores (deer, prong-

horn, rabbit), and even small mammals, reptiles and amphibians.

Associated to the megafauna there have been found some lithic remains of little significance, although it has been detected a cut mark on a giant sloth bone. Initial pollen analyzes showed the existence of a temperate coniferous forest with several springs draining into a former lake. However, no radiometric dates for the site were obtained until now.

The Barranca del Muerto site provides a context that corresponds to the Late Pleistocene and more specifically to an indeterminate range of the Rancholabrean NALMA. In relation to its most significant characteristics, we must emphasize the abundance of large mammals, among which stand out three taxa of the Xenarthran group: the giant sloth (*Eremotherium laurillardi*), the mylodon (*Paramylyodon harlani*) and the glyptodont (*Glossotherium* sp.), as well as the Proboscidean *Cuvieronius* sp. Moreover, the known fauna indicates the occurrence of a warm and humid climate, which favoured, in one hand, the development of a tropical deciduous forest, and secondly, of grasslands and savannas. However, it should be noted that the final conclusions must await the detailed study of the materials and their final identification.

### 18. EARLY HOMO SAPIENS, AND THE NATIVE FAUNA EXTINCTION IN THE SOUTH AMERICA SOUTHERN CONE

Chichkoyan, Karina Vanesa (*Institut Català de Paleoecologia Humana i Evolució Social (IPHES); Àrea de Prehistoria, Universitat Rovira i Virgili (URV)*) [karinavch@gmail.com](mailto:karinavch@gmail.com)

Belinchón, Margarita (*Museum of Natural Science of Valencia*) [museociencias@valencia.es](mailto:museociencias@valencia.es)

Martínez-Navarro, Bienvenido (*IPHES, Institut Català de Paleoecologia Humana i Evolució Social (IPHES), 43007, Tarragona, Spain. /Àrea de Prehistoria, Universitat Rovira i Virgili (URV), 43002, Tarragona, Spain./ ICREA, Barcelona, Spain*) [bienvenido@iphes.cat](mailto:bienvenido@iphes.cat)

Lanata, José Luis (*IIDyPCa, CONICET, UNRN*) [jllanata@gmail.com](mailto:jllanata@gmail.com)

Dispersion is a survival *Homo sapiens* adaptive strategy to confront variable environmental stresses in different spaces. To compare how it developed in diverse paleoecological settings is useful in order to understand how this adaptive capacity was used in niche construction or modification. Resources to be exploit, competency with

other species and passing through different climatic or geological barriers, are keys items in this question.

America is an excellent opportunity to understand how dispersion was, in a landscape free from previous Hominini intervention. Focus emphases over the Pampean Region, Argentina, located at 36° S and 64 W. *Homo sapiens* would have created new niches of predation which would have allowed a fast dispersion timing.

Taphonomical analysis was done in Rodrigo Botet Collection housed in the Museo de Ciencias Naturales de Valencia, Spain. This is the result of non-systematic excavations done at the north-eastern sector of the Pampas Region at the end of XIX century. Taphonomical history of these bones, species and skeletal parts can give information about agents involved in its burial, ecology of the native fauna and its habitat. This evidence can be related with human's movements into the region at a coarse-grain level and thus understand how ecological relationship were constructed.

11,466 elements were analysed, from which 10 elements, coming from different species, were detected showing different kinds of anthropic traces: four *Mylodontidae* bones, one *Megatherium* sp. rib and other two from *Macrauchenia patachonica*, three osteoderms with pentagonal and hexagonal shape, one from *Glyptodontidae* and two from *Eutatus*.

These native fauna developed during Pleistocene times and extinct just after humans colonized the region –except *Eutatus*, which survived until recent times. Because its size, they have low carnivore predation and consequently few avoidance behaviours. Also slow sexual maturity and low reproduction structure. In these populations, stressed by paleoenvironmental changes, sporadic human predation could have influenced its extinction. Dispersion into empty Hominini continents constituted a new ecological situation into human's evolution. Therefore different dispersion dynamics can be compared and evaluated between first entries of humans in South America and Iberic Peninsula. While in Europe early *Homo sapiens* dispersions could have taken at least 10.000 years, in America, the dispersion would have been fastest, between 3.000 or 2.000 years.

This contrast with the general idea that fast dispersion is favored with previous knowledge. This should have happened in Europe, were previous hominid incursions happened since early Pleistocene. America, in return, was an uninhabited. Recognition of resources and geophorms should have taken longer time. Thus in contrast

with what was proposed for America, in Iberic Peninsula, adaptation to previous Hominini existing niches and competition for resources would have delay dispersion in this space.

ORAL

### 19. LATE PLEISTOCENE AND EARLY HOLOCENE HUMAN ADAPTATIONS IN THE URUGUAY RIVER BASIN: ECOLOGY, CLIMATIC CONDITIONS AND TECHNOLOGICAL INNOVATIONS

*Suárez, Rafael (Depto. Arqueología Facultad de Humanidades y Ciencias de la Educación, Universidad de la República) suarezrafael23@gmail.com*

This paper present and review the current investigations on the middle basin of Uruguay River. Starting from actual archaeological evidences, it discusses around different models and interpretations generated in Argentina, South of Brazil and Uruguay. The most recent research on Northern Uruguay has yielded the earliest records of fauna (extinct and actual) in an early archaeological site situated within the Uruguay River basin. The data from the Pay Paso 1 site is compared with previous evidence from other sites of the region, like K87 (Uruguay) and RS-I-66 y RS-I-69 sites (Southern Brazil) in order to establish that, during the early peopling of this area, there was an interesting cultural and ethnic diversity reflected in the material culture manifested through different designs of projectile points.

I suggest that chronological and cultural variability in the different projectile point types respond to an internal social reorganization of hunter-gatherers groups that had to deal with climate change, faunal, ecologic shifts associated with the expansion of the subtropical forest by the riverbanks that occurred during the Pleistocene Holocene transition. At a regional level, a settlement pattern emerges where the early sites are located on the banks of Uruguay River near the mouth of rivers and arroyos, near *rapidos*, natural passages (*pasos*), and small cascades (*cachoeiras*). This pattern suggests that the sites are located in strategic places, closely related to hunting, fishing and raw material procurement. Finally, an archaeological and behavioural model for the early peopling for the Uruguay middle River basin is presented.

ORAL

### 20. THE HUNTER-GATHERER AS SUSPECT: A BIOGEOGRAPHIC AND ECOPHILOSOPHIC REVIEW ON THE CONTROVERSY MAN/EXTINCTIONS IN SOUTH AMERICA

*Monjeau, Adrián (Fundación Bariloche & Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) amonjeau@gmail.com*

*Rapoport, Eduardo H. (Laboratorio Ecotono, Centro Regional Universitario Bariloche, Universidad Nacional del Comahue) rapoport@cab.cnea.gov.ar*

The myth of the *bon savage* has exerted a wide influence over anthropological thinking. The myth advances the idea that humans are a "natural" component of nature, a noble hunter-gatherer living in ecologically sustainable harmony with the environment. In many protected areas, this idea has shaped policies on the management of natural resources. However, the correlation between the entrance of humans into new environments and the peaks of extinction that follow seem to contradict this view of humans. A complex variety of positions have been taken on this issue: were humans guilty of causing the Quaternary extinctions? This controversy space hinges around an intricate web of cause and effect interactions ranging from climate, area, fire, technology, the differential coevolution, available energy, natural and anthropic causes, to current problems of scale in the interpretation of what is politically correct or ecologically incorrect in protected areas.

In the present review, we propose a multivariate model, based on a multi-causal vision of the scenario produced by the extinctions of the megafauna. The patterns of extinction between 100,000 BC and 1,500 AC are analyzed and compared with those of the European influence (1500 AC to the present time). There is a disproportionate rate of large mammal and bird extinction in relation with the appearance of man on islands or in partially isolated environments. Most extinctions (68% in mammals and 82% in birds) occurred on islands during the first 100 years of human occurrence. On the other hand, the percentage of genera extinctions in continents (Eurasia 1%, Africa 7%, North America 73%, South America 79%, Australia 86%) are correlated with the continental area. There is also a strong positive correlation between the maximum mammal mass and the continental area. During the glacial ages, predators (including *Homo sapiens*) and preys were pushed together to the same refuges. Similarly, at present, hunter-gatherers and their potential preys are pushed into non-developed areas. Since 1500,

at least 83 species of mammals, 128 species of birds, 21 reptiles, 5 amphibians, 81 fish, 375 invertebrates and 380 species of plants have become globally extinct. In modern times, an average of 20 to 25 species of mammals and birds is extinguished every 100 years, which raises the rate of extinction 200 times the natural background. A theoretical model of faunal extinction related with a body mass/area relationship, energy available and human presence is proposed.

According to this multi-causal proposition, we claim that the persistence of a species in the ecosystem will depend on their available energy for biomass productivity. Therefore, extinction rates should be related with the carrying capacity of the predator/prey system, rather than on an alleged ethical content attributed to hunter-gatherers, because they were part of an inescapable ecological melt-down process. The link between the situation of hunter-gatherers and indigenous populations in protected areas is confusing, and must be thought of in terms of similarities and differences, so that theory can contribute to decision-making.

Recently new approaches about American regional peopling are being produced from several disciplines and contribute to explain different social and biological aspects from ancient populations. Patagonia, the southern region of South America, presents evidence of early archaeological sites, with an accepted chronology of 14,500 cal BP in Chile and 13,900 – 12,800 cal BP for Argentinian locations.

The study of mitochondrial DNA can be used to determine the genetic structure and the evolutionary history of human groups. Different clades have been described so far in South America. They exhibit different mutations and sometimes a geographic specific dispersion. For example: B2 haplogroup is more frequently found in the Andean region, A2 in extant samples of Argentinian Mesopotamia, and C1, D1, D4h3a and some of their variants in ancient Patagonian groups. The aim of this study is to provide new data about the maternal lineages that inhabited Patagonia during the Late Holocene and determine their regional distribution.

A total of 58 human samples were analyzed, their chronology go from 4800 ybp to contact period, they belong to museum collections or archaeological sites from different locations in Patagonia. DNA was extracted after demineralization, proteinase K digestion, organic solvent extraction and concentration with silica columns and/or with QIAamp DNA Investigator kit (Qiagen). Haplogroups were typified by PCR-RFLP and sequencing of the hypervariable region I (HVR I). Analyses were performed to calculate genetic diversity, their association with the geographic distribution (Mantel Test) and the differentiation among Patagonia populations (AMOVA).

So far DNA of 33/58 samples (57.0%) could be assigned by RFLP, 19 (57.6%) samples belong to D haplogroup, 12 (36.4%) to C and 2 (6.0%) to A. HVR-I sequences were obtained in 20/33 individuals. The following lineages were identified: A2, C1, D1, D1g, D1j and D4h3a. Statistical analysis revealed that no genetic differentiation would exist among the studied groups.

As previously described, most of the individuals analyzed were characterized C1 and D1. We also detected D1j, D1g and D4h3a on the Atlantic coast, traditionally

accepted as founder lineages coming south by a Pacific coastal route, and present in extant natives. This raises the question about whether the initial peopling occurred from the Pacific coast with a subsequent expansion or it came from the North through an Atlantic route, or both. Finally, we could postulate a reduced genetic diversity and no population structure, perhaps the result of founder effect and/or genetic flow among the Patagonian natives.

Our results suggest a better explanatory performance of the Recurrent Gene Flow (RGF) model and support the idea that the phylogenetic history is better recovered in the integrated morphospace. We suggest that incorporating modern concepts of the Evolutionary Developmental field can be crucial to enhance the interpretation of morphological diversification on the skull and other complex phenotypes in the context of micro and macro evolutionary studies.

ORAL

## 22. CRANIOFACIAL EVIDENCE AND THE NEW WORLD SETTLEMENT: USING EVO-DEVO CONCEPTS TO ENHANCE THE PHYLOGENETIC SIGNAL OF SKULL SHAPE DATA.

*de Azevedo, Soledad (Centro Nacional Patagónico, Consejo Nacional de Investigaciones Científicas y Técnicas) deazevedo@cenpat.edu.ar*

*González-José, Rolando (Centro Nacional Patagónico, Consejo Nacional de Investigaciones Científicas y Técnicas) rolando@cenpat.edu.ar*

Skull size and shape data has been widely used to infer past and modern within and among group affinities. However, we are far from an extensive knowledge about the causation and underlying factors determining the patterns of skull variation and covariation. Its relevance for reconstructing dispersal of anatomically modern humans and among-population diversification processes relates to the fact that phylogenetic signals, even when massive evidence indicates their presence, are often blurred due to the fact that the vertebrate skull is a complex phenotype where morphological integration and modularity coexist and simultaneously act as covariance generators and structuring processes.

In this context, we applied the Factor Model (Mitteroecker and Bookstein 2007), Geometric Morphometric techniques and basic and partial Mantel tests to analyze the integrated and modular shape spaces on Early and Late skull samples of Native American, Asiatic and Australian populations. We have tested the congruence of different competing scenarios against observed biological distances matrices computed on the different morphospaces: a shape space where covariation sources are summarized by a few common integrator factors between modules, or modular shape spaces where local factors influence specific regions of the skull (face and neurocranium).

ORAL

## 23. UNDERSTANDING PROCESSES AND CONDITIONS SURROUNDING EARLY CULTURAL EVOLUTION ON THE CANADIAN PLATEAU

*Villeneuve, Suzanne (Simon Fraser University) suzanne\_villeneuve@sfu.ca*

Understanding the processes and conditions surrounding early cultural developments and emergent complexity is of central concern in studies of human and cultural evolution in the Americas and elsewhere. One of the major themes in research on this topic has involved understanding why transitions from more egalitarian organizations to non-egalitarian, hierarchical relations occur. This transition is one of the most important issues in hunter/gatherer adaptations on the world stage today since it represents a major threshold in cultural developments leading to contemporary types of societies with all their inequalities and complexities.

Most prehistorians believe that small groups of simple hunter/gatherers, or foragers, undertook the initial peopling of the Americas and that these groups characterized early human adaptations until sometime during the Archaic period. As simple foragers, these Paleo-Indian and possible pre-Clovis groups are generally thought to have consisted of highly mobile, low density, small egalitarian bands. It is generally assumed that these groups did not rely on stored foods, they lacked any significant notions of private ownership, they had few or no prestige objects, they had no socioeconomic inequalities and no economically-based competition. However, at various times in different regions, fundamental changes began to occur in this simple forager system together with some new fundamental technological innovations. Population densities increased, band sizes increased, some sites were repeatedly occupied or used by semi-sedentary groups, more permanent architecture became established, storage of food was adopted, prestige items

began to appear (implying private ownership), cemeteries with notable grave goods occurred together with other evidence that makes it possible to begin thinking about emerging socioeconomic inequalities. Groups with these new adaptations are generally referred to as complex or transegalitarian and hunter/gatherers.

In the Americas, one of the key geographical areas for studying the transition to more complex hunter/gatherer societies has been the Northwest Coast and Plateau of North America. As in other regions, debates have arisen over the timing and conditions surrounding the emergence of inequalities. Models focus on whether inequality emerged with early village developments under conditions of resource abundance and changes in procurement or storage technology, or whether inequalities occurred later in village development under resource and demographic pressures during periods of climate change. These models are testable by examining the timing of cultural changes in relation to coterminous environmental conditions or technological changes and their magnitude.

Attempts have been made to use various types of analysis to monitor economic, social and climatic changes over time in Canadian Plateau sites (Hayden 1997, 2000, 2004; Prentiss et al. 2003, 2007). However, a number of new techniques and methods have recently provided an improved means of monitoring changes over time, and are helping build a more comprehensive dataset and approach to evaluating models (Villeneuve 2014).

This research on the Canadian Plateau is of considerable importance as it is making theoretical progress possible in the discipline, especially for understanding processes surrounding early cultural developments and early adaptive patterns and changes of hunter/gatherers.

Changes in social structure and cultural practices can potentially promote unusual combinations of allele frequencies that drive the evolution of genetic and phenotypic novelties during human evolution. These cultural practices act in combination with geographical and linguistic barriers and can promote faster evolutionary changes shaped by gene-culture interactions. However, specific cases indicative of this interaction are scarce.

Here we show that quantitative genetic parameters obtained from cephalometric data taken on 1,203 individuals analyzed in combination with genetic, climatic, social, and life-history data belonging to six South Amerindian populations are compatible with a scenario of rapid genetic and phenotypic evolution probably mediated by cultural shifts.

We found that the Xavánte experienced a remarkable pace of evolution: the rate of morphological change is far greater than expected for its time of split from their sister group, the Kayapó that occurred around 1,500 years ago. We also suggest that this rapid differentiation was possible due to strong social-organization differences that probably triggered reproductive isolation.

Our results demonstrate how human groups deriving from a recent common ancestor can experience variable paces of phenotypic divergence, probably as a response to different cultural and/or social determinants. Assem-

bling composite databases involving cultural and biological data will be of key importance to unravel cases of evolution modulated by the cultural environment.

**25. FAUNAL DYNAMICS IN SOUTHERN EUROPE AT THE TIME OF THE FIRST HUMAN DISPERSAL**

*Palombo, Maria Rita (Dip. Scienze della Terra, Sapienza Università di Roma, Italy) mariarita.palombo@uniroma1.it*

Deconstructing the dynamics of Southern European mammalian faunas during the Early Pleistocene is of crucial importance to infer to what extent, if any, climate changes might have promoted dispersals, diffusion and at least temporary settlements of archaic human populations in these regions before and during the marked transition of Earth's climatic system known as the Mid-Pleistocene Revolution.

The South European Quaternary fossil record is particularly suitable for studying the role of climate change at local and regional levels because of the complex physiographic and climatic heterogeneity of the study area, the complex history of invasions of species of varying geographical origin and provenance, and the presence of important barriers that at times either prevented the range of some taxa from reaching some regions or caused delays in the dispersal of a taxon in some territories.

This research aims to provide fresh data by analysing timings and mode of dispersal in South Europe of large mammals, focusing on asynchronous versus diachronous bioevents across geographical and ecological boundaries, and analysing the changes in local versus regional functional dynamics through time. The data base consists of taxonomically revised lists of species from selected faunal assemblages ranging in age from about 1.6 to 0.5 Ma.

By combining the strands of available information, we can observe that during most of the Pleistocene, cause-and-effect relationships between climatic oscillations and faunal changes were the cumulative result of the response of individual species to physical and biotic environmental changes. The major environmental perturbations, triggering dispersal events and removing keystone species, modified the structure of the pre-existing mammalian faunas, merging previously indepen-

dently-evolved taxa into new palaeo-communities. The altered internal equilibrium gave rise to new inter-guild and intra-guild competition/coevolution dynamics, thus leading to shifts in community structures over periods generally exceeding Milankovitch's cycles. Diachroneity in local turnover across the study region probably relied on differences in local biotic dynamic patterns, though different manifestations of global climate changes in different geographic settings would have contributed to the scale of local appearance/disappearance bioevents. Over the post-Olduvai Early Pleistocene, climatic changes led in most of SW Europe to an environmental instability in a more arid, open context. This might have facilitated the dispersal of hominin groups, because the increased habitat heterogeneity and the rebuilding of the structure of mammal palaeo-communities possibly allowed more flexible, opportunistic species, such as hominins, to exploit a broad spectrum of resources. The new scenario likely allowed pursuit, ambush, and pack hunting predators to differentiate better their niches and to partition resources, thus reducing inter-specific competition. This might have given certain new opportunities to archaic hominins viewed as opportunistic scavengers with limited technological capabilities.

POSTER

**26. MAJOR ATMOSPHERIC CHANGES IN THE TROPICAL REGION DURING THE EARLY PLEISTOCENE (1.9 MA) AND OCEANOGRAPHIC IMPLICATIONS IN EASTERN EQUATORIAL PACIFIC**

*Povea de Castro, Patricia (Universidad de Barcelona) patriciapovea@ub.edu*

*Cacho Lascorz Isabel (Universidad de Barcelona) icacho@ub.edu*

*Moreno Caballud, Ana (IPE-CSIC) amoreno@ipe.csic.es*

*Pena, Leopoldo (Lamont-Doherty, U.Columbia), Luis Valero Montesa - luisvalero@ub.edu (Universidad de Barcelona) leopoldo@ldeo.columbia.edu*

Climate variability has shaped the major environmental changes along the Quaternary and it is believed to be closely tied with human evolution. The early Pleistocene, around 1.9 Ma, was a critical period in hominid evolution and some hypothesis link evolutionary changes in this period to climate change. In particular, it has been proposed that during this period occurred a strong development of Walker circulation (Ravelo et al., 2004). But there are not evidences of the impact of these changes in the Intertropical Convergence Zone (ITCZ) which ultimately control rain patterns at low latitudes.

This study aims to identify coupled atmosphere-ocean changes in the Eastern Equatorial Pacific (EEP), by means of the ODP Site 1240 lithic and biogenic components. We analysed  $\delta^{18}\text{O}$  in benthic and planktonic foraminifera, Total Organic Carbon (TOC), biogenic Silica (Si), terrigenous content, and Fe XRF composition. The obtained results are compared with other tropical records from Equatorial Atlantic Ocean and Indian Ocean in order to evaluate those changes in a broad context.

$\delta^{18}\text{O}$  benthic record provides a robust chronological framework, extending from 1.6 to 2.2 Ma.  $\delta^{18}\text{O}$  planktonic and benthic records show a glacial-interglacial variability paced by changes in the obliquity cycle, and the  $\delta^{18}\text{O}$  planktonic indicates the occurrence of relatively cold interglacial between 1.8 and 1.65 Ma. Throughout the studied period, Fe and lithogenic content, show an extraordinary resemblance. In base to these records, it can be clearly distinguished the glacial periods prior to 1.85 Ma, dominated by low Fe and sparse lithogenic grains, poorly sorted and coarser, which could reflect the dominance of stronger trade winds. This would stimulate the equatorial upwelling which is consistent with high TOC and Si fluxes. Diatom mats deposition during these periods suggests a major upwelling of rich-silica waters probably from the Southern Ocean (Calvo et al., 2011). Moreover, glacial periods after 1.85 Ma show an increase of Fe and fine/better sorted lithic grains which suggest weaker trade winds and reflect an enhanced wet deposition with an ITCZ southern position.

The high resolution of the studied period allow to establish a sequence of changes demonstrating a complex evolution of the ITCZ during glacial but also during interglacial periods which were likely linked to the progressive enhancement of the Walker circulation. Strong changes occurred from 2.1 Ma with an ITCZ northward location only during glacial periods. At 1.85 Ma moved slightly southwards during glacial periods but it have and likely changed the position also during interglacial. The 1.85 Ma shift can be also detected in other areas under ITCZ influence, also suggesting an intensification of upwelling and winds on the west coast of Africa. These changes could be related to the drier conditions described in African low latitudes which triggered a gradual replacement from woodland to savannah grasslands (deMenocal, 2004). Defining a clear sequence of climate changes during the early Pleistocene will serve to place the context for the environmental changes that may have a role in the evolution from *Homo habilis* to *Homo erectus*.

The Oued Sarrat (Kef area, northwestern Tunisia) is an endorheic basin with a wide extension. It shows a well exposed series of grey and clastic shales with a thickness which exceeds 10 m.

Clay sediments coming from the systematic excavation of the lower palustrine-lacustrine black deposit are washed through sieves with water and then dried. Residues are sorted and observed under the binocular microscope. The microvertebrates seem to be abundant and diversified, so we have identified an association of different kind of fossil teeth belonging to seven small mammals species, including one insectivora (*Crociodura* sp.) and six rodents (*Mus aff. spretus*, *Mus cf. hamidae*, *Paraethomys cf. rbiae*, *Praomys* sp., *Meriones* sp., and *Eliomys* sp.). There are also some bone fragments from other small vertebrates such as one freshwater fish (*Cyprinidae*

indet.), two anurans [*Discoglossus pictus* (Alytidae) and *Bufo bufo* (Bufonidae)], one terrapin [*Emys* sp., or *Mauremys* sp.], three squamates [an indeterminate small lacertid or scincid lizard, *Natrix maura* (Natricidae) and an indeterminate colubrid snake (Colubridae)], and one small-sized bird (*Passeriformes* indet.).

The combination of the paleomagnetic data together with those coming from the biochronology provided by the most significant taxa (*Mus aff. spretus*, *Mus cf. hamidae*, *Paraethomys cf. rbiae*, *Praomys* sp. and *Meriones* sp.) suggest an age for the lower black palustrine level related to the early Middle Pleistocene, close to 700 ka BP (Martinez-Navarro *et al.* 2014).

This microvertebrate fossil assemblage also informs on the good climatic and paleoecological conditions, basically supported by amphibians and reptiles, for the dispersal and colonization of the northern African latitudes by early hominins carrying with them the Acheulian technology.

## 1. TRADITIONS AND INNOVATIONS OF THE LATE BRONZE AGE MATERIAL CULTURE OF SOUTHERN TRANSURALS

*Shcherbakov, Nikolai (Bashkir State Pedagogical University named after M.Akmulla, RF,Ufa) sherbakov@rambler.ru*

*Shuteleva, lia (Bashkir State Pedagogical University named after M.Akmulla, RF,Ufa) shutelevai@gmail.com*

*Leonova, Tatiana (Bashkir State Pedagogical University named after M.Akmulla, RF,Ufa) leonotan@mail.ru*

*Kraeva, Ludmila (Orenburg Pedagogical University, RF) kraeva\_ludmila@mail.ru*

*Golyeva, Alexandra (Institute of Geography, Russian Academy of Science, Moscow, RF) alexandragolyeva@rambler.ru*

The Late Bronze Age on the territory of Southern Transurals is connected with plenty of archeological cultures and population groups: Srubnay and Andronovsky. Interaction of these population groups constitutes special mixed material culture having stable common features of independent Srubnay and Andronovsky cultures, as well as stable local features. These population groups brought to the region method to produce bronze. The biggest mines of the region are Kargaly mines (Chernykh, 2007). New methods to produce ceramics were also discovered; they combined two traditions – Srubnay and Andronovsky.

Traditional concept of the Late Bronze Age, explaining cultural diversity of continuity of Abashevsky, Srubnay and Andronovsky cultures, came to formation of chronological scales in 1970 – 1980. Application of natural science methods (radiocarbon dating, paleopedology, tracology, osteologic analysis, bronze metallographic analysis, application of ceramics spectral, technical and process analysis methods, etc.) proved that these conclusions were not quite correct.

All these methods were applied to investigate archeological micro-district in Urshak river basin (Southern Transurals). Area of micro-district investigated is 23,4 km<sup>2</sup>, it includes group of 5 settlements (Muradymovsky settlement, Usmanovo I – IV settlements) and 4 burial mounds (Kazburun I – IV burial mounds). Collection of bronze articles, found out in this micro-district comes only from Muradymovsky settlement. In Muradymovsky settlement the traces of bronze-foundry production (stone foundry moulds fragments, slags), estimated place of bronze production as well as different bronze articles were identified. In Russian Academy of Science laboratory of natural science methods in archeology

they analyzed metallographic specimens of bronze-foundry production. Bones and stones still prevailed in materials of tools produced. Though trace analysis of rich anthropologic material found out in Muradymovsky settlement, identified traces of human bones working by metal ware. In 2008 – 2013 radiocarbon analyses of anthropologic materials were performed: AMS-dating of teeth buried in Muradymovsky settlement and Kazburun I burial mound, as well as AMS-dating of ceramics belonging to above mentioned settlements. The results can be grouped (Beta Analytic 1890 – 1750 BC). Osteologic analysis data proved unity of species composition of flock in all settlements. To define methods to produce ceramics belonging to Kazburun I mound and Usmanovsky III settlement, process and technical analysis of ceramic material was performed, that let identify presence of two similar traditions observed in materials of both monuments - Srubnay and Alakul.

In the process of investigations dates of settlements and mounds of the Late Bronze Age were obtained; the data let age chronological frameworks by 150-200 years. Bronze production centers were found out on the territory of the settlement. Independent cultural tradition in ceramics production was identified.

Investigations conducted let unite different cultural traditions in one period of the Late Bronze Age. Cultural traditions in use and production of bronze, resources were same on this territory. However the use of metal was not essential in economic and cultural type. Stone and bone industry prevailed in inhabitants' life.

ORAL

## 2. EARLY STATE FORMATION IN VIDARBHA DURING IRON AGE

*Sawant, Reshma (Deccan College, Pune, India) drreshma.sawant@gmail.com*

*Shete, Gurudas (Deccan College, Pune, India) shete.gurudas@gmail.com*

The present paper focuses on the 'Early State' formation process during the Iron Age, c. 8<sup>th</sup> century BCE to 4<sup>th</sup> century BCE, in the Vidarbha region which also coincides with the existence of Megalithic Culture. Iron Age sites in Vidarbha have revealed the existence of two ethnic groups, viz., A. people erecting megalithic structures for disposal of the dead, and B, people following a different mode of disposal of the dead. Important excavated

sites of group 'A' are - Junapani, Mahurjhari, Takalaghat-Khapa, Naikund, Bhagimohari, etc.; and of group 'B' are - Kaundinyapur, Paunar, Adam, etc.

On the basis of the study of archaeological evidence from published excavation reports, the following observations can be made with regard to the process of state formation during the said period:

### 1. *Significance of Craft Specialization*

There is significant evidence of technological progress and extensive use of metal craft and lapidary. Megalithic burials have yielded a number of iron objects, particularly agricultural tools and a variety of offensive and defensive weapons. The use of metals, especially iron, by Vidarbha Iron Age people suggests that the need for these was becoming quite enormous and the reason behind this may be related to military, agriculture, and increasing exchange.

### 2. *Proto-administrative Functionaries*

The sites of Adam and Pauni have furnished evidence of rampart as part of collective protective strategies which indicates social ranking: the ruler and the ruled. Such construction shows the capacity of an authority, to direct or to impose manpower to carry out public works, though not necessarily through specialized administration.

The presence of rampart and variety of iron weapons supports the existence of a warrior class which was probably necessary to defend their state from other tribes, *Janapadas*, and *Mahajanapadas*.

### 3. *Inter-regional and Long Distance Exchange and Inter and Intra-site Hierarchy*

The long distance exchange of useful goods or raw material are more likely to occur successfully when they can be arranged and administered by a leader (Service 1975: 292). The occurrence of iron implements, gold ornaments, beads of shells and semi-precious stone from common distant sources at various sites suggest widened exchange network as well as hierarchy of sites (producers, receiver, and middlemen).

The study suggests that this period witnessed manifestation of a process that transformed the society into a class differentiated one. In a nut shell, c. 8<sup>th</sup> to 4<sup>th</sup> centuries BCE, the region of Vidarbha experienced the formulation of 'Early State' which is demonstrated through, 1. large number of sites which give an idea about the demography of contemporary population; 2. archaeological evidence of craft and agriculture which definitely

point to enough surplus to play a role in exchange network; 3. existence of some sort of authority to prepare defensive measures and regulate trade; 4. elaborate burial practices which adequately reflect social stratification; and 5. lastly, wide spread and uniform megalithic burial practices indicating common ideology among the majority of population.

## ORAL

### 3. A CHANGING PATTERN OF SOCIO-CULTURAL SYSTEM FROM CHALCOLITHIC TO THE EARLY HISTORIC PERIOD IN WEST BENGAL? A STUDY BASED ON DIFFERENT TECHNOLOGIES AND INDUSTRIES.

*Basu, Durga (Dept. of Archaeology, Calcutta University) durgabasu57@gmail.com*

In recent Indian historical researches, a new interest among the scholars developed about the study of various ancient industries, considering their growth as an important socio-cultural phenomenon. In a given society multitudinal growths of industries and development of technology not only indicate economic development but also show a complex form of society. Moreover development of various industries helps us to understand a changing pattern of a simple village life to a sophisticated urban culture. The present paper aims to highlight the gradual transformation of the socio-cultural system from chalcolithic village culture to the Iron-age culture in West Bengal.

Since the present attempt is based on the study of technological development and various industries emerged during early historic phase (N.B.P. culture) in West Bengal, different excavated industrial materials will be discussed. A comparative study will be made of the materials discovered from both of these cultural phases, highlighting a transition from the chalcolithic to the Iron age or early historic period. The study will include typological, technological and stylistic differences of the materials.

In West Bengal, there are two clear cut cultural zones of Pre-historic chalcolithic settlements and the early Iron-age culture marked by N.B.P. period. From these two settlement areas one can trace the transformation of simple agricultural village life to an urban culture. A significant change has been noticed in the socio-cultural system during N.B.P. period in comparison to the previous chalcolithic phase. One can observe the change through the study of new technological development in agriculture and specialized industries like metal, ceramic, bead and

others. The base that was created in the chalcolithic stage received developmental impetus during early historic period.

The present effort will help us to understand the genesis of the changing patterns of socio-cultural system which was directly connected with various industries and technological development.

#### 4. IRON TECHNOLOGY IN NORTHERN INDIA: A RE-APPRAISAL OF EMERGING PATTERN

*Srivastav, Omprakash (Centre of Advanced, Department of History, Aligarh Muslim University, Aligarh, India) sramakrishna.pisipaty@gmail.com*

There are a large number of unresolved issues related to the beginning and growth of iron technology in India. There are misconceptions/ misplaced notions due to lack of right information on the subject. What is required is a critical evaluation of data and deeper inquiry of relatively unknown facts. To attain this goal the following strategy has been devised:

Literature survey for collection of data from different sources, viz. (a) archaeological (b) literary (c) ethnographical (d) archival.

Collection and analysis of ore, iron objects crucibles, slag, furnace remains for retrieving further information and reconstruction of metallurgical processes.

Survey and documentation of tribal regions for collection of in depth information on traditional iron working. The introduction of Iron Technology emerges in Northern India from the Proto-historical phase (1100-700 B.C.) from the PGW level. The excavated site i.e. Jakhera iron objects has been found from the early levels of PGW phase, which is known as Proto-PG level. The present paper deals with the study of various types of iron tools and implements recovered from the archaeological excavations. The area under study is rich in yielding the iron implements such as arrowheads, spearheads, knives, bangles, chisels, nails, bars/rods, ploughshares, diggers, sickles, etc The detailed study of iron implements have been undertaken to understand the changes in shape and size and their prolific use if any within a cultural period and one cultural to another. The above-mentioned iron implements may find support from the cotemporary texts, which do not provide a picture of wide famili-

arity with these metals for the purpose. There is a need to undertake a holistic approach to resolve the issues related to iron in India.

The main aim of the present study is to bring out a comprehensive history of iron technology in India using a multidisciplinary approach.

To study in detail the iron technology with a multidisciplinary approach using all possible sources.

To correlate the resource-zones and the related important cultural centers of ancient India.

To undertake ethnographic investigations in remote areas for the surviving remains of traditional iron working. To interpret and synthesize the data collected in the form of a book on ancient Indian iron technology covering all its aspects.

Conclusion: (1) Socio-economic Implication of Use of Iron through the Ages, (2) Technology adaptation and productivity, (3) Innovations in Iron and distribution through trade, (4) Cultural dynamics.

#### 5. EARLY IRON AGE HUMAN ACTIVITIES ON SOUTHERN PART OF INDIA: FROM RECENT ARCHAEOLOGICAL EXCAVATIONS.

*Pisipaty, S. Rama Krishna (Prof. & Geoarchaeologist Department of Sanskrit & Indian Culture Sri Chandra Sekharendra Saraswathi Viswa Maha Vidyalyaya) sramakrishna.pisipaty@gmail.com*

The influence of metal technological knowhow had also been appeared in the southern part of India from the beginning of the last millennium BCE. No doubt, it was a major breakthrough in the history of mankind. Because, it had a turn towards successive stages of modification from the barbaric mode to the sophisticated and comfortable way of living lifestyle with the master over utility of metals like copper/bronze and iron for different purposes. Besides being technological attainment, the use of these metals improved general living patterns and also governed economic processes during the Early Iron Age.

Construction of structures with big boulders (mega-liths) for after death rituals was another practice developed during this period which is not only providing their constructional technological skills but also the development

of socio-cultural trends which prevailed thousands of years, still in practice in many pockets. Further, another greatest technological achievement in blacksmiths' workshop was originate from the Indian subcontinent i.e. Carburization of iron also known as *Wootz Steel* (Corrosion-Resistant Iron). It was well developed indigenous technology by the end of the last millennium BCE in India.

Recent archaeological excavations and material related to the Early Iron Age technologies, settlement pattern, socio-cultural trends on the southern part of India are the subject matter for present paper.

The above discoveries and researches in the southern part of India revealed that by the end of the last millennium BCE, advanced iron technologies like carburization, commercial based production, etc. technological achievements appeared in the region. Besides, after death rituals and constructions with mega-lights were also developed in great extent.

### 1. WARRIOR IDEOLOGY, BURIAL CUSTOMS AND GENDER ROLES IN EUROPEAN BRONZE AGE SOCIETIES (2500-800 BC)

*Brandherm, Dirk (Queen's University Belfast) d.brandherm@qub.ac.uk*

At several points in time between the mid 3rd and the early 1st millennium BC, abrupt changes can be observed in the expression of male and female identities through the funerary record of European Bronze Age societies. This paper explores to what extent such changes may be linked to a cyclical waxing and waning of warrior ideologies.

A number of case studies are scrutinized whose chronology ranges from the Beaker period to the Bronze Age/Iron Age transition in Central Europe, comparing male and female grave assemblages and frequency ratios in the funerary record.

Recurrent episodes of warrior ideologies rising over the course of the Bronze Age generally coincide with environmental and/or societal crises. These episodes tend to be relatively short and are usually followed by longer intervals of apparently more stable conditions, during which the focus in the expression of male identities shifts from the display of martial prowess to that of more peaceful means of peer polity interaction.

In a long-term perspective there is clear evidence for cyclical patterning in the impact warrior ideologies had on the representation of male and female identities in the burial record.

### 2. WAR PSYCHOLOGY IN EUROPEAN COPPER AND BRONZE AGE AND ITS MARKS IN FORTIFIED SETTLEMENTS

*Delfino, Davide (Universidade do Trás os Montes e Alto Douro/ Instituto Terra e Memória, Mação (Portugal), Quaternary Group of Geosciences of FCT) davidedelfino@libero.it*

What are the dynamics that led to the rise of the fortifications in the human settlements from the Recent Prehistory? It is possible to answer this question with a psychological and archeological approach.

On the one hand the psychology of combat, which for a general foundation can also be applied to prehistoric humans, explains some of the dynamics of impression / reaction typical of the human being subjected to danger or death. Five psychological steps identified in a combat psychology study by Dave Grossman, can be applied at pre and protohistoric warrior (and not only) to understand human behavior and its consequences in creating physical protection to the villages. On the other hand the analysis of archaeological data into and nearby settlements, fortified or not fortified, which witness fight scenes, explains the dynamics of the necessity to protect the settlements from the Neolithic (Rubané culture) to the Bronze Age ( Aegean world)

In such cases, the most recent (Bronze Age) build structures considerable such as fortifications, does not imply a real use in real fights, but more probably a deterrence function, maintaining ties with the principles of the psychology of combat: in many cases are more fighting evidence nearby protective structures in Neolithic that do not in Bronze Age.

Which clearly cannot speak of war in the modern sense to the prehistoric age, however it is clear a temporary bellicosity level of fighting since Neolithic. According to L. Keeley, primitive fights are no less bloody of modern warfare. These gradually produced the necessity to protect the settlements with architectures that became, over time, probably many more architectures to psychological deterrence, which fortifications who suffered fighting.

### 3. THE GROUP OF CUIRASSES FOUND IN THE DANUBE REGION IN THE LATE BRONZE AGE

*Jankovits, Katalin (Pázmány P.K. Universität) msuch.gutierrez@uam.es*

In the Danube north from Budapest, near Pilismarót in Hungary, one cuirass has been found. The breast and back plates of the cuirass were built of bronze plates. The complete cuirass is a unique item and it belongs to the group of cuirasses found in the danube region (Caka, Ducové, Cierna nad Tisou, Nadap, Pázmándfalu). In the Danube region the cuirasses show an influence of the Aegean. In the period of the Late Tumulus culture (Bz D, Bz D-Ha A1), in the Caka culture, different rich warrior tombs were discovered in Hungary and in Slovakia.

These Tombs and the corselets in the Danube region demonstrate the importance of the militar aristocracy in the Late Bronze Age. An intact armour was found in grave 12 of Dendra in the Aegean, which was composed of a high, separate neck guard, interlocked plates and a coat-of-chain built of two parts underneath. Two fragmentary cuirasses of the same type are known from the settlement of Thebes. They are dated from the LH II-III A2/B1 period. The shape of the cuirass from the Danube and its high neck guard are similar to the miniature bronze cuirass, worn as a pendant, from the hoard find of Brandgraben (Steiermark) dated from Bz D-Ha A1 and the bipartite cuirass found in the Seine at Saint-Germain-du-Plain. On this cuirass from the Danube, flat rivets hold the two plates together on both sides. Similar, although conical rivets were used in the cuirasses from Cierna nad Tisou and Saint-Germain-du-Plain. A motive of semicircular, punched dots can be seen on the bottom of the black plate of the cuirass from the Danube. This and the solution of the shoulder strap on the right shoulder show similarity to the cuirass from Saint-Germain-du-Plain. The finely punched dot row ("Gleich-Buckel-System") and the plastic rib are characteristic decorations of the cuirasses of the Danube region. The cuirass from the Danube can not exactly be dated in lac of accompanying finds, nevertheless the listed characteristic suggest that it came from the Bz D-Ha A1 period.

ORAL

#### 4. SYMBOLS FOR PROTECTION IN WAR AMONG EUROPEAN SOCIETIES (1000 BC - 1000AD)

*Coimbra, Fernando (Universidade do Trás os Montes e Alto Douro/ Instituto Terra e Memória, Mação (Portugal) coimbra.rockart@yahoo.com*

The emergence of warrior societies in Europe is interconnected with the spread of several symbols, which are used by the warriors to affirm their role and their importance in society. In spite of other meanings that some of these symbols could have had in earlier times, a new social value - protection in war - can be observed with the rise of warrior societies.

In this paper the author analyses motives like the swastika, the triskel and the pentagram, which appear associated with warriors and their weapons in a very diverse range of iconography and artefacts, such as rock art, pottery, funerary tombstones, helmets, shields, fibulae, spears, axes and swords, among other examples. In a methodological way, these motives are studied accord-

ing a context - their association with warriors or with war. Previous or later contexts of the same symbols are also considered but only with the aim of understanding them better regarding the context of warrior societies. The analyses of the mentioned context allows understanding that those motives take advantage of a previous known symbolism and get reinforcement in meaning and diffusion in protohistoric times, among several European cultures through time and space.

The value of protection in war of the studied symbols can result from earlier examples with already a strong meaning in society, when they appear in a religious or in a sacred context, being associated with deities, appearing in funerary cults of different peoples and chronologies.

ORAL

#### 5. SINGULARITIES OF THE BRONZE AGE FUNERARY PHENOMENA IN THE MIDDLE TAGUS AREA.

*Cruz, Ana (Instituto Politécnico de Tomar) anacruz@ipt.pt*  
*Graça, Ana (Instituto Politécnico de Tomar) anagrace@ipt.pt*

Although this section chronology is bound by the Bronze Age and cultural contacts between Atlantic and Mediterranean, we think that is important to establish a diachronic funerary pattern in order to clarify the ideological changes, reflected in the Holocene communities' concepts, social, economic and political set.

The funerary-symbolic phenomena in Portuguese Bronze Age on the area of the Middle Tagus Valley, includes burials in karstic cavities contexts, reusing megalithic monuments and *tumuli*.

From this point, starts the contextualization of these data in the environment of the increasingly complex societies connected by the encounter between sea and ocean.

So, we studied the Portuguese middle Tagus area funerary archaeography and its inclusion in a wider universe, through bibliographic data research.

Our data from archaeography were gathered in excavations and archaeometric studies.

The bibliographic research starts in the Mediterranean world of the Sumerian, the emergence of the pharaohs, the Minoan civilization or the long distance trades carried by the Phoenicians in Mediterranean Sea. Also the

settlement of the Iberian cultures developed after “Los Millares substitution for “El Argar” until Tartessos.

After we carried on with the Atlantic Bronze Age influences through migrations or long distance trades based on different kinds of bronze artefacts or amber commerce.

The outcomes must target two contexts:

The first is the Portuguese regional context of the Middle Tagus.

The second is the trans-regional context composed by the Mediterranean and the Atlantic realities.

Concerning these two wider contexts we state that our study area, although it might be put geographically in both; has its own singularities (even within the Portuguese territory funerary contexts), with micro regional roots.

Towards the archaeological record uniqueness we assume an indigenous approach.

Although perceiving that these communities must have had knowledge of the wider exchange networks presence, it is not possible to ignore the archaeography, where the data point towards a very unique ideology, in which the technological novelties are not crucial to the symbolic and funerary behavior

Thus, we are in the process of creating an explanatory model that we have called mutualistic cosmogony.

ORAL

## 6. WARFARE IN VALCAMONICA ROCK ART NEW EMERGING DATA FROM PASPARDO AREA

*Sigari, Dario (Cooperativa Archeologica Le Orme dell'Uomo)  
dariothebig@anche.no*

Warrior engravings represent nearly 25% of the entire Iron Age carvings corpus in Valcamonica rock art (Zanetta, 2009). They appeared in Valcamonica rock art tradition in the last centuries of the Bronze Age (XII-IX century BC), becoming the most common figures in the I millennium (Anati, 1982).

Armed anthropomorphs are depicted: standing alone with raised arms; duelling, sometimes there is a third standing and supervising figure, which can be complete or not; riding horses; hunting (Fossati, 2005).

Most of the scenes involving warriors are supposed to be representation of duels. Whilst there are few scenes which are thought to be war and violent activities depictions: see rock 34 in Luine, rock 4 in In Valle, rock 1 and 50 in Naquane (Fossati, 1991; Bevan, 2005; Sigari, 2011). The site of In Valle, in Paspardo, has been systematically studied between 2008 and 2011, 30 years after the first systematic study, taken in the eighties (Abreu & Fossati, 1988; Fossati, 2007; Sigari, 2011). The big rock of In Valle, labelled as rock 4 has been divided into nearly 20 panels to better study the engraving and the rock itself.

Sector C is the northern part, under the upper channel. Its figurative complex is very simple and highly readable. Eight fighting warriors named C05, C06, C07, C09, C10, C11, C12, C13 are the main subject of this panel.

The scene, into which they are grouped, is highly dynamic thanks to the different position the warriors stand. The uncommon number of involved subjects, their position, the different weapons they handle, the analysis of the overlappings has questioned whether the scene is a common duel scene or not. Is it an animated scene like a comic strip? Or does it portray a fight involving more people? Might it be a war scene?

Archeological and rock art data from Valcamonica, comparative rock art and archaeo-anthropological data from the rest of the world do not exclude the idea of a war representation, thus indicating the first example of a battle depiction in cammunian rock art repertory.

However this interpretation does not explain why representing a battle and what it would mean for the ancient population.

Certainly Valcamonica engravings belong to a new social context, which differs from other warfare rock art scenes, such as the Spanish or the Saharian ones. The whole rock art complex suggests the emergence of a new social class, the warrior class. Their power involves different aspects of social and cultural life. In this sense, once more, it cannot be avoided the possibility of a real fight representation on rock 4 in In Valle.

ORAL

## 7. THE BRONZE AGE BATTLEFIELD IN THE TOLLENS VALLEY, MECKLENBURG-WESTERN POMERANIA, NORTHEAST GERMANY ? COMBAT MARKS ON HUMAN BONES AS EVIDENCE OF EARLY WARRIOR SOCIETIES IN NORTHERN MIDDLE EUROPE?

*Brinker, Ute (State Authority for Culture and Protection of Monuments, Mecklenburg-Vorpommern) ute.brinker@im-ail.de*

*Schramm, Annemarie (State Authority for Culture and Protection of Monuments, Mecklenburg-Vorpommern) annemie\_schramm@web.de*

*Orschiedt, Jörg (Freie Universität Berlin, Institut für Prähistorische Archäologie) jorschiedt@zedat.fu-berlin.de*

*Flohr, Stefan (Thuringian State Office for the Preservation of Historical Monuments and Archaeology, Weimar) flohrs@uni-hildesheim.de*

*Jantzen, Detlef (State Authority for Culture and Protection of Monuments, Mecklenburg-Vorpommern) d.jantzen@kulturerbe-mv.de*

The discovery of numerous human skeletal remains, partly with traces of violence, as well as horse bones and weapon finds, dating to about 1250 BC, brought the Tollense valley into the focus of interdisciplinary research. The remarkable finds are currently interpreted as the remains of a Bronze Age group conflict on a previously unexpected scale.

So far, c. 9300 well-preserved commingled human bones of more than 124 individuals, mostly young males, have been recovered. Several exhibit clear traces of violence, e.g. strong impression fractures on skulls, or long bones with embedded arrowheads. Fine cut marks and notches, in particular on ribs, have also been identified.

In order to examine whether these minor traces could be caused by arrowheads or stabbing weapons, experiments were conducted with replicas of Bronze Age arrowheads and daggers on half-carcasses (pigs). Different types of injuries caused by these experiments were compared with the human material, using macroscopical examination as well as microscopical and radiological analysis.

About one third of the experimental shots caused lesions on ribs. Different types of injuries were identified, e.g. notches of varying angles and depth, or tangential impacts that broke off bone fragments, depending on the point of impact. Fine cut marks were only caused by daggers. The injuries patterns produced by these experiments are very common in the Tollense bone assemblage. In addition to traces of blunt and sharp force, the

use of bows and arrows, daggers, lances and wooden clubs are evident. This indicates considerable interpersonal violence.

The osteological analysis combined with archaeological experiments highlights the scenario of conflict with use of distance and close-combat weapons. The range of weaponry and numbers of victims indicates a high intensity of Bronze Age group conflict not of local but of supra-regional significance. This can be interpreted as evidence of early warrior societies in Northern Middle Europe.

ORAL

## 8. METALWORK'S MODEL AND SCRAPS BRONZE CIRCULATION BETWEEN MEDITERRANEAN AND ATLANTIC IN MIDDLE TAGUS IN FINAL BRONZE AGE

*Delfino, Davide (Universidade do Trás os Montes e Alto Douro/ Instituto Terra e Memória, Mação (Portugal), Quaternary Group of Geosciences of FCT) davidedelfino@libero.it*  
*Graça, Ana (Instituto Politécnico de Tomar) anagrace@ipt.pt*

The area of the Middle Tagus River, is now considered as one of the regions during the Late and Final Bronze Age saw both the arrival of bronze metallurgy in Mid-Southern Portugal, both the intersection of different metallurgical models related at three metallurgical circles: Continentals, Atlantics and Mediterranean's. The region is strategically located along a "water ways" of Tagus, Zêzere and Ocreza rivers and between the Beira region, rich in copper resources and Atlantic coast.

Contexts with few but significant finds of bronze artefacts in the municipalities of Mação and Abrantes, reveal two aspects: the widespread business of collecting bronze scraps to be recycled; the clear circulation of models related at the three circles metallurgical thanks, probably, to the navigation of the Tagus and to accessibility of the valleys of the Zêzere and Ocreza. Denotes particular interest, in these two dynamics, the bronzes workshop of Castelo Velho do Caratão hilltop settlement, the hoard of Porto do Concelho, the small open village of Quinta da Pedreira and the Castelo de Abrantes hilltop settlement area.

Two facts stand out: the metallurgical activities, especially scrap recycling, it is not only the prerogative of walled hilltop settlements, but is also present in small open village; also most of the concentration of storage of finished objects and scrap bronze is in an area surrounded

by walled hilltop settlements, or near these.

The view that emerges is that there may exist artifacts or scrap bronze collector's centers in the walled hilltop settlements, some of them close to the river waterways, with a redistribution in small open villages perhaps single-family. Following this model of circulation, it can be concluded that different metallurgical models circulate in the region through the river waterways, with a circulation system managed by local elites in hilltop walled settlements.

ORAL

## 9. THE EMERGENCE OF WAR IN HUMAN SOCIETIES.

*Ruzza, Stefano (Assistant Professor of Conflict, Security and Statebuilding Department of Cultures, Politics and Society University of Turin) stefano.ruzza@unito.it*

*Berruti, Gabriele Luigi Francesco (PhD Student of International Doctorate in Quaternary and Prehistory, Department of Geology, University of Trás-os-Montes e Alto Douro; Associazione Culturale "3P") gabrielefberruti@gmail.com*

The transformation of agricultural societies in warrior societies is a crucial moment in human history, and its study represents a challenge for both anthropological archaeology and social sciences. These new societies created their own myths and patterns of social behaviour, introducing a new human practice - war - and a new human actor: the warrior. The proposed paper focuses on the emergence of the practice of war in Bronze Age societies by adopting a multi-disciplinary approach, mostly grounded in - but not limited to - archaeology and political science.

Bronze Age strongholds, colonies and open mines (above many other possible examples) are visible traces, well documented by their archaeological remains, of the deep and pervasive social, economic and technological changes related to war. This latter is indeed one of the most peculiar human behaviours. But how did the concept and practice of war emerged in Bronze Age societies? Why did war become - according to archaeological finds - one of the most important propulsive forces behind these societies? These broad and far-fetching questions are dealt through three inherent sub-questions, i.e.: What is war?

Why war is waged?

How war is prepared and waged?

These three "core" questions are addressed through a multidisciplinary approach, including theories and em-

pirical findings from political philosophy, archaeology, history, ethology and political science.

The proposed argument merges material and socio-cultural analysis, in order to open new venues to the understanding about the emergence of war as a human practice, the relationship between war and society, and their mutual influence.

By integrating different disciplines and methods, the paper aims to open new grounds and allow for fresh hypothesis about birth, development and impact of war on human society.

ORAL

## 10. REPRÉSENTATION DE LA GUERRE À L'ÂGE DU BRONZE D'ITALIE SEPTENTRIONALE ENTRE XVII<sup>E</sup> ET XIII<sup>E</sup> SIÈCLE: ARMES DANS LE MOBILIER FUNÉRAIRE, LES HABITATS ET LES DÉPÔTS

*Cupitò, Michele (Dipartimento dei Beni Culturali - Università di Padova) michele.cupito@unipd.it*

*Rubat Borel, Francesco (Soprintendenza per i Beni Archeologici del Piemonte e MAE) francesco.rubatborel@beniculturali.it*

Thanks to recent research and new studies on the main contexts of northern Italy it is possible to identify the development of the ways of combat and of representation of warriors through time on a regional scale, in correspondence to the different cultural *facies*.

In XVI-XV centuries there is a strong regionalisation in grave goods, settlement and hoards (swords in the East and panoply made of dagger, axe and spear in the West), whereas later, between the XIV and XIII centuries, there is widespread diffusion of swords (used in combat or to represent warriors).

The main contexts will be analysed: in the East, where the complex "palafitticolo-terramaricola" facies develops, we will consider the examples of the Olmo di Nogara necropolis and the Pila del Brancon hoard; in the West, where contacts with central-western Europe are stronger, the examples of the Viverone settlement and the Cascina Ranza and Oggiono-Ello hoards.

We will discuss the manners of combat, and their change through the centuries, the ways of representation of warriors in the different areas of northern Italy, considering the different socio-political organizations and the

nearby territories.

ORAL

### 11. BRONZE AGE SETTLEMENTS AND DWELLINGS IN GALICIA. SEEKING CONNECTIONS WITH EUROPE.

*Díaz Rodríguez, Mikel (Universidad de Santiago de Compostela) mikel.diaz.rodriguez@hotmail.com*

*Prieto Martínez, M. Pilar (Universidad de Santiago de Compostela) mpilarprietom@hotmail.com*

Settlements from the second half of the second millennium BC and the first few centuries of the first millennium BC are relatively unknown in Galicia. The best-studied sites are metallic deposits and burials, while less attention has been paid to the settlements, a problem that is further aggravated by having practically no datings. However, in recent years a number of studies have been published that deal with the record from these types of sites. Based on the data that is now available, we believe it is possible to offer a preliminary summary of the basic features of certain elements from these settlements, such as studies concerned with how their domestic space was organised, or regarding their emplacement. A great deal of work still has to be done on the internal organisation of these settlements, as only very small areas have been excavated, but our aim is to offer a general overview of the current situation.

Our empirical base is quite small (11 sites), although we do have radiocarbon datings for most of them, and it is possible to clearly define the typical structures found in the settlements. The province of Pontevedra contains the majority of these sites (7), which are Carballeira do Espírito Santo (Silleda), Mesa de Montes (Cangas), Monte Buxel (Pazos de Borbén), Monte dos Remedios (Moaña), Os Pericos (Ribeira), Setepías (Cambados) and Chan das Pozas (Campolameiro). In the region's other three provinces we have a considerably smaller number, with two sites in A Coruña: A Lagoa (Toques) and Punta de Muros (Arteixo); one in Lugo, the petroglyph of Pena Fita (Lugo) and another in the province of Ourense, the settlement of O Fuxiño (Piñor).

Based on the existing data, we have found clear similarities with other European regions, both in the Atlantic and Mediterranean areas, especially with regard to the layout of the dwellings in the settlements. As a result, in addition to identifying similarities between the metalurgy and pottery, we can demonstrate a connection be-

tween Galicia and other regions through studying these settlements.

Our aim is to identify and offer an initial definition of the features that make it possible to identify connections between Galicia and other parts of Europe, and from there to try and understand a number of possibly European influences not only on the organisation of the dwellings, but also the families in this part of the north-west Iberian Peninsula.

---

ORAL

### 12. NEW DEVELOPMENTS IN GALICIAN POTTERY FROM THE SECOND HALF OF THE SECOND MILLENNIUM BC. FROM THE REGIONAL TO THE EXTRA-REGIONAL: WIDE HORIZONTAL RIM VESSELS AND STAMPING

*Nonat, Laure (L'Université de Pau et Pays de l'Adour - Univ. Santiago de Compostela) laurenonat@hotmail.com*

*Prieto Martínez, M. Pilar (Universidad de Santiago de Compostela) mpilarprietom@hotmail.com*

*Vázquez Liz, Pablo (Universidad de Santiago de Compostela) pvliz@hotmail.com*

In Galicia (NW Spain) there are few sites dating from the second half of the second millennium BC, and these have not been investigated in any detail, with the attention mainly focused on metallic material culture. The pottery is usually considered as being very uniform in nature and lacking decoration. However, recent studies have shown that this idea of homogeneity and a lack of decoration for pottery from this stage of the Bronze Age is untrue. This said it is possible to identify an important legacy from the undecorated pottery that accompanied Bell Beaker pottery, as well as some new shapes indicating important new developments in prehistoric pottery know-how, not only in Galicia but also in the north of Portugal. In this paper we will focus on a specific type of pottery, known as Wide Horizontal Rim (*WHRv*) pottery, which is mainly decorated and exclusively found in the NW Iberian Peninsula, as it makes it possible to support and even update a theme that has been firmly rooted in the specialised literature for many years, based on the type of relationships that unite, or otherwise disunite, the east and west of Western Europe.

Effectively, some of the vessels belonging to this type of pottery contain a type of decoration that is unique in the NW Iberian Peninsula for two main reasons: (1) the use of a new technique, stamping, which appears for the

first time in this region. Until recently, in Galicia stamping was presumed to be a technique that belonged to the Second Iron Age; and (2) in the use of new motifs, which recur in Late Prehistory: concentric circles, in clearly defined patterns.

The combination of these new developments is especially noteworthy because, on the one hand, these developments seem to coincide at the same time in cultures in France and Eastern Europe, and on the other hand, because they clearly reveal the active involvement of Galicia within the mesh of networks of circulation in Europe, which can clearly be seen from the Neolithic onwards.

In summary, in our paper, by exploring pottery studies in general and WHR pottery in particular, we aim to show the possible relationships Galicia had as a key territory with the European continent and its Atlantic areas.

## 1. FUNERAL OUTFITS AS ELEMENTS OF SOCIAL DIFFERENTIATION DURING THE THIRD MILLENNIUM ANE IN SETTLEMENT OF VALENCINA DE LA CONCEPCIÓN (SEVILLA)

*Pajuelo Pando, Ana (Universidad de Sevilla) anapajuelo@gmail.com*

*López Aldana, Pedro Manuel (Universidad de Sevilla) aldanaostrogodo@gmail.com*

Possession of certain components and products beyond death involves the perpetuation of social inequality generated in the society of the living.

In social formations of the III millennium BC this circumstance is manifested forms clear, both funerary buildings, a complex and monumental showing a significant investment of labor, and other minor and formal simplicity; when reuse of structures, a priori, no purpose-built this functionality funeral.

This marked difference between burial containers is often betrayed in artefactual component in the form of offerings, regardless of the population composition that house.

We analyze in this paper these social practices at the site of the Copper Age Valencina de la Concepción, relating the structures, types of products, partnerships thereof, the possible spatial relationships buried, materials premiums and the specialization of its articles.

## 2. OFFERING OR WASTE? THE FUNERARY ENSEMBLE OF LALLANA CAVE.

*Vega Maeso, Cristina (Universidad de Cantabria) cvega-maeso@gmail.com*

*González Morales, Manuel R. (Universidad de Cantabria) moralesm@unican.es*

La Llana Cave is located in Andrín (Llanes, Asturias). Into this cave, a superficial deposit, atop of a Mesolithic shell midden, included the remains of several ceramic vessels, three bevel-cut bones, a polished tooth, and a small metal piece reminding a Palmela point. All of them seem to represent waste of different kinds of technological procedures. However, there is no evidence of in situ domestic activity. By contrast, in a small niche, few meters

away to the lower galleries of the cave, an almost complete human skeleton was also disposed on the surface. All these elements can be parts of a single set, whose association needs to be explained.

To achieve this goal, we followed this methodological path: first, we have carried out a typological study of archaeological remains to determine their general characteristics, and to establish their relative dating and possible contemporaneity; second, the human bones were dated by AMS to check if its chronology was similar to the rest of the materials; finally, a micro spatial study of all these elements was performed in order to understand the possible process of dispersal.

Radiometric and typological methods provide similar dates. This coincidence could indicate a possible association or a relationship between the different elements of the archaeological record. This idea is reinforced by the lack of evidence about any other activity except the burial. In consequence, these residues were unlikely to be the result of a different action within the cave.

The available data suggest that la Llana didn't have a domestic use at the time when the archaeological ensemble was deposited. The set of residues seems an offering that, somehow, may be related to the human remains.

ORAL

## 3. THE TRIPARTITE FUNERARY CONTEXT OF ALTO RIBATEJO (PORTUGAL)

*Cruz, Ana (Instituto Politécnico de Tomar) anacruz@ipt.pt*  
*Graça, Ana (Instituto Politécnico de Tomar) anagrace@ipt.pt*  
*Berruti, Gabriele (Universidade de Trás-os-Montes e Alto Douro) ilgabbro79@gmail.com*

Funerary context of Alto Ribatejo datable to the recent Prehistory derives from the regional entity itself which is also tripartite both in hydrographic terms (Nabão, Zêzere and Tagus rivers) and in geological terms (Limestone Massif, Hesperian Massif and Quaternary Terraces).

The lithological and geomorphological diversity contributed to the variability of tripartite funerary *modus operandi*: karstic environments in small cavities, megalithic monuments and *tumuli*. All these contexts exhibit "votive offerings" that accompany a vast period ranging from Early Neolithic to Late Bronze Age.

In what concerns the interpretation of the operational chains of behaviour of the living towards the inevitability

of death, we observe an archaeographical and physical approach to death that can be recorded, interpreted and theorised by the data obtained through excavation contexts, artefact typologies and bone radiocarbon dating.

There are considerable differences in the treatment of (positive and negative) structures, i.e. bodies and grave goods. There are pro-individualisation postures of death (Cave of Nossa Senhora das Lapas, Cave of Cadaval, *tumulus* 1 of Souto) and pro-socialising postures of death (Dolmen 1 of Val da Laje and Cave of Morgado Superior). There are graves in the cave where human bones and grave goods appear completely de-contextualised, piled up, not for taphonomic reasons but due to direct interventions of the living who re-use a cavity in a systematic manner. This suggests a first phase of the individual burial of the corpse followed shortly thereafter (once the first corpse is decomposed) by another giving rise to a secondary deposition (cave of Morgado Superior, cave of Cadaval and Dolmen 1 of Val da Laje). There is also a socialisation of death which is evidenced in the stratigraphic sequences of bones (*Gruta dos Ossos*). Strong evidences of burial and cremation are also found.

But in fact and once the operational chains of the “architectures of death” (stone architectures and architectures of the deceased and their grave goods) are understood, the real challenge lies in trying to find a metaphysical and dialectical explanation of the cognitive and mythological context which we comfortably call “culture”.

#### **4. A SPECIAL BODY: EXPOSURE RITUALS OF A SEATED CADAVER FROM THE COPPER AGE (III<sup>RD</sup> MILLENNIUM CAL BC) CEMETERY OF HUMANEJOS (PARLA, MADRID, SPAIN)**

*Garrido Pena, Rafael (Universidad Autónoma de Madrid) rafael.garrido@uam.es*

*Flores Fernández, Raúl (Professional Archaeologist) raulfloresfernandez@gmail.com*

*González Martín, Armando (Universidad Autónoma de Madrid) armando.gonzalez@uam.es*

*Herrero Corral, Ana Mercedes (Universidad Complutense de Madrid) anaherre@uam.es*

*Gutiérrez Sanz, Carmen (Universidad Autónoma de Madrid) carmen.gutierrez@uam.es*

Recent rescue excavations have discovered a huge Copper Age site near Parla (Madrid), with nearly 2000 nega-

tive structures, both domestic and burial ones. Amongst the graves excavated in this site there is a very special one where the body was found seated inside a pit, probably supported by a sort of wood structure that maintained straight the back of the corpse, until the burial pit was finally filled up with sediment and deliberately closed. Thus it seems that this body was exposed during a certain time inside this tomb, but when the skull and upper part of the skeleton loosed the soft tissues and several bones fell down, it was finally interred. No grave goods were found inside the grave but a small flint arrowhead that was recovered beside the skull. But was it really a grave offering? What is the meaning of the presence of this item inside this special tomb? Has it something to do with the death of this individual?

The complete bioanthropological study is presented, together with the use-wear analysis of the flint arrowhead that give us clues to interpret this complex find.

Moreover such a singular treatment of this individual demands a social and ritual explanation, and this could be done in the context of exposure rituals of corpses, which is a very interesting feature of burial symbolism, with known examples in the ethnographic literature. This sort of practices is always related with certain beliefs about the afterlife world and the way to achieve the final rest for the deceased members of the group.

ORAL

#### **5. CONTEXTUALIZATION OF FUNERARY EVIDENCE FROM THE CAVE SANT'ANGELO IV, NORTHEASTERN CALABRIA, ITALY**

*Ippolito, Francesca (Groningen Institute of Archaeology) f.ippolito@rug.nl*

The cave of Sant'Angelo IV or Grotta dell'Antenato is part of the Sant'Angelo karst system located N-W of Cassano allo Jonio, Calabria, Italy. It consists of a series of caves frequented from the Neolithic to the Bronze Age. Among them, the cave of Sant'Angelo IV shows the first evidence of settlement at the end of the Middle Eneolithic and during the period between the end of the Eneolithic and the beginning of the Middle Bronze Age in Northeastern Calabria or Sibaritide.

The research was based on the analysis of pottery, bone remains and radiocarbon dating.

Pottery and skeletal remains from this cave indicate the presence of at least three tombs dating to three different

periods and showing ritual practices already attested at contemporary funerary contexts in other Italian regions. Moreover, a peculiar find was found in this cave, representing the cultural aspect of Rodi'-Tindari-Vallelunga (RTV), attested for the first time in the study-area. Furthermore, the presence of finds similar to ceramics found at sites located along the Northern Adriatic coasts suggests long range cultural interactions which took place between the Eneolithic and the beginning of the Middle Bronze Age, otherwise poorly documented in the Sibaritide so far.

Considering the lack of evidence for the period between the Neolithic and the second phase of the Middle Bronze Age in the Sibaritide, the finds from Sant'Angelo IV constitute a starting point to fill in the settlement record for this area. The funerary function of the cave-site will be analyzed considering the surrounding context, by taking into account both the data provided by the nearby cave-sites and the open-air settlement evidence, in order to interpret the communities' perception of the funerary and daily use of their territory.

ORAL

## 6. EGYPTIAN AFTERLIFE. PREDYNASTIC AND EARLY DYNASTIC GRAVE GOODS-A VIEW FROM TELL EL-FARKHA.

*Rosinska-Balik, Karolina (Institute of Archaeology, Jagiellonian University in Krakow, Poland) k.rosinska.balik@gmail.com*

*Debowska-Ludwin, Joanna (Institute of Archaeology, Jagiellonian University in Krakow, Poland) joanna.debowska-ludwin@uj.edu.pl*

The Afterlife for Ancient Egyptians certainly played a great role in their beliefs. The care with which their prepared their deceased for the infinite existence has been observed in many aspects: preparation of the body itself, construction of sophisticated tombs, all the rituals concerning the celebration of inhumation process, the wide range of grave goods in which deceased was equipped. All this aspects seem to be present from the beginning of Egyptian state. Research on Predynastic and Early Dynastic periods teaches us that this tradition is at least partially present even before the Egyptian unification.

The Tell el-Farkha cemeteries reveal up to date over 120 graves with very diverse structures, grave offerings and even various body arrangements. There were observed different sets of Afterlife equipment for a departed. This

sets differ not only in kind and amount of the goods, not only they were differentiated by sex of the dead person but also took different place in the tomb structure.

In the presentation we would like to discuss all kinds of goods such as: pottery, stone vessels, tools, jewellery, other small luxury items and extraordinary artifacts. We would also like to make an attempt to find any patterns in equipment concerning sex and/or age of the deceased and propose some interpretation based on selected examples.

ORAL

## 7. LA DÉPOSITION D'OBJETS FUNÉRAIRES DANS LES TOMBES DU BRONZE FINAL EN FLANDRE.

*De Mulder, Guy (Ghent University) guy.demulder@ugent.be*

Les tombelles du Bronze ancien et Bronze moyen sont mal conservées en Flandre ce qui limite notre connaissance sur la déposition funéraire d'objets dans cette période. Dans les quelques monuments intacts, qui ont été fouillés, des offrandes funéraires ne sont pas reconnus.

La pratique de déposition d'objets funéraires se manifeste pour le premier temps au Bronze final. Néanmoins cette pratique reste limité au environ 50% des personnes incinérés et déposés dans une tombe selon les dates archéologiques disponibles. Les communautés du Bronze final montrent une absence de normes strictes au niveau des gestes funéraires. L'apparence de la tombe suggère des rites funéraires sobre et une sorte d'égalité dans la mort. La construction de la tombe est simple. Les ossements, si oui ou non dans une urne, sont déposés dans une fosse creusée dans le sous-sol. Le traitement des objets funéraires est très diverse. Ils peuvent être passée dans le feu du bûcher; d'autres sont ajoutés au ossements incinérés au moment de la déposition de la tombe. Des combinaisons d'objets brûlés et intacts ne sont pas rares dans les nécropoles. Les artefacts brûlés peuvent être déformé ou représenté par quelques tessons. Aussi la position des objets dans la tombe est caractérisée par cette variabilité. La majorité est déposée dans l'urne, mais des exemples des tasses au dessus ou à coté de l'urne sont aussi connus.

Parmi les objets choisis pour accompagner le défunt sur le bûcher et dans la tombe figure surtout la céramique; plus spécifique des éléments de service à boire comme des gobelets et des tasses. Les métaux sont rares et sont représentés par des objets de parure en bronze. Des fragments d'os animalier dans une tombe sont plutôt

une exception.

La transition vers le premier âge du fer montre une communauté aux deux visages concernant la déposition d'offrandes funéraires. D'une partie, les gestes funéraires restent globalement simples dans la majorité des nécropoles, de l'autre côté les tombelles de Court-Saint-Etienne illustrent les changements dans les rites funéraires. Ces tombelles sont équipées d'un mobilier riche avec des armes, des éléments de harnachement de cheval et le service à boire comme dans les autres régions de l'Europe.

ORAL

## 8. THE LATE BRONZE AGE BUTTONS FROM HAN-SUR-LESSE (BELGIUM): A NEGLECTED MATERIAL

*Duriau, Alexandre (Université libre de Bruxelles) alexandre.duriau@ulb.ac.be*

In the village of Han-sur-Lesse (Namur, Belgium) the river Lesse, an affluent of the Meuse, goes underground through the limestone hills of Boine. Over a period of thousands of years its course has created a network of caves. Among these, the *Grotte de Han* is one of the main tourist attractions in Belgium. As early as 1902, it was subjected to archeological explorations led by E. de Pierpont. These digs' findings were numerous and varied but have not been conserved. The set of items included in the present study comes from the bed of the river Lesse, precisely from the *Trou de Han* which is the point at which it surfaces once more. Since 1963, systematic underwater digs led by the *Centre de Recherches Archéologiques Fluviales* (Centre for Archeological River Digs) directed by M. Jasinski have brought to light thousands of objects. The oldest date back to the end of the Neolithic period. However, the main period of origin is the Late Bronze Age. The number and variety of metallic objects is unique in Belgium: among them are axes, spear points, pins, bracelets, knives and gold jewellery. The layout of the site and the presence of exceptional objects have led E. Warmenbol to interpret this site as a 'Gateway to the Underworld' (*bouche des enfers*). The deposits of intact or intentionally broken objects could thus be linked to the world of the dead.

This study has been carried out on a particular class of objects: bronze buttons from the *Trou de Han*. Compared to weapons, tools and gold jewellery, bronze buttons may appear uninteresting. However, their number ranks them among the most common metallic objects found

on the site. In effect, almost 120 buttons have been found since 1963. The typological study of this material, far from monotonous, permitted us to identify several different types of buttons based on formal criteria such as the method of fixing to clothes - loop (*bélière*) or bar (*traverse*) - and shape or decoration of the visible face of the button (*cabochon*). The study then used comparisons with other better-dated buttons in order to situate them chronologically. We focused on buttons from an area including the whole of Belgium, Luxemburg, the east of France, the west of Switzerland, the west and south west of Germany. By taking into account the context and environment of these finds we were able to better determine the different uses of the buttons from Han (decoration for horses' tack or clothing, etc.).

## 1. THE SUN IN CELTIBERIAN ICONOGRAPHY AND ITS COSMOGONICAL INTERPRETATION

*Burillo-Cuadrado, M<sup>a</sup> Pilar (Universidad de Zaragoza) mpilar.burillo@gmail.com*

The few texts on Celtiberian religious belief mean it has to be studied from the iconography and the few structural remains that have been preserved. Unlike those of other cultures, these focus mainly on a single motif, the Sun.

We have been able to determine the existence of three different iconographic syntaxes intended to tell the same story, the solar myth. The oldest images are found on bronze plates, staffs and fibulae. The sun is depicted realistically in two ways, as radiant or non-radiant concentric circles, associated with the figure of a horse. On monochrome pottery, the sun is depicted as a left-facing or right-facing swastika, is associated with the horse and an anthropomorphic figure with an equine head, which usually takes the form of a protome of a horse throughout the Celtiberian world. However, neither the swastika nor the protome of a horse appears on the polychrome pottery of Numancia, on which the sun is depicted realistically.

On the basis of structuralist and phenomenological theoretical approaches, and a 3D analysis of the pottery, it has been possible to carry out a cosmogonical interpretation of Celtiberian iconography.

The sun appears as the highest deity. In order to explain its diurnal motion, radiant circles or right-facing swastikas are used, and circles with no rays and left-facing swastikas for its nocturnal return. The horse figures carry the sun and are in themselves identified with the solar deity. The sun would return through an aquatic sphere situated in the upper Cosmos.

To this should be added the discovery of a sanctuary in the Celtiberian city of Segada. It is built as a great platform, and indicates the dominant direction of the setting sun at prominent points on the horizon at the equinoxes and the summer solstice.

## POSTER

### 2. COMPLEJIDAD FUNERARIA EN LA PUNA MERIDIONAL DE ARGENTINA DURANTE EL HOLOCENO TEMPRANO (CA.8400-8000 AP)

*Martínez, Jorge G. (Instituto Superior de Estudios Sociales-CONICET/Instituto de Arqueología y Museo. Universidad Nacional de Tucumán. Argentina) jormartin1969@yahoo.com.ar*

Presentamos en este trabajo la información proveniente del hallazgo de dos estructuras funerarias detectadas en el interior del alero rocoso Peñas de las Trampas 1.1. el cual se ubica a 3582 msnm en la localidad de Antofagasta de la Sierra, en la Puna meridional de Argentina. Las condiciones climáticas de gran sequedad propias de ambientes de Puna, jugaron un rol fundamental en la preservación de todo tipo de restos orgánicos hasta el presente. Estos contextos fueron datados entre ca.8400-8000 años AP. Se trata en ambos casos de estructuras de cavado revestidas con gramíneas, en cuyo interior fue hallado un gran número de elementos culturales, los cuales constituyen, con algunas diferencias, depósitos intencionales. Dentro de estas estructuras, fueron recuperados restos óseos humanos correspondientes a seis individuos, tres en cada estructura. Estos fueron hallados en asociación a numerosos restos de tecno-facturas variadas de gran complejidad artesanal, incluyendo cueros gamuzados (cosidos y pintados de color rojo), numerosas cuentas de collar confeccionadas con valvas de moluscos y semillas, fragmentos de malla de red teñidos de rojo y pintados en negro, adornos hechos con plumas entretejidas, y finos cordeles de fibra vegetal.

Además del análisis espacial de la disposición de todos los elementos materiales de las dos estructuras, se hizo un detallado análisis de las materias primas y de la con-

fección técnica de los distintos objetos y artefactos que fueron registrados en asociación primaria con los restos óseos humanos.

Todos estos restos de origen orgánico si bien se encuentran en muy buenas condiciones de preservación, se presentan altamente fragmentados. En base a los análisis realizados, pudo establecerse que más del 90 % de los elementos mencionados fueron manufacturados con materias primas alóctonas, i.e. fuera del ambiente natural de la Puna. Las cuentas de semillas vegetales y fibras que componen los cordeles vegetales, provienen de fibras de palmeras ubicadas en pisos ecológicos distantes a más de 200 km (llanuras de este). Las valvas de moluscos provienen de la costa del Océano Pacífico, cuya distancia mínima es de 350 km. Dado que se trata de un tipo singular de hallazgo, se crea la imposibilidad de comparar con otros contextos sincrónicos, y por lo tanto una limitación al abordar la dimensión simbólica o el significado como ofrenda o ajuar suntuario de todos estos elementos asociados a los enterratorios.

Nuestro análisis lleva a diferenciar las evidencias de este sitio dentro del noroeste de Argentina, con respecto a que no se corresponden con el patrón funerario generalizado "arcaico" propuesto por Standen y Santoro (1994) para sitios tempranos del norte de Chile, lo cual genera un plus de variabilidad muy interesante para seguir explorando. Los numerosos elementos funerarios procedentes de ambientes ecológicamente diferenciados, lleva a plantear un modelo de gran interacción entre diferentes grupos humanos que habitan efectivamente dichos espacios y que las prácticas funerarias estarían reflejando tempranas relaciones sociales de alianzas y/o parentesco dentro de estas sociedades altamente nómades.

### 1. 50 YEARS OF "PRÄHISTORISCHE BRONZEFUNDE"

*Dietz, Ute Luise ("Prähistorische Bronzefunde", Akademie der Wissenschaften und der Literatur, Mainz / Goethe-Universität Frankfurt a.M.) dietz@em.uni-frankfurt.de*

The international editing project "Prähistorische Bronzefunde" (PBF) is now working for nearly 50 years. Up to now, 175 volumes have been published, documenting about 140,000 copper and bronze objects from the Copper, Bronze and Early Iron Ages.

In addition to a short overview on PBF's long history, especially on the situation during the time of the Iron Curtain, there will be a presentation of the project's reception. There will also be an outlook on the chances and perspectives of a digital edition.

ORAL

### 2. TWO NEW BRONZE HOARDS FOUND ATTĂRTĂRIA (ALBA COUNTY), ROMANIA

*Bors, Corina (National History Museum of Romania (MNIR), Bucharest) corina.bors73@gmail.com*

Considering the topic of the UISPP2014 session entitled "50 years of Prähistorische Bronzefunde", but also the features of two newly discovered bronze hoards, the paper will bring into attention new evidence in regard to the phenomenon of bronze deposition during the 9<sup>th</sup> – 8<sup>th</sup> c. BC within the Carpathian basin. In 2012, within the framework of a large scale rescue excavation national program undertaken along the Mureş river valley (southern Transylvania), occasioned by the construction of a future motorway, was made a very important archaeological discovery: two bronze hoards. The hoards were discovered on the southern limit of a very large prehistoric site, located on the left bank of the middle Mureş valley, at Tărtăria (Alba county), preliminary dated during the 8<sup>th</sup> c. BC (the middle Hallstatt period, the Basarabi type pottery style). The context and structure of the two deposits are of particular importance, since it is the first time when such hoards belonging to the so-called "Bălvăneşti - Vinţ" series (referring to the terminology used for nowadays Romania's territory) are discovered during an archaeological excavation. The two bronze hoards were discovered within a ditch, marking the southern limit of the

site. The structure of the deposits is complex and varied, containing weapons, tools, jewelry and harness objects. The first hoard comprises more than 300 objects, being the largest ever found corresponding to the 9<sup>th</sup> – 8<sup>th</sup> c. BC period in the Carpathian basin, while the second consists of 50 objects. In both cases, the metal objects were placed in ceramic vessels. The majority of the objects are made of bronze, yet there are also weapons and tools made of iron, along with others made of animal bones (teeths). The preliminary analysis of certain objects indicate wider connections to the north Pontic areas, as well as to the south-western Balkan ones, providing new data to discuss upon the long-distance exchanges and contacts during the first centuries at the beginning of the first millennium BC in the Carpathian basin.

ORAL

### 3. THE RÍA DE HUELVA AND THE DEPOSITION OF PAIRED OBJECTS IN THE EUROPEAN BRONZE AGE

*Brandherm, Dirk (Queen's University Belfast) d.brandherm@qub.ac.uk*

The phenomenon of structured paired-object deposition has long been recognized as a significant feature of later prehistoric ritual practice. It is particularly well attested for, but by no means limited to the deposition of Bronze Age metalwork. Interpretations aiming at an explanation for this phenomenon tend to focus on the motif of the 'divine twins' and its significance for Bronze Age cosmologies, but given the wide range of different forms in which this practice manifests and its long development over time, this is perhaps insufficient to explain its complexity.

Building on earlier work by the author, this paper will provide a brief overview of diachronic trends in the practice of multi-piece sword deposition from the Middle through the Late Bronze Age, to then go on and explore related patterns in complex multi-piece assemblages, using the Ría de Huelva find as a prominent example in case.

As a result from this exercise, both the original interpretation of this assemblage as lost cargo and its alternative reading as a cumulative funerary or cenotaph deposit are rejected.

It has to be acknowledged that without comprehensive corpora such as the Prähistorische Bronzefunde, low-frequency or low-density patterns that only become dis-

cernible by adopting a diachronic wide-area approach, such patterning would almost certainly remain undetected.

---

ORAL

#### 4. A PROPOS DES CORPUS D'OBJETS EN BRONZE D'ITALIE DU NORD: QUELQUES OBSERVATIONS.

*Cupitò, Michele (Dipartimento dei Beni Culturali - Università di Padova) michele.cupito@beniculturali.it*

*Rubat Borel, Francesco (Soprintendenza per i Beni Archeologici del Piemonte e MAE) francesco.rubatborel@beniculturali.it*

The increase of new data and the numerous reassessments of various categories of bronze artefacts make necessary the update of some existing *corpora* – in primis the most dated ones – for the Italian territory.

Moreover, it would also be necessary to plan and realize ex novo new *corpora* on categories that have not been analysed before, taking into consideration the context of provenance, the functional and metallographic analyses, the contacts and the production processes. Since this problem is shared by the other Countries, we would like to ask our foreign colleagues how they intend to deal with the issue: online open publications, committees, etc.

We will therefore synthetically present some works undertaken as part of the research of the two proponents, who already studied systematically new contexts or bronze artefacts categories (specifically swords, axes, pendants and arm rings) from Northern Italy. These could be a useful basis for the development of new studies updating and/or realizing new *PBF*.

---

ORAL

#### 5. BRONZE SPEARHEADS BETWEEN CARPATHIAN BASIN AND APENNINE PENINSULA AT THE TRANSITION FROM BRONZE AGE TO IRON AGE

*Pabst, Sabine (Philipps-University Marburg) pabsts@staff.uni-marburg.de*

In the extensive area between the Carpathian basin and the Apennine peninsula several typologically related spearhead shapes occur during the late Bronze Age and early Iron Age. The region of origin of these types

of spearheads (especially the types with flame-shaped blade and with a profiled socket) is to be pinpointed by chronological and typo-genetic analyses in the environment of the Carpathian basin. New supra-regional investigations on the typology and chorology as well as on the find contexts and the equipment structure of the finds that contain spearheads in the different regions provide insight into particular directions of spreading and the underlying communication routes and social processes. In the lecture the initial results of two research projects will be presented, dealing with the recording of bronze spearheads in Hungary (within the series "Prähistorische Bronzefunde") on the one hand and with the cultural relations between the Carpathian basin and the Apennine peninsula at the transition from the Bronze Age to Iron Age on the other.

#### A NEW MIDDLE HALLSTATT SITE ON THE MUREȘ VALLEY: TĂRTĂRIA - PODU TĂRTĂRIEI VEST AND THE RELATED BRONZE HOARDS

*Bors, Corina (National History Museum of Romania (MNIR), Bucharest) corina.bors73@gmail.com*

*Irimus, Luciana (National History Museum of Romania (MNIR), Bucharest) luciana\_dr@yahoo.com*

*Rumega, Vlad (National History Museum of Romania (MNIR), Bucharest) vladrumega@gmail.com*

The preventive archaeological research campaign 2012 on the site Tărtăria – Podu Tărtăriei vest / Valea Rea (Tărtăria 1) was occasioned by the construction works of the A1 motorway, crossing the southern part of Transylvania from west to east. The site is located about 0.3km south to the Mureș river, north to the Tărtăria village, on a plateau situated on the upper left terrace of the valley. Throughout an open area archaeological excavation it was fully investigated an area of about 2ha, where 269 archaeological complexes (mostly from the middle Hallstatt period, namely the time of the Basarabi style pottery) were identified and excavated. From a functional point of view these were (most probably) semi-sunken dwellings, offering/votive pits (with pottery broken in situ), refuse pits, extraction pits, as well as remains of the "level of culture".

As regards the middle Hallstatt habitation, there are also a series of particular discoveries, namely two ditches marking the southern and eastern limits of the site, two hoards comprising more than 400 bronze and iron

objects (Ha B<sub>3</sub>-C / the so-called Bâlvănești - Vinț series), and a collective grave. It was uncovered a significant quantity of pottery characteristic for the Basarabi culture (more than 120 vessels restored up to now), as well as a great number of metal objects (weapons, tools and adornment object made of bronze and iron). Considering all the data recorded and the preliminary analysis of the very rich archaeological finds, the site from Tărtăria – Podu Tărtăriei vest / Valea Rea (Tărtăria 1) represents a very important prehistoric site dating from the middle Hallstatt period.

## 1. THE SCIENTIFIC REVOLUTION OF THE SIXTIES IN PREHISTORY AND PROTOHISTORY

*Djindjian, François (Université de Paris 1 Panthéon Sorbonne & CNRS UMR7041 Arscan) francois.djindjian@wanadoo.fr*

### Abstract

The post second war period (1955-1975) has been a scientific revolution in the advance of Prehistory and Protohistory: advanced field techniques and archaeological data recording, new disciplines (Archaeometry, Geoarchaeology, palaeoenvironmental reconstitutions, quantitative and computational archaeology, etc.) involving major methodological and technical advances, which have diffused in the whole archaeological field. The present paper has the purpose to remember this golden age and to replace the scientific revolution in the general context of the progress of Sciences and of the early and new paradigms of the Archaeology of the period (« *Culture historical Archaeology* », Marxism, and « *New Archaeology* »).

### Résumé

L'après deuxième guerre mondiale (1955-1975) a été une révolution scientifique dans l'histoire de la préhistoire et protohistoire : amélioration des techniques de fouilles et d'enregistrement des données de terrain, émergence de nouvelles disciplines (archéométrie, géoarchéologie, reconstitutions paléoenvironnementales, archéologie quantitative et computationnelle, etc.) apportant des progrès méthodologiques et techniques majeurs, qui ont diffusé dans le domaine archéologique tout entier. La présente communication a pour but de se remémorer cet âge d'or et de le replacer cette révolution scientifique dans le contexte général de l'avancement des Sciences et des paradigmes anciens et nouveaux de l'Archéologie de cette période (« *Culture Historical Archaeology* », Marxisme et « *New Archaeology* »).

ORAL

## 2. MARXISM IN THE EUROPEAN ARCHAEOLOGY OF THE SIXTIES: THE CASE-STUDIES OF ITALY AND FRANCE

*Guidi, Alessandro (Università Roma Tre) alessandro.guidi@uniroma3.it*

As many scholars noted, Marxist theory (as Childe defined it, "not a set of dogmas... but a method of interpretation and a set of values" [Childe 1952, 25]) was widely incorporated in post-war European archaeology, probably as a result of a different political climate that favoured the diffusion of Marxist thought and, from another side, of the prevailing legacy of the most influential cultural and artistic *avant-garde* to the left-wing parties.

The paper explores the evolution of these theoretical trends in the two countries in which Socialist and Communist parties were stronger: Italy and France, especially in the Sixties and in the early Seventies, a period in which on the other side of the Atlantic and in England the sudden burst of New Archaeology caused a deep crisis of traditionalist approaches.

As a matter of fact Marxist archaeology had more or less the same impact in Western Europe, with a true fight of the new generation against the academic establishment.

This is not surprising, given "the materialism inherent in most Marxist traditions in Europe, reminiscent of the strongly American processual archaeology, coupled with the evolutionary views of the New Archaeology which themselves had Marxist affiliations" (Hodder 1991, 15); a point of view shared by Renfrew, who dedicated same paragraphs of his archaeological handbook to the comparison between Marxism and Processual theory (Renfrew-Bahn 2012).

These trends were particularly strong in Classical and Medieval Archaeology; the paper will also examine, in the same period, the first attempts (not by chance of Marxist archaeologists!) to import processual theory in Italy (overall in prehistoric and near eastern archaeology).

ORAL

## 3. PREHISTORY AND PROTOHISTORY IN THE SOVIET UNION DURING THE SIXTIES

*Iakovleva, Lioudmila - (Institute of Archaeology NAS Ukraine (Kiev) and CNRS UMR 7041 Arscan) l.iakovleva@wanadoo.fr*

### Abstract

Archaeology in the Soviet Union, after the last world war, has known an exceptional growth, made possible by the centralized organization of the Academy of Sciences, an important number of specialized archaeologists and very many field operations. However, the intervention of

Joseph Stalin, himself, in 1950, in Pravda, to condemn, as non-Marxist, the theory of the stadial evolution of N. Marr, official doctrine of archaeology since 1919, has upset the archaeological community, which then has lost any theoretical framework. Soviet archaeologists then refocused on archaeological excavations and the publication of their results following a standard description framework leaving little place for interpretations. The most significant methodological contributions of this period are the development of open air excavations techniques (following Efimienko), the invention of usewear studies (Semenov) and the importance given to geoarchaeology (Velichko, Ivanova), archaeozoology (Pidoplichko) and palaeoenvironmental studies (Dolukhanov). The theoretical framework of archaeology, in its formal approach, is treated by Klejn in St. Petersburg and Gening in Kiev.

#### Résumé

L'archéologie en Union soviétique, après la seconde guerre mondiale, a connu un essor exceptionnel, rendu possible par une organisation centralisée par l'Académie des Sciences, un effectif important d'archéologues spécialistes et de très nombreuses opérations de fouilles sur le terrain. Cependant, l'intervention de Joseph Staline, lui-même, en 1950, dans la Pravda, pour condamner, comme non marxiste, la théorie de l'évolution stadiale de N. Marr, doctrine officielle de l'archéologie depuis 1919, a bouleversé la communauté archéologique, qui s'est retrouvé sans cadre théorique.

Les archéologues soviétiques se sont alors recentrés sur les campagnes de fouilles archéologiques et la publication de leurs résultats suivant un canevas descriptif normalisé laissant peu de place aux interprétations. L'apport méthodologique le plus significatif de cette période est le développement des techniques de fouilles de plein air (à la suite d'Efimienko), l'invention des études tracéologiques (Semenov) et l'importance donnée aux études géoarchéologiques (Velichko, Ivanova), archéozoologiques (Pidoplichko) et paléoenvironnementales (Dolukhanov). Le cadre théorique de l'archéologie, dans son approche formelle, est traité par Klejn à Saint-Pétersbourg et par Gening à Kiev.

#### ORAL

### 4. THE CONTRIBUTION OF THE POLISH PREHISTORIANS TO THE RENEWING OF THE LITHIC STUDIES

*Burdukiewicz, Jan Michal (University of Wroclaw, Insitute of Archaeology) janmibur@gmail.com*

Polish prehistorians paid great attention into lithic studies since beginning of 20<sup>th</sup> century. The founders of lithic studies in Poland were Stefan Krukowski and Ludwik Sawicki, who introduced technological and spatial analysis of lithic assemblages in opposite to widespread use of typological type fossils in other countries. Their approach was broadly extended in sixties of by R. Schild, B. Ginter, J.K. Kozłowski and other Polish prehistorians as general approach, called firstly Dynamic Technological Classification and later The Dynamic Technological Analysis. The best examples of such approach with inspiration of D. Clarke were later published in the book "Unconventional Archaeology", edited by R. Schild (1980).

Polish comprehensive approach is focused on complete processing of lithic artifacts, divided into successive sequences (or groups) from acquisition of raw material, core reduction, processing of blanks to tool shaping and repairing, later their up including all wastes dropping and archaeological site formation. All archaeological data were analyzed in broad geologic and ecologic setting concerning settlement period as well as postdepositional circumstances.

The important assumption was careful excavation of the isolated archaeological assemblages with recording their spatial position, detailed morphological and technological classification. Such assemblages were analyzed by distinctiveness of raw material, morphological, technological and metric attributes. Taxonomic analysis after that was made by appropriate statistical methods. Dynamic Technological Analysis was usually supplemented by an analysis of the spatial organization of stone processing, refitting network as well as macro- and micro-wear of usage or hafting. All-inclusive settlement units, distances of raw material acquisition and circulation were afterward used in formulation of economic and social concepts of hunter-gatherer societies and their temporal changeability.

The Dynamic Technological Analysis approach is fairly similar to the method of chaîne opératoire developed in France, which was applied to the stone assemblages much later. However, chaîne opératoire method bases also on sequence analysis of lithic artifact processing, starting from extraction of raw material, through the stages of core and blank processing, retouch of tools up to use the tools and their abandonment.

Although Dynamic Technological Analysis and chaîne opératoire methods are quite similar, it is possible to show significant differences. The chaîne opératoire is more as acquiring and handling and focused on a "bio-

graphical description" of certain groups of artifacts instead of whole assemblage.

Dynamic Technological Analysis is focused on quantitative and statistical methods, used in the analysis of the sequences and identifying the similarities and differences between the entire lithic assemblages. The quantification and statistical analysis of the lithic assemblages can objectively recognize some trends and attributes of every group of artifacts in the resource management and application of technological treatments. Currently, computer databases allow to collect much broader number artifact attributes and a more detailed analysis of the archaeological assemblages.

Dynamic Technological Analysis shows differences between domestic and workshop facies as well as technological trends, taxonomic units and settlement patterns of prehistoric societies. This resulted in the original method of highlighting and comparing lithic artifact assemblages, which is one of the most important aspects of the study of the Stone Age in Poland.

ORAL

## 5. PORTUGUESE ARCHAEOLOGY IN THE 60IES OF THE 20TH CENTURY: REVOLUTION OR TRANSITION?

*Martins, Ana Cristina (Tropical Research Institute / Uniarq-Centre for Archaeology, University of Lisbon) ana.c.martins@zonmail.pt*

Of transition, par excellence, the years between the end of World War II and the 70 are crucial for understanding the change in the archaeological activity in general, and in Portugal, in particular, largely in the wake of the *New Archaeology* (1958). The reasons for this phenomenon were many, underlying the growing role played by university in archaeological training; the rising of archaeological internationalization; the new excavation methods; the mentors of a new generation of archaeologists; the presence of foreign experts among us, likewise the German Archaeological Institute (1971).

This period, mediated between the late '50s and early '70s, is fundamental to understand, deepest and largely, national archeology, when a significant part of our leading archaeological institutions persisted in a historical-culturalist and structure-functionalist speech, while young scholars eager for *New Archaeology*, receiving and disseminating it between colleagues and different national institutions.

Studying coeval Portuguese archaeology means to comprehend more broadly archaeology in Portugal within the general framework of European Archaeology, filling still scarcely known pages of a history inextricable of the History, Philosophy and Sociology of Science and Technology.

To discuss about the ways and the many forms of reception, circulation and dissemination of *New Archaeology* in Portugal, we will practice an historical approach. In doing so, we will use mainly both written and iconographic primary sources from public and private archives, namely the documentation in the custody of the Portuguese Association of Archaeologists and the National Museum of Archaeologists, together with several secondary sources published by Portuguese archaeologists between the end of the 50ies and the beginning of the 70ies.

Evaluating the many forms of reception, circulation and dissemination of *New Archaeology* in Portugal, we will be able to understand if the 60ies were of revolution or of transition, when comparing to coeval examples, naming protagonists, institutions, outcomes and outputs.

The links between particularities of Portuguese archaeology and the many forms of reception, circulation and dissemination of *New Archaeology* in the country, provide undeniable contributes to the historicization of the discipline. In this framework, we hold that a study on the History of Archaeology cannot fail to consider the significant role of the many international scientific relations about this particular issue.

## 5. MARXISM IN THE EUROPEAN ARCHAEOLOGY OF THE SIXTIES: THE CASE-STUDIES OF ITALY AND FRANCE

*Guidi, Alessandro (Università Roma Tre) alessandro.guidi@uniroma3.it*

As many scholars noted, Marxist theory (as Childe defined it, "not a set of dogmas...but a method of interpretation and a set of values" [Childe 1952, 25]) was widely incorporated in post-war European archaeology, probably as a result of a different political climate that favoured the diffusion of Marxist thought and, from another side, of the prevailing legacy of the most influential cultural and artistic *avant-garde* to the left-wing parties.

The paper explores the evolution of these theoretical trends in the two countries in which Socialist and Com-

unist parties were stronger: Italy and France, especially in the Sixties and in the early Seventies, a period in which on the other side of the Atlantic and in England the sudden burst of New Archaeology caused a deep crisis of traditionalist approaches.

As a matter of fact Marxist archaeology had more or less the same impact in Western Europe, with a true fight of the new generation against the academic establishment.

This is not surprising, given “the materialism inherent in most Marxist traditions in Europe, reminiscent of the strongly American processual archaeology, coupled with the evolutionary views of the New Archaeology which themselves had Marxist affiliations” (Hodder 1991, 15); a point of view shared by Renfrew, who dedicated some paragraphs of his archaeological handbook to the comparison between Marxism and Processual theory (Renfrew-Bahn 2012).

These trends were particularly strong in Classical and Medieval Archaeology; the paper will also examine, in the same period, the first attempts (not by chance of Marxist archaeologists!) to import processual theory in Italy (overall in prehistoric and near eastern archaeology).

## 6. HISTORICIZING THE 14C REVOLUTION

*Delley, Géraldine (Université de Neuchâtel, Institut d'archéologie) geraldine.delley@unine.ch*

Since the middle of the 1970's, disciplinary histories have established that the 14C dating method has revolutionized the comprehension of time in prehistory. This paper proposes a critical analysis of the implementation and reception of this innovative tool in the field of the Swiss lake-dwelling research. Focusing on the institutionalisation and the integration of the method in the daily practice of prehistoric research, this contribution aims at shedding light on a paradoxical situation. Between 1950 and 1980 the 14C dating method was recognized as an important methodological innovation by the archaeological community whereas, during this same period, the results thereby obtained remained poorly exploited. The analysis is based on published and unpublished sources (correspondence, reports, interviews) produced in the framework of wetland archaeology research in Switzerland between 1950 and 1980.

The analysis reveals that the relatively quick institutionalization of the method in Switzerland was independent from the recognition of the heuristic potential of the 14C method. Different elements explain this situation. On the one hand, the modernity of the method, coupled with the influent discourse of the politics of sciences regarding collaborations between different fields of research (humanities, natural and exact sciences), contributed to a quick recognition of the innovation amongst archaeologists. On the other hand, however, other circumstances – among which the epistemological origins of the actors of the research and the competition, within the field of archaeology, of different means of measuring prehistoric time and conceiving dates (archaeological chronologies and dendrochronology) – explain the weak interest archaeologists manifested for the new chronologies produced by the 14C method.

The contextualized historical analysis of the development of the 14C dating method reveals an absence of correlation between the development of such a methodological tool, its institutionalisation and the epistemological logics of the actors. Finally, this contribution tackles the critical issue of the long process necessary for the transformation of a technical tool into a method.

## 7. LECTURE DE L'ART MOBILIER À TRAVERS LES TRAVAUX DE LÉON PALES SUR LES PIERRES GRAVÉES DE LA MARCHE (VIENNE)

*Welté, Anne-Catherine - (Université de Franche-Comté, Besançon) acwp@netcourrier.com*

1955-1975 : deux décennies d'une grande importance dans l'histoire de la préhistoire au cours desquelles s'opère une véritable mutation dans les conceptions de travail, avec l'année-charnière 1958, qui voit la publication d'une part d'un des derniers grands ouvrages de l'abbé H. Breuil : *Les Cavernes du Volp : Trois-Frères, Tuc d'Audoubert à Montesquieu-Avantès, Ariège* (réalisé avec le Comte H. Bégouën), suivi l'année d'après par *les Hommes de la pierre ancienne* (réalisé également en collaboration avec R. Lantier), et d'autre part de trois articles d'André Leroi-Gourhan dans le Bulletin de la Société préhistorique française, intitulés : *La fonction des signes dans les sanctuaires paléolithique, le symbolisme des grands signes dans l'art pariétal paléolithique* et *la Répartition et groupement des animaux dans l'art pariétal paléolithique*. L'abbé H. Breuil fût la figure emblématique du « premier » XXème siècle marqué par la découverte de la ma-

jeunesse et la mobilisation permanente. L'objectivité des faits, dûment mesurés, devrait permettre de remplacer les passions et subjectivités qui facilitent les divisions. Les sciences humaines doivent donc être quantifiées pour éliminer leur gangue philosophique. Ainsi émerge un « second » XX<sup>ème</sup> siècle où l'analyse mécaniste du fonctionnement de la pensée semble s'imposer dans tous les domaines de l'activité humaine. De nouveaux procédés (analyses mécanographiques, statistiques) doivent permettre d'éloigner le hasard dans le raisonnement et de rationaliser le vivant.

Comment se situe le travail de L. Pales à La Marche dans ce mouvement des idées ? L. Pales (1905-1988) a suivi l'enseignement du comte H. Bégouën (1863-1956), et a été initié au déchiffrement des parois gravées du « sanctuaire » de la grotte des Trois-frères par l'abbé H. Breuil (1877-1961). Médecin-colonel, il quitte l'armée en 1957 et se consacre quasi exclusivement à la recherche en anthropologie et en préhistoire. Dès 1951-1952, l'abbé lui avait montré les pierres gravées de La Marche et avait exprimé le souhait de lui en confier l'étude. Il accepta cette tâche, « dont nul n'avait imaginé l'ampleur et la difficulté... » (1969, 26). Quel protocole d'analyse ce chercheur a-t-il mis en œuvre pour étudier cet ensemble de 1512 pierres (décompte de 1965) considéré par lui-même comme incomplet ?

#### ORAL

### 8. THRACIAN ARCHAEOLOGY IN BULGARIA. REVOLUTION IN THE INVESTIGATIONS AND IN THE KNOWLEDGE ABOUT THE THRACIANS.

*Gergova, Diana (National Institute of Archaeology with Museum-Bulgarian Academy of Science, Sofia Institute of Archaeology, University of Rzeszow, Rzeszow, Poland) dianagergova@gmail.com*

Thracology - one of the new disciplines that emerged in the end of the 60ies and the beginning of the 70ies of the 20<sup>th</sup> century, as an integral part of the Paleo-Balkan and Indo-European studies institutionally was supported by the found in 1972 Institute of Thracology and by the Department of Thracian archaeology at the Institute of Archaeology with Museum at the Bulgarian Academy of science. The development of this interdisciplinary

discipline was very much dependent on the archaeological investigations - the only one that could offer the acquisition of new and objective archaeological sources for the understanding of the culture of the Thracians.

Since 1972 to 1989 these investigations were financially supported by the state and had been provided often in collaboration with foreign institutes, universities and specialists from Poland, Tchechoslovakia, East and West Germany, France, Great Britain, The Netherlands, Japan, etc. This period could be really called the Golden Age of Thracian archaeology.

New methodological and technical advances were introduced for these most exhaustive investigations. The Golden Age of Thracian archaeology was characterized by the introduction of the most advanced approaches in field survey and the creation of the National Information system "Archaeological map of Bulgaria" that allowed for the first time to have an objective picture also of the Thracian settlement system and its development during the different periods (end of the Chalkolithic - to the Roman conquest). Unknown categories of sites had been registered and excavated like Thracian sanctuaries and cult places of different types, megalithic monuments, rock tombs and niches, political centers, etc. Special attention had been paid to the investigations of the Thracian burial rites and the excavations of the monumental tumuli with tombs, as well as to the study of the urbanogenic processes and cities in Thrace. Investigations of the Greek colonies and emporia change dramatically the notion about the Thracian-Greek relations in the process of the colonization. This period was characterized by the intensive interdisciplinary field and laboratory studies and contributions in their archaeological applications (areal photogrammetry, geophysical prospecting, geoarchaeological, paleoseismical and archaeoastronomical studies, archaeometric investigations, etc.)

After 1989 in the time of economic and social changes the scientific research as well as some of the institutions were deprived from any regular state financial support and left to private sponsors that in fact did not exist. Systematic long term investigations of some important sites continued on a smaller scale mainly thanks to the international collaboration of the teams. The greater part of the field investigations were connecting with the preventive archaeology. The financial sources from the infrastructural projects lead to the discovery of even more new categories of sites.

Thracian archaeology had contributed both to the better reading of the ancient written sources, as well as to

the much more objective understanding of different aspects of the civilization of the Thracians, their relations with the contemporary ancient people and contribution to the formation of the culture of Ancient Europe.

### 9. NEW ARCHAEOLOGY AT COCINA SITE. MAKING NEW SCIENCE WITH OLD DATA.

*Díez Castillo, Agustín (Universitat de València) adiez@uv.es*  
*García Puchol, Oreto (Universitat de València) oreto.garcia@uv.es*

*Cabanilles, Joaquim Juan (Museu de Prehistoria de València -S.I.P.-) joaquim.juan@dival.es*

*Pardo Gordó, Salvador (Universitat de València) pargor@uv.es*

*McLure, Sarah (Department of Anthropology, The Pennsylvania State University) sbm19@psu.edu*

In the Iberian Peninsula the impact of the New Archaeology in the late 1960s and early 1970s was reflected in several theoretical issues but also in the way things were recorded on the field. The New Archaeology did change the way archaeological fieldwork was done forever. Archaeologists lived the illusion of finally being able to read history books without destroying their sheets. In the 1970s more and more sites were being recorded rigorously by a increasing number of youth scholars, among them the fieldwork of Prof. Javier Fortea at the mesolithic key site of Cocina could be an example.> Unfortunately, in Cocina's case, the more than rigorous fieldwork never was fully published in the form of a monograph volume, even when the impact of the few Fortea's paper changed the way the Iberian Prehistory looked at the Mesolithic and the neolithization process forever (Fortea 1973, ...). Methodologically speaking is also a prime example of the way archaeological findings should be recorded in any excavation. Prof. J. Fortea and his collaborators mounted, at the time, a fixed structure to take aerials of each of the archaeological sheets they were reading, anticipating times to come were orthorectification can be better accomplished, but at the same time they recorded in paper the 3d provenance every artefact or biofacts, along with a little description of each piece. Those paper inventories were accompanied of carefully drawings were the findings were recorded according to a color code depending of their nature (flint, bone, seed, bead, ...). Planar coordinates (x, y) were referred to each square meter unit while the depth of the finding (z) was always referred to the same zero level.> Thanks to the careful fieldwork of Prof. J. Fortea and colleagues

we have been, first of all, able to gather all the findings in a relational database with spatial capabilities (postgis) and, secondly, to represent all of them in 3D with the aid of R -packages rgl, alphashape3d, akima, spatstat, foreign, VectStatGraphs3d, VectStatGraphs2d-, among others we have able to define zones of special interest due to three dimensional density of the findings. Even if a 3D representation of a forty year old excavation is good enough, what has been more crucial for us is the ability to reinterpret the stratigraphical sequence proposed then by Fortea, reinforcing in some points his interpretation but also challenging some of them. In conclusion, we have had a unique occasion to add value to several months of rigorous fieldwork giving sense to all the work made in 1970s by our colleagues. Our results, aside of helping us to have anew look to the neolithization process in the area, served to support rigorous fieldwork recording even in the lack of technologies. Now it is possible to record millions of points in a few seconds with laser scanners like Faro but the work done in the earliest 1970s by Prof. J. Fortea have shown the importance of a good record to will allow others to go back to the data later on time.

### 10. THE NEW ARCHAEOLOGY AND THE ARCHAEOLOGY OF AUSTRALIA.

*Murray, Tim (Faculty of Humanities and Social Sciences, La Trobe University, Melbourne, Australia) T.Murray@latrobe.edu.au*

In 1980 Murray and White (Tim Murray and J.P. White Cambridge in the Bush? World Archaeology 13(2): 255-263), found in the new archaeology of the 1960s the seedbed of approaches and methods that underwrote the development of prehistoric archaeology of the continent of Australia. The great themes of the new archaeology approach to hunter-gatherer archaeology laid out first by Binford and others, and subsequently by British archaeologists such as Eric Higgs and Mike Jarman, were highly influential, but then so too were what would now be described as positivist approaches to theory building and methodology flowing from the work of Binford and David Clarke. Thirty three years have elapsed since that first assessment and Australian prehistoric archaeology is much changed both in focus and approach. It is thus an excellent time to reflect on the inheritance of so much path-breaking research in the 1960s and 1970s, particularly the socio-political context within which prehistoric archaeology is practiced in Australia.

POSTER

**11. BEYOND THE THEORY: ?NEW ARCHAEOLOGY?  
IN MESOLITHIC STUDIES IN CANTABRIAN SPAIN**

*Cubas, Miriam (Instituto Internacional de Investigaciones Prehistóricas de Cantabria-Sociedad de Ciencias Aranzadi) mcubas@aranzadi-zientziak.org*

*Fano, Miguel Ángel (Universidad de La Rioja) miguel-angel.fano@unirioja.es*

One century ago, in 1914, research on the Mesolithic in the Cantabrian region started with the archaeological excavation of the site of El Penical by Count Vega del Sella. This marked the beginning of the research line whose theoretical approach has been modified from the historical-cultural paradigm consolidated in the first moment to the different approaches followed today.

The historical-cultural paradigm dominated the theoretical framework almost entirely until the 1960s and its principal aim was the establishment of the prehistoric chrono-cultural sequence in the region. Although the influence of this paradigm is still current today, the impact of New Archaeology could be observed from the 1960s onwards in Mesolithic as well as in Palaeolithic studies. In the case of the Mesolithic, this theoretical influence is significant through the research on the *Asturian* culture carried out by American and British archaeologists.

In this paper, we review the literature on Mesolithic studies in the Cantabrian region and the influence of New Archaeology in the development of this research.

The influence of the new paradigm involved the introduction of systematic surveying, excavations and sampling programs. In addition, the processual perspective involved the introduction of new study techniques, such as radiocarbon dating, sedimentology, and the use of statistics for the analysis of archaeological remains. Indeed, this approach implied the interpretation of the *Asturian* as a cultural adaptation. The concept of the culture as an adaptive system produced an interest in environmental reconstruction, subsistence and settlement patterns. This has led to the development of synchronic approaches, focused on one historical moment, without considering the dynamics of cultural transformations. Indeed, the study of the Neolithisation process is scarcely considered in processual archaeologists' research.

As a result, the influence of New Archaeology succeeded in overcoming the chronological problem related

to the chronology of the *Asturian*. Despite its impact in the western part of the Cantabrian region, processualism was not very influential in Mesolithic studies in the Basque Country. The effect of New Archeology has continued until today, through the importance of studies related to the economy, settlement patterns, etc., although this theoretical approach is a "re-formulation" of general systems theory. However, in the last decades of the 20<sup>th</sup> century we can observe studies within a diachronic perspective, focusing on research into the Mesolithic as a way to understand the Neolithisation process.

### 1. 3DI – ENHANCING THE RECORD, EXTENDING THE RETURNS, 3D IMAGING FROM FREE RANGE PHOTOGRAPHY AND ITS APPLICATION DURING EXCAVATION

*Powlesland, Dominic (Field Archaeologist in Residence, McDonald Institute of Archaeological Research, University of Cambridge Visiting/Honorary Professor, Universities of Leeds, York, Huddersfield and Vienna) d.powlesland@btinternet.com*

Changes in digital photography, games computing hardware and software developments over the last decade, have transformed the potential application of digital photography during excavation. Most particularly when applied to photogrammetry using Structure from Motion software for documenting structures and even landscapes as well as excavations in progress. Experiments undertaken by the Landscape Research Centre in Yorkshire over the last six years have revealed the potential benefits of using 3Di for recording excavations, in plan and in section, but unfortunately also provide an opportunity for field archaeologists to disengage with the recording process and diminish the returns from excavation. Like so many aspects of computing when applied in the field we can either enhance our potential to interpret the archaeology that we encounter, or use it to simply speed up our throughput and hide poor practice and limited observation. In many ways 3Di provides an opportunity for us to achieve the nirvana of archaeological recording, a record that is so detailed that we can truly re-examine excavations through their archived data. To do this, however, we need to apply the same levels of rigor and observation that we should to any part of the excavation and recording process and remember that new technology does not replace the eyes, touch and on site drawings but provides an opportunity to expand the record in a format that serves both the excavator and the public at large in a way that has never been possible before.

### 2. THE SCIENTIFIC ARCHAEOLOGICAL VALUE OF MANUAL 3D MODELING

*Lanjouw, Tijm (Leiden University) t.j.r.lanjouw@arch.leidenuniv.nl*

3D is hot now, but in 1985 it was even hotter. But there was no LIDAR, no high density point clouds, no ad-

vanced photogrammetric software, there was only manual modelling of 3D geometry using code. It was the subject of prestigious million-dollar projects dressed to impress. The immediate response of the 'sceptic archaeologist' was of course to question its actual scientific value. Some considered 3D modelers no more than sophisticated illustration tools while others embraced the new technology with enthusiasm, reciting its scientific merits ever since the early 90s. But it seemed hard to shed the stigma of 'pretty picture generators'. Then came the technology that allowed for high resolution 3D models. It really opened up new worlds and made new discoveries possible on all possible spatial scales. But what about the oldest of techniques, that of manual modelling: did it do the same? How has the technology been applied to the scientific good over the last 30 years? Are we maybe just talking about pretty pictures with some, albeit limited scientific value? Or did it change the game more than we think? Instead of presenting yet another 3D model, in this paper I will be looking back at how manual 3D modelling was used and perceived in the past and ask whether our thinking about it has made any progress.

ORAL

### 3. MULTI-SCALE APPROACHES USING INTEGRATED SOLUTIONS FOR 3D ANALYSIS OF PREHISTORIC SITES

*Muth, Xavier (Helimap System SA) xavier.muth@gmail.com*  
*Castel, Jean-Christophe (Muséum Histoire Naturelle de Genève) Jean-Christophe.Castel@ville-ge.ch*  
*Camus, Hubert (Prothée) camus.hubert@laposte.net*  
*Vallet, Julien (Helimap System SA) julien.vallet@helimap.ch*

Over the last decades, remote sensing technologies have become more and more powerful, and thus omnipresent even in civil applications. The data recorded are more reliable, extensive and accurate. In many applications, these technologies have become quickly essential. Here, we show what kind of information these new techniques can bring, what insight can be gained in prehistoric sciences, and why these new data sets are pertinent. Focusing on photogrammetry and LiDAR technologies, we evaluate their potential for the understanding of prehistoric sites and their surroundings.

The study area covers a couple of kilometers around Pech Merle Cave (Quercy, South West of France). It takes part in the scientific research on regional human settlement and fauna occupation during the upper paleolithic. The presented data acquisition presented focuses di-

rectly on two sites: Petit Cloup Barrat, a seasonal shelter which has been occupied at least during a large period from 24.000 to 16.000 BP, and Igue du Gral, a natural trap which gives a unique rich and large sequence of fauna bones between 30.000 and 10.000 BP.

However, as both sites are located in a karstic area (Parc Régional des Causses du Quercy), its understanding is very dependent on the karst comprehension itself.

An aerial survey, that covers both sites and more largely the Pech Merle area was conducted in July 2013. The Helimap System was used for this acquisition. It is composed of several sensors for high accuracy positioning (GPS antenna and Inertial Measurement Unit), a high-resolution camera and a LiDAR system for the simultaneous recording of images and 3D points clouds. For these ~500 ha covered by a flight at 300 m over the ground, the absolute positioning accuracy of the data is better than 5cm and the density of the obtained points cloud reaches 30 pts/m<sup>2</sup>. Additional tests have been done on cliffs area with an oblique configuration and thermal imagery. Moreover, both Petit Cloup Barrat and Igue du Gral sites have been digitized by photogrammetry and integrated into the global LiDAR model.

The obtained LiDAR data enables a very precise landscape analysis. The topography under vegetation is revealed. For this karstic region especially, the survey is even more relevant. The paleokarst visible on the surface can be clearly identified. Thanks to the high density of the points cloud, every hole on the surface wider than half a meter can be easily detected. Moreover, the integration of the cave models under the ground model provided by the LiDAR acquisition enables an easier analysis of the karst in concordance with the clues at the ground surface. The 3D reconstruction of the cave is also very useful to better understand the cave filling and thus, the spatial distribution of the bones.

Many other applications can be developed with photogrammetry at the site scale. These tools are essential not only for conservative purposes, but also for other applications such as, for example, the digitizing of geological section and the assessment of excavated volume.

ORAL

#### 4. THE USE OF 3D GIS IN ARCHAEOLOGICAL RESEARCH.

*Klinkenberg, Victor (Leiden University) m.v.klinkenberg@arch.leiduniv.nl*

Geographic Information Systems (GIS) have been an important tool for archaeologists for decades now. A promising recent development is the introduction of the third dimension in GIS. Many software developers have announced to have introduced a fully functional "3D GIS". However, although in these programs it is possible to display and transform spatial features in three dimensional space, formal methods of spatial analysis have not made the leap to 3D. Therefore, these 3D GIS cannot be seen simply as a 3D version of the conventional 2D GIS. I have used the 3D element of modern GIS software for several archaeological research projects. From these, it appears that the use of the third dimension in GIS analyses presents both clear opportunities and limitations which I will discuss in this paper. I will argue that the current use of the third dimension in GIS is an important step forward, albeit one of many steps on a path still ahead.

ORAL

#### 5. TOWARDS 3D GIS

*van Leusen, Martijn (Groningen Institute of Archaeology) p.m.van.leusen@rug.nl*

In December 2012 a joint session of the Dutch, German and Flanders chapters of CAA (Computer Applications and Quantitative Methods in Archaeology) considered the theme of 'Z-the third dimension'. In several papers and an extensive plenary discussion those present considered the feasibility and desirability of extending current 2.5D GIS capabilities into three spatial dimensions. This paper will present the main aspects of these discussions.

#### 6. 3D TECHNOLOGY IN PECULIAR SITE: THE LOWER GALLERY OF LA GARMA CAVE (OMOÑO, CANTABRIA, SPAIN)

*Maximiano, Alfredo (IIIPC. University of Cantabria) maximianoam@unican.es*

*Arias, Pablo (IIIPC; University of Cantabria) pablo.arias@uni-can.es*

*Ontañón, Roberto (Museo de Prehistoria y Arqueología de Cantabria; IIIPC. University of Cantabria) ontanon\_r@cantabria.es*

*Bárcia, Camilo (IIIPC. University of Cantabria) camilobarciagarcia@gmail.com*

Currently, the application of computational resources (Geomatics) is a widespread praxis as mediation to archaeological problems (i.e. recording, analysis and visualization of results).

In this communication we introduce a case study where a confluence of many computational resources in data capture (e.g. Total Station, Laser Scanners, Photogrammetry), analysis (Geostatistics, Rock art, Refitting, Taxonomy of archaeofaunal and Lithic...) and visual results (simulations, virtual scenes ...) are the best and only possible way to improve the quality of research based on the creation of 3D products.

The cave of *La Garma* is a Paleolithic site where original access to the cavity was collapsed sometime in the XV millennium BP. This isolation cut off from the outside and there is not any type of sedimentary process and any natural taphonomic events and/or concomitant anthropogenic activities linked with formation process dynamic. Therefore, it preserved *in situ* exceptional occupation floors (aprox 100.000 items, and 6 recognizable structures) (Ontañón 2003; Arias *et al.* 2011) and variety of rock art (paintings and engravings).

This so singular case involves the convergence between scientific research and diffusion of large and complex archaeological record (which have remained in their same places in the *Lower Gallery*) with the guarantee of preservation and dissemination of the prehistoric heritage to the lay public.

This situation makes indispensable the use of leading technology in 3D, nonintrusive data capture and analysis of archaeological evidences with the minimal impact over this exclusive archaeological heritage (It was included in the World Heritage List since 2008), and these practices are the reference vector from the first archaeological interventions that have been performing since the moment of its discovery (the late 90's of the XX century). In this communication we introduce several initiatives launched for the digital processing of all archaeological evidence, synthetically: Laser scanner technology was used for volumetric modeling of the cave; High resolution Photogrammetry for maximum details in occupations

floors; 3D Scanning artifacts *in situ* (lithic, archaeofaunal...); Non-intrusive method like: GPR, XRF; use of GIS platform like management geo-database and analytical tool (Maximiano *et al.* 2013)

All these activities allow us to work outside the archaeological site, from a digital and virtual environment (in our Lab) with different types of 3D models which we interact with thousands of entities compiled from the site (e.g. debitage, lithic objects, archaeofaunal, pigment, structures, fireplace, rock art...) At the same time, we are generating high quality metadata and a digital environment where we can replicate/simulate all sectors of the cave, analyze (Bárcia 2013) and interacting (Arias *et al.*; in press) with sets/collections of entities/objects without impairing to the archaeological heritage in the cave. As a result, preservation and minimal impact on these unique contexts is ensured keeping them unchanged for future generations and for improvements in research methodology that enables address problems with the current *state of technology* are not addressed.

*Elorza Arana, Artzai (Laboratório de Fotogrametria Arquitectónica (Univ. Valladolid) artzai.elorza@gmail.com*

*Gonçalves Seco, Luis (Centro de Investigação em Ciências Geo-Espaciais (Univ. Porto), Instituto de Ciências del Patrimonio, Consejo Superior de Investigaciones Científicas, Instituto Universitario da Maia) lgseco@gmail.com*

*Fonte, João (Centro de Investigação em Ciências Geo-Espaciais (Univ. Porto), Instituto de Ciências del Patrimonio, Consejo Superior de Investigaciones Científicas) joaofonte@gmail.com*

High-definition 3D digital models of objects, sites or landscapes are increasingly been made available to researchers and general public. Entire countries are being surveyed with airborne Laser scanning systems, extensive 3D digital artefacts collections are being built by museums, entire archaeological excavations are being

record in 3D. In brief, a lot of focus and effort is being put into 3D scanning for archaeological research. But are we benefiting from all the information that this data can deliver?

The most common approach for 3D scanning data visualisation has been to produce a mimesis of the way we see things in reality. Although allowing a good perception of shape and morphological detail in most cases, this technique is limited by the same constraints that archaeologists face in the real world sites: faded or damaged testimonies of anthropic activities are often very hard and tricky to perceive and interpret.

A recently developed technique, called Morphological Residual Model, tries to overcome this problem by transforming high resolution 3D scanning data sets into contrasted depictions of surface morphology, unveiling astonishing details of engravings that are not perceived by human vision even in controlled lighting conditions. To overcome some of the difficulties that 3D visualization presents for most archaeologists, a tool for visualizing MRM results within the Reflectance Transformation Imaging viewer (RTI) environment is currently being developed.

These techniques are currently being tested in the context of a research project on the open air rock art site of Monte Faro, in the region of Valença (north-western Portugal). As fieldwork developed, the assemblage extended from the four sites published in the 1980s and 1990s to over one hundred carved rocks. The large majority of sites exhibit cup-marks, cup-and-ring motifs and animal figures typical of the Iberian Atlantic Art tradition, either found in isolation or in complex arrangements.

The results achieved so far emphasize the ability of the MRM approach not only to reveal faded carvings but also as an innovative and effective way of depicting morphology.

#### ORAL

### 8. USING DIGITAL PHOTOGRAMMETRY TO PRODUCE 3D MODELS AT PREHISTORIC DITCHED ENCLOSURES: PERDIGÕES AS A CASE STUDY.

Caro, Jose L. (University of Malaga) [jlcaro@uma.es](mailto:jlcaro@uma.es)  
Márquez-Romero, Jose E. (University of Malaga) [jemarquez@uma.es](mailto:jemarquez@uma.es)  
Jimenez-Jaimez, Victor (University of Southampton) [V.J.Jimenez-Jaimez@soton.ac.uk](mailto:V.J.Jimenez-Jaimez@soton.ac.uk)

The Perdigões archaeological complex (Reguengos de Monsaraz, Portugal) is a prehistoric site near the Guadiana river, comprising at least 12 ditched enclosures, several hundred pits, an area with megalithic tombs and a set of standing stones (*cromeleque*). It is located in one of the richest archaeological landscapes of Iberia, with notable examples of Prehistoric monumental architecture such as menhirs and portal tombs (*antas*). A team from the University of Malaga (Spain) has been carrying out fieldwork in collaboration with the Portuguese entity ERA Arqueologia at the site since 2008. This includes geophysical (2008-2009) and microtopographical (2011) surveys of the whole site, as well as both open-area excavations (2012-2013) and trenches (2009-2010, 2013) in the area surrounding Gate 1.

Digital photogrammetry is an inexpensive computerised method that enables the creation of three-dimensional models from photographs using image pattern recognition. The technique can be employed during the process of excavation to better record the archaeological evidence, to generate 3D models of the stratigraphical units and to digitalise singular findings. It is also useful activities aiming to spread knowledge and awareness about the site. In this paper we will describe the basics of the method and its workflows, and three specific applications at Perdigões. Later, we will compare digital photogrammetry with alternative solutions for the digitalisation of cultural heritage, such as LIDAR and total station scanners with LASER.

Digital photogrammetry has been utilised in three separate aspects of research at Perdigões:

- Generating DTM (digital terrain models) of large excavation areas like that laid out by us around Perdigoes' Gate 1 (about 1000m<sup>2</sup>).
- Producing 3D models of different excavation trenches made on the site, e.g. a trench over Ditch 1.
- Creating models of outstanding findings, like small idols. This task is particularly difficult because of the small size of the objects.

Each of these purposes requires specific modelling techniques and workflows, namely equipment, software programs and techniques like photography, polygons, mesh and texture, all of which will be presented in this paper. Digital photogrammetry allowed the generation of a comprehensive model of the large excavation area around Gate 1 of Perdigões that would have been more difficult and expensive using other methods like LIDAR. This excavation recording has been used to obtain paleo-reconstructions of the site. Furthermore, digital photogrammetry has enabled the creation of partial 3D

models of the archaeological evidence, which can be later used in the process of analysis and knowledge dissemination.

Digital photogrammetry can help archaeologists in many ways, from digitalisation of archaeological contexts and structures in large areas to small artefacts. The resulting models are realistic in terms of looks and textures and can be used in a variety of activities, from recording to interpretation to public access.

ORAL

### 9. 3D MODELING BY DIGITAL PHOTOGRAMMETRY APPLIED TO THE PALAEO-LITHIC MAMMOTH BONE DWELLING SITE OF GONTSY (UKRAINE)

*Iakovleva, Lioudmila - (1. Institut d'Archéologie NAS Ukraine & UMR 7041 Arscan) [liakovleva@wanadoo.fr](mailto:liakovleva@wanadoo.fr)*

*Egels, Yves - (Institut Géographique National) [yves.egels@free.fr](mailto:yves.egels@free.fr)*

#### Résumé

La technique de photogrammétrie numérique a été utilisée pour obtenir une modélisation 3D de l'habitat paléolithique à cabanes en os de mammoths de Gontsy (Ukraine). La zone de l'habitat étudiée contient trois cabanes en os de mammoths, des fosses, des zones d'activités et des foyers. Les difficultés qu'il a fallu surmonter sont l'insuffisance de contraste (couleur du loess), la faible discrimination des objets (répétitivité des ossements de mammoths) et l'existence de nombreuses zones aveugles (superposition des ossements).

#### Abstract

The digital photogrammetry technique was used to obtain a 3D modeling of a palaeolithic settlement with mammoth bone huts in Gontsy (Ukraine). The processed settlement area contains three mammoth bone huts, pits, working areas and hearths. The difficulties that had to be overcome are the lack of contrast (color of the loess), the small discrimination of artefacts (repeatability of the mammoth bones) and the existence of many blind areas (overlay of the bones).

*Daire, Marie-Yvane (Laboratoire Archéosciences UMR 6566 CReAAH/Centre de Recherche en Archéologie, Archéosciences, Histoire, Bâtiment 24?25 Campus de Beaulieu, 263 Avenue du général Leclerc, Rennes, France) [marie-yvane.daire@univ-rennes1.fr](mailto:marie-yvane.daire@univ-rennes1.fr)*

At present, sea-level rise is one visible effect of climate change, and human activity is also threatening much coastal and island territory on a global scale. The vulnerability of coastal heritage is increasingly coming into focus, particularly in areas such as the European Atlantic façade, where the combined results of sea-level rise, coastal environment dynamics and human activity are significantly altering the coastline. In this context, one of the aims of the eSCOPES Project (*Evolving spaces: coastal landscapes of the Neolithic in the European Land's Ends*, Marie Curie-IEF) is to provide cost-effective tools for monitoring at-risk coastal archaeological sites.

The project uses close-range photogrammetric techniques ('Structure from Motion') to record, 3D model and monitor changes in the architecture of selected megalithic monuments in three areas of the European Atlantic façade: the isle of Coalen (Côtes-d'Armor, Brittany, France), the Pénestin peninsula (Morbihan, Brittany, France) and the isle of Guidoiro Areoso (Ría de Arousa, Galicia, Spain). The sites have been chosen taken into account their location in different environmental settings, their different structural characteristics and their high vulnerability.

In addition to the photogrammetric record, a 3D laser scanning has recently been performed in Guidoiro Areoso in order to provide a series of comparative reference models.

The project is still ongoing. Two fieldwork campaigns have so far taken place (September 2013 and February-

March 2014). As a result, we have obtained more than 1200 photographs for each site so far. Several palaeosols and structures associated with, or in close proximity to, the megalithic monuments have also been documented. A third and last fieldwork campaign will take place in September 2014. Some preliminary 3D models have already been obtained and are being object of in-depth analysis.

The use of close-range photogrammetry appears as a cost-effective way to efficiently apprehend coastal archaeological site erosion.

The comparison of the 3D models for each site (surface loss, quantitative analysis) will provide a three-dimensional quantitative and a visual estimate of the erosion rate for the archaeological sites, constituting a powerful tool for decision-making processes to inform best practice in managing coastal heritage.

Additionally, the detailed three-dimensional record of the selected case studies will also allow safeguard the potential for architectural analysis of the sites even in the event of severe damage or destruction.

## ORAL

### 11. IMAGE BASED MODELING AND LITHIC ARTIFACTS

*Chu, Wei (University of Cologne) wchu@uni-koeln.de*  
*De Reu, Jeroen (Ghent University) Jeroen.DeReu@UGent.be*

In recent decades, archaeology has been increasingly concerned with creating narratives of cultural behavior through the lens of stone tool residues. Macroscopic stone tool systematics, however, have remained largely unchanged since the early part of this century as researchers continue to rely on visual typologies, basic classificatory forms, and simple orthogonal measurements to draw conclusions. Though three-dimensional (3D) analysis has become *de rigueur* in other areas of archaeology including site excavation, fossil reconstruction, and heritage management, its application to the stone artifact record has remained limited in spite of clear analytic potential. Despite the ambition of some modern archaeologists to apply 3D recording techniques to new archaeological finds or to the reassessment of key sites and assemblages, the capital and time required as well as the complexity of 3D registration methods (i.e. laser scanning, structured light scanning, and computer tomography) have severely limited its broad application.

Recently, however, image-based 3D modeling, a technique for recovering 3D shapes and appearances of objects from 2D images, has demonstrated itself as a low-cost alternative to traditional methods. It requires little more than a digital camera and low-cost or open source software packages. Our results show that image-based 3D reconstruction can be an accurate cost-effect alternative to range based methods. Overall, this suggests that image-based 3D reconstruction can be highly useful in the analyses of lithic material from a wide range of geographical and chronological contexts.

## POSTER SESSION

## POSTER

### 12. GEOMETRIC DOCUMENTATION AND DIFFUSION OF THE ROCK-ART IN THE MOUNTAIN RANGE OF ALBARRACÍN (SPAIN): ARAM PROJECT.

*Angas, Jorge (3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza) j.angas@3dscanner.es*  
*Bea, Manuel (PostDoc Researcher "Torres Quevedo", 3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza & MINECO. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza) manubea@unizar.es*

Rock-art is one of the fields works that brings the most difficulties in its documentation, both geometric and graphic. The main difficulty is the importance of the objective register of each painted or engraved motif, as well as its relationship with the geometry of the place and substrate where they were created. This point is very important, because the reliable reproduction of the graphic and metric character allows us to research and explain the semiotics of each rock-art group.

In recent years, there have been important results that have enabled the improvement of the quality of graphic documentation of the decorated sites, with very notable progress in 3D documentation of rock-art. This improvement of data acquisition allows the perfect presentation and also a "real" perception of the represented works. Nevertheless, there is not yet a methodological standardization that we can use to document, to research, to spread and to preserve rock-art. On the other hand, the proliferation of new technologies and methodologies for document and spreading of Cultural Heritage in general has been quite relevant, and rock-art in particular, as

a constant in the last few years, evolving in time with the available technology.

In the latest three years, we have applied our own documentation methodology on 15 rock-art shelters from Albarracín, Bezas and Tormón. We developed a register system that combines the data acquired by 3D scanning technology (structured white light, time-of-flight, phase shift), photogrammetry, high-resolution spherical images both terrestrial and aerial and, finally, their organization by metadata.

The principal result of this research has been to contribute in a different concept for the registration, analysis and appreciation of rock-art allowing us a more exhaustive exploitation of the graphic and metric documentation. Additionally, it contributes to the gradual change towards the tri-dimensional graphic representation by using new digital supports.

A large part of the obtained information has been processed in order to create new products to improve the impact of the spreading by using a web platform. So, the documentation generated has been transformed and uploaded to the *RAMA Project: Rock-Art and Multimedia Accessibility* web page (<http://proyectoaram.tecnitop.com/>). The owners of this website want to open a digital platform where a large number of documented rock-art sites (Palaeolithic, Levantine and Schematic) as a nexus between different cultural areas in the Iberian Peninsula, can be exposed.

POSTER

### 13. FROM PENCIL TO 3D VIRTUAL MODEL. THE BREWERY FROM TELL EL-FARKHA, EGYPT.

*Rosinska-Balik, Karolina (Institute of Archaeology, Jagiellonian University in Krakow, Poland) k.rosinska.balik@gmail.com*

*Debowska-Ludwin, Joanna (Institute of Archaeology, Jagiellonian University in Krakow, Poland) joanna.debowska-ludwin@uj.edu.pl*

Methods and techniques of field work documentation are constantly being improved. In the era of visual media, it has become necessary to upgrade traditional drawings and records of structures unearthed during archaeological prospection. Documentation process of excavated sites has always been crucial especially when a considered feature, accordingly to specific destructive character of archaeological examination, is accessible to

researchers for limited time. Parallel to graphic and visual improvement go possibilities of data interpretation. The new way of view produces not only eye-catching images but it could be a great resource for further consideration, testing hypotheses or research result presentation. In my paper I would like to present development in documentation techniques implemented during over 15 years of excavation at the Tell el-Farkha site in Egypt. This Pre- and Early Dynastic site gives great opportunities since different types of features are registered on it starting from domestic structures at a settlement area, through industrial installations and ending on graves. I would like to focus on some specific structures discovered over the time – breweries. Several examples of these devices were recorded at the site and during the passing years they were documented in various styles. The goal of my paper is to present them all with all their pros and cons

POSTER

### 14. 3D MODEL OF THE SITE STRATIGRAPHY AS A RESEARCH TOOL

*Urbanowski, Mikołaj (Szczecin University, Institute of History, Archaeological Department) m.urbanowski@univ.szczecin.pl*

Since the beginning of the scientific archaeology the excavation is regarded to be an unidirectional research tool. Although this general opinion is still true, the capabilities of a 3D stratigraphic documentation significantly limit the necessary data loss and allow to virtually re-excavate the site as many times as it will be necessary.

The excavation of Late Middle Palaeolithic site in Stajnia Cave, Poland (N 50° 36'58,28", E 19° 29'04,24"), where conducted by the author so that it was possible to create a kind of photographic tomography of the site, which was cut into numerous plans and sections. Such methodology slowed the excavation, although it didn't disturb precise attribution of the finds to the stratigraphic unit, as well as to measure their 3D position within the site. All the partial photos were combined into a mosaic full-scale pictures, which were subsequently converted into a textures for the 3D model of the site stratigraphy. The model was enriched with the result of the 3D scanning of the site, which allowed to complete the model of the cave and its infillings.

The effects of the usage of such research tool fully rewards the time and effort which was invested during

the excavation. The possibility of visualisation of the subtle interfaces between the layers, which from definition are three-dimensional, thus difficult to trace in two-dimensional traditional documentation, allowed to make a very precise stratigraphic interpretation. For the sites like Stajnia, where the stratigraphy is heavily distorted by the cryoturbation, such tool is invaluable. After creating meshes from all the layers, it is also possible to create artificial cuts of the sediments in places of the site where it was not possible during the excavation. After several years of usage of system of documentation and visualisation it became a must-have-solution for the whole research team involved in research in Stajnia

POSTER

**15. QUICK 3D RECORD: A LOW-COST METHOD OF DOCUMENTATION AND ANALYSIS OF SCATTERED ARCHITECTURES IN THE EMCHAHE PROJECT**

*Mañana-Borrazás, Patricia (Institute of Heritage Sciences, Spanish National Research Council) patricia.manana-borrazas@incipit.csic.es*

*Blanco-Rotea, Rebeca - (Technological Research Institute, Santiago de Compostela University) rebeca.blanco.rotea@gmail.com*

*Sánchez-Pardo, José Carlos (Santiago de Compostela University) josecarlos.sanchez@usc.es*

This work makes part of the Marie Curie CIG *EMCHAHE project: Early Medieval Churches: History, Archaeology and Heritage* (2013-2017), lead by José Carlos Sánchez-Pardo at the University of Santiago de Compostela (Spain). The research area of this project is the archaeology and history of the early medieval rural churches and their value for cultural management in Galicia (Northwest Spain). The project has two major goals. First, to generate new archaeological/historical knowledge on the social dynamics in such a peripheral area of Europe during the period of transformations that goes from the end of the Roman World until the peak of the feudal system (5th-11th centuries) by means of the study of the remaining evidences of the religious buildings of this period. Second, to learn how to re-direct all this knowledge towards a proper and effective management and communication of the important and rather unknown heritage value of the remains of these buildings: architectural, archaeological (unearth or visible), artistic, documentary or even toponymic. Both objectives are interrelated since only an adequate historical knowledge allows a correct heritage management.

EMCHAHE is a project with several methodological challenges that we must face with limited resources. One of these challenges is the territorial scale, which involves the analysis of a large number of sites scattered through three rural areas of Galicia. This dispersion increases the problems and the cost of the access and the study of each church. Another one is the difficulty of identifying and analysing evidence of early medieval phases in the churches due to the frequent existence of several reforms and reconstructions. Therefore, it is necessary to apply a church documentation method as agile in field as accurate enough, which allows recording the graphic and geometric information necessary for a detailed study (stratigraphic analysis of the walls, identification of architectural elements, etc.) with the lowest cost.

The poster will summarize the workflow and results of this quick and low-cost record of scattered churches proposal. Close-range photogrammetry is a low-cost technique that allows a correct, accurate and detailed record of each church, basis for visualizing, analyzing and representing the architectonic features and the creation of 3D models and reconstructions. After several months of fieldwork and post-processing, we have developed an specific and well-adapted work system for this project. This has allowed us to document a high number of churches and to speed up the work in relation to other methodologies.

The project is still ongoing, but we have some methodological conclusions. The most important, we are now able to create a digital copy of the building using photogrammetry and make the field documentation agile and accurate. This digital copy can be used later to make decisions or recover information without returning to the place. It can be also used as basis for heritage outreach, the presentation of the results and reconstruction hypothesis that include not only the 2D stratigraphy but the volumes of the ancient buildings that have survived in the interior of the current churches.

**16. WHAT CAN WE FIND ON A MANDIBLE? 3D IMAGING OF AN EPIGRAVETTIAN ART OBJECT FROM GROTTA PAGLICCI (FOGGIA, SOUTHERN ITALY).**

*Moretti, Erika (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - Università di Siena) erykamor4@gmail.com*

*Arrighi, Simona (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - Uni-*

*versità di Siena) s.arrighi@hotmail.com*

*Boschin, Francesco (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - Università di Siena) fboschin@hotmail.com*

*Crezzini, Jacopo (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - Università di Siena) crezzini@unisi.it*

*Ronchitelli, Annamaria (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - Università di Siena) annamaria.ronchitelli@unisi.it*

In this work we tested the application of 3D microscopy to technological analysis of artistic engravings on Palaeolithic mobiliary art objects. The aim of this research is to understand the technical and artistic procedures followed by prehistoric artists. Here we analysed an unpublished right mandible of *Bos primigenius* (auroch), coming from the portable art assemblage of Paglicci Cave (Foggia, Southern Italy). This site shows an artistic production of exceptional importance that offers an essential record about Paleolithic mobiliary art in Italy (from Gravettian to Final Epigravettian). The studied mandible, coming from Evolved Epigravettian layers, displays an engraved motif of difficult interpretation.

Before studying the archaeological piece we produced an experimental programme in order to compare archaeological data with those obtained through replication under controlled parameters. We produced a set of experimental engravings on bone using burins and not retouched blanks. The experimental and archaeological engravings were analysed by means of a Hirox 3D Digital Microscope KH-7700. Cross sections from the median part of each groove have been observed and metrical parameters have been collected (depth, breadth at the floor and breadth at the top of the groove). In order to describe the shape of each cross section the ratio between the breadth at the top and the breadth at the floor, as well as the ratio between the breadth at the top and the depth of cut marks have been calculated.

Results of the analysis revealed that the overall contours of the figure was engraved first, while engraved lines inside were added afterwards. The experimental data pointed out that the morphometric analysis reveal no discriminating characters between the engravings produced by burins and those produced by not retouched blanks; on the other hand the micromorphological analysis showed a clearer context, where we can characterize the engravings produced by the two kinds of tool. The analysis of archaeological piece revealed a high homogeneity of the micromorphological and micromorphometrical data, feature which suggests the use of a single

tool in the realization of the figure, probably a burin. In addition to it the morphometric data collected on the mobiliary art object were compared with those collected on a sample of cut marks from the same site. Significant differences were found between the two samples: in particular the cut marks cross-sections are V-shaped, whilst the art object is characterised by U-shaped engravings. As regards the micro-morphological data, this research seems to give good indications for the detection of parameters that allow us to recognize the kinds of tool used for engraving. The application of 3D microscopy reveals new perspectives for the identification of techniques and gesture of prehistoric artists. Finally, the differences found between the art object and the cut marks are of great interest for developing protocols able to separate between butchering marks and engravings of dubious origin.

Ojo Guareña Karstic Complex is one of the biggest interconnected cave systems in Spain of 110 km long. It contains an impressive archaeological record of human activities from Upper Pleistocene, and it was listed in 1970 as Spanish Cultural Heritage. The diversity and variety of passages and sites include living areas cave vestibules,

rock art, human bones, grave goods or archaeological objects inside passages. Among these sites, the human footprints site of the "Sala y Galerías de las Huellas" is one of the most singular and vulnerable archaeological sites of Ojo Guareña karst.

The Sala and Galerías de las Huellas form a network of passages located inside the slope of Circo San Bernabe, at 1250 m westward from Cueva Palomera entrance. In 1969, an important set of well-preserved human bare footprints were found, preserved in the soft clay sediments of the floor. Due to difficulty of combining the documentation and preservation of these footprints, the study of this site has not been possible until the advance of new non-invasive remote sensing techniques.

In this work, we show the preliminary works carried out since 2012, focused on the accurate three-dimensional reconstruction of the human footprints site, using non-destructive 3D laser scanner methods and GIS techniques. The latter allow us to analyze the tracks and the characteristics of the human group who explored this cavity during the Prehistory. These works have been carried out combining 3D laser scanner technology with GIS methodologies, obtaining a model of the cavity floor, where the footprints and their internal morphology can be observed in detail. Currently we have identified more than 900 prehistoric human footprints and at least 16 distinct tracks, which could belong to around 8 individuals.

### 18. 3D NUMERICAL SIMULATION OF A FIRE IN A SIMPLIFIED GALLERY OF THE CHAUVET-PONT-D'ARC CAVE

*Lacanette, Delphine (I2M UMR 5295) lacanette@enscbp.fr  
Ferrier, Catherine (PACEA UMR 5199) c.ferrier@pacea.u-bordeaux1.fr*

*Mindeguia, Jean-Christophe (I2M UMR 5295) jean-christophe.mindeguia@u-bordeaux.fr*

*Debard, Evelyne (Université Lyon 1 - Département des Sciences de la Terre) evelyne.debard@univ-lyon1.fr*

*Kervazo, Bertrand (CNP Périgueux - PACEA UMR 5199) bertrand.kervazo@culture.gouv.fr*

The Chauvet-Pont-d'Arc cave located in the South-East of France shelters numerous fire marks on its walls (flakes, rubefaction, soot deposits). Hearths have been rearranged, and it is difficult to find the position of the fireplaces corresponding to the marks on the walls. Yet this information would be important to give interpre-

tations of the function of the fires and to check which behaviours were possible near the fires. Unfortunately it is impossible to reproduce the fires in this environment. We propose to use 3D numerical simulation of a fire burning in a volume like the Megaceros gallery of Chauvet-Pont-d'Arc to check whether it was possible or not to stay near the fire.

We use a Computational Fluid Dynamics code to simulate the combustion and the smoke transport. Fire Dynamics Simulation (FDS) is an open source code developed by the National Institute of Standards and Technology (NIST) in the United States. The methodology has been validated on an experimental fire in an underground quarry (LaScArBx IThEM program). The numerical data for the temperature on the wall of the fire, and for the carbon monoxide rates at the entrance of the quarry were compared to the experimental ones with a good agreement. The observations contributed also to the validation, as the smoke transport was video recorded during the experiment and matched with the simulations.

Temperatures at the wall near the fire exceed 300°C, i.e. the temperature of rubefaction of the limestone. This red colour is actually observed in the cave in these areas. Besides, simulation shows that smokes loaded with soots are concentrated in the upper parts of the domain. Observations by geoarchaeologists in the cave have located the soot deposits in the upper parts of the Mégacéros gallery.

Moreover, the highest concentrations of the toxic gases are also found numerically at the vaults of the gallery. The Fractional Effective Dose (FED) is a parameter commonly used in toxicology. It evaluates the exposure time available to escape from a place in fire or to survive post exposure. It provides valuable data of the possible behaviours of people in the environment of a fire.

The numerical results, corroborated with the observations in the Chauvet-Pont-d'Arc cave, showed that it was possible to stay near a fire, in the lower parts of the gallery.

3D numerical simulations have shown it was possible for Palaeolithic men and women to put additional wood to the fire during the burning, and to circulate around it, provided they have stayed in the lower parts of the galleries. The upper parts concentrate the heat and the toxic gases.

These first simulations on a simplified geometry have given valuable qualitative results. In order to go further

with quantitative ones and to get more precise information, we will integrate the precise geometry of the cave, based on its 3D numerical modelling. Furthermore, we will try several positions for the hearths, in order to identify which original position led to which mark on the walls.

**1. UNDERWATER RESEARCH OF THE MIDDLE PALEOLITHIC IN DALMATIA, CROATIA**

*Karavanić, Ivor (University of Zagreb, Faculty of Humanities and Social Sciences, Department of Archaeology) ikaravan@ffzg.hr*

*Zubčić, Krunoslav (Croatian Conservation Institute) kruno.zubcic@gmail.com*

In recent years, work on Middle Paleolithic sites in Dalmatia (south Croatia) has intensified. It focuses on several cave sites, an open air, and an underwater site, as well as on land and underwater survey of particular parts of the region. This research is funded by Croatian Science Foundation, Ministry of Culture of Republic of Croatia and the University of Zagreb.

Kaštel Štafilić - Resnik is Middle Paleolithic underwater site at the depth of about 4m. Small scale underwater excavation and systematic collection of surface finds at this site using a grid have been ongoing since 2008. In 2014 underwater survey of some parts of Dugi island was also carried out. The methodology and preliminary results of underwater research of the Middle Paleolithic in Dalmatia will be presented on a poster.

The site of Kaštel Štafilić - Resnik represents elements (lithics) from one or several open-air habitation sites from the time when the sea level was considerably lower than today. Stone tools, pseudo-tools and numerous naturally broken pieces of local chert were found. All artifacts belong to the Mousterian industry, and there are also indications of the Levallois technique. Although the finds are disturbed (due to the action of waves and other factors) it seems that their accumulation is mainly not a result of displacement from another locality that was far away from the present site. However, only some of the finds may have arrived to their present position through erosion from another place.

It is vitally important to continue with this research in order to get a more complete picture of the area occupied by the Paleolithic people and their mobility patterns. We hope that this will allow a comparison of the land sites with those now under water, a reconstruction of formation processes of underwater sites, and further improve methodology of research of such sites.

*Vos, Peter (Deltares), Jorn Zeiler - abone@planet.nl (Archeobone) Peter.Vos@deltares.nl*

In November 2011 archaeologists of City of Rotterdam Archaeological Service (BOOR) conducted underwater research in the Yangtze harbour, Rotterdam Maasvlakte, The Netherlands. The research was commissioned by the Port of Rotterdam Authority as a result of the expansion of the Rotterdam harbour area and was supervised by the Cultural Heritage Agency of the Netherlands.

The results of geological, botanical, zoological and archaeological analyses of the retrieved material generated new information on the occupation of a relatively high river dune by Mesolithic hunter-gatherers, and on the development history of the surrounding landscape ca. 9,000 years ago.

Rather than using diving techniques the underwater investigations were carried out from a board of a vessel using a wire-operated, horizontal closing grab. Three small trenches (total area ca. 375m<sup>2</sup>) were excavated in layers in a fairly controlled manner. This kind of underwater excavations cannot achieve the same level of precision as is possible on land, but the many soil core samples

taken in the project's preliminary phase allowed detailed descriptions of the geomorphological stratigraphy. The excavation resulted in 316 bulk bags of soil. This soil was sieved on land, using sieves with mesh sizes of 10 and 2mm, after which archaeologists and volunteers carefully sorted the residues, documenting a total of ca. 46,000 finds. 68 soil sub-samples were taken from the bulk bags for archaeobotanical analysis.

Remains of Mesolithic occupation were discovered at all three grab locations, from depths ranging between 18 and 20m below modern MSL. The finds span the age range from ca. 8400 to 6500 BC, when the site transformed from dryland (an inland dune) to wetland (drowned delta subsurface). At the foot of the inland dune, the conditions allowed for excellent preservation of organic material, such as bone, charcoal and plant food remains, as well as stone and flint artefacts. As a consequence, the site has offered a major contribution to our knowledge of subsistence economy during the Early and Middle Mesolithic in temperate Europe. Furthermore, much detailed information on local environmental conditions and landscape development was to be revealed.

The landscape ecotones around the site yielded abundant food resources on and around the river dune. Under the influence of rising sea levels the Rhine/Meuse river valley gradually transformed into the mouth area of those rivers. At 6500 BC, the site was finally transgressed: drowned in an estuary and swallowed up by the sea.

The Rotterdam Yangtze Harbour research project demonstrates the preservation of Mesolithic sites along the river Rhine, at depths in nowadays coastal and offshore areas. Furthermore, it demonstrates the feasibility of archaeological investigation of such submerged sites, even at depths between 18 to 20m beneath sea, lake and harbour floors. Never before had such a submerged Mesolithic site been excavated at such a great depth. The scientific report (in English) will appear in the autumn of 2014, providing a full description of all finds as well their landscape context.

### 3. THE DWELLINGS SITES OF MARANHÃO, BRAZIL

Guida Navarro, Alexandre (Universidade Federal do Maranhão, Brasil (UFMA) [altardesacrificios@yahoo.com.br](mailto:altardesacrificios@yahoo.com.br))

We are developing the project "The People of the Waters: the *estearias* of north-central portion of the Baixada

Maranhense". The *estearias* were dwellings sites which were built with wooden pillars that served as support for higher buildings. They are located in the lowlands of a micro-region near the island of São Luís, Maranhão, and they comprise an area of approximately 20 000 km<sup>2</sup> within the Legal Amazon, being a region with over 500 thousand inhabitants (IBGE census 2006). It is a very poor area with the lowest life indices not only of the State of Maranhão, but Brazil as a whole, whose population lives from subsistence traditional agriculture, fisheries, small livestock and vegetable extraction, especially the *baçaú* coconut. The main cities in this area are Penalva, Viana and Santa Helena. The *estearias* are located along the many lakes that are characterized by the formation of a compound water system of rivers, floodplains and lakes of varying sizes that are defined by the seasonality of weather.

To create the archaeological letter we are conducting a systematic study of the geographical area comprised by *estearias* of the north-central portion of Baixada Maranhense. We are realizing intensive survey in the region with the aim of recording and cataloging the sites with GPS and GIS (Geographical Information System). After cataloged the sites, we will create a database to understand the process of occupation of the lakes and its expansion in the surrounding area.

To create the archaeological letter we are conducting a systematic study of the geographical area comprised by *estearias* of the north-central portion of Baixada Maranhense. We are realizing intensive survey in the region with the aim of recording and cataloging the sites with GPS and GIS (Geographical Information System). After cataloged the sites, we will create a database to understand the process of occupation of the lakes and its expansion in the surrounding area.

The investigation of the processes of human occupation in allied *estearias* analysis of cultural material will build a cultural landscape of these populations, their relationship with the aquatic landscape and the built environment and the dispersal area:

- 1 . Who were the prehistoric societies that inhabited the lake regions?
- 2 . Why people chose the lacustrine environment to live?
- 3 . What the exact area of the land occupation?
- 4 . Did exist long distance trade?
- 5 . When did collapse these people and why?

ORAL

**4. THE CASE-STUDY OF VILLAGGIO DELLE MACINE:  
A REFLECTED IMAGE OF THE PAST**

*Angle, Micaela (Soprintendenza per i Beni Archeologici del Lazio) micaela.angle@beniculturali.it*

*Achino, Katia Francesca (Universitat Autònoma de Barcelona) katiаfrancesca@libero.it*

*Cerino, Pamela (Università degli Studi di Tor Vergata) pame-la.cerino@gmail.com*

The site of Villaggio delle Macine, dated to the Latest Early Bronze Age - Early Middle Bronze Age (XIX-XVI BC), is an exceptional case of pile-dwelling for the central Tyrrhenian Italian area, for its available datasets and estimated width (about one hectare). It was recovered across the shore of the volcanic Albano Lake in 1984 and subsequently investigated, firstly through underwater analysis and subsequently through surveys and limited excavations. A drastic progressive lake's water drop due to climatic factors and uncontrolled water-takings led to the emersion of the site. This condition favoured the archaeological research, although the change of anaerobic state caused some preservation issues for both organic items and stratigraphy.

At Villaggio delle Macine many different features have been found, such as piles, pottery, bronze artefacts (axes, daggers, swords and instruments), lithic industry (lithic cores, flakes and *débitage*), bones (also bone industry, such as deer bones carved to obtain axe handles and awls), ambers and glassy faïence, seeds and fruits, clay fishing weights and a large amount of millstones and grindstones (from which the site's toponym derives). In order to understand the natural and cultural formation processes of the settlement preliminary geological, palaeoecological and archaeological researches were carried out; furthermore, taphonomy and post-depositional processes which deformed the archaeological record are currently under study, through an ongoing analysis of the site's abandonment plan. Because of the high variability showed by material consequences of social past actions, a multidisciplinary approach seems essential to reconstruct the most likely prehistoric/Bronze Age scenario.

The aforementioned markers allow to underline the different specialised activities carried out in some functional areas; the studies of game remains, fruits and seeds discovered in the settlement show that the site had a subsistence economy, based not only on summer-autumn agricultural productions (cereals and leguminous

cultivation) but also on collection activities (semi-domestic and wild fruits), hunting (in particular deer and roe), breeding and fishing. Furthermore, the material results of some handcraft activities have been identified, such as crop blending and milling, the treatment of game, as well as food consumption, preservation and cooking; finally, some sectors are hypothetically defined as ateliers, due to the presence of all *chaîne opératoire's* stages of lithic industry.

These interesting preliminary results show the potential of the site, although its study is still in progress. Hence, through a multidisciplinary approach, which integrates and combines all the aforementioned markers, a more precise idea of the role that the villag itself used to have will be developed. The preservation of organic items such as poles can give an additional contribution to the analysis, for example through the application of dendrochronological techniques, which have recently started to be undertaken. Furthermore, through the ongoing study of the site's abandonment plan, we should proceed to observe the material effects of the biasing factors (post-depositional processes and taphonomy) which affect and deform the distribution and density of the archaeological record.

ORAL

**5. WET SITES ARQUEOLOGY: THE CASE OF BACELINHO CAVE (ALVAIÁZERE)**

*Figueiredo, Alexandra (Instituto Politécnico de Tomar, Laboratory of Archaeology and Conservation of Underwater Heritage, Geociencias Center, Portugal) alexfiga@ipt.pt*

*Monteiro, Cláudio (Universidade de Trás-os-Montes e Alto Douro, Portugal) claudio.monteiro.cr@gmail.com*

*Farias, Deisi (Universidade do Sul de Santa Catarina, Brasil) deisiarqueologia@gmail.com*

*Tognoli, Anderson (Laboratory of Archaeology and Conservation of Underwater Heritage, Geociencias Center, Portugal) ar.tognoli@gmail.com*

The Bacelinho Cave is a mine cavity with traces of the classic era exploration, located in Alvaiázere, Central Portugal.

Its high humidity and extension, over 500m<sup>2</sup>, led to the closure of a set traces of the actions of soldiers and slaves who worked in the exploration of ore.

Among the recovered objects stand out some important artefacts, like Roman weapons, including two swords in iron and other elements of attack.

The working methods in their exhumation, and humidity due to the state of the archaeological site where they were discovered, and the conservation techniques employed in its, form part of the disciplinary scope of Underwater Archaeology. In this sense this article is intended to serve as a reminder of the importance of experience and knowledge of the behavior of objects in wet or underwater sites in all cave excavations, often neglected by the authorities and teams that have only terrestrial expert in their composition, usually caused by the association of this discipline to the river or sea nautical archeology.

In this sense the concept of underwater archaeology have to be rewritten given to the wet sites also an prominent place, because of the set of traces that can be lost without this expertises. Also it seems to discuss the importance of this discipline in all graduated courses conducting the future archaeologists to a knowledge that even if they are not linked to nautical archeology or diving, may need to employ in a multiplicity of sites where high humidity sign.

So with this paper and starting with the case of Bacelinho Cave we propose to discuss the problematic of the methodology and the thecnics applied to the archaeology wet cave places.

ORAL

## 6. THE HISTORICAL PORT: THE GENESES OF PORT ACTIVITY IN SOUTHERN BRAZIL

*Márcia Fernandes, Rosa Neu (Universidade do Sul do Brasil)  
marcia.neu@unisul.br*

Até o século XVIII toda iniciativa de ocupação do sul do Brasil era planejada com objetivo de consolidar a expansão do território colonial. Após a independência houve a intensificação de ações empreendedoras coloniais de iniciativa privada, principalmente no Sul do Brasil. Nesse sentido, os portos foram fundamentais para a ocupação e a formação do território. No entanto, alguns Portos que possuíam grande movimentação de cargas e pessoas, no século XVIII e XIX, perderam sua competitividade, principalmente pela evolução no tamanho dos navios. Esse fato trouxe graves consequências para a população dessas cidades. A presente pesquisa focou nos Portos históricos do Sul do Brasil: Antonina - Estado do Paraná, Laguna, - Estado de Santa Catarina e Pelotas - Estado do Rio Grande.

A metodologia de pesquisa empregada foi pesquisa documental, na qual agregou-se materiais ou documen-

tos primários (sem tratamento analítico) e nas fontes secundárias de primeira e segunda mão dos próprios arquivos dos portos históricos.

Os resultados apontam para cidades portuárias empobrecidas, mas com um passado muito rico. Foram entrepostos comerciais importantes e desempenharam um papel relevante para a historia do Brasil. Atualmente todos os três portos apresentam dificuldade para manter a regularidade na movimentação portuárias, fato que se reflete na economia regional.

Estes portos apresentam atualmente pequena movimentação de carga, mas poderiam representar grandes possibilidades de redução de custos de transportes. Podem funcionar como portos específicos, como pontos centrais no interior e serem alternativas na flexibilidade com relação ao serviço marítimo num contexto global, pois alguns portos alcançam o status de porto concentrador (hub port), enquanto que outros cumprem serviços de alimentação (feeder port).

Os portos são geradores de crescimento local, mas requerem investimentos constantes capazes de atraírem outras atividades econômicas e ampliem a capacidade produtiva de uma região. Em suma, os portos de Antonina, Pelotas, Laguna e Porto Alegre têm grande significado para as economias locais. São áreas que representam grande campo de pesquisa para arqueologia subaquática, principalmente pela intensa movimentação que apresentaram durante a formação do território brasileiros e por armazenarem, no fundo do seu leito, resquícios do rico e recente passado.

## 7. ARCHAEOLOGICAL CHART OF SHIPWRECKS SITES OF BAÍA DE TODOS OS SANTOS, SALVADOR - BAHIA - BRAZIL

*Gusmão, Daniel Martins (UFS) dmgusmao@yahoo.com.br  
Rambelli, Gilson (UFS) gilson.rambelli@gmail.com*

The Baía de Todos os Santos ( BTS ), located in State of Bahia, Brazil, considered the second largest bay in the world, with a surface of 1,233 km<sup>2</sup>. It was the scene of the Greats Voyages, in 16th century and remains the important scene of maritime historical events until today. Memorable shipwrecks of different flags that happened in these waters, approximately two hundred forty records of shipwrecks were cataloged, of way systematic by the Brazilian Maritime Authority. What makes BTS a

place of great archaeological potential for research in aquatic environment

The Baía de Todos os Santos ( BTS ), located in State of Bahia, Brazil, considered the second largest bay in the world, with a surface of 1,233 km<sup>2</sup>. It was the scene of the Greats Voyages, in 16th century and remains the important scene of maritime historical events until today.

Memorable shipwrecks of different flags that happened in these waters, approximately two hundred forty records of shipwrecks were cataloged, of way systematic by the Brazilian Maritime Authority. What makes BTS a place of great archaeological potential for research in aquatic environment.

Over time various types of instruments have been created to support the navigation, especially when related the management and protection of coasta , marine and river area . Portulanos, sea ??routes, nautical charts, in this case, are historical documents of first order, to know and interpret the landscape of the past and the heritage elements associated with them.

To this, this research will analyze the Nautical Charts seeking to give a view this archaeological potential existing in the Baía de Todos os Santos. Culminating in instrument management and protection of submerged archaeological sites, like the remnants of shipwrecks such as the remains of Scottish clipper Black Adder, wrecked in 1905.

In the last years many nations have adopted by the UNESCO General Conference in 2001 for the Protection of the Underwater Cultural Heritage as a normative instrument that favors the in situ conservation as a first measure to be taken. Stimulating international cooperation in study of "traces of human existence having a cultural character, historical or archaeological, that are partially or completely, periodically or continuously, for at least 100 years." This way, the results obtained in development this research will encourage the adoption by Brazil, according to the UNESCO Convention.

Based on the assumptions of the International Hydrographic Organization (IHO) that conduct the production of nautical charts for over eighty member countries and has as a main objective ensure that all the seas, oceans and inland waters of the world were studied and mapped . The considerations of this research still in evolution, are based in studies of formation processes of archaeological shipwreck sites, that according with your historical valuation by society left to be defined as "hull

shipwrecked". Is conceptualized a new proposal to IHO the are "Historic wrecks", places that should be protected from interventions unauthorized indicated in nautical charts through a specific symbology contributing to the management and protection of underwater cultural heritage.

ORAL

## 8. UNDERWATER ARCHEOLOGICAL CHART OF SERGIPE: PROTECTION AND MANAGEMENT OF CULTURAL HERITAGE IN UNDERWATER SERGIPE

*Trindade dos Anjos, Larissa Ramos (UFS) larissaanjos\_2@hotmail.com*

*Rambelli, Gilson (UFS) gilson.rambelli@gmail.com*

During the 16th century the brazilian territory was scene of greed of many European nations. Countries seeking to expand and legitimize themselves economically. Sergipe, located in northeast of country, belongs to the Brazilian coast. It has countless shipwrecks unknown by its own people. Shipwrecks dating from period of the greats voyages, as the Nau Gabriel Soares in 1591.

This project is part of Archaeology Laboratory of Aquatic Environments, Universidade Federal of Sergipe. Your principal objects is create an archaeological chart with the highest number of shipwrecks recorded through written and printed sources. Thinking about the possibility of future works in underwater archeology, and allows a management program on this heritage already registered.

From the year 1807 to 1969 were recorded about 150 shipwrecks in coast of Sergipe. This new material will be added, with more 59 shipwrecks, being reported from manuscripts issued by the Brazilian Maritime Authority and filed on Public Archives of State of Sergipe, shipwrecked between the years 1839-1919.

The Brazilian Maritime Authority had the duty of monitor all existing maritime traffic in territory of Sergipe, not only sea but also rivers. The commercial navigation was given by the cabotage system, browser always had the coast in your view field. These accidents were usually reported by Brazilian Maritime Authority and sent to the President or Secretary of Province.

During the 19th century the economy of Sergipe began to be noted for its sugar production. The best way to carry the products would be by the rivers navigable in the

state. In the same way that this river helped, also brought problems. The ships just could enter in the rivers in high tide, to avoid accidents in the sandbanks. Accidents such as groundings and shipwrecks happened often doing different victims.

Inventoried some shipwrecks lost throughout the Sergipe coast, we could extract some data as the year of shipwrecks, the ship name, its origin and place where happens the shipwreck. Has possible observed some reasons that caused the wreck, mostly caused by anthropogenic and natural factors. Through the reading of manuscripts, it's possible analyzed the daily life of "seaman" and how developed the navigation on the coast of Sergipe.

Underwater Archaeological Chart is important to ensure the management and preservation of underwater cultural heritage in Sergipe, and in this particular case, the remains of shipwrecks. Shares of heritage education also take part this project as a way of social awareness for that these archaeological sites don't suffer depredations, damaging archaeological researches that can happen in the future.

The importance of archaeologist learn about dive and specialize in scientific diving using as an archaeology tool, make part of objectives this project. Because Underwater Archaeology is assignment archaeologist diver!

### 9. FLUVIAL GEOARCHAEOLOGY AND UNDERWATER ARCHAEOLOGY IN LAGO RICO ARCHAEOLOGICAL SITE, CENTRAL PLATEAU OF BRAZIL

*Theodoro da Silva, Rosiclér (Pontifícia Universidade Católica de Goiás, Brasil) silva.rosicler@gmail.com*

*Rubin de Rubin, Julio Cezar (Pontifícia Universidade Católica de Goiás, Brasil) rubin@pucgoias.edu.br*

*dos Santos Correa, Daniel (Pontifícia Universidade Católica de Goiás, Brasil) daniel.archeology@hotmail.com*

*da Silva, Sérgio Meire (Pontifícia Universidade Católica de Goiás, Brasil) sergia\_ms@hotmail.com*

*Batista Barbosa, Jordana (Pontifícia Universidade Católica de Goiás, Brasil) jordana.batista@hotmail.com*

The first results of the archaeological research being developed at the interfluvium of the Peixe and Araguaia rivers in the Central Plateau of Brazil, indicate the need and potentiality of applying fluvial geoarchaeology and underwater archeology to address a number of issues related

to the Lago Rico ceramic site.

The site located on the left bank of the Peixe river, in an area of approximately 120,000m<sup>2</sup>, surrounded by surface prospecting.

This site features cultural remains in a section of a low slope as well as two other areas. The first in the alluvial terrace (erosive margin), by a lagune formed October to March, in a seasonal river channel, and the second in the floodplain (depositional margin), close to the alluvial terrace, upstream of the first section, evidencing the erosive-depositional behavior of the river in the archaeological site area. Satellite images show intense migration of the Peixe river channel in the floodplain near the archaeological site.

The depositional segment, current floodplain, presents evidence of a different environmental context from the current one, more precisely an ancient erosive margin, allowing the hypothesis that part of the site may have been eroded transporting cultural remains downstream. To investigate these hypotheses, the use of underwater archeology is critical for firstly, the identification of cultural remains in the lagune area and the depositional margin, since these sites do not allow for traditional surface excavation even during the drought periods and secondly, obtaining information to aid in characterizing the behavior of the river channel and description of stratigraphic profiles, as the low turbidity of the water allows good visualization. Issues such as the characterization of the Lago Rico site, its occupation by prehistoric groups and the relationship between the area of the village and the dynamics of the Peixe river can best be addressed through fluvial geoarchaeology and underwater archeology, a new approach to the region

## 1. STATUS AND PERSPECTIVES FOR THE FINAL PALAEO-LITHIC OF NORTHERN EURASIA

*Eriksen, Berit Valentin (Centre for Baltic and Scandinavian Archaeology) berit.eriksen@schloss-gottorf.de*

The purpose of this session is to discuss current and ongoing work with respect to the Final Palaeolithic of Northern Eurasia, to generate discussion of general interest, and to set the agenda for future research focus areas.

From a chronological perspective we are concerned with the emergence from an Upper Palaeolithic substrate of hunter-gatherers adapted to life in the more temperate conditions of the Late Glacial and Early Postglacial and their dispersal into previously unoccupied territories. To pursue this aim we invite archaeological and palaeo-environmental researchers dealing with the diversity of man and environment relationships during the Late Glacial and Earliest Postglacial, i.e. the period from approximately 15,000 to 8,000 BP. Given the magnitude of changes in climate, landscape, vegetation and fauna during this period, the Final Palaeolithic cultures of Northern Eurasia were characterized by a variety of adaptive responses, reflected in technologies, settlement patterns, subsistence practices, social organizations and even ideologies. Underlying this regional diversity of specific environmental and cultural changes were the fundamentals of climatic change in conditions that was relatively rapid and extreme and that clearly had major influence on contemporary hunter-gatherer land-use patterns. The general thematic focus of our session highlights all of these research questions.

ORAL

## 2. THE CHANGEABILITY OF LATE GLACIAL SETTLEMENT PATTERNS AND SUBSISTENCE IN NORTH EUROPEAN PLAIN

*Burdukiewicz, Jan Michal - (Institute of Archaeology, University of Wrocław) janmibur@gmail.com*

Late Glacial (15-10 ka BP) was a period of recolonisation of Northern Europe after LGM. The first human societies, who emerged in empty area of North European Plain, were Hamburgian hunter-gatherers originating in the Magdalenian milieu.

According to the recent research from the area of about 600,000 km<sup>2</sup> are known roughly 2000 settlement units representing three main archaeological technocomplexes: Shouldered Points (SPT – Hamburgian), Arched Backed Points (ABPT – Federmesser) and Tanged Points (TPT – Brommean, Ahrensburgian and Swiderian).

The basic spatio-temporal units are the sites, which represent settlement remains the most frequently by camp sites (lithic assemblages, rare habitation traces, fire places, etc.). Such units can be seen as homogenous and corresponding to a single stay of one basic social group (family and task groups). The heterogenous are sites representing several stays of one group in various periods, several stays of various groups with the similar technology and tool-kit or several groups with various equipments.

The detailed spatial analysis of artifacts, stratigraphy, refittings and technological features enabled the recognition of homogenous and heterogenous sites. However, the researchers did several mistakes and many times treated “mixed” as homogenous. Another possibility in the research of Late Glacial settlement patterns is an analysis of a long distance raw material procurement. Extended research of environmental data from Late Glacial gives an opportunity to show the ecological setting of first settlers of North European Plain.

The earliest settlers of North European Plain after LGM were hunter-gatherers of SPT, who arrived during the first warmer period (14,7-14 ka BP) in tundra conditions, following reindeer herds. They are represented by circa 200 settlement units, which were located mostly in the southern part of the area, usually agglomerated in small valleys with possibly good food supply of hunted reindeers and occasionally small game.

The further taxonomic unit ABPT with a much simplified lithic technology are represented by circa 300 settlement units, which existed during Allerød period (14-12,7 ka BP), when European Plain was already covered by a birch forest followed in second part by birch-pine forests, which were inhabited by forest animals, like deer, elk, etc. ABPT groups were more randomly dispersed.

Already in the second part of Allerød, after Laacher See volcano explosion, originated in Northern Germany and Denmark first unit of TPT, Brommean, which were followed during Younger Dryas (12.7-11.5 ka BP) by Ahrensburgian and Swiderian) existing even in Preboreal period. They existed in park tundra conditions hunting again on large reindeer herds and they are represented

by circa 1200 settlement units with a sophisticated long distance raw material circulation.

The three Late Glacial taxonomic units represent the really efficient adaptation systems during recolonisation of North European Plain. There are three main concepts of their origin: 1 – three waves of recolonisation or 2 – three systems of adaptation with demographic increasing of the same populations, 3 – mixture of two above mentioned concepts, however stimulated by strangers from the south.

### 3. STABLE ISOTOPE ANALYSIS OF THE HUMAN OF RHÜNDA (GERMANY): INTENSE EXPLOITATION OF AQUATIC RESOURCES IN THE EUROPEAN NORTHERN PLAINS DURING THE YOUNGER DRYAS

*Drucker, Dorothee G. (Department of Geosciences, Biogeologie, University of Tübingen, Germany) dorothee.drucker@ifg.uni-tuebingen.de*

*Rosendahl, Wilfried (Abteilung Weltkulturen und Umwelt, Reiss-Engelhorn-Museen, Mannheim, Germany) Wilfried.Rosendahl@mannheim.de*

*Van Neer, Wim (Laboratory of Biodiversity and Evolutionary Genomics, University of Leuven, Leuven, Belgium) wvanneer@naturalsciences.be*

*Görner, Irina (Vor- und Frühgeschichtliche Sammlung, Museumslandschaft Hessen Kassel, Kassel, Germany) i.goerner@museum-kassel.de*

*Bocherens, Hervé (Department of Geosciences, Biogeologie, University of Tübingen, Germany) herve.bocherens@uni-tuebingen.de*

The Younger Dryas or GS-1 (ca. 12.8-11.6 ka cal BP) is the last severe cold episode of the Lateglacial before the definitive global warming of the early Holocene. In the northern Plains of Europe, this period witnessed the return of reindeer herds that were actively hunted by the Ahrensburgian hunter-gatherers. Besides this typical Pleniglacial species, horse, large bovines, elk, hare, bird and fish were exploited. However, their remains are found in a lesser extent than those of reindeer in archaeological sites such as Stellmoor in northern Germany or Remouchamps in Belgium. One of the very few human remains dated to the Younger Dryas in northern Europe was found near Rhünda (Central Germany; Rosendahl, 2002).

An isotopic study was conducted on the skull of Rhünda to reconstruct the diet ( $^{13}\text{C}$  and  $^{15}\text{N}$  abundances in collagen) and environment ( $^{18}\text{O}$  abundances in phos-

phate) of the specimen. The interpretations were based on the comparison with the abundances of the same stable isotope measured on reindeer (*Rangifer tarandus*), horse (*Equus* sp.) and bison (*Bison bonasus*) from the Ahrensburgian sites of Stellmoor (North Germany) and Remouchamps (Belgium).

As in Stellmoor (Drucker et al., 2011), the return of the tundra-like conditions is clearly reflected in the relatively high collagen  $^{13}\text{C}$  and low phosphate  $^{18}\text{O}$  abundances of the reindeer of Remouchamps, which were due to higher availability of lichen in colder conditions than during the Lateglacial interstadial period. The low pedogenesis rate in such a cold context was reflected by the relative low  $^{15}\text{N}$  abundances in the collagen not only of reindeer but also horse and bison. The low  $^{18}\text{O}$  abundance of the human of Rhünda was consistent with a source of drinking water depleted in  $^{18}\text{O}$  during this period as testified by the results on the reindeer from Stellmoor. The abundances in collagen  $^{13}\text{C}$  and  $^{15}\text{N}$  of a secondary consumer (carnivore, omnivore) are typically enriched compared to the collagen of the animal providing the protein pool of the diet (e.g. Bocherens and Drucker, 2003). In the case of Rhünda, the reindeer did not appear as a significant contributor to the protein of the diet based on the abundances of  $^{13}\text{C}$ . Considering the abundances of  $^{15}\text{N}$ , none of the analysed herbivores could explain the high value of the human collagen. Thus, the consumption of freshwater resources, with higher  $^{15}\text{N}$  abundances than the terrestrial resources, must be considered to explain the isotopic signature of the human of Rhünda. Indeed, the isotopic values of late Paleolithic fish specimens from Belgium fit the expected range of collagen value of the prey of the human from Rhünda.

Such an intense consumption of aquatic prey could be a result of the low plant availability during the harsh conditions of the Younger Dryas as it is the case nowadays in high latitude hunter-gatherer populations (e.g. Cordain et al., 2000). A low biomass of animal herbivores should also be considered has a reason why some human groups exploited intensively the freshwater ecosystem for their subsistence in the northern plains of Europe.

ORAL

### 4. SHOULD I STAY OR SHOULD I GO? ALTERNATIVE BEHAVIOURAL STRATEGIES OF LATE MAGDALENIAN HUNTERS AND GATHERERS CONFRONTED WITH CLIMATIC AND ENVIRONMENTAL CHANGES

*Grimm, Sonja B. (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) grimm@rgzm.de*

In north-western Europe, the Upper Palaeolithic Magdalenian way of life disappeared during the Lateglacial Interstadial. The exact dating remains a matter of debate and, probably, of regional differentiation. However, if regional differences had an impact on the process of behavioural change, a correlation of this disappearance with global climatic and environmental changes must be considered more critically.

Therefore, several archaeological assemblages from northern France, Belgium, Central Rhineland, the Netherlands, and northern Germany were correlated in a high-resolution chronostratigraphy which allowed the comparison with developments revealed by climatic and environmental archives. In a second step, observable differences and similarities of the archaeological assemblages were recorded to assess the normative behaviour of quasi-contemporary assemblages and to reveal changes of these norms over time.

At the beginning of the Lateglacial Interstadial, the limits of normative behaviour became wider but no significant change was observed. In these wider limits several different, modified versions of the typical Late Magdalenian behavioural norms appeared gradually. These modified versions spread northwards and, thus, expanded the Magdalenian settlement area. The norms in these northern expansions were more comparable to the Late Magdalenian than contemporary behavioural expressions in the previously inhabited regions. Perhaps, some more traditional Magdalenian hunters and gatherers followed the familiar biotope which gradually shifted northwards, whereas those hunters and gatherers remaining in the changing southern environments had to be more innovative in their survival strategies. During the continuous amelioration of the Lateglacial Interstadial, the northern environments also changed further towards light forests but the behavioural developments in these northern areas seemed independent from the southern strategies. However, after a cold return, a revolutionary behavioural shift occurred in the south. With the expansion of light temperate forests to the north, these newly established southern norms also spread into the north.

The environmental changes in the early Lateglacial Interstadial challenged the members of the Late Magdalenian society. Alternative behavioural strategies were chosen for different biotopes resulting in separate developments. With the experience of natural limits to the

gradual adaptive strategy in both areas and the appearance of more similar biotopes, behavioural strategies approached shared norms again.

### **5. BETWEEN THE MAGDALENIAN AND FEDERMESSE- ER GRUPPEN. THE ARCHAEOLOGICAL EVIDENCE FROM THE SOUTHERN NETHERLANDS**

*Rensink, Eelco - (Cultural Heritage Agency, Amersfoort) e.rensink@cultureelerfgoed.nl*

*Verpoorte, Alexander - (Leiden University) a.verpoorte@arch.leidenuniv.nl*

In the southern Netherlands, the Magdalenian represents the earliest human occupation after the Last Glacial Maximum. Taking into consideration the occurrence of Dutch Cretaceous flint in the settlements of Andernach and Gönnersdorf, the Dutch Magdalenian sites of Sweikhuizen, Mesch and Eysersheide can be indirectly dated to the final phase of the Pleniglacial, ca. 13.300-12.700 BP. What happened between this period and the first occupation of people of the (early) *Federmesser Gruppen*, from ca. 11.500 BP onwards, is largely unknown.

The paper examines the contribution of the Late Palaeolithic record of three geographical regions in the southern Netherlands to the investigation of this 'intermediate' period: the hilly loess area, the sandy coversand area and the Meuse valley area.

### **6. A LATE PALAEOLITHIC DOG FROM BONN- OBERKASSEL AND WOLF DOMESTICATION AS A HUMAN ADAPTIVE STRATEGY**

*Street, Martin (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) street@rgzm.de*

Two human skeletons discovered in 1914 during basalt quarrying at Oberkassel in the German Rhineland were recognized as being of Upper Palaeolithic age and swiftly published as part of a comprehensive monograph. Animal remains recovered with those of the humans were originally mentioned only in a cursory fashion but were presented in more detail in the 1980s, at which time cranial elements of a canid were identified as a domestic dog. A re-examination of the highly fragmented faunal

specimens in the 1990s revised previous identifications, assigning some postcranial material to this species, and provided a series of direct 14C dates for the complex of Oberkassel human and animal remains.

On the occasion of the centenary since the Oberkassel discovery a broad range of new analyses was initiated, among them studies of the dog remains which were examined using e.g. CT scanning for specific pathological-morphological features and sampled for their aDNA and for renewed 14C dating using state of the art methodology.

The results of new analyses of the late Palaeolithic Oberkassel canid confirm its status both morphologically and genetically as a specimen of domestic dog and provide new details relevant to current discussions of the status of small Upper Pleistocene canids and their identification as dogs. The context of recovery, in association with two human skeletons interpreted as a formal burial, highlight the particular status accorded to the animal. The dog from Bonn-Oberkassel provides some of the earliest convincing evidence for a far earlier domestication of the wolf than has been accepted until comparatively recently. In a broader context and against the background of claims for even earlier evidence for the keeping of wolves the domestication process can be argued to be a further behavioural adaptation specific to anatomically modern humans and not observed in earlier hominin populations.

### POSTER

#### 7. THE EARLY MESOLITHIC OF THE NORTHERN EUROPEAN LOWLANDS

*Groß, Daniel (Centre for Baltic and Scandinavian Archaeology) daniel.gross@schloss-gottorf.de*

The poster presents results of a PhD thesis that deals with human-environment interactions in the early Holocene of the northern European lowlands. It is investigated if early Mesolithic traditions spread out into the area under consideration due to active colonization processes or to a successive widening of the people's habitat. Additionally, aspects like reliability and quality of excavations and sites are discussed.

The analysis compares several sites by published information. The methods used include environmental reconstructions which are derived from faunal remains and palynological samples such as functional interpre-

tations of the sites by artefact inventories. Multivariate statistics, factor analyses and cluster analyses as well as the calculation of different ratios are the tools used to approach the aforementioned research questions.

The early Mesolithic sites in the northern European lowlands show pronounced ties to their environment. As a result, the colonization of the area under consideration started after it was already reforested. Following this, it is appropriate to describe settlement in those areas as subsequent to environmental changes. This is also underlined by the very opportunistic, broad-spectrum subsistence strategy, which nonetheless relied on a familiar package of resources. Individual sites which show a more specialized exploitation of a single resource have to be seen as discrete phenomena which warrant further investigation. Furthermore it became obvious that investigations which compare different sites are dependent on the quality of the published information. In this respect there is still a lot to be done for archaeological research because most excavations are not entirely published yet. The focus of further investigations has to be the establishment of a more solid data base. To establish this, an elaborated publishing strategy is needed so that the results can be widely used. Standard guidelines would help in this respect. An evaluation of human-environment relationships is only possible if researchers can compare their results on a common ground and a supra regional scale. This is crucial to understand the transition from the Final Palaeolithic to the early mesolithic.

Since many pre-Neolithic sites are only known from surface collections it is often difficult to recognize palimpsests, especially in chronozones where artefacts are typologically indifferent, like in the Preboreal and Boreal. As a result, the functional interpretation becomes difficult as long as few sites with a reliable stratigraphy are known. Following this, the human-environment interaction is also difficult to interpret. As a consequence research may intensify surveys in areas that promise good preservation and stratigraphies. By applying such a more focused research strategy it might be possible to gain better insights into the relation of a site's character and its environment.

POSTER

## 8. THE MAGDALENIAN OF HOHLE FELS CAVE: CENTRAL EUROPE AT THE END OF THE PLENIGLACIAL

Taller, Andreas (University of Tübingen) [andreas.taller@uni-tuebingen.de](mailto:andreas.taller@uni-tuebingen.de)

Napierala, Hannes (University of Tübingen) [Hannes.Napierala@ifu.uni-tuebingen.de](mailto:Hannes.Napierala@ifu.uni-tuebingen.de)

Conard, Nicholas (University of Tübingen) [nicholas.conard@uni-tuebingen.de](mailto:nicholas.conard@uni-tuebingen.de)

The Palaeolithic cave site of Hohle Fels is situated in the Ach Valley in the Swabian Jura of Southwestern Germany. Its stratigraphy encompasses layers from the Middle Palaeolithic, as well as the Aurignacian, Gravettian and Magdalenian from the Upper Palaeolithic.

In the Magdalenian, Hohle Fels served as a base camp and was occupied mainly in the winter months. The occupation dates very close to the end of the Pleniglacial, around 12.500 BP, shortly before the onset of the late glacial interstadial cycle beginning with the Meiendorf-amelioration. This is in good accordance with most of the Magdalenian sites in southern Central Europe. The Central European Magdalenian seems to encompass very little time-depth (ca. 13.000-12.500 BP) since only very few Magdalenian sites in the region predate this time of comprehensive settlement. Virtually no Magdalenian sites date into the late glacial interstadial cycle itself. It seems therefore that the Magdalenian was in fact closely linked to the climatic and environmental conditions of the late Pleniglacial, as its abrupt end can be observed with the onset of the Meiendorf Interstadial.

The Magdalenian layers of Hohle Fels yielded close to 25.000 lithic artefacts, including 8.695 pieces larger than 1cm, 1.115 tools and 129 cores. Blank production was focused on blades and bladelets, which were made in a unidirectional manner on well prepared cores. Almost 50% of the tools are backed pieces, which shows their importance for the Magdalenian craftsmen. A functional analysis carried out on a sample of these pieces revealed that not all of them were used as inserts in composite projectile heads or projectile points. Although 19% of the backed elements show fractures diagnostic of an impact and therefore indeed served as projectile parts, some other pieces were used as cutting inserts in knives (for meat, hide or leather,) or for working plant fibres and wood. Some pointed pieces even performed perforating tasks. The cutting edge angles of the pieces mirror the intended use: the harder the material to be worked, the wider the cutting edge angle in order to obtain a more robust edge.

Next to the lithics, many artefacts of organic materials were found (harpoons, antler javelin heads, needles, awls) as well as jewellery (beads, perforated animal teeth, perforated molluscs). Other symbolic expressions are limestone rocks decorated with painted red double dotted lines.

The hunted fauna is dominated by horse, reindeer and hare. However, there are also several thousands of bones and scales of fish found in the Magdalenian layers. Species that were fished include *Salmo trutta*, *Salvelinus alpinus*, *Thymallus thymallus*, *Lota lota*, *Hucho hucho* and *Esox lucius*. The harpoons are most probably to be seen in connection to this result, as some of the fish species mentioned are quite big, e.g. *Esox Lucius* (ca. 20kg max.), but especially *Hucho hucho* as those can grow to a weight of approx. 30kg.

ORAL

## 9. DISCUSSING THE CULTURAL SIGNIFICANCE OF LITHIC PROJECTILE IMPLEMENTS ? A CASE STUDY OF HAMBURGIAN SHOULDERED AND TANGED POINTS

Weber, Mara-Julia (Centre for Baltic and Scandinavian Archaeology) [mara.weber@schloss-gottorf.de](mailto:mara.weber@schloss-gottorf.de)

Traditionally, archaeological entities in the Palaeolithic and Mesolithic have been defined and hence distinguished from one another on the basis of their projectile implements, mostly of lithic raw material. This has also been the case of the Late Upper and Late Palaeolithic archaeological record in North-West Europe, which has been subdivided into three big units characterised by shouldered, curve-backed and tanged points. These units have also been correlated with the three major Lateglacial biozones in this part of Europe. However, the western and northern zone of the distribution area of the Hamburgian represent an exception, since they witnessed the appearance of tanged points – of the Havelte type – in the course of the Hamburgian and preceding the curve-backed points.

In this paper, potential causes of this introduction of Havelte tanged points in the Hamburgian, characterised thus far by shouldered points known from the Magdalenian in general, will be examined. As a basis of this discussion, technological and functional aspects of the two point types will be compared, using examples from Schleswig-Holstein (northern Germany). In addition, the environmental conditions under which these points served as projectile implements will be taken into

account.

The similarities and differences between the Hamburgian shouldered and tanged points are of such a nature that a development from one type of the other is possible and that they could have been used in a comparable manner. With regard to the factors at the origin of the appearance of the Havelte points, changes in the hunting circumstances stand alongside with social expressions, whereas the absence of clear changes in other parts of the Hamburgian material culture seem to exclude cultural changes.

In conclusion, this example illustrates the difficulties archaeologists have in evaluating the significance of single elements of the hunting system for prehistoric groups. Moreover, ethnographic examples show the complexity of this topic.

#### **10. ARCHED- AND TANGED POINTS TECHNOCOMPLEXES IN NORTHERN CARPATHIANS. CURRENT STAGE OF RESEARCH**

*Valde-Nowak, Pawel (Institute of Archaeology, Jagiellonian University; Institute of Archaeology and Ethnology, Polish Academy of Sciences) p.valde-nowak@uj.edu.pl*

*Kraszewska, Anna (Institute of Archaeology, Jagiellonian University) ania.kraszewska@gazeta.pl*

*Stefański, Damian (Institute of Archaeology, Jagiellonian University; Paleolithic and Mesolithic Department, Archaeological Museum in Kraków) damian.stefanski@ma.krakow.pl*

The goal of this work is to review the present discussion and the perspectives of the Late Palaeolithic in the northern part of the Western Carpathians and in the Northern Subcarpathia region during the Allerød and the Younger Dryas oscillations. The area of Subcarpathia, especially dunes of the upper Vistula valley, has been explored many times since the second half of XX century (e.g. Kraków-BorekFałęcki, Kraków-Kobierzyn). It brought numerous collections proving dense Late Palaeolithic settlement around Kraków. Although the Tanged Point Technocomplex (TPT) prevailed, traces of Arched Point Technocomplex were also reported. Since the 80's, methodological researches in the northern part of The Western Carpathians have unexpectedly revealed rich remains of the Late Palaeolithic settlements. It mainly represents the APT settlement (SromowceNiżne, NowaBiała). The recent progress has been achieved as a result of extensive rescue excavations which brought a

number of methodically acquired lithic assemblages (e.g. Kraków-Kurdwanów, Kraków-Bieżanów, Mucharz). This issue has boosted a discussion on the Late Palaeolithic settlement in the region. The discussion is focused on the techno-typological aspect of a material culture, detailed analysis of raw material procurement, usage of land and spatial arrangements of assemblages. The numerous accumulations show a variety of cultural entities including the Tarnowian, Witowian, Swiderian and Brommean cultures. The investigated area represents two main raw material provinces: the north Subcarpathia with Jurassic flint and the northern part of the Western Carpathians – where radiolarites were mainly found however other rocks were present, as well. Both cases are characterized by local production only merely enhanced with imported materials. The settlement is almost completely represented by open air sites although caves are also present (Zalasrockshelter). The extent of the assemblages varies from rich settlement units yielding several thousands of artefacts to tiny spots of about dozens of lithics. Only in case of a few archaeological sites an environmental record was acquired. It hinders a construction of a reliable chronology and therefore some comparative studies over the adjacent area are necessary. The basic reports indicate the northern part of the Western Carpathians and the Northern Subcarpathia region as “contact zone”, proving a local character of them as well as a strong affection from the part of the North European Plain.

#### **11. A FAMILY HUNTING UNIT AT TROLLESGAVE, DENMARK: THE CONTRIBUTION OF LITHIC TECHNOLOGY AND MICROWEAR**

*Donahue, Randolph (University of Bradford) r.e.donahue@bradford.ac.uk*

*Fischer, Anders (Danish Agency for Culture) afiklb@privat.dk*

Microwear analysis, in combination with refitting and analysis of lithic reduction, is applied to reconstruct the function and social organisation at the Late Glacial site of Trollesgave, Denmark. Analyses of the flint knapping and the spatial distribution of its products reveal the traces of at least three individuals: expert, medium competent, and inexperienced. Based on the quality of craftsmanship and the aberrant habits of disposing their products of the latter two are inferred to be children. As with Bromme Culture sites in general, the assemblage consists of primarily three types of tools. There is a strong association between these types and their use: end scrapers for dry hide scraping; burins for working hard material,

primarily bone; and tanged points primarily for projectile tips. Nearly all divergence from this pattern can be referred to the activities of the children. The site appears to be occupied by a single family hunting (and fishing) unit.

## 12. INFLUENCE OF THE EXTREME INUNDATION EPOCH ON THE FINAL PALAEO-LITHIC CULTURES OF NORTHERN EURASIA

*Chepalyga, Andrey (Institute of Geography Russian Academy of Sciences) tchepalyga@mail.ru*  
*Pirogov, Andrey (Paleo.org Project) an.pirogov@gmail.com*

After the Late Glacial Maximum (LGM, 20-18 ka BP) during the Late Glacial Deglaciation (LGD, 16-10 ka) another very important event the Extreme Inundation Epoch (EIE, 16-14 ka) (Chepalyga, 2004) was discovered.

Four types of inundations in the different landscapes were found:

1. Marine transgressions filled Ponto-Caspian depressions and formed Cascade of Eurasian Basins. The territories covered by waters are: marine depressions (Caspian Sea marine depression, more than 1 mln. km<sup>2</sup>) as Epicenter of Cascade of Eurasian Basins (Chepalyga, 2005) from Aral Sea to Aegean Sea (more 1.5 mln. km<sup>2</sup>). General characteristics of marine-lake basins of CEB are: total aquatorium space — 1 mln 500 000 km<sup>2</sup>, including flooded space — more 1 mln km<sup>2</sup>, water volume — up to 700 000 km<sup>3</sup>, water system of CEB covered the space 3000 km from East to West and 2500 from North to South.

Cascade of Eurasian Basins is an inner system of basins which were connected by spillways: Aral-Sarykamysh basin — Uzboy spillway — Khvalynian basin — Manych-Kerch spillway — Neuwexinian basin — Bosphorus spillway — Sea of Marmara basin — Dardanelles spillway — The Mediterranean Sea.

2. River inundations (superfloods) in river valleys, when water discharge rose to 5-15 times more than recent. River valleys formed underfit channels with abnormal width to 3-5 km.

3. Slope inundations connected with permafrost melting and solifluction provoked by thermocast lakes activation.

4. Interfluvial flooding by permanent lakes similar to recent alases in Yakutia (paleoalases).

Total EIE events covered area reached 10 mln. sq km in the N-W Eurasia between the Atlantic Ocean and the Yenisei river.

Described processes of the EIE were catastrophic and greatly influenced on ancient peoples: waste inundations, migrations, losing the most fertile land, increased population density. Great alimentation deficit together with critical instability of environment provoked stress, famine and great human crisis. Extinction of great mammals and spread of large water space changed human diet to small mammals and birds and possible stimulated appearance of new type of hunting weapons — bow with arrow. Type of houses was changed to light dwelling like wigwam or teepee, according smaller family groups. These processes could stimulate of economy type change from wild non productive to productive economy: cattle breeding and agriculture.

The numerous water basins produced barriers for human communications from North to South on 2000 km. Manych-Kerch spillway (strait) between Caspian and Black Sea was an effective barrier for Late Palaeolithic culture exchange between East Europe and Middle East — 16-14 ka (Chepalyga et al, 2005). This isolation led to fragmentation of habitat area and form of separate languages and language families (Chepalyga, 2010).

So, main human evolution events (productive economy, civilization beginning, and first language diversification) were connected not only with climatic extremes (LGM), but much more with the inundation events of the EIE in North Eurasia.

---

ORAL

## 13. TOWARDS AN ARCHAEOLOGY OF MIND IN THE FINAL PALAEO-LITHIC: LOOKING FOR NEW AVENUES TO UNDERSTAND CULTURAL BEHAVIOR AND MATERIAL CULTURE CHANGE IN THE PLEISTOCENE-HOLOCENE TRANSITION.

*De Bie, Marc (Flanders Heritage & Vrije Universiteit Brussel) marc.debie@wo.vlaanderen.be*

Archaeological debate on the Pleistocene-Holocene transition in Northern Eurasia has so far mainly focused on descriptive approaches of taxonomy, regional classification, techno-functional analysis and settlement organization. The interpretation and explanation of cultural behavior and (material) culture change has mostly been related to changing environmental conditions.

Many current topics of debate have been addressed for more than half a century now (spatio-temporal distribution, raw material, material culture, environmental change, ...) and mostly emphasize economic behavior of these hunters and gatherers. How did they survive (subsistence), what functional activities were they carrying out in order to survive (technology) and what made them occupy certain areas at certain moments in time (environmental constraints)? These are of course basic questions and necessary conditions for any population to survive, but they are hardly specifically human. Questions of ritual behavior, spirituality, (self)consciousness or religion have more scarcely been addressed with regard to these societies. This might be due to an overall lack of surviving art, burials or other expressions of mental concepts that are generally used in considerations of the human mind, e.g. in the Upper Palaeolithic or in the Middle to Upper Palaeolithic transition debate, as well as in the Mesolithic or Neolithic.

This paper explores whether other avenues might be found to start addressing these themes in the final Paleolithic as well. Two specific and somewhat contrasting cases exemplify that whilst major technological change didn't inevitably necessitate the presence of creative and inspiring intellects, symbolico-religious minds were indeed present in these populations and archaeologically visible. Our first claim is that fundamental technological changes, such as for instance the initiation of the microburin technique at the end of the final Paleolithic, did not necessarily invoke creative, innovative minds. Other factors, including human-independent material constraints, can in fact instigate long-term innovation. Our second claim is that indications of (spi)ritual behavior may be found though in other areas of the human condition than the ones we usually consider, e.g. in the spatial distribution of camp site activities, as exemplified with a case in Belgium.

By considering both investigations in a wider context, the paper explicitly attempts and invites to further explore, test and debate both theses with future studies and to search for additional avenues in cognitive archaeology for the Final Palaeolithic in Northern Eurasia.

## 1. PRECOCIOUS OR UBIQUITOUS? FEDERMESSER-GRUPPEN ELEMENTS IN THE HAMBURGIAN

Weber, Mara-Julia (Centre of Baltic and Scandinavian Archaeology) mara.weber@schloss-gottorf.de

On the North European Plain, the *Federmesser-Gruppen* are preceded by the Hamburgian, which represents the first human occupation of this area after the Last Glacial Maximum and belongs to the Magdalenian tradition. According to the present record of radiocarbon dates, the Hamburgian and the *Federmesser-Gruppen* are not separated by a considerable amount of time but the question of a potential transition between them remains unsolved thus far. Typologically, the pioneer techno-complex differs from the *Federmesser-Gruppen* in its lithic projectile implements – shouldered points in the classic Hamburgian and tanged points in the Havelte Group – and the richness as well as the nature of its tool types. However, lithic elements with affinities to straight- or curve-backed points or to scraper types considered characteristic of the *Federmesser-Gruppen* appear in assemblages of both the classic Hamburgian and the Havelte Group in different regions of the distribution area of the Hamburgian.

This paper will give an overview of these specific assemblages and the varying interpretations of the apparent co-existence of lithic elements attributed to two different techno-complexes. Moreover, the example of Teltwisch 1 in the Ahrensburg tunnel valley (Schleswig-Holstein, Germany) will be discussed in detail taking into consideration typological, technological and spatial data.

At the present state of research, the results of these studies rather tend to a real prehistoric co-existence of components that, individually considered, would be attributed to two different techno-complexes. However, the likelihood of admixtures from neighbouring sites is more or less important depending on the nature of the different sites.

Finally, the presented observations will contribute to the discussion of the origin of the *Federmesser-Gruppen* on the North European Plain.

ORAL

## 2. BACKED PIECES LITHIC TECHNOLOGY IN THE WESTERN POLISH PLAIN

Pyżewicz, Katarzyna (Institute of Prehistory, Adam Mickiewicz University in Poznań) kpyzewicz@gmail.com  
Witold Gruzdz (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw) wittold@gmail.com  
Rozbiegalski, Piotr (Institute of Prehistory, Adam Mickiewicz University in Poznań) p.rozbiegalski@gmail.com  
Rakoca, Aleksandra (Institute of Prehistory, Adam Mickiewicz University in Poznań) rakoca.a@gmail.com

The purpose of the presented paper is to investigate the lithic technology of the Backed Pieces complex. The research was performed by analysing the morphological features of debitage and the reduction processes. Until recently Polish archeology was dominated by the studies associated with the use of dynamic technological classification. Rarely there were presented with the results of applying refitting methods focused on spatial analysis. The studied Late Paleolithic inventories came from few excavation sites (i.a. Święty Wojciech, Santocko, Rogalinek) which are located on the western part of the Polish Plain.

During the detailed interpretation of the particular stages of *chaîne opératoire* we applied the combination of the refitting method, experimental research and microscopic analysis of flint materials.

As a result of our studies we made an attempted to distinguish characteristics of Backed Pieces lithic technology, which differentiate this method of debitage from others - used among other Late Paleolithic and Early Mesolithic societies in the western Polish Plain.

Special attention was paid to the aspect of duality in the approach to the lithic technology among the Backed Pieces groups. These kinds of differences were noted in the preparation of cores as well as blade production and the toolkit used for the debitage.

Late Paleolithic assemblages with Backed Pieces in the western Polish Plain were produced by using two characteristic methods of blade reduction. First method was based on isolation of core platform by facetting before application of direct percussion with hard hammer. A second method was aimed producing more regular and slender blanks with soft stone percussion.

ORAL

### 3. SIMILAR BUT DIFFERENT. FEDERMESSER SETTLEMENT IN POLAND

*Sobkowiak-Tabaka, Iwona (Institute of Archaeology and Ethnology Polish Academy of Sciences) iwona.sobkowiak@iaepan.poznan.pl*

For the first time inventories related to the Arch Backed Piece techno-complex (Azilian industry at the time) were defined in Poland by S. Krukowski in the 1920s. After almost 100 years of excavations and studies, approximately 110 Federmesser assemblages (including stray finds) have been recorded, of which nearly 50 have been registered at Rydno (northeastern foothills of the Holy Cross Mountains). Based mostly on the lithic inventories marked by substantial technological, typological and morphological differentiation (especially in the group of backed points), three taxonomic units were distinguished (Federmesser Culture, Tarnowian and Witowian) and, lately, also their local variants.

However, the genesis of particular taxonomic units and the wide variety of the Polish assemblages causation are still poorly understood.

The utilisation of chocolate and Cracow- Częstochowa Upland Jurassic flint as well as occasional finds of exotic raw materials, namely obsidian and radiolarite, have been reported, but otherwise most lithic assemblages were made of Cretaceous erratic flint.

The number, size and structure of inventories as well as the character of features indicate various kinds of settlement patterns – from short-stay sites, workshops and camp sites to large aggregations of sites – i.e., Rydno (ochre mine).

Given thirteen radiocarbon dates which have been obtained from different archaeological contexts, Federmesser settlement in Poland can be confined to the period of the Allerød (GI-1a-GI-1c) and the very early Younger Dryas (GS-1). Fairly numerous archaeobiological studies can be used to reconstruct paleo-environmental changes during those periods, conveniently even at the micro-regional scale.

The recognition of subsistence strategies is hardly possible due to the scarcity of animal remains.

Federmesser sites in Poland are located in different kinds of landscapes, i.e., lowlands, highlands and mountains,

which testifies to the great flexibility of the hunter-gatherer societies and their skills in the exploration of diverse environments. The exploitation of contrasting types of biotope together with various functions of sites could have fostered the diversity of lithic tool-kits. The long-term persistence of the Federmesser settlement can provide another plausible explanation.

A wide distribution of different kinds of rocks, sometimes exotic, is indicative of the mobility of these societies and suggests an important role of exchange of goods and of relationships between individuals and groups.

Federmesser groups can be seen analogously to M. Otte's account of the Magdalenian culture, namely as a conglomerate of communities of not necessarily common origin and functioning in different periods, who, in consequence of the adaptation to environmental conditions, generated a similar economic strategy and a conjunctive social and ideological structure.

ORAL

### 4. TWO LATE PALAEOLITHIC ARCHED-BACKED POINTS VARIETIES IN NORTHERN CARPATHIANS

*Valde-Nowak, Pawel (Institute of Archaeology, Jagiellonian University; Institute of Archaeology and Ethnology, Polish Academy of Sciences) p.valde-nowak@uj.edu.pl*  
*Kraszewska, Anna (Institute of Archaeology, Jagiellonian University) ania.kraszewska@gazeta.pl*

The issue of arched-backed points from the Allerød Interstadial period is best understood in its two Western European variants: Azilian and Federmesser. Intensification of the archaeological research in the northern Carpathian Mountains led to discovery of two relatively big sites of such technocomplexes. Our aim is to focus on them as each one represents a different technological and typological variant.

Both sites are situated within small areas of occurrence of radiolarites and both of them prove that this raw material was exploited. We will present some elements differentiating backed points as well as different ways of stone processing. In view of the proposal of classification of the Arched-backed Points complexes, it may be concluded that one of these sites may represent the Witów group while the other indicates a link with the Federmesser culture. This is even more interesting since both sites are 20 km away from each other and placed in the same river basin. Moreover, it is difficult to indicate

inventories in the Carpathian range providing a context for either of the variants. Only few finds of arched-backed points were made within a radius of several tens of kilometers; furthermore, their connection with the techno-complex we are interested in is not certain. Both sites have features of base camps, most probably with a dwelling construction, situated on a big river in the Central Western Carpathians, where no traces of such settlements have been reported so far. In both cases the assemblage inventories may be regarded as household stone-processing workshops.

The value of these findings is also emphasized by their geographical location. Firstly, they prove that the arched-backed points groups embraced a mountainous landscape, in this case the Tatra Mts. and the Pieniny Mts., with its characteristic climate and fauna. Secondly, intensive studies of the discovered inventories will allow us to better define a South-Eastern boundary of the area penetrated by the population of the Federmesser culture. Thirdly, the finds provide new information for the discussion about the scale of presumed southern (Epi-Gravettian) influences on Arched-backed Points communities developing in the European Lowland in the Allerød period.

## 5. SETTLEMENT STRATEGY IN THE LATE PALAEO-LITHIC OF BOHEMIA AND MORAVIA

*Moník, Martin (Palacky University) martin.monik@gmail.com*

Differences in topography of Late Palaeolithic sites are discussed in this paper and compared to the topography of older (Magdalenian) settlement in the area. All data (altitude, cardinal directions, watercourse distance, vertical drop) are statistically evaluated in order to detect different strategies of groups supplied with different chipped stone materials.

Topographic data are acquired on the basis of known literature or recent surface prospection, certain collections have been recently re-analyzed in order to identify specific composition of chipped stone industry. Maps of Late Palaeolithic and Magdalenian settlement of Bohemia and Moravia have been created, statistical analysis has been made using the Statistica (Stat Soft inc.) program.

ORAL

## 6. LATE PALEOLITHIC LAND USE IN NORTHERN BAVARIA

*Sauer, Florian (Institut für Ur- und Frühgeschichte Erlangen) florian.sauer@fau.de*

The archaeological landscape of northern Bavaria - especially the Oberpfalz region - knows an extensive amount of late Paleolithic sites. Most of these sites - the frequent occurrence of backed points marks them as belonging to the Federmesser-groups - are known due to surface collections by private collectors, who have been surveying the region for more than 50 years. Only very few sites are known as a result of excavations which mainly took place in the early 20th century and therefore in most cases lack stratigraphic or faunal information.

As mentioned above, most of the sites are known thanks to amateur collectors. The better part of the more than 100 sites classified as late Paleolithic are open air sites that have been brought to the surface by plowing. Therefore it is quite probable that both the vertical and most of the horizontal stratigraphic information is lost to us.

So the wealth of the late Paleolithic sites of northern Bavaria lies not in the well documented intrasite phenomena but in their geographical position, in the abundance and accessibility of the rich, but unstratified and sometimes admixed lithic assemblages and the diversity of the used raw materials that can be quite easily assigned to sources of origin. These three scales of information should bear the potential to draw a more or less colorful picture of the behavior of the late glacial hunters and gatherers in this region.

The scale of geographical information is to be examined with the help of a GIS based archaeological predictive model. This APM will not only focus on typical geographical proxies like aspect, slope or distance to water, but will also take into account ethological ideas - especially concerning the predominant game that is known from different sites in Germany. The results of the geographical scale are then to be combined with information from attribute analyses of several surface collections and the few published sites, containing Federmesser-group artefacts. The attribute analysis already shows a very diverse but also typical pattern of raw material utilization. It shows the frequent use of cherts of the Abensberg-Arnshofen type from the Danube-basin as well as the use of cretaceous flint from the end moraine areas around Erfurt in Thuringia. The combination of tool types in the Bavarian sites also differs from those coming from other

regions in Germany. Burins regularly play a much more important role in the assemblages of this region than for example in those of the Rhineland. This may be due to different land use with a focus on other vegetational or faunal resources. In the end, the combination of the different scales of information will allow the creation of a spatial pattern which can be interpreted in terms of late Paleolithic land use in northern Bavaria.

ORAL

## 7. FROM CHAÎNE OPÉRATOIRE TO ADAPTIVE CYCLES: CONTEXTUALISING EARLY AZILIAN AND FEDERMESSER-GRUPPEN IN THEIR ENVIRONMENT

*Grimm, Sonja B. (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) grimm@rgzm.de*

*Mevel, Ludovic (Laboratoire "Préhistoire et Technologie", UMR 7055) ludovic.mevel@mae.u-paris10.fr*

The onset of the Lateglacial Interstadial in North-West Europe is characterised by significant climatic and environmental changes. In this unstable period, the first Azilian inventories appeared in the archaeological record. They were clearly related to Late Magdalenian behavioural traditions which were highly resilient during the unstable Late Weichselian Pleniglacial. However, changes in spatial organisation, subsistence strategies, resource procurement, and technical behaviour suggest that the hunter-gatherers increasingly adapted to a temperate environment during the Lateglacial Interstadial. By the mid-Lateglacial Interstadial, the so-called Federmesser-Gruppen occurred which also seemed to be related to a Magdalenian substratum. These inventories were usually associated with forest environments. Thus, the temporal, spatial, behavioural, and ecological relationship of the Late Magdalenian, Early Azilian, and Federmesser-Gruppen is essential for the understanding of the process of adaptation and, consequently, of an important mechanism of behavioural evolution.

At first, a consistent high-resolution chronological framework was created in which climatic, geological, environmental, and archaeological data could be set in a reliable chronological order. In a next step, well dated assemblages from northern France and western Germany were compared to analyse the relationship between the Lateglacial archaeological complexes. Therefore, a technological analysis of lithic industries was used allowing an assessment of the behavioural evolution at different scales of space and time. A necessary objective of this

approach is the discussion of intra- and inter-regional variability among the prehistoric inventories in the context of function and available natural resources. Moreover, these lithic studies had to be accompanied by spatial and faunal evidence to understand variations as part of an adaptive process.

The results of this comparative analysis indicate that the frequently proposed technical impoverishment during the Lateglacial Interstadial reflected an increasing knowledge about the locally and regionally available resources and their properties. In addition, the availability of other resources such as wood made the use of alternative systems possible. The development of some of these resources was not constantly and, thus, changes in the archaeological record also appeared cumulatively. Furthermore, the human willingness to change small things to prevent larger changes can be considered as a source of delayed reactions which in periods of significant environmental variation can result in severe threshold situations for complete societies.

In consequence, the process of adaptation in the Lateglacial can be described as inconstant and depended on the availability of alternatives. Therefore, many Magdalenian behaviours were still preserved during the Early Azilian but became unnecessary in an increasingly temperate environment. Moreover, the small scale adaptations and the neglect of a fundamental change in the behaviour resulted only during a period of severe and short-lived environmental fluctuations in a social collapse and reorganisation.

## 8. PALAEOETHNOGRAPHY OF EARLY AZILIANS. THE CONTRIBUTION OF PARIS BASIN.

*Debout, Grégory (UMR7041) gregory.debout@mae.u-paris10.fr*

*Bignon-Lau, Olivier (UMR7041) olivier.bignon-lau@mae.u-paris10.fr*

*Bodu, Pierre (UMR7041) pierre.bodu@mae.u-paris10.fr*

This contribution aims to review the current knowledge concerning the Early Azilian period in the Paris Basin. This area has been densely occupied by the groups of the Upper Magdalenian. By contrast, Early Azilian sites already known are scarce, but show good archaeological preservation. It is particularly the case of the Le Closeau site located at the bottom of the Seine valley. It has been possible to realize a complete palaeoethnographic inves-

tigation, as it has been done previously on the famous Magdalenian sites of Pincevent and Etiolles, for example. Our results enable us to accurately document the Early Azilian palaeoethnography and to highlight the singularity of their lifestyle.

ORAL

## 9. THE EMERGENCE OF AZILIAN ON THE EDGE OF THE WORLD: TECHNICAL SYSTEMS AND MOBILITY IN THE NORTHWEST OF FRANCE

*Marchand, Grégor (CNRS) gregor.marchand@univ-rennes1.fr*  
*Naudinot, Nicolas (Université de Nice) nicolas.naudinot@cepam.cnrs.fr*

The Tardiglacial coast line flooding deprives us of major information concerning the exploitation on the maritime resources during the Azilian, but it does not totally forbid us to think about the economical consequences of a human setting-up on the edge of European continent. At that time, the current Armorican peninsula is a peneplain which lines the Paleo-Manche estuary. On this crystalline massif, the flint is present only in the form of pebbles along the shores, what implies for prehistoric men a permanent link with the ocean, completed by a more or less use of local rocks (Eocene sandstones, quartzites). These geographical and geological constraints are obviously a key determining factor in population mobility and economic networks.

Technical evidences of this organization can be detailed for Early Azilian within two recent excavations in the rock-shelters of Kerbizien (Huelgoat) and the Rocher de l'Impératrice (Plougastel-Daoulas), in the west of Brittany. In such spaces confined by the walls and with little domestic area, the technical signature that we perceive is extremely original compared to the later choices (Recent Azilian or Mesolithic period). The important fractionation of the reduction process on a wider area and a specialization of the activities in the sites themselves are especially noticeable and open on new economic models. The importation of flint pebbles from the shores is obvious as well as the importation of blades produced in the sedimentary basins, which implies routes of more than 300 km. The integration of local rocks in the toolkit reveals another facet of human mobility, including a regular land surveying by these populations.

The genesis of this particular economic organization is certainly to link with the technical system transformations at the beginning of Azilian. These changes lead to recent Azilian technical system as we know it in tens of

site of western France, les Chalognes (Mozé-on-Louet) being the best-known. The evolution seems very progressive for the lithic system, as well as the symbolic registers. The economic network we perceive in both sites grew up probably with complex interactions with the environment.

ORAL

## 10. LANDSCAPE USE IN THE LATEGLACIAL OF SOUTH EAST BRITAIN

*Mills, William (University of Oxford) william.mills@stx.ox.ac.uk*  
*Barton, Nicholas (University of Oxford) nick.barton@arch.ox.ac.uk*

Recent discoveries in the Wey Valley, a major tributary of the Thames, have highlighted the need to re-examine the question of the relationship between Lateglacial (LG) hunter-gatherers and their use of landscape. The new sites probably date from around the beginning of the second half of the Interstadial (equivalent to the Allerød, 13,950–12,900 Cal BP), when more open environments were replaced by birch and pine woodland and elk, wild cattle and red deer formed the main available hunted species. This period in Britain also coincided with the appearance of Federmesser industries. The flint assemblages at this time become increasingly dominated by tool inventories that include curve-backed blades (*pointes á dos courbé*) but also with well made blades and in the early part of this phase tools such as shouldered points. These recent excavations also highlight the necessity for the re-evaluation of British museum collections of open-air sites preceding the recent advances in the characterisation of LG lithic assemblages in northern Europe.

During this time large river valleys may have played an increasingly important role for humans as places for targeting particular resources (raw materials, meat animals as well as plants) and for channelling movements in the more densely vegetated landscapes of southern Britain. In this paper we examine the position of Later Upper Palaeolithic (including Federmesser) sites in relation to the floodplain of the Wey Valley and in terms of proximity to raw material sources.

The study focusses on a combination of cross-referenced location and descriptive data provided by national databases analysed spatially with a Geographic Information System (GIS) as well as the systematic re-evaluation of museum collections of lithic material from this region.

This is on-going research and I will be presenting the preliminary results for the Wey Valley, a tributary to the Channel River via the Thames, testing the iterated hypothesis of whether river valleys were corridors enabling movement of groups within north western Europe during the LG.

The archaeological layer does not appear to be greatly disturbed as indicated by initial refitting evidence and the presence of fine artefact debris. The surface condition of the flint artefacts is also very well preserved and preliminary results suggest excellent potential for micro-wear analyses. Optically Stimulated Luminescence (OSL) dating studies are in progress and so far broadly confirm a Late Glacial age for the sands. Fitting the Guildford site accurately into a Late Glacial framework presents one of the key challenges in the post-excavation work. It remains to be demonstrated whether the assemblage is part of a transitional phase of the early Federmesser or belongs to a more developed phase within the equivalent of the Allerød interstadial.

---

POSTER

**11. A NEW LATER UPPER PALAEOLITHIC SITE AT GUILDFORD FIRE STATION, SURREY, UK**

*Attfield, Ben (Oxford Archaeology, Janus House, Osney Mead, Oxford) twistedjohnson@hotmail.co.uk*

*Barton, Nicholas (University of Oxford) nick.barton@arch.ox.ac.uk*

*Donnelly, Michael (Oxford Archaeology, Janus House, Osney Mead, Oxford) m.donnelly@oxfordarch.co.uk*

*Roberts, Alison (Ashmolean Museum, Oxford) alison.roberts@ashmus.ox.ac.uk*

A rare example of a well-preserved Later Upper Palaeolithic open-air site has recently been discovered in Guildford, Surrey in South-east England. The site came to light during the preparations to build a new Fire Station and the excavations, funded by Surrey County Council, were undertaken by Oxford Archaeology in advance of the development. Excavations revealed two or possibly three dense clusters of flint artefacts covering an area of ~65 m<sup>2</sup> and stratified in sandy sediments just above the present floodplain of the Wey Valley at Guildford. The flint assemblage consists of ~5550 artefacts, excluding finer knapping debris.

A high proportion of the debitage can be classified as blades, some of them well made and slightly curved in profile with carefully prepared faceted butts. All stages of the *chaîne opératoire* seem to be present from the initial shaping and preparation of the cores, including cortical flakes, crested pieces, core tablets and other rejuvenation flakes, to the final discard stages. There are also over 100 retouched tools which is a relatively large number for a British LUP site. The most important categories include scrapers on the ends of blades, burins (both dihedral and truncation), a few piercers and becs, end truncated blades and a number of blades with scalar 'Magdalenian' retouch. Amongst the backed pieces are broken backed blade/lets and points. Two of the latter appear to represent curved backed bi-points of *Federmesser* type but neither of them is complete.

# A6a Human occupations in mountain environments: a comparative methodological perspective

## 1. PREHISTORIC FREQUENTATIONS IN THE ALPS: THE PROJECT SURVEY ALTA VAL SESSERA (PIEDMONT - IT)

*Rubat Borel, Francesco (Soprintendenza per i Beni Archeologici del Piemonte e del Museo di Antichità Egizie) francesco.rubatborel@beniculturali.it*

*Berruti, Gabriele Luigi Francesco (Department of Geology, University of Trás-os-Montes e Alto Douro; Associazione culturale 3P - Progetto Preistoria Piemonte) gabrielefberruti@gmail.com*

*Berté, Davide (Sapienza Università di Roma; Associazione culturale 3P - Progetto Preistoria Piemonte) dvb83@libero.it*

*Daffara, Sara (Associazione culturale 3P - Progetto Preistoria Piemonte) saradaffara@virgilio.it*

*Scoz, Luca (Muse-Museo delle Scienze di Trento; Associazione culturale 3P - Progetto Preistoria Piemonte) luca.scoz@gmail.com*

Val Sessera is an underpopulated Italian alpine valley located in the northeastern Piedmont between the provinces of Biella and Vercelli.

We expose here the data obtained during the first and the second year of the project "Survey Alta Val Sessera" held in 2013 and in 2014 under the scientific direction of Soprintendenza per i Beni Archeologici del Piemonte in collaboration with Associazione Culturale "3P" and DocBi that had as its purpose the identification of mesolithic frequentations in the Valley.

The interpretative scheme employed starts from the one developed for Trentino and the South Tyrolean region by Broglio and Improta. This model has already been shown to be applicable also to the western part of the Alps within the research carried out in the area of Monte Fallere (AO).

During the campaigns, surveys in the valleys of the creeks Sessera and Dolca have been carried out using the patterns of settlement and mobility in the alpine environment developed by K. Kompatscher and N.M. Kompatscher, in order to identify the most interesting areas to investigate.

In the considered areas were made samplings in each place that answered to at least two of the four parameters set by K. Kompatscher and N.M. Kompatscher about the mesolithic occupations in high altitude areas.

The samples were carried out by performing the decortifications of the turfy surfaces on an area of 50x50 cm and

the subsequent restoration of the previous environmental situation. Along the paths and in the areas where the turf was relieved or removed by the passage of cattle, we carried out intensive surveys. For each artefact found and for each survey done we took photographic documentation and positioning by GPS technology.

Preliminary results indicate that the valley of the Sessera creek was occupied by human groups using knapped lithic industries while we have not had similar findings in the valley of the Dolca creek. The activities carried out led to the identification of nine sites characterized by the presence of lithic industry made of local quartz. These frequentations should be placed chronologically after the Late Glacial Maximum.

The findings, though the technological study suggests their Mesolithic belonging, have no diagnostic elements for a more precise chronological collocation.

The importance of the data obtained from these first two years of the project "Survey Alta Val Sessera" consists in having successfully tested a method of research aimed at identifying human frequentations at high altitude also in this part of Piedmont.

The data will be compared with those coming from the other alpine regions in attempt to obtain a more complete picture of the Mesolithic occupation of the alpine environment.

## 2. SITE DETECTION IN THE APPENNINES: TWO CASE STUDIES

*van Leusen, Martijn (Groningen Institute of Archaeology) p.m.van.leusen@rug.nl*

The problem of detecting human occupation in mountain areas has been the object of investigation by the Department of Classical and Mediterranean Archaeology of the University of Groningen (NL) in several research programs since 2005. Here I would like to present two case studies, both conducted in the Italian Appennines, that illustrate the approach developed and the kinds of results obtained. Case study 1, on the Monti Lepini (anti-Appennine chain, Lazio region), will focus on the re-interpretation of legacy site data in the light of modern systematic surveys; case study 2, on the Pollino massif (on the border of Calabria/Basilicata regions), will focus

on the detection and interpretation of ephemeral/seasonal occupation traces. It will be argued from these two cases that a substantial concerted research effort is needed to build the comparative methodological perspective advocated by the session organizers.

### 3. PREHISTORIC COPPER PYROTECHNOLOGY IN THE SWISS ALPS: APPROACHES TO SITE DETECTION AND CHAÎNE OPÉRATOIRE

*Della Casa, Philippe (University of Zurich) phildc@access.uzh.ch*

*Turck, Rouven (University of Zurich) rouven.turck@uzh.ch*

*Naef, Leandra (University of Zurich) leandra.naef@uzh.ch*

It has been known for decades that prehistoric copper pyrotechnology was performed in the Oberhalbstein valley (Grisons, Switzerland). However, this copper deposit is among the least explored ancient mining areas of the Alps so far, though various hypotheses on the importance of the copper produced in the valley since the Early Bronze Age have been repeatedly expressed.

A new project by the Dept. of Prehistoric Archaeology at the University of Zurich now focuses on a systematic evaluation of the research situation within a Central and Eastern Alpine framework: surveys, datings, ore analyses, analyses of slags and residues, chaînes opératoires of copper production and use, as well as local Bronze Age settlements with traces of metal working are at the heart of this new research.

Recent fieldwork has provided very promising results: structured slag heaps and production areas with a smelting furnace dating to the beginning of the Iron Age were documented. The contribution will focus on methodical approaches to site detection (survey) and reconstruction of operational sequences.

### 4. CAUCASIA TOP DOWN - 10 YEARS OF GIS AND REMOTE SENSING APPLICATION ON A LBA HIGH MOUNTAIN CULTURAL LANDSCAPE IN THE NORTH CAUCASUS (RUSSIA)

*Reinhold, Sabine (DAI Eurasia-Department, Berlin) sabine.reinhold@dainst.de*

*Belinskij, Andrej B. (GUP Nasledie, Stavropol) abelinski@gmail.com*

*Korobov, Dmitrij S. (Institute of Archaeology, Moscow) dkorobov@mail.ru*

The Caucasus is Europe's highest fold mountains systems, geographically similar to the Pyrenees or the Alps. With a much less intensive modern infrastructure as e.g. in the Alps, site localisation is task to specific survey projects. This overview will present the results of 10 years of multidisciplinary research by a joint Russian-German project in the North Caucasus. This scaled landscape archaeological research focused on the reconstruction of the economic and social parameters of a high mountain community.

Using high resolution aerial photos, satellite images and systematic field survey a complete cultural landscape with more than 260 sites on a remote mountain plateau up to 2400 m asl was documented with an accurateness, that has few parallels in European landscapes. This is due to a nearly intact environment and a high visibility of ancient sites on remote sensing images. Downscaling the site location process, we focused on microregions and single sites, using geophysical prospection, soil analysis and excavation to reveal activity areas in the sites, especially the precise localities of animals.

As a result a complete mountain agricultural system can be reconstructed in its economic as well as its social and ideological aspects. It date to the local Late Bronze Age, i.e. the second half of the 2<sup>nd</sup> millennium BC and is one of the earliest real Almwirtschafts-systems known.

### 5. PLACE-BASED DETECTION OF THE TRANSITION TO AGROPASTORALISM FROM COLLUVIAL SEDIMENTS OF THE FRENCH WESTERN PYRENEES MOUNTAINS

*Leigh, David S. (University of Georgia, Geography-Geology Bldg., 210 Field Street, Athens, Georgia 30602, USA) dleigh@uga.edu*

*Gragson, T.L. (University of Georgia, Geography-Geology Bldg., 210 Field Street, Athens, Georgia 30602, USA) tgragson@uga.edu*

*Coughlan, M.R.*

We detect transition to agropastoral occupation in a mountain landscape by radiocarbon dating physical and

geochemical signatures of conversion from native forest to pasture within colluvial stratigraphic sections. Our study sites are located on hillslope benches, toeslopes, or depressions immediately beneath zero-order hollows draining few to several hectares in the commune of Larrau (Pyrénées Atlantiques, France). Sample sites are chosen to maximize likelihood of spatially and temporally uniform sedimentation (primarily by slopewash). This constitutes a place-based strategy of deciphering the chronology of agropastoral activities within individual fields, which is applicable to other mountain ranges of the world. Stratigraphic columns are augured in contiguous sample levels with decadal to centennial temporal resolution. We find that the colluvial sediments contain evidence of fires that initially cleared and subsequently maintained pastures. Natural or non-anthropogenic fires are very rare in this environment. We therefore interpret the unusually high concentrations of charcoal, rapid sedimentation rates, and high levels of magnetic susceptibility evident in colluvial strata as evidence of intentional fire use. The relative abundance of n-alkane carbon chains (C31/C27) across levels further discriminates sediment that accumulated under forest versus pasture. Results from a limited number of sections thus far indicate that intense burning and clearing occurred during the late Holocene, starting at about 4000 cal yr BP, but sporadic and limited fires also occurred on the landscape during the early and middle Holocene. After 4000 cal yr BP the sedimentation rates increased at least twofold, constituting "legacy" sediment. Elsewhere, similar shifts in fire regimes and vegetation assemblages are found in direct association with anthropogenic proxies (e.g. agricultural pollen taxa, fungal spores of sheep dung, and archaeological sites). Consequently, our method may provide a good indicator of human presence and land-use activities for mountainous areas where archaeological sites are sparse and artifact assemblages are limited.

**6. RESEARCH PROSPECTS OF SINGLE PLATFORM MICRO-UNMANNED AERIAL VEHICLES (UAVS): UNCOVERING THE UPLAND ZONE ARCHAEOLOGICAL HERITAGE OF THE MIRKOVO BASIN, BULGARIA**

*King, Helen (Northumbria University) helen.m.king@northumbria.ac.uk*

*Chapman, John (Durham University) j.c.chapman@durham.ac.uk*

*Dumanov, Boyan (New Bulgarian University) bdumanov@abv.bg*

*Gaydarska, Bisserka (Durham University) b\_gaydarska@yahoo.co.uk*

*Entwistle, Jane (Northumbria University) jane.entwistle@northumbria.ac.uk*

*King, Nigel (QuestUAV) nigel.king@questuav.co.uk*

Autonomous sensor platforms such as unmanned airbourne vehicles (UAVs) are becoming an established technology in many fields of monitoring and their use is steadily increasing, including in the field of cultural heritage. This paper presents the output achievable by a micro-UAV for the rapid generation of aerial imagery, digital terrain models (DTM) and broadband vegetation indices for archaeological prospection from a single platform. Combined, these datasets can be used in the rapid survey of areas of interest that would not normally be considered practical due to time and cost implications and to identify archaeological features that are not readily visible in aerial imagery alone.

The adoption of a single platform with a dual camera set up was used to generate a suite of datasets covering an area of 10km<sup>2</sup> in seven flights. This study provides a work-flow protocol for the deployment of a micro-UAV, data acquisition and processing that can be used for site prospection and site investigation. Real-time processing of the aerial imagery and generation of well established indices (e.g. normalised vegetation index (NDVI), false colour composites, NDVI colour composites) enabled in-field decision making and planning to maximize the best use of researchers in the field.

The time spent post-processing data was significantly reduced as all data was sourced from one platform. The single platform also enabled a high resolution of output (~5cm and 10cm DTM) and aided in the identification of features, such as palaeochannels, pits, remains of buildings and other structures, and relict field layouts and boundaries.

The datasets generated provided new insights into the wider context of known sites and highlighted additional areas of (human) disturbance for field reconnaissance. The Mirkovo Basin is one of the best-mapped upland basins in the Balkans. The results have made significant improvements to the Heritage Mapping aims of the District Council.

**7. A "TOTAL ARCHAEOLOGY PROJECT" ON THE UPLANDS OF SAN VITO DI CADORE (DOLOMITES, BELLUNO PROVINCE, ITALY)**

*Carrer, Francesco (Department of Archaeology, University of York, UK) francesco.carrer@york.ac.uk*

*Cavulli, Fabio (Dipartimento di Lettere e Filosofia, Università degli Studi di Trento, Italy) fabio.cavulli@lett.unitn.it*

*Fontana, Federica (Dipartimento di Studi Umanistici, Università degli Studi di Ferrara, Italy) federica.fontana@unife.it*

*Visentin, Davide (Dipartimento di Studi Umanistici, Università degli Studi di Ferrara, Italy) davide.visentin@unife.it*

*Cesco Frare, Piergiorgio (Via Maraga 11, 32100 Belluno, Italy) glcesco1@alice.it*

*Mondini, Carlo (Associazione Amici del Museo di Belluno, Italy) carlomondini46@libero.it*

*Pedrotti, Annalisa (Dipartimento di Lettere e Filosofia, Università degli Studi di Trento, Italy) Annalisa.Pedrotti@lett.unitn.it*

In the paper we will report the first results of the ongoing archaeological survey project developed in the uplands of San Vito di Cadore (Dolomites, Belluno province, 1800-2700 m a.s.l.) from 2011 to 2013. The adoption of a "total archaeology" approach has enabled to record different types of evidence without chronological limits, from prehistoric sites - Late Palaeolithic and Mesolithic - to present day structures, thus allowing a diachronic perspective on human occupation in this area.

The methodology adopted has implied a multi-scale analysis. During the survey different categories of data have been recorded, such as single artefacts micro-scale - and wall structures - macro-scale.

The position of every evidence has been recorded with an handheld GPS. Moreover written and photographic documentation has been drawn up directly on the field. The final step was the creation of a webGIS for the analysis of all the collected data (<http://laboratoriobagolini.it/ais/>).

The archaeological evidence recognised consists of six main categories:

1. Prehistoric sites represented by lithic artefacts which mostly refer to an occupation of the area by Mesolithic hunter-gatherer groups;
2. agro-pastoral sites, like small dry-stone structures (huts), boulders for the distribution of salt to the live-

stock (called "massi del sale", literally "salt boulders"), rock-shelters, small and large dry-stone enclosures;

3. mining exploitation

4. rock engravings, like boundary cross-shaped markers, writings and cup marks; however, the circular engravings are a specific feature of this territory and can be preliminarily interpreted as border markers;

5. World War I structures: trenches, presumed structures for artillery and platforms for military campsites;

6. isolated hearths and rock shelters that testify the modern and contemporary presence of hunters and hikers.

Although this research is still at a preliminary stage, results obtained so far highlight an intense human occupation of this upland territory since prehistoric times. The present Alpine landscape of this gorgeous sector of the Dolomites is the result of several thousand years of human influence. Human occupations and modifications occurred over time and are still active, frequently overlapping one another. According to these considerations, new research and dissemination perspectives should be taken into consideration. First of all the adoption of a "total archaeology" methodology seems to be essential in order to fully understand the evolution of the cultural landscape in this territory. Moreover collected data represent a promising starting point for the creation of tourist itineraries capable of merging naturalistic and archaeological aspects in such a peculiar environment as the Belluno Dolomites.

ORAL

**8. SURFACE SURVEYING IN HIGH MOUNTAIN AREAS, IS IT POSSIBLE? SOME METHODOLOGICAL CONSIDERATIONS**

*Gassiot Ballbe, Ermengol (Universitat Autònoma de Barcelona) ermengol.gassiot@uab.cat*

*Clemente-Conte, Ignacio (IMF-CSIC) ignacio@imf.csic.es*

*García Casas, David (Universitat Autònoma de Barcelona) david.garc83@gmail.com*

*Mazzucco, Niccolò (IMF-CSIC) nicco.mazzucco@gmail.com*

*Obea Comes, Laura (Universitat Autònoma de Barcelona) laura.obea87@gmail.com*

*Rodríguez Antón, David (IMF-CSIC) david.anton79@gmail.com*

Until the last twenty years or so, the high mountain areas were almost excluded from the archaeological research. Firstly, because it was assumed that above 2.000 m.a.s.l. in Europe climatic and environmental settings preclude any stable human settlement. Secondly, because the steep slopes and the rugged terrains typical of the mountain areas make difficult to implement systematic surface surveys. However, this latter point is only partly true. Sampling strategies for flat terrains are difficult to apply in abrupt mountain areas. Nevertheless, recent projects of research in high mountain Alpine and Pyrenean areas have been applying new sampling strategies, which allow to surveys extensive surfaces in this kind of environments. This presentation discusses the methodological organization of the systematic surveying of mountain areas between 1.700 and 2.900 m.a.s.l. in Central Pyrenees, more specifically in the National Park of Aigüestortes i Estany de Sant Maurici. This debate involves not only the field organization of survey and the sampling strategies, but also other problematic: e.g., how to record dispersed but continuous evidences over the space.

As a result of these new surveys in high-altitude environments, unexpected humanized past landscapes are emerging. New images that challenge the historical reconstructions and the visions of the mountain areas traditionally proposed from archaeology.

ORAL

### 9. UNCOVERING THE FROZEN PAST- SURVEYING & MONITORING GLACIAL ARCHAEOLOGICAL SITES

*Callanan, Martin (Dept. of Archaeology and Cultural History, NTNU-University Museum, Trondheim, Norway) Callanan@ntnu.no*

Glacial archaeological sites are usually located in remote mountainous regions. Many of these sites are now melting and retreating due to warming climates. Managing heritage sites in ice patches, glaciers and in permafrost is particularly challenging for a number of reasons. Firstly, they sometimes contain fragile organic artefacts and eco-facts of great scientific value that need to be recovered quickly. Secondly, the melting processes are uneven and occur over long periods of time, making long-term monitoring necessary. Thirdly, the remoteness of many of these sites means that there are often serious logistical issues to be addressed before archaeological surveying and monitoring can begin.

As global climates look set to continue to warm up, sites will continue to degrade and new artefacts and sites will be exposed. This is the case both in glacial archaeological regions already identified and in several regions around the world where targeted surveys have yet to be organised. For this reason it is important to undertake a review of the surveying and monitoring methods currently employed within this field.

In this presentation, we will look at examples of glacial archaeological sites from around the world and at some of the artefacts and information they have produced about how humans have used remote mountain landscapes in the past. We will also review the different surveying and monitoring approaches that have been employed in the different regions.

### 10. MISSING ELEMENTS IN CULTURAL UNDERSTANDING OF HYDROTHERMAL LANDSCAPE OF CARPATHIANS IN MIDDLE PALEOLITHIC

*Magda Cieśla - (Institute of Archaeology, Jagiellonian University) nn8065@gmail.com*

*Paweł Valde-Nowak (Institute of Archaeology, Jagiellonian University) p.valde-nowak@uj.edu.pl*

As soon as in 1950', when the excavations at Middle Paleolithic sites in Slovakia (such as Ganovce, Horka-Ondrej, Beharovce or Bešenova) had begun, the correlation between archaeological inventories connected with microlithic Taubachian and presence of travertine (sedimentary rock, formation of which in many cases is related to hydrothermal activity) was observed. Connection between two phenomena, cultural and geological, has never played a major role in the discussion of Neanderthal presence in Central Europe, as many sites outside of the Carpathians have not displayed any connection with travertine or thermal waters. Nevertheless, new analysis of data leads to the conclusion, that in light of some new evidence, this problem should be discussed again, especially in context of layer XIX of Obłazowa Cave.

The karst system of Calvero de la Higuera (Pinilla del Valle) formed in Late Cretaceous limestones and dolomites at the Upper Lozoya valley pop down located in the Eastern part of the Spanish Central System at the Guadarrama mountain range. The archaeological fieldworks, started in 2002, revealed the presence of a middle elevation mountain (1,100 m asl) fossil multilevel karst modeled by lithological-structural controls and Quaternary local base lowering. At least three levels of subhorizontal caves detected hanging above the current thalweg of the Lozoya River. The whole karst system dismantled as result of bed rock weathering and surface processes, and istotally infilled by Middle-Late Pleistocene alluvial sediments, with debris and colluvium deposits. The systematic fieldwork shown Middle-Late Pleistocene human activity and carnivores inhabitants at the complex karstic system composed by the caves of Buena Pinta, Camino, Des-Cubierta and Navalmaillo rock shelter. Camino and Buena Pinta sites were identified such as carnivores inhabitants where the paleontological record summary includes human remains (*Homo neanderthalensis*). At the upper level (Des-Cubierta cave) was identified Middle-Late Pleistocene human activity with important paleontological remains. Finally in the Navalmaillo rock shelter recognized like as Neanderthal site with abundance artifact records.

ORAL

## 12. MOUNTAINOUS SETTLEMENTS MODALITIES DURING PALAEO-LITHIC IN THE LESSER CAUCASUS (REPUBLIC OF ARMENIA)

If the Great Caucasus is a strong border in the isthmus between Black and Caspian seas, the Lesser Caucasus, with its piedmont with volcanic plateaus, is looking like an area more opened and crossed during Palaeolithic; however, it remains a mountainous region, close of a "middle stage mountain" in Western Europe, with strong topographic and climatic factors.

Recent works in Republic of Armenia allow us to compare very different strategies of settlements and economic exploitations: the set of Middle Palaeolithic sites in the Kasakh middle valley (Aparan district), the Kalavan 2 site Mousterian layers and the Kalavan 1 Epigravettian settlement (Gegharkunik district).

At first, we will explain how these sites have been spotted: a large survey based on geomorphologic problematic with specified goals versus diachronic survey in the known area of a prospector.

Then, we will suggest the patterns we have built with our results: to try to get further than the classical dichotomies Neanderthal-residential versus anatomically

modern human-logistic mobility systems, we are going to try to define these patterns and may be nuancing them also, by examining choices and modalities of these mountainous settlements.

We will end by discussing the geographic dynamic of these lithic techno-complexes in front of the Great Caucasus border.

ORAL

### 13. THE MESOLITHIC WITH GEOMETRICS IN THE SOUTH OF "PICOS DE EUROPA" (NORTHERN SPAIN)

*Neira Campos, Ana (Universidad de León) aineic@unileon.es*

*Fuertes Prieto, M. Natividad (Universidad de León) n.fuertes@unileon.es*

*Herrero Alonso, Diego (Universidad de León) malloango@gmail.com*

In this work we present the main features of a Mesolithic that we have called "Mesolithic with geometrics". It appears in two caves, El Espertín and La Uña (levels III and IV), both located in the south versant of Cantabrian Range, and their chronology goes from the second half of VII mil. cal BC until the end of the VI mil. cal. BC.

This work will be focus on two main issues, the GIS analysis of the sites, and the analysis of the lithic industry. As for the last one, the petrographic characterization of the raw materials will let us examine its acquisition patterns. Also, a techno-typological study of the lithics, focusing on the retouched tools, will be presented.

Some similar traits of these caves are its altitude over sea level (more than 1200 m in both cases) and the small size of the sites. As for the lithics, the raw materials used and the scarcity of geometrics are much the same, and also they share a lithic industry with deeply rooted archaic features linked to the Upper-Paleolithic/Azilian regional tradition.

Nevertheless, there are also some differences between them, as for the geographic situation of the caves and the osseous industry.

ORAL

### 14. A NEW STONE AGE TRANSIT ROUTE ACROSS THE MAIN RIDGE OF AUSTRIAN ALPS

*Leitner, Walter (University of Innsbruck Institute of Archaeology) walter.leitner@uibk.ac.at*

In the course of an Interreg IV-project between Austria and Italy a new prehistoric alpine transit route frequented and prospected by hunters, gatherers and shepherds could be detected. The track area is to be considered very important on the one hand as a hunting and meadow ground and on the other hand as a mining district where Rock Crystal and soapstone has been quarried out. Especially the excellent quality of quartz leads to the cognition that this material had a remarkable economic value and played a significant role in the early countertrade of the Alps.

ORAL

### 15. HUNTING AND FARMING IN THE MOUNTAINS: TWO NEOLITHIC SITES IN THE NORTHEASTERN ITALIAN ALPS

*Santaniello, Fabio (Università degli studi di Trento) fabio.santaniello@unitn.it*

*Grimaldi, Stefano (Università degli studi di Trento) stefano.grimaldi@unitn.it*

*Pedrotti, Annalisa (Università degli studi di Trento) annalisa.pedrotti@unitn.it*

Lithic assemblages coming from two northeastern Italian Neolithic sites have been techno-functionally analysed.

The open air early Neolithic site of Lugo di Grezzana, Verona ("Fiorano" facies, 5300-4900/4700 BC cal) is located in the Monti Lessini, a region rich in flint formations. La Vela open air site, in the Adige valley, provides a stratigraphic sequence ranging from the early Neolithic ("Gaban" facies, 5000 – 4700 BC cal) to the middle Neolithic (Square Mouth pottery, VBQ I, ca.4700 BC cal, and VBQ II, 4500/4440-4300 BC cal). The research will focus on lithic raw material procurement/production/functional strategies which have been adopted in these sites.

The early-middle Neolithic transition is characterized by environmental, economical, and social changes such as the increasing presence of bovines among the domesticated animal species, and an observed variability in settlement strategies.

Results show that early Neolithic lithic production is characterized by a high presence of unidirectional blades while, during the two VBQ phases, the production is characterized by the presence of flakes. Differences in raw material provenance as well as in functional purposes are also noticed.

*Souto, Martín (Universidade de Santiago de Compostela) martin.souto@usc.es*

*Fraga, María Isabel (Universidade de Santiago de Compostela) misabel.fraga.vila@usc.es*

The conceptual and methodological bases of modern archaeology demand collaboration between different disciplines to achieve the same objective: to explain adequately the mechanisms of change and evolution in past cultures. In this multidisciplinary context, the study of botanical remains and geochemical record from different deposits helps to characterize past societies, from the standpoint of social and economic development.

In this case, we focus our attention on the studies carried out in the Eastern Cantabrian Range (Ordunte Mountains, Northern Iberian Peninsula). We present a multi-proxy study of the peat bog of Zalama (1330 m. asl). This is a very special place, because is an ombrotrophic (rain fed) and blanket bog formed through paludification of the summit plateau. These kinds of deposits are extremely infrequent in the Iberian Peninsula, and this case, Zalama peat bog, is probably the most south-westerly recorded example of blanket bog in Europe.

The studies carried out determine the use of this area related to pastoral activities in a relatively early chronology. As mentioned, is located in the northern Atlantic area of the Iberian Peninsula, with oceanic climatic conditions.

This area has been considered a marginal area for Neolithic technocomplex. Continuity between the Mesolithic and the Neolithic was assumed, with a long duration of hunting-gathering practices even when some Neolithic materials were available. Further, archaeologists also assumed there would be difficulty in the adoption of neolithic way of life due to the geographic conditions of the Atlantic valleys. The results presented herein, with other from nearby archaeological sites documents the use of this area by the first farmers-cattle rangers of the atlantic area of the Iberian Peninsula.

ORAL

## 17. LITHIC RESOURCE MANAGEMENT IN MOUNTAIN ENVIRONMENTS. DISCUSSION BASED ON THE CASE OF THE ANDEAN SECTOR OF TIERRA DEL FUEGO.

*Mansur, Maria Estela (CADIC-CONICET) estelamansur@gmail.com*

*De Angelis Hernán (CADIC-CONICET) hernandeangelis@yahoo.com.ar*

Lithic resource management constitutes one of the most important variables for the technological organization of hunter-gatherer societies. As essential resources for the manufacturing of tools that are themselves involved in processing and consumption of different types of resources, rocks constitute the starting point of all production processes. Consequently, the whole technological organization relies on aspects of lithic resource management: identification, collection, processing and use/consumption. In this work, we present a discussion on lithic resource management in mountain and piedmont environments, from new research conducted in the Andean area of Tierra del Fuego.

The materials studied correspond to a regional project on the exploitation of resources and population dynamics in the central area of Isla Grande de Tierra del Fuego. In this project surveys were conducted in different environments, with location of sites, delimitation and excavations. Lithic analysis was conducted following a technofunctional perspective that includes the interrelated study of the technological (raw materials and manufacturing techniques) and functional aspects (microscopic analysis) of the lithic series. Materials belong to sites located in different topographic and environmental positions and with different functionalities, such as camp sites, ceremonial sites, etc.

The raw materials used in the lithic assemblages come essentially from two geological formations, the Le-maire formation (Jurassic) and Yaghan formation (Cretaceous). However, the mountain slopes are covered by subantarctic forest, which produces a very low visibility, hinders access to lithic raw material sources and difficult raw material extraction. Besides outcrops, there are areas associated with lacustrine bodies, mainly located at piedmont sectors, where raw material is accumulated in secondary supply sources. Lithic analysis shows predominant exploitation of materials from secondary sources. Those most commonly used are rhyolites and cinerites, and in lesser measure shales, characterized by their good knapping quality, mainly depending on rock particle size. Usually the best knapping quality rocks are cinerites and shales, although rhyolites are the most abundant. Another characteristic of the assemblages is the predominance of local materials, although there are some allochthonous materials, coming from sources located at different distances, such as a silicified tuff from a primary outcrop located at more than 250 km.

From the results obtained, it is possible to discuss some more general aspects regarding the exploitation of lithic resources in mountain regions. These landscapes may seem, at a first glance, as ideal provision places for hunter-gatherers because of abundance of rock materials. However these are not always accessible in terms of visibility and possibility of exploitation. On the other hand, not all rocks can be used for the manufacture of all types of tools. We can then propose that hunter-gatherer societies that highly depend on lithic resources seek to exploit outcrops where visibility and accessibility are high, but that also search for a variety of raw materials with different characteristics that allow manufacturing of different artifacts. From these data, it is possible to discuss mobility and seasonality of hunter gatherer groups, in relation to raw materials, availability of other resources and the fuegian ethnographic model.

ORAL

**18. INDIGENOUS KNOWLEDGE AND SKILLS OF THE BHOTIYA WOMEN OF UTTARKASHI, HIMALAYAS**

*Channa, Subhadra (Department of Anthropology Delhi University) channa.subhadra@gmail.com*

The women of the pastoral sheep herding communities on the upper Himalayan ranges have nurtured skills of

wool processing, knitting and carpet weaving from the distant past. They have developed skills passed down the generations for making beautiful items out of raw wool that is given to them by the men of their community, who herd sheep and go long distance trading as a livelihood. The women, who are tabooed from going to the pastures, receive the wool in the village and know how to process, spin and dye the wool and then either knit or weave carpets out of them. They have nurtured these skills as household work and are today able to use it for commercial purposes and find a ready market for many of their items. This transition to market is giving them cash income and is supportive of their social transactions such as gift giving. The women are able to sustain their traditional role playing and augment it in the changing circumstances while keeping alive their traditional crafts and skills. Although they sell their products in the market, every item of production is still collected by them from primary sources and is part of their natural environment.

This community is one of the several that have traversed the natural geographic barriers of the Himalayan range for centuries, ferrying resources from one region to another, using the natural passes made by the river gorges. These age old practices have continued till almost the present times but are today threatened by climate change and manmade changes in the environment.

Field work was done in the Uttarkashi region of the Himalayas on the pastoral community of the Bhotiyas who have also been transborder traders engaged in the Tibetan salt trade. The data is mostly primary in nature collected by interviews and observations spread over about three years, intermittently. Some secondary sources have also been consulted from archives and books.

The work is ethnographic and descriptive so no specific conclusions exist, only a discussion is undertaken in the conclusions.

This paper will discuss the interface of indigenous knowledge, traditional skills and a cash economy in the backdrop of a subsistence mode of living and long sustained life worlds that have evolved in relation to a particular habitat and livelihood patterns. It will also touch upon the transformations brought about by climatic and technological changes.

ORAL

## 19. EL ALMOGAREN DE RISCO CAÍDO: EL TEMPLO PERDIDO DE LOS ANTIGUOS CANARIOS.

*Cuenca Sanabria, Julio (PROPAC S.L., Gran Canaria, Spain)  
<http://www.propacarqueologos.com>  
de León Hernández, José (Inspector de Cultura y Patrimonio Histórico- Arqueólogo, Cabildo de Gran Canaria, Spain)  
[deleon@grancanaria.com](mailto:deleon@grancanaria.com)*

En el año 1996 se descubrió en las tierras altas de la vertiente noreste de la isla de Gran Canaria en el Archipiélago Canario, el Almogarán de Risco Caído, un extraordinario complejo arqueológico de carácter religioso y astronómico de los antiguos canarios. El complejo cultural de Risco Caído, se localiza a 1000 m sobre el nivel del mar, en la localidad de Barranco Hondo, el municipio de Artenara, formando parte de un poblado de cuevas excavadas, muchas de ellas de tiempos históricos, deshabitadas desde principios del siglo XX. Dos de estas cuevas, las de mayor tamaño y complejidad constructiva, presentan manifestaciones rupestres grabadas en bajo relieve en las paredes interiores y en el suelo. Siendo la figura del triángulo píbico femenino la más representada, siempre asociada a las cazoletas o cúpulas, que tanto se encontraron en las paredes como excavadas en los suelos de toba volcánica. Si bien estos grabados poseen una gran importancia dentro de las culturas de los antiguos canarios, por su valor ideográfico y porque apenas se identifican en unos pocos lugares de la isla, lo más sorprendente y singular de este conjunto, es la construcción de una de las cuevas, que representan un hecho sin parangón en la arqueología del Archipiélago y de los contextos culturales de donde eran originarias aquellas poblaciones, tanto por la técnica constructiva, como por los fenómenos arqueoastronómicos y simbólicos asociados a dicha construcción. Todos los indicadores arqueológicos parecen apuntar a que se trata de un antiguo monumento religioso de los aborígenes canarios, sobre el que no se tenía conocimiento. El hecho de que estas cuevas fueron utilizadas como pajero hasta tiempo muy reciente, ayudó a que pasaran desapercibidas para la arqueología, hasta que el arqueólogo, especializado en el estudio de la religión de los antiguos canarios, Julio Cuenca Sanabria, las descubrió durante los trabajos de prospección arqueológica que llevaba a cabo en ese territorio montañoso de Gran Canaria. En el año 2011, La Consejería de Cultura y Patrimonio Histórico del Cabildo de Gran Canaria, ante el interés científico y patrimonial del Sitio Arqueológico, que presentaba un precario estado de conservación, debido a los derrumbes del escarpe donde se sitúa el complejo de cuevas excavadas, pro-

cedió a iniciar un ambicioso programa de recuperación del yacimiento. Este amplio programa ha consistido en la realización de un diverso tipo de intervenciones, tanto de obras de conservación, como de investigación, de restauración y protección, empleándose las últimas tecnologías de reproducción, diagnóstico y análisis, de esta obra prodigiosa de los aborígenes canarios, para concluir, con la adquisición de dichas cuevas, en su puesta en valor, acondicionando el yacimiento a las visitas. Actualmente se trabaja en la construcción de un Centro de Interpretación en la localidad de Artenara, en cuya demarcación se localiza el monumento arqueológico, que servirá de apoyo y complemento a este extraordinario monumento arqueológico. Risco Caído y los santuarios de montaña de Gran Canaria. Risco Caído, se enmarca en un espacio cultural más amplio, vinculado al mundo de las creencias de los antiguos habitantes de la isla. El prodigioso y espectacular relieve del interior de Gran Canaria sirvió para construir y dar apoyo a una singular forma de practicar sus cultos religiosos, que tiene su máxima representación en una serie de santuarios de montaña, en ocasiones asociados a construcciones singulares excavadas o construidas en lugares casi inaccesibles, que parecen situarse en rutas predeterminadas. Aunque, posiblemente existieron diferentes rutas, siguiendo el eje costa cumbre, en una isla surcada por grandes barrancos, será en el macizo central de Gran Canaria, en torno a lo que fue una gran caldera de explosión (Caldera de Tejeda), donde se identifican algunos de los santuarios más espectaculares de los antiguos canarios, siendo Risco Caído, vinculado a una importante ruta centro noroeste, el que alcanza la mayor complejidad y perfección constructiva y simbólica. En ese contexto, la investigación arqueológica vincula una relación funcional entre este templo calendario aborigen de Risco Caído, y lo que denominamos el Santuario de Risco Chapín, a escasos kilómetros, ubicado en el Pinar de Cueva Caballero y la Montaña de Los Moriscos (1772 m), donde se localizan los yacimientos rupestres de Cueva Candiles, Cueva Caballero y Cueva del Cagarrutal, un complejo de cuevas excavadas que presentan en sus paredes interiores la misma tipología de grabados, con representaciones de triángulos píbicos y cúpulas.

Este extraordinario complejo cultural se excavó en la vertiente Sur Suroeste del escarpe que conforma la pared norte de la Caldera de Tejeda, en el centro montañoso de la Isla. Desde este conjunto, donde se divisa el complejo arqueológico y, también cultural, de la Sierra del Bentayga, se bajaba a la cabecera del gran barranco de Agaete, pasando por el santuario o Almogarán de Risco Caído, como hito principal de lo que fue uno de los lugares de peregrinación más importantes de la isla

de los antiguos canarios. Según nos relatan las primeras crónicas tras la conquista, a estos lugares de culto, acudía la población a celebrar los rituales cuando era convocada por el estamento religioso. El relato simbólico de la luz. Los trabajos arqueológicos que se vienen realizando desde comienzo del año 2012 en este complejo cultural, han permitido identificar ciertos elementos excepcionales y novedosos, en relación al conocimiento del que se disponía hasta ahora, sobre la cultura de los antiguos canarios. Elementos que, en buena medida, cuestiona la idea preconcebida sobre el grado de desarrollo de aquellas sociedades, tanto en conocimientos y habilidades técnicas como en el del pensamiento abstracto y simbólico. Actualmente se trabaja en determinar el significado de alguno de los fenómenos que se producen en el interior de la cueva principal de Risco Caído. Quizás el elemento más excepcional, único en el archipiélago canario y sin precedentes en los contextos culturales de donde eran originarios los aborígenes de las islas, es la cueva de planta circular, algo prácticamente único en la arquitectura aborígen, con techo abovedado y con un orificio o ventanuco en su parte media por donde entra la luz solar en ciertas épocas del año, bañando, precisamente, los citados grabados púnicos y proyectando una sucesión de imágenes cambiantes entre equinoccio y equinoccio. La investigación que se viene realizando sobre lo que ocurre en el interior de esta cueva a lo largo del año, debido a la proyección de la luz solar entre equinoccios y durante el solsticio de invierno por la entrada de la luz de la Luna llena, puede dar lugar a un descubrimiento sin precedentes sobre las prácticas culturales de las culturas que vivieron en las canarias antes de la conquista, y que representa, por sus características, una manifestación única no sólo en ámbitos culturales insulares, aislados durante muchos siglos, y muy limitados desde el punto de vista de los recursos estratégicos. Tampoco a nivel internacional no son muchos los ejemplos en que más allá de que la luz juegue el papel de marcador, pueda, además representar un relato simbólico perfectamente diseñado. Lo que no cabe duda, es que la cúpula que se eleva a cinco metros del suelo y la ventana construida en ella, fueron diseñadas y construidas para que funcionaran, y aún hoy lo hace, como un gran proyector de imágenes en movimiento, que cambian de formas, según pasan los días y los meses, entre los Equinoccios de Primavera y Otoño, siendo el momento culmen de ese recorrido el Solsticio de Verano. En los estudios realizados se ha podido comprobar cómo la entrada de los rayos de luz del Orto Solar en el interior de la cueva y la proyección de la imagen lumínica en los grabados rupestres conforma lo que parece ser un relato que podría tener que ver con la fertilidad de la tierra. Así durante al menos los seis meses del año

comprendidos entre Marzo y Septiembre, en el interior de esta cueva se produce una secuencia de imágenes logradas entre la figura proyectada por la luz solar al atravesar el conducto artificial, y los grabados realizados en la pared Oeste de la Cueva, que podría corresponder con un relato, una historia que nos habla de las prácticas culturales de aquellas poblaciones que ha llegado hasta hoy, posiblemente vinculada al control del ciclo agrícola, a través no sólo de un calendario de una enorme perfección y precisión sino de la secuencia de imágenes que adquieren diferente tipología, en ocasiones recordando figura antropomorfas.

"Grain de mil" flint, first described in the 1980s, is a high-quality, siliceous raw material characterised by a matrix rich in rounded elements and Bryozoan fragments. Documented initially from several Pyrenean sites, it was subsequently identified from archaeological contexts across the Aquitaine Basin and spanning the entire Upper Palaeolithic period, but most notably Aurignacian and Magdalenian sites. Over the last decade, sources of "grain de mil" flint have been documented in the Charente-Maritime, with other possible sources mentioned for the neighbouring Dordogne, meaning that the exact origin(s) of this flint variety remains unknown. Is this flint linked to a specific geological facies of the Charente-Maritime or can it be collected anywhere in the northern Aquitaine Basin?

In order to address this issue, we conducted several raw material surveys across the entire northern region of the Aquitaine Basin, with more than three hundred raw material sources being sampled. Archaeological and survey samples were analysed at low to middle-high-powered magnification (up to x 50) based on sedimentary geology and micro-palaeontological data.

Several criteria for distinguishing "grain de mil" flint were identified at mid- to high-powered magnification, demonstrating that sources of this raw material variety are located uniquely in the extreme north-western part of the Aquitaine Basin in Charente-Maritime. In terms of archaeological material, our analysis identified "grain de mil" flint from the Charente-Maritime to have been transported by Upper Palaeolithic groups across the Aquitaine Basin, reaching as far as the Pyrenees. Despite the non-local origin of this raw material and the presence of another very high-quality flint variety in the Bergerac region, 'grain de mil' flint was nevertheless exploited across the entire Aquitaine Basin.

The simultaneous presence of these two high-quality materials in Pyrenean archaeological sites poses interesting questions concerning Upper Palaeolithic raw material provisioning strategies and transport patterns. What factors influence the selection and exploitation of particular raw materials or structure the raw material provisioning territories of prehistoric group? Further refining the sourcing of "grain de mil" flint not only provides new insights concerning these important questions but forces us to rethink previous models.

ORAL

**A2. CHERTS FROM THE AGUA-SALENZ FORMATION: DISTRIBUTION, PETROLOGICAL CHARACTERIZATION AND ITS EXPLOITATION IN THE SOUTHERN PYRENEES DURING THE MAGDALENIAN PERIOD**

*Sánchez de la Torre, Marta (SERP. Universitat de Barcelona)*

*martasanchezdelatorre@ub.edu*

*Mangado Llach, Xavier (SERP. Universitat de Barcelona)*

*mangado@ub.edu*

Defined in the geological literature as a black chert rich in organic skeletal components (Caus et al. 1993, 1997), cherts from the Agua-Salez Formation, and its corresponding to the east, the cherts of the Pardina Formation, appear as nodular cherts within packstone limestones with pithonelles and sponge spicules, that are ascribed to the Conacian period (Upper Cretaceous). These nodular cherts have been located in the area of Sopeira basin and also in the south of the Turbon massif (Huesca, Spain), where several primary and sub-primary outcrops were detected, as well as remains of ancient flint knapping workshops.

These nodular cherts can reach 35 cm long and possess a high knapping aptitude. In order to identify the use of

this chert by the Magdalenian hunter-gatherer settled in the central and eastern part of the Pyrenees and its foothills, a petrological characterisation has been undertaken.

To carry out this study several fieldworks have been conducted, in which the geographical extension of these Formations has been marked off and many samples of cherts have been collected and later analysed according to the archaeopetrological protocol of analysis.

Firstly, a macroscopic approach has been carried out using a stereoscopic microscope OLYMPUS SZ61 (6.7 to 45 increases). Secondly, many thin sections have been prepared at the Thin Section Services of the University of Barcelona and have been analysed with a petrographic microscope OLYMPUS BX41 (40 to 400 increases).

Finally, in order to know the chemical and mineralogical composition of many selected samples, two geochemical techniques of characterization have been applied: the X-ray diffraction (XRD) and the X-ray fluorescence (XRF) at the laboratories of the National Research Centre for Human Evolution (CENIEH) in Burgos.

The characterization of cherts from the Agua-Salenz formation has provided us very useful results for the study of the circulation of lithic materials and mobility patterns during the Magdalenian in the southern slope of the Pyrenees. We are faced to a new territorial marker, whose exploitation by human groups has been attested.

This communication also aims to show the distribution of these cherts from the Agua-Salenz formation in several Magdalenian sites located in the central and eastern part of the southern Pyrenees. These data has enabled us to better know where those groups moved around and how it was their relation with the lithic sources.

---

ORAL

### **A3. SILICEOUS RAW MATERIAL MANAGEMENT IN WESTERN PYRENEES: MAGDALENIAN OCCUPATION OF BERROBERRIA (NAVARRRE, SPAIN)**

*Elorrieta Baigorri, Irantzu (Universidad del País Vasco (UPV/EHU) i\_lobai@hotmail.com*

The Western Pyrenees is an area remarkable for its well-known flint outcrops that were exploited as siliceous raw material sources by the prehistoric societies that occupied the place. Berroberria cave (Urdax, Navarre) is located in this part of the Pyrenees and it has a large

Magdalenian stratigraphy. In this work the results of the siliceous raw materials provenance of the collection of the level G are presented. The selected level dates from the Middle Magdalenian (around 14500 cal BC).

Relevant data have been obtained from the archaeopetrologic analysis of the lithic industry. The employed methodology is based on the identification of the textural macroscopic characteristics determining of each flint by stereoscopic microscope. Once they are described, they are compared with the flint samples from the near outcrops in order to confirm its origin. Similarly, the technologic and typological characteristics of the lithic industry are analyzed and later matched up to the information of the siliceous material provenance.

The results are revealing to know how the resource management by the hunter-gatherer societies of Berroberria was. Firstly, the acquisition points of the siliceous sources have been pointed and defined from the characterization of the elements that integrate the industry. The generated map shows the mobility along a territory that reaches a distance of around 160 kilometres from the site to the most distant outcrop.

Secondly, it has been evaluated how the diverse flint varieties detected in the site are managed. The concept of "chaîne opératoire" is taken into account in order to recognize the acquisition, configuration and discard stages of the lithic industries. The Flysch flint is the most used and the one that best shows the technological process, therefore the flint that offers more information.

The raw material provenance studies include information about the availability and supplying potential of the territory, drawing the management and mobility map of the societies that inhabited the environment. The data obtained in this work need to be contrasted with other data of sites of the region. In this way a model of flint exploitation will be obtained for the Western Pyrenees or different patterns limited to smaller areas.

Studies about the procurement of lithic raw materials are usually based on the study of primary geological outcrops, leaving apart the so called "secondary deposits", formed by the dismantling of preexisting ones. Secondary deposits present varying features not comparable with those of the primary outcrops. For this reason, their study can be very interesting depending on the geographical context.

Recurrent exploitation of this kind of deposits is evident in Roca dels Bous (Eastern Pre-pyrenees). Cobble fragments abound among lithic remains in late Middle Paleolithic archaeological levels. These cobbles were collected in fluvial deposits of Segre river, that drains a vast watershed from the metamorphic Pyrenean axial zone southwards carrying lithologies of different types and ages (Ordovician – Oligocene).

We developed a geoarchaeologic study in which quaternary terraces near Roca dels Bous were systematically sampled. The purpose was to know in detail the availability of raw materials in these deposits. At a later stage, the study of N12 archaeological level of Roca dels Bous (composed by more than 25.000 lithic remains) has shown a strong dominance of a particular lithology: the so called black quartzite, relatively scarce in quaternary terraces according to the results of our surveys.

An interesting and unexpected scenario outlines for a very specific period of the late Middle Paleolithic in which there was an intensive exploitation of terrace quaternary deposits. Such exploitation was clearly selective and was aimed at obtaining a very particular type of rock: the black quartzite.

---

ORAL

#### **A5. RAW MATERIAL PROCUREMENT IN THE LATE MIDDLE PALEOLITHIC AND EARLY UPPER PALEOLITHIC AT COVA GRAN (EASTERN PRE-PYRENEES, IBERIA)**

*Roy Sunyer, Miquel (CEPAP-UAB) miquel.roy@uab.cat*  
*Mora Torcal, Rafael (CEPAP-UAB) rafael.mora@uab.cat*  
*Benito-Calvo, Alfonso (CENIEH) alfonso.benito@cenieh.es*

Lithic raw material provenance is an essential aspect to identify settlement and mobility patterns of prehistoric groups. In southern Pre-pyrenees, these patterns are poorly known compared to its adjacent region of the South of France.

Cova Gran de Santa Linya (Lleida, Iberia) has a wide archeo-stratigraphic sequence comprising chronologies ranging from the end of the Middle Paleolithic to the early Upper Paleolithic. It includes a key and controversial period of our evolutionary origins as the Middle/Upper Paleolithic transition (MP/UP).

We present the study of the provenance of lithic raw materials of six archaeological units of Cova Gran: S1B, S1B1, S1C (Middle Paleolithic) and 497A, 497C, 497D (Upper Paleolithic), formed in barely altered sedimentary contexts. This will allow us to trace the changes in raw material procurement patterns between 20.000 and 50.000 Ky, a time period that involves the presence of two different hominid (*H. neanderthalensis* vs *H. sapiens sapiens*). Results provide valuable data to the current circulation models of raw materials and to the debate that characterizes the transition from the Middle Palaeolithic (MP) to the Upper Palaeolithic (UP). While in MP significant amounts of quartzite are detected, the UP levels are characterized by flint as the only rock type. Local flint types are the major raw materials used but regional and long distance mobility markers have been identified.

Features observed in these archaeological units show confined mobility patterns near the settlement along the entire sequence. However significant changes are seen between MP and UP units with the presence/absence of quartzite and the use of regional resources.

La Grotte du Noisetier s'ouvre à 850 m d'altitude dans la vallée d'Aure, sur la commune de Fréchet-Aure (Hautes-Pyrénées, France). La présence de vestiges archéologiques dans cette cavité a été signalée en 1985 et deux campagnes de sondage y ont été menées par M. Allard en 1987 et en 1992-93. La reprise des travaux en 2004 était motivée par le caractère quasiment inédit de ce site, pourtant d'un intérêt majeur pour la compréhension des stratégies d'occupation du territoire et des comportements humains à la fin du Paléolithique moyen.

De nombreux résultats nouveaux ont déjà été obtenus, remettant en cause l'interprétation initiale du site comme une halte de chasse dédiée à l'exploitation des herbivores de montagne. Il a pu être démontré en effet que l'assemblage faunique avait une histoire complexe puisque les restes d'Isard (*Rupicapra pyrenaica*) ont été essentiellement accumulés par les carnivores (*Cuon alpinus*) tandis que le Cerf (*Cervus elaphus*) et le Bouquetin (*Capra pyrenaica*) ont été chassés par les Néandertaliens. L'utilisation de l'os dans la sphère technique est bien documentée, notamment à travers l'emploi de diaphyses osseuses comme retouchoirs sur silex et sur quartzite.

L'industrie lithique est essentiellement réalisée aux dépens de matériaux locaux soigneusement sélectionnés. Les ressources locales sont complétées par une importation ponctuelle de silex depuis différentes sources distantes dessinant un vaste territoire connu ou par-

couru. Les débitages Discoïde et Levallois coexistent et l'outillage moustérien est fortement influencé par les propriétés des matières premières locales. Des variations dans la composition de l'outillage semblent toutefois perceptibles au sein de la séquence (association de biface et hachereau dans un niveau, faciès à outils multi-ravivés par retouches écailleuses scalariformes quinoïdes dans un autre). La présence de quatre dents déciduales humaines complète une image complexe qui renvoie plus à celle d'un site résidentiel qu'à une halte de chasse en montagne.

It has traditionally been thought that movement of human groups across the Pyrenees would have been difficult in the Palaeolithic, although there are data contradicting this view. It may even be proposed that a Pyrenean region existed in the Palaeolithic with specific cultural traits and a series of sites, especially in the Magdalenian. The existence of routes across the central parts of the Pyrenees is not incompatible, however, with a preference for the western and eastern routes between the Iberian Peninsula and the rest of Europe. With this hypothesis, we propose to explore the western route for the movement of populations, the one that crosses the Basque Country, through different kinds of record: the location of the archaeological sites themselves, the distribution of lithic raw materials, the technocomplexes, and the similarities and differences in the cultural and subsistence behaviour of the human groups.

Situé au centre de la chaîne des Pyrénées, le site de Gargas – grotte ornée et habitat – fait l'objet de nouvelles recherches depuis 2004. A partir des études croisées des matières premières utilisées pour les assemblages lithiques, osseux et les parures, ainsi que de l'analyse archéozoologique des vestiges de faune, nous avons obtenu un meilleur aperçu des ressources mobilisées par les groupes gravettiens ayant fréquenté cette grotte entre 28 000 et 25 000 BP. Le cadre économique s'inscrit dans un environnement de piémont, entre moyenne montagne et grandes plaines alluviales (celle de la Garonne et de la Neste) tant dans les ressources vivrières (faune chassée, ramassage des bois de chute des cervidés) que lithiques (quartzites alluviaux, silex du Flysch et des Petites Pyrénées).

Dans ce contexte particulier, nous aborderons les stratégies d'approvisionnement en silex piémontais développées par les Gravettiens, étant donné l'absence de cette matière première aux alentours de la grotte dans un rayon de 25-45 km.

A une échelle régionale, on perçoit toutefois un élargissement des sphères économiques et sociales jusqu'à l'Atlantique et le Périgord, à travers l'origine des supports des parures (coquillages percés) et de certains silex allochtones.

#### ORAL

#### **B2. ADAPTATIVE STRATEGIES OF HUNTER-GATHERER GROUPS IN MONTANE ENVIRONMENTS IN THE UPPER PALAEOLITHIC: COÍMBRE CAVE (ASTURIAS, SPAIN)**

*Alvarez-Alonso, David (UNED) dalvarez@gijon.uned.es*

*Yravedra, José (Universidad Complutense) joyravedra@ghis.ucm.es*

*Arrizabalaga, Avaro (Universidad del País Vasco) alvaro.arrizabalaga@ehu.es*

*Jordá Pardo, Jesús F. (UNED) jjorda@geo.uned.es*

Cueva de Coímbre (Besnes, Peñamellera Alta, Asturias) is located on the south-west side of Mt. Pendendo (532m) in the small valley of the River Besnes, a tributary of the River Cares (Álvarez-Alonso et al., 2009, 2013b). Coímbre (135m asl) is located within the geological region known as Cantabrian Spain, more precisely in the Cuera Region, where it is situated in the front part, very near the bound-

ary with the Picos de Europa Unit (Marquínez, 1988). The cave formed in Lower Carboniferous limestone, on the southern edge of Sierra del Cuera (which reaches an altitude of 1000m in this sector), to the north of the Picos de Europa Central Massif, with altitudes of well over 2000m (Martínez García, 1981). The surroundings of the cave, which is situated in an inland valley but near the modern coast and at a low altitude, can be described as mountainous, with valleys, hills and more rugged peaks with high escarpments, which provide the area with a relatively large variety of ecosystems.

The Cave of Coímbre contains an important archaeological deposit divided into two different areas, in which most of the excavations carried out to date have taken place in Zone B. Coímbre B displays a full and very interesting Magdalenian sequence (with lower, middle and upper Magdalenian levels), in addition to a Gravettian layer. The excavations were performed from 2008 to 2012 (Álvarez-Alonso et al., 2009, 2011, 2013a, 2013b).

The hunter-gatherers who lived in Coímbre in the Upper Palaeolithic made use of several adaptation strategies allowing them to exploit all the abiotic and animal resources the environment afforded them. In this way, the faunal assemblage includes remains of ibex and chamois, associated with the mountains and crags in the immediate surroundings of the site, and also red deer, roe deer, aurochs and horses, indicating the exploitation of the animal resources living in the Besnes valley, at the foot of Sierra del Cuera.

When the faunal remains in the Magdalenian levels, dated between 16.4 and 12.8 ka BP, and those in the Gravettian layer, of about 24 ka BP, are analysed in greater detail, significant differences are identified, which indicates a differential use of the terrain. Thus, in the Gravettian, the preferential hunting of aurochs and red deer suggests the valleys in the vicinity were exploited while steeper and more mountainous areas were visited less. In contrast, in the Magdalenian, the most common faunal remains belong to ibex, which was hunted the most. Together with ibex, chamois is also very common, whereas bovids are found in very small numbers in the Magdalenian levels. These patterns reflect a change in the hunting behaviour of the occupants of the cave, in which the hunting of valley resources was transformed into a more intensive use of animals in more rugged areas, such as ibex and chamois.

ORAL

### **B3. EXPLOITATION DU MILIEU MONTAGNARD PAR LES MAGDALÉNIENS ET LES AZILIENS DES PYRÉNÉES FRANÇAISES : QUE NOUS APPREND LA FAUNE ?**

*Chevallier, Aude (Univ Paris I - UMR 7041 - Equipe Ethnologie préhistorique) aude.chevallier@gmail.com*

*Kuntz, Delphine (Post-Doctorante, UM 5608 TRACES) kuntz@univ-tlse2.fr*

Cette communication se propose d'interroger la fréquentation du milieu montagnard par les Magdaléniens et les Aziliens des Pyrénées françaises à travers l'exploitation de la faune, à partir de données inédites et bibliographiques. La chronologie de la reconquête des territoires d'altitude sera d'abord abordée à l'aide des nombreuses datations radiocarbone disponibles. Le désenglacement des Pyrénées ne semble pas s'être déroulé au même rythme sur toute la chaîne (Jalut & Turu i Michels, 2009 ; Calvet, et al., 2011 ; Delmas, et al., 2012) et on peut en effet s'attendre à observer des décalages géographiques dans le réinvestissement des différentes vallées. La comparaison des spectres de faune d'occupations situées à différentes altitudes permettra ensuite de caractériser les gibiers recherchés et de mettre en évidence une éventuelle variation dans les espèces exploitées à différents étages altitudinaux. Sur le versant sud des Pyrénées, une certaine complémentarité est évoquée entre les sites de plaine, plutôt orientés vers l'acquisition du cerf, et les sites de hauteur, où le bouquetin est souvent la première espèce chassée (Costamagno & Mateos Cachorro, 2007). On peut alors se demander si le même schéma peut être mis en évidence sur le versant nord de la chaîne. En mobilisant les indices de saisonnalité, on pourra aussi s'interroger sur les modalités de fréquentation du milieu montagnard : était-il parcouru à l'année ou seulement à certaines saisons ? Dans les Alpes italiennes, les sites d'altitude semblent avoir été occupés majoritairement au cours de la belle saison (Broglio, 1992 ; Phoca-Cosmetatou, 2009) et on pourrait s'attendre à ce qu'il en soit de même dans les Pyrénées françaises.

ORAL

**B4. FROM WHERE CAME THE AZILIAN FROM ANDORRA? AN APPROACH TO THE POSSIBLE INFLUENCES IN THE FORMATION OF THE EPIPALEOLITHIC-MESOLITHIC IN THE INNER PYRENEES**

*Martzluff, Michel (Université de Perpignan-UMR 7194) marztzulf@univ-perp.fr*

*Turu, Valenti (Fundacio Marcel Chevalier) igeofundacio@andorra.ad*

*Guilaine, Jean (Institut de France) jguilaine@wanadoo.fr*  
*Remolins Zamora, Gerard (Fundacio Marcel Chevalier) me-nairo@hotmail.com*

The monographic publication of Balma Margineda offers, since 2004, a database wanting fullest possible on "Azilian" industries and "Sauveterriennes" in their stratigraphic and paleo environmental (C. 10-4, Allerød at Boréal) context. The fact that this reference had little influence in the literature syntheses of the Epipaleolithic-Mesolithic of the Ebro Basin and even Aquitaine make it a problem. Thus, industries observed in Andorra are more comparable with Cantabrians sites, central Languedoc or the Alps rather than those from the Pyrenees. The Azilian from Andorra is necessarily linked to its surroundings we were led to point out this specificity.

We propose to pay attention to the study of primary sources and the environmental data (especially for layer C8 containing harpoons) to explain sporadic passages from the south or north in the eastern Pyrenees. The massive use of acid lavas (and rock crystal) are related with a lamellar breakdown of these prismatic materials in layer C8. Quartzite decreasing and lamellae increasing in C8 and C7 confirms a lithologic preference. Although there are veins of lava in Andorra, most of the rhyolite outcrops seems to come Cadi Cerdanya. The results of geomorphic studies conducted in recent years on the glaciated areas of the Pyrenees indicate that the direct passage by passes from the valley of the Ariège was hardly possible during the Bølling - Allerød interval; probable path then would be through Oriège to the Cerdanya plain devoid of the Late Glacial freeze.

Several factors may explain this ambivalence: 1) A cluster analysis disparity that make it difficult to assess the details (type of cutting, microlithism more or less accentuated, use of truncation, etc.). 2) The presence of special tools "à bord abattu" that may related to uses that we don't really know if the traceology technique is not used (backed knives, darts). 3) Pronounced typological variability of the "pointes à bord abattu" in the Azilian of

Andorra within a dominant fusiform group, which makes comparisons with other assemblages from neighboring foothills. 4) In these mountains the typological variability may reflect episodic stations of several groups of hunter-gatherers settled on both sides of the chain. Barely perceptible stratigraphy despite rapid sedimentation, the influx from the basins of the Ebro and Garonne are better identifiable typology, especially compared to known sets of Aquitaine (absence of large Malaurie segments and tips of Andorra).

The sharp increase in the rhyolite at layer C8 indicates more frequent paths through the Cerdanya in Allerød coming from the Ariège. However, certain flint tools from the Azilian industry point more to the Spanish Ebro side".

ORAL

**B5. UPPER PALAEOLITHIC MOBILITY PATTERNS IN THE WESTERN PYRENEES: COST AS A MEANS FOR ANALYZING FLINT PROCUREMENT STRATEGIES THROUGH GEOGRAPHIC INFORMATION SYSTEMS**

*Sánchez, Aitor (Universidad del País Vasco) aitor.sanchezl@ehu.es*

*Domínguez-Ballesteros, Eder (Universidad del País Vasco) eder.dominguez.ballesteros@gmail.es*

*Maite García Rojas - (Universidad del País Vasco) maitensx@gmail.com*

*Prieto, Alejandro (Universidad del País Vasco) alejandro.prieto@ehu.es*

*Calvo, Aitor (Universidad del País Vasco) aitor.calvo@ehu.es*

*Ordoño, Javier (Universidad del País Vasco) javier.ordoño@gmail.com*

Research on mobility patterns of the prehistoric societies in the Western Pyrenees based on the exploitation and distribution of lithic raw materials is actually under review due to three main facts. Firstly, the development of studies concerning the petrological characterization of the different flint types. Secondly, the progressive application of such an approach to the analysis of archaeological lithic assemblages. And, thirdly, the increasing use of mobility models thanks to the analytical tools provided by Geographic Information Systems (GIS).

The present study seeks to include the knowledge derived from the aforementioned approaches to deep on the understanding of the mobility patterns of the Upper Palaeolithic societies. To that end, a general accessibility model to each flint outcrop from the studied area is elaborated, based on the most accurate methods for

calculating cost factor in human movement and on the application of some common Spatial Analyst tools of ArcGIS.

The created model reflects on the map the spatial relation between the main flint procurement sources and the archaeological sites with petrological evidence of their exploitation located to both Pyrenean sides. This is used for: 1) defining the spread dynamics of flint from each source by generating isocost lines; 2) creating a corpus of measures, based on cost units, to provide quantitative data in order to establish and compare any possible journey planning and patterning in the spatial management of raw materials; and 3) identifying least cost paths between each archaeological site and flint outcrops, which could be the main axis of these journeys. A joint analysis and discussion of the results provide a new approach to the mobility and territoriality of the Upper Palaeolithic groups who settled the Western Pyrenees. Furthermore, new clues on the use of the region as a flow area for early human populations are obtained, stressing the idea of a Basque Crossroad as proposed by some scholars in the last decade.

#### DISCUSSION

#### C. THE RESOURCES MANAGEMENT AND THE OCCUPATION OF THE PYRENEES DURING THE HOLOCENE

ORAL

### C1. LES OCCUPATIONS HUMAINES DANS LA GROTTTE DES ERMITONS (MASSIF DE L'ALTA GARROTXA, PYRÉNÉES MÉDITERRANÉENS) AU LONG DE LA PRÉHISTOIRE

Maroto, Julià (Universitat de Girona) [julia.maroto@udg.edu](mailto:julia.maroto@udg.edu)  
Ortega, David (Institut Milà i Fontanals (CSIC) [ortega@imf.csic.es](mailto:ortega@imf.csic.es)

Rivals, Florent (Institut Català de Paleoecologia Humana i Evolució Social (IPHES) [frivals@iphes.cat](mailto:frivals@iphes.cat)

Solés, Alba (Atzagaia SL) [albasic.labisbal@gmail.com](mailto:albasic.labisbal@gmail.com)

La grotte des Ermitons (Sales de Llierca, nord-est de la Péninsule Ibérique) se trouve à l'intérieur du massif calcaire de l'Alta Garrotxa, dans les Pyrénées Méditerranéens. Elle

est dans un milieu extrêmement abrupt et son accès est à partir de la Vallée du fleuve Llierca.

Malgré son difficile accès, d'une partie, et malgré être un site archéologique modeste, qu'au même temps présente des problèmes de résédimentation, la grotte des Ermitons nous montre des occupations humaines pendant quatre périodes différentes: Paléolithique moyen de l'ISO 5, Paléolithique moyen récent, Néolithique moyen et Bronze final.

On présente l'analyse des aspects économiques, paléoenvironnementales et culturels de ces occupations, avec des contrastes entre eux. Les néandertaliens du Paléolithique moyen auraient profité la grotte comme hôte de chasse du bouquetin et la diversité des matières premières du milieu pour la fabrication de ses utiles, au même temps qu'ils convièrent avec les grands carnivores. Les berges et les agriculteurs de la Préhistoire récente, qui auraient ses habitats dans les zones adjacentes au massif, utiliseraient les grottes du son intérieur pour le stockage des graines.

ORAL

### C2. CULTURAL EVIDENCES OF THE MESOLITHIC BEHAVIOUR IN THE PYRENEAN NORTH AND SOUTH FACES: CONVERGENCES AND DIVERGENCES

Alday Ruiz, Alfonso (Universidad del País Vasco) [a.alday@ehu.es](mailto:a.alday@ehu.es)

Domingo Martínez, Rafael (Universidad de Zaragoza) [rdomingo@unizar.es](mailto:rdomingo@unizar.es)

Fullola Pericot, Josep Maria (Universidad de Barcelona) [fullola@ub.edu](mailto:fullola@ub.edu)

Mangado Llach, Javier (Universidad de Barcelona) [mangado@ub.edu](mailto:mangado@ub.edu)

Montes Ramírez, Lourdes (Universidad Zaragoza) [Imontes@unizar.es](mailto:Imontes@unizar.es)

Petit Mendizábal, M.<sup>a</sup> Àngels (Universidad de Barcelona) [petit@ub.edu](mailto:petit@ub.edu)

Soto Sebastián, Adriana (Universidad del País Vasco) [kura-jadri@yahoo.es](mailto:kura-jadri@yahoo.es)

Valdeyron, Nicolas (Université de Toulouse II-le Mirail) [valdeyro@univ-tlse2.fr](mailto:valdeyro@univ-tlse2.fr)

Historiographical traditions have considered both Pyrenean versants as two independent areas, with the exception of the Pyrenean Culture, that L. Pericot proposed to explain the megalithic phenomenon in this territory. However, north-south connections were actually common throughout the prehistoric times. The Pyrenees are

a territory where ideas and products can be shared, but also, due to their geomorphological features, both versants develop their own entities.

In this sense, some French and Spanish research teams are responsible of intense fieldworks dealing with the Mesolithic (*sensu lato*). They evidence for this period a dense population of the region and fluent exchanges. Hunter-gatherer groups were well established in both sides of the Pyrenean range and developed consecutive cultural solutions: Microlaminar Mesolithic/Sauveterrian; Notches and Denticulates Mesolithic; Geometric Mesolithic. These phases shared points in common, but kept their own personalities across the concerned regions.

This study intends to offer a common approach to the disposable information, harmonising data to offer a proposal that should be global, synthetic and fluent. The wide series of radio-chronological dates will evidence the rhythms of the cultural developments; the lithic raw material and specific tool-types will show not only the personality of the communities but also the borrowings among them; the description of the activities carried out by the human groups, the game management and the geographical disposition will define the concept of territoriality and will allow us to evaluate whether the populations were becoming sedentary.

Therefore, our main aim is to build an inclusive discourse that could explain the common actions and dynamics of the last hunters-gatherers that dwelled in the Pyrenean counterforts, without disdaining the particular processes.

---

ORAL

### **C3. LITHIC PRODUCTION AND USE AMONG THE LAST HUNTER-GATHERERS OF THE UPPER EBRO VALLEY: THE CASE OF LEVEL IIIB2 OF ATXOSTE (VÍRGALA MAYOR, BASQUE COUNTRY).**

In this work we present a comprehensive study on the lithic industries as a means of approaching to the socio-economic systems of the last hunter-gatherers groups from the VIII-VII millennia BP in Atxoste settlement.

Complementing the data coming from raw material, technological and use-wear analysis, we have recognized the main patterns of production and management of flint industries.

The results show a strong interrelationship between manufacture and use strategies of the lithic tools and permit us to throw some light on the sense of occupations and also on the understanding the role of the settlement in the human groups subsistence. While it is true that Atxoste may act as a strategic enclave, the new data coming from our researches reveal that the occupations would have been longer than expected for a rock-shelter, making us reconsider the strategies of land occupation of these Mesolithic communities.

The combination of three disciplines (raw material, technological and use-wear analysis) has proved to be a powerful tool not only for understanding the lithic tools management, but also the behaviours and organization patterns of prehistoric societies.

Current research in the high mountain environments is challenging the traditional perceptions that from archaeology have been proposed during the last century. Indeed, the Pyrenees had been object only of partial and discontinues researches. Despite that, has been often claimed that the Pyrenees have represented a path or connection bridge between the predominant chronological models. Intensive surveys and open-air excavations in the Southern Central Pyrenees, over the last 14 years, revealed the existence of an extensive archaeological record, with hundreds of settlements and others types of archaeological vestiges. In the National Park

of Aigüestortes i Estany de Sant Maurici, where surveys and excavations have been carried out between 1.600 and 2.900 m.a.s.l., almost 350 new sites have been documented. This sequence covers the entire Holocene period, among which a Mesolithic occupation of the alpine altitudes; an early Neolithic use of the valleys bottom around 2.000 m.a.s.l. and, later, a new phase of occupation at higher altitudes after ca. 5300 calBP. The combination of such archaeological dataset with paleoenvironmental proxies has improved our reconstruction. As result, we are able to outline an innovative scenario for of the prehistoric colonization, occupation and exploitation of the high mountain areas of Central Pyrenees.

*Clemente-Conte, Ignacio (IMF-CSIC) ignacio@imf.csic.es*

The aim of this work is to advance a reconstruction of the productive activities that were carried out with the lithic tools recovered in three Early Neolithic sites (VI-V millennium calBC) located at different altitudes (1300-1800 m.a.s.l.) in the Central Spanish Pyrenees, between the Cinca and Noguera Ribagorçana rivers. The study of the archaeological materials was based on an integrated approach that considers lithic resources as a part of an overall process of production; analyses have been made integrating different disciplines: provenance, technological and traceological analysis. Both local (1-10 km of distance) and exogenous (30-150 km) raw-materials have been identified, each one transformed and used on the basis of its technical proprieties and its accessibility. The traceological analysis evidenced the existence of diverse economic processes, both primary - associated to the main productive cycles - and secondary - scarcely structured, result of occasional or punctual activities. Our data contributed to the interpretation and the understanding of the analysed sites and of their functionality.

This work addresses the geoarchaeological study (stratigraphy, sedimentology, radiocarbon dating and XRF geochemistry) of exokarstic sediments from a doline near the Neolithic archaeological site called Els Trocs Cave (Abella, Huesca), located in high altitude mountain area of the Central Pyrenees (1564 m asl). We detect and characterize palaeoenvironmental change and human impact proxies in the area for the Neolithic. The results obtained point to the occurrence of Neolithic anthropic deforestation events and subsequent soil erosion/sedimentation phases in order to get pasture areas.

We study a 190 cm long sedimentary record from a doline nearby the Els Trocs cave from 2 cores obtained in 2010. The research includes: sedimentological study (stratigraphy and sedimentary facies description), high-

resolution geochemical analysis (XRF core scanner), statistical multivariate analysis (PCA), mineralogical analysis by X-ray diffraction (XRD), particle size analysis and the radiocarbon dating by AMS.

The Age-Depth model of the sedimentary core was obtained from 5 radiocarbon dates using the R-CLAM software. The obtained ages comprise the last ca. 8000 years.

Three sedimentary facies were observed corresponding to 1) charcoal rich red clays, 2) clastic red clays and 3) organic matter rich red clays. The recovered sedimentary record was divided in 2 main stratigraphic units. In the basal Unit 1 alternating facies 1 and 2 subdivide the unit in 5 lithostratigraphic subunits. The Unit 2 is homogeneous and is uniformly constituted by the facies 3 with an increasing organic content towards the top.

The geochemical analysis of the sediments was undertaken using an Avaatech XRF core scanner. 28 chemical elements were measured: Al, Si, P, S, Cl, Ar, K, Ca, Ti, V, Cr, Mn, Fe, Rh, Ag, Ni, Cu, Zn, Ga, Ge, As, Br, Rb, Sr, Y, Zr, Nb and U. A multivariate statistical analysis, Principal Component Analysis, was applied to the XRF results. Seven main components were extracted and explain the main variations in organic matter content, charcoal content, edaphization processes or allochthonous sediment input in the studied record.

The sedimentological, geochronological and geochemical study of an exokarstic sedimentary sequence cored in a doline nearby the Neolithic archaeological site of Els Trocs points to the existence of deforestation events (charcoal-rich facies) between 7500-7300 yr cal BP, coinciding with the Neolithic occupation of the cave. The deforestation is interpreted to be anthropic in order to get high mountain pasture areas for ovine cattle during spring and summer.

In addition to deforestation, subsequent soil erosion and increasing sedimentary rates in the surrounding exokarstic dolines are detected.

The combined study of the Els Trocs archaeological site and the exokarstic sedimentary record has enabled the detection and characterization of palaeoenvironmental changes due to the human impact during the beginning of the Neolithic in the high altitude mountain area of the Central Pyrenees.

The Upper basin of the Vero forms a small valley surrounded by mountains up to 1500 m in the central area of the province of Huesca. During the Late Neolithic and the Chalcolithic its 25 km<sup>2</sup> territory hosted a detached ensemble of archaeological sites that indicate an intense exploitation: two occupational caves (Drólica and Carasca) or sepulchral (Cristales), three dolmens (Capilleta, Caseta de las Balanzas and Pueyoril) and even two schematic rock-art shelters (Peña-Miel I and II) can be related to this phase. A coherent series of more than ten radiometric dates help us to frame a dense human occupation of this territory for several centuries between 3100 and 2500 cal BC.

Then, and even nowadays, the agricultural economy seems to be based on sheepherding and farming, which is seriously limited due to the poor environmental conditions, both climatic and orographic. The altitudes in the lower zones are around 850 m, and the two main chalcolithic caves, Drólica and Cristales, are at 1200 m. Currently, the landscape is covered by a scarce Mediterranean-type vegetation, adapted to a hard climate with a precipitation index up to 900 mm per year, but severe temperatures. The abrupt landscape of the surrounding areas, where the rivers Vero and Cinca force their pass south through narrow canyons, makes this basin a clear corridor to communicate the smoother region of the Somontano with the Pyrenean valleys. This condition is also well documented for the Middle Ages, when a dense grid of fortifications and watch-towers were built in order to secure the territory.

In this sense, our spatial research is focused on two vectors: the relationships between these sites, with special attention to their catchment territories and their visual

domains, in order to recognize the landscape exploitation patterns; and the inner management of the domestic spaces, based on the spatial distribution of the archaeological remains in the settlements.

Bronze Age studies carried out in the Cantabrian Region have traditionally focused on prestige goods and funerary contexts. As a result of this, the lack of information about daily activities, subsistence strategies, and human settlement on a regional scale was evident in the state of art. However, current research has achieved new discoveries in recent years, allowing a reconstruction of some aspects of the economic structure, settlements, material culture and the palaeoenvironment during the Bronze Age. Indeed, besides the funerary practices discovered in 1983 in San Adrian (Parztuergo Nagusia, Gipuzkoa), research has now revealed the presence of Upper Palaeolithic and Early Bronze Age occupations.

This paper presents a first characterization of the retrieved evidence and a preliminary evaluation of the archaeological site and its environment. San Adrian is a tunnel-shaped cave located at 1,000 meters a.s.l. in the Aizkorri mountain range, opening a passage beneath the Atlantic-Mediterranean watershed in northern Iberia. The strategic character of this mountain site is demonstrated by the presence of Upper Palaeolithic and Bronze Age occupations, and by the construction of a road passing through it and the fortification of both its entrances in the Middle Ages.

The aim of the archaeological survey started in 2008 was to identify, describe and evaluate the heritage potential of the cave, because previous fieldwork had only managed to make surface finds in the side galleries, including a medieval hoard and Bronze Age human remains. The work carried out by the research group at San Adrian includes a series of test pits and the excavation of an area nine square metres in size following stratigraphic criteria. In the current state, we identified at least two contexts corresponding to Late Upper Palaeolithic and Bronze Age occupations in the cave.

Fieldwork included the sieving and flotation of sediment and the collection of samples for different types of analysis: palynology, carpology, sedimentology, and radiocarbon dating. The evidence is being studied by a multidisciplinary team according to expertise requirements for each topic: palaeobotany and environment, archaeozoology, sedimentology, geology, physical anthropology, prehistoric industries (lithics, pottery and bone) and archaeological and historical documentation.

Because of its recent discovery, Upper Palaeolithic evidence remains still under study, but first results on Bronze Age layers can be presented. The ongoing archaeobotanical and archaeozoological studies reveal the exploitation of domestic plants and fauna complemented by

hunting and foraging of wild species. At the same time, the archaeological artefacts and their production sequences show the exploitation of nearby resources on both sides of the mountain range, while prestige goods are absent. This evidence is also used to estimate the regularity of cave occupations and to propose a model of seasonal exploitation of the mountain environment. The results obtained reveal the exploitation of resources from both the Mediterranean and Atlantic basins, and contribute towards an understanding of the daily activities of Bronze Age societies. In addition, the evidence shows the exchange and circulation of quotidian products between the Cantabrian region and inland Iberia in other networks than those of prestige goods.

### 1. NORTH AMERICAN SOLUTREAN CONNECTIONS: A PERSPECTIVE FROM BERINGIA

*Dixon, E. James (Director, Maxwell Museum of Anthropology) [jdixon@unm.edu](mailto:jdixon@unm.edu)*

Archeological and genetic data from northern Eurasia and North America indicate the first New World colonists migrated from northeast Asia during the late Pleistocene. Lithic technological analysis suggests that northern Eurasian Solutrean-like technology may have provided the technological foundation for subsequent North American lithic industries. This early migration may have first occurred along the southern coasts of eastern Beringia and southward along the coasts of the Americas. Early Solutrean-like technology subsequently developed into at least two distinct North American technological traditions: 1) the Western Stemmed Point tradition, and 2) the Clovis complex. This hypothesis suggests that technological similarities between early North American Paleoindian technological traditions and European Solutrean industries may be explained by a common relationship to a larger Eurasian technological tradition that subsequently developed distinct New and Old World technological adaptations.

ORAL

### 2. CHANGES AND CONTINUITIES IN THE LITHIC ARCHAEOLOGICAL RECORD OF THE UPPER SANTA CRUZ RIVER BASIN (PATAGONIA, ARGENTINA) BETWEEN THE MIDDLE AND LATE HOLOCENE

*Franco, Nora Viviana (CONICET - Universidad de Buenos Aires) [nvfranco2008@gmail.com](mailto:nvfranco2008@gmail.com)*

*Vetrisano, Lucas [lucasvetri@yahoo.com.ar](mailto:lucasvetri@yahoo.com.ar) (Universidad de Buenos Aires)*

The Santa Cruz river originates in the Andean mountains and has its mouth in the Atlantic Ocean. Human circulation is limited to the west, where the southern Ice Field is located. The area comprises lowlands and highlands with *Nothofagus* forest to the west and steppe to the east. The highlands have passes which allow human movement to the Pacific coast. The climate is wet to the west and more arid to the east. Paleoclimatic studies have shown the existence of more arid and wetter periods in the past. There is also evidence of rock fall-off

and ashes coming from volcanic eruptions, which would have affected human life.

The first evidence of human utilization of the upper Santa Cruz river basin dates to the early Holocene, and comes from Chorrillo Malo 2 rock shelter, located south of it. The use of the area seems to have been discontinuous until ca. 4,300 <sup>14</sup>C yr BP when, according to technological and raw material information, both lowlands and highlands have been integrated within the home range of the same cultural group. Between ca. 3,800 and 3,600 <sup>14</sup>C yr BP, the same cultural group buried their dead at the same rock shelter. A similar kind of burials was identified at similar ages at spaces located between 150 and 250 km to the south, supporting the idea of regular social ties between human groups using these spaces.

The purpose of this paper is to analyze the existence of technological continuities and changes in the lithic archaeological record recovered from two rock shelters (Chorrillo Malo 2 and Río Bote 1) located in the lowlands, south of the Santa Cruz river basin. There is a distance of ca. 60 km between the two sites.

Here we will concentrate on strata dated between ca. 6000 to 2800 <sup>14</sup>C yr BP. Analysis will focus on cores, flakes and tools which can provide information on the technology involved. Raw material availability will be taken into account in order to understand lithic variability during this time period.

Although the two sites could have had different through time, in both of them Levallois technology was identified between ca. 4,300 and 3,600 <sup>14</sup>C yr BP. This technology is also present at the Pacific slope of the highlands by ca. 4,500 <sup>14</sup>C yr BP. Previous deposits show the presence of blades, although no evidence of core preparation has been recovered until the moment.

Results obtained are useful to understand the process of incorporation of a new technology -which implies additional effort and time in core preparation- into the area and the integration of these spaces within the home range of a single cultural group.

ORAL

### 3. MINIATURE PROJECTILE POINTS IN THE LATE PLEISTOCENE/EARLY HOLOCENE

*Flegenheimer, Nora - (CONICET-AyA) [norafleg@gmail.com](mailto:norafleg@gmail.com)*

*Mazzia, Natalia - (CONICET-AyA) [natymazzia@yahoo.com.ar](mailto:natymazzia@yahoo.com.ar)*

Weitzel, Celeste - (CONICET-AyA) [celweitzel@gmail.com](mailto:celweitzel@gmail.com)

In spite of their reduced size, miniatures always call for special attention in archaeological contexts. Miniature projectile points have been described both in North and South American early peopling literature and are explained as toys, practice pieces or ceremonial objects. In the southern cone they were part of the tool repertoire corresponding to an early technology which lasted few millennia spanning the Pleistocene /Holocene transition.

In this presentation, the focus is on the significance of miniature points found at Cerro El Sombrero Cima (Buenos Aires province, Argentina), an early site in the Argentine pampas. Information from both objects and space has led to propose that the hilltop was a look-out with control of the surroundings and a place chosen for refurbishing weapons and discarding tools broken elsewhere. Small projectile points are represented by six specimens, five are fishtail projectile points (FTPP) and the sixth is a non described stemmed type, here referred to as ESP. They are found both during surface collection and excavation associated to the full sized points recovered at the site.

All miniature points are complete specimens which is an exceptional trait in the assemblage mostly composed of broken tools. Raw material employed to manufacture these miniature points is the same used for the full sized specimens. Also, all miniatures have a low labor investment, some show minimum retouch on the blades while others were only marginally shaped. No attention has been paid to represent the three dimensional aspect of these objects. This simple manufacture has been effective in producing points which exhibit an outline clearly recognized as the type represented. Yet, technical traits of full sized points show a variable complexity and on occasions include complete bifacial reduction and fluting. Thus these small points are clearly different from their full sized counterparts in technology. Also, life history of miniatures and full sized points discarded at the site are different, while the former possibly were made at the same place where they were used and discarded, the full sized points were used elsewhere. Also fatty acids and sterols analyses have revealed contrasting results for both groups of artifacts.

Miniature points in use among Late Pleistocene/Early Holocene hunter gatherer societies are an interesting case to reflect about people materializing abstractions, encoding visual communication, and developing special practices related to particular places. Miniaturizing

reduces detail and demands selection. It is our proposal that in these miniatures the outline has been selected as the significant trait probably encoding social meanings. We propose that in this particular case, design not technique was the most significant trait represented. Finally, the role of these miniatures among early pampean hunter gatherers will be addressed.

ORAL

#### 4. CAZADORES EN MOVIMIENTO Y SUS RASTROS EN ANTOFAGASTA DE LA SIERRA DURANTE EL HOLOCENO MEDIO INICIAL (PUNA MERIDIONAL DE ARGENTINA)

*Martínez, Jorge G. (Instituto Superior de Estudios Sociales-CONICET/Instituto de Arqueología y Museo-Universidad Nacional de Tucumán. Argentina) [jormartin1969@yahoo.com.ar](mailto:jormartin1969@yahoo.com.ar)*

*Pintar, Elizabeth L. (Austin Community College, Austin, Texas (USA) [lizziepintar@gmail.com](mailto:lizziepintar@gmail.com)*

Diversas evidencias arqueológicas del noroeste de Argentina, confirman que la caza de animales fue la principal actividad de subsistencia. Tempranas ocupaciones humanas en la Puna septentrional se remontan hacia fines del Pleistoceno ca.11,000 años (Aguerre *et al.* 1973; Aschero 1979, 1984; Hernández Llosas 2000).

Para la Puna meridional argentina, las evidencias arqueológicas más tempranas provienen del sitio Peñas de la Trampas 1.1 (3582 msnm) con dataciones entre ca.10,190-10,030 AP (Martínez 2013). Análisis zooarqueológicos permiten definir que la interacción hombre-fauna queda definida por la caza sistemática de camélidos silvestres: vicuña (*Vicugna vicugna*) y guanaco (*Lama guanicoe*)(Elkin 1996).

Como objetivo principal se evalúa la variabilidad en los diseños y materias primas de puntas de proyectil líticas, y de los sistemas de armas asociados dentro del lapso ca.8000-6000 AP en la microrregión de Antofagasta de la Sierra (Puna meridional de Argentina).

El abordaje se basó en el estudio comparativo de caracteres tecno-tipológicos (*sensu* Aschero 1975, 1983) referidos al diseño de puntas recuperadas en estratigrafía en los sitios Cueva Salamanca 1, Peñas de la Cruz 1 y Quebrada Seca 3, para el Holoceno medio inicial, lapso de transición paleoambiental hacia un período hiper-árido a escala macroregional (ca.6500-3500 AP). Este fue el punto de partida para poder establecer los sistemas de

armas asociados, y en base a ello, las técnicas de caza en las que fueron empleados.

La recuperación de otros componentes de los sistemas de armas, como fragmentos de astiles, intermediarios y gancho de propulsor, nos permitió definir con mayor certeza el uso simultáneo de propulsor de gancho y lanza arrojadiza para el lapso bajo estudio. De este modo nos aproximamos a la dinámica en el uso sincrónico de distintos espacios y sistemas de armas, orientados a la caza de camélidos.

Se identificaron distintos tipos morfológicos (*sensu* Aschero 1988) de puntas de proyectil, y sumado al interjuego registrado en cuanto al uso diferencial de materias primas líticas locales vs. alóctonas, pudo distinguirse un esquema de micro y otro de macromovilidad en torno al uso de distintos sistemas de armas, "cotos" de caza y al aprovisionamiento de recursos líticos. En cuanto a este tópico, análisis de Fluorescencia de RX sobre artefactos y desechos de talla de obsidiana, permitieron identificar cinco fuentes de procedencia. El rango de distancias varía entre 40 y 120 km a los sitios bajo análisis, lo cual denota una amplitud importante en las redes de circulación/interacción de gente y materias primas, conectando diferentes sectores dentro de la Puna meridional de Argentina.

La información surgida a partir del análisis integral realizado, nos permite plantear que en relación a otros grupos de artefactos, las puntas de proyectil son muy buenos indicadores de movilidad y trayectorias espaciales de su uso, permitiendo "rastrear" hasta sus contextos de producción, uso y descarte. En una escala regional, diseños y materias primas de puntas de proyectil permiten definir cierta circunscripción territorial para el lapso 8000-6000 AP, donde los registros de cazadores-recolectores de Puna norte y Puna sur no presentan evidencias de interacción.

## 5. LOWLANDS HUNTERS TECHNOLOGY: THE CASE OF LITHIC PROJECTIL POINTS

*López Mazz, José (Dpto. Arqueología. FHCE/Universidad de la República, Uruguay) lopezmazz@yahoo.com.ar*

*Marozzi, Oscar (CURE/Rocha/Universidad de la República) oscar.marozzi@lappu.edu.uy*

*Aguirrezábal, Diego (CURE/Rocha/Universidad de la República) diego.aguirrezabal@gmail.com*

Au long of 25 years of field works, scholar team recovered 100 projectile points, from San Miguel Hills, trough

extended marches of San Miguel, Las Maravillas, Los Indios and Laguna Negra, still Atlantic coast of Cabo Polonio. The material are in very different state of conservation, and came from domestic settlement, cemeteries and hunt camps.

The sample was produced in a controlled archaeological task. Most of them are located in a very detailed stratigraphic and archaeological record, associated with radiocarbon dates. The sample cover different chronological and cultural periods, from Pleistocene/Holocene transition human occupation, Early Holocene hunter gather to a Middle and Late Holocene mounds builders.

This presentation analyse lithic row material procurement, forms and measures of different types, and knapping technics employed. The results suggest changes in social mobility and in propulsion system of projectile points. Is a good opportunity to discuss the evolution of hunter gatherer mode of production, in a specific environment.

Con el descubrimiento de sitio Catalán Chico (Departamento de Artigas, República Oriental del Uruguay) realizado por Antonio Taddei, (Taddei, 1967), Uruguay entra categóricamente en las discusiones arqueológicas de la zona de la Cuenca de Plata, así como de América Latina. Este lugar está situado en el noroeste del departamento de Artigas. Por las características morfológicas de sus artefactos líticos y por los diferentes estudios geocronológicos realizados en esta época, hallaron que este sitio podría ser uno de los más antiguos del territorio del Uruguay, su edad aproximada sería de unos 10.000 A.P. Los materiales arqueológicos de este sitio fueron inter-

pretados a través de diferentes perspectivas teórico-metodológicas.

Hoy en el marco de una perspectiva tecnológica, los primeros análisis atestiguan una diversidad de los conocimientos técnicos en este sitio. Un gran número de sistemas técnicos de producción basados en diferentes modos de "debitage" y de "façonnage" son puestos en evidencia, y para cada una de estas modalidades la producción de un tipo o de varios tipos de soporte que serán transformados o no en herramientas específicas. La diversidad así atestiguada indica múltiples comportamientos técnicos ciertamente jerarquizados

The southern Brazilian territory was occupied in different moments (13,000 BP in the South and 3,000 BP in the North) and with distinct interior routes, by two different cultural groups of hunters/gatherers whose costumes were remarkably connected to the manufacture of stone tools. The two populations are the group of Umu tradition and the group of Macro-Ge linguistic branch (Xokleng and Kaingang).

The archaeological sites associated with hunters/gatherers located on the southern border of the State of Santa Catarina show great morphological and technological diversity. Polished and flaked materials are often found associated, supporting the hypothesis of a palimpsest of different occupations, or pointing that in the same chronological period this territory may have been a crossroad between culturally different groups, with consequent cultural exchanges.

In this study we present a preliminary analysis of the lithic material found in open-air sites located in the Extreme South of Santa Catarina. We will focus on settlement patterns, technological organization and chronology of the prehistoric hunter/gatherer group of this region.

ORAL

## 8. BLADE PRODUCTION IN SOUTH BRAZIL

*Lourdeau, Antoine - (Muséum National d'Histoire Naturelle, Paris - France) antoine.lourdeau@mnhn.fr*

*Carbonera, Mirian (Universidade Comunitária da Região de Chapecó, Chapecó - Brasil) mirianc@unochapeco.edu.br*

*Hoeltz, Sirlei E. - sirleinhoeltz@yahoo.com.br (Archeo Pesquisas Arqueológicas Ltda, Cuiabá - Brasil)*

*Viana, Sibeli A. - sibelij@pucgoias.edu.br (Pontifícia Universidade Católica de Goiás, Goiânia - Brasil)*

Current archaeological researches in South Brazil, in the western part of Santa Catarina, are yielding new data for understanding the Early Holocene regional settlement. The greatest novelty is in lithic productions, which differ, in part, from what it was known until now in the area.

In three archaeological sites in the Linha Policial locality, two archaeological programs succeeded one to another: a rescue project between 2006 and 2010 by Scientia company; and, since 2013, a Franco-Brazilian academic field. Surveys and excavations yielded lithic artefacts that demonstrate a complex technical system.

The analyses identify bifacial shaping and large flakes *debitage* – which are common in this period and region, and define what regional archaeologists name Umu Tradition – associated with a unique production for South Brazil: blade *debitage*. This blade production was realized by a centripetal preparation of the core's flaking surface and a unidirectional production of blades. The blades were obtained by two techniques: internal percussion with stone and marginal percussion with soft hammer. Laminar blanks show very different functional potentials.

Such findings contribute to a better understanding of the first steps of the settlement of South Brazil and invite to discuss the notion of Umu Tradition, because it conducts to a too homogeneous perception of South Brazilian prehistory.

ORAL

## 9. LANDSCAPE ARCHEOLOGY IN THE NORTHERN REGION OF SÃO PAULO STATE, BRAZIL

*Rocha Luz, Juliana Aparecida (Faculdade de Ciências e Tecnologia, Universidade Estadual Paulista (FCT/UNESP) juli-luzz@yahoo.com.br*

*Barrocá Faccio, Neide - (Faculdade de Ciências e Tecnologia, Universidade Estadual Paulista (FCT/UNESP) nfaccio@terra.com.br*

*Rodrigues Nunes, João Osvaldo (Faculdade de Ciências e Tecnologia, Universidade Estadual Paulista (FCT/UNESP) joaoosvaldo@fct.unesp.br*

A study was undertaken in an area with eight archeological sites in the northern region of São Paulo state, Brazil. The aim was to investigate regional settlement patterns. The study adopted the theoretical-methodological hypotheses of Landscape Archeology. In that context the Geomorphology–Geography interface offers a significant contribution to investigating factors related to the implantation of the sites in the landscape. Geographic information (maps, plans, and satellite images) was used and the indispensable corroboration of the data for landscape analysis and salvaging archeological material was done by field work carried out in the area of the archeological sites. Effectively the methodology consisted of: locating, delimiting and mapping the sites using geoprocessing techniques; verifying the degree of degradation of the sites; characterizing the region's geomorphological, geological and pedological aspects; verifying the types of settlement and the use made of natural resources, and producing images to support landscape analysis. The results show that the sites in question were inhabited by populations associated to the Aratu Tradition and their possible descendants the Kayapo, located in the northern region of the state of São Paulo. The indigenous groups associated to the Aratu Tradition that produced the pottery installed their villages on gentle slopes leading down to the rivers, or close to perennial rivers and stream or on the upper and lower slopes of hills or flat-topped mountains.

The peoples that produced the material culture (pottery or stone) associated to the Aratu adition preferred the tops of flat-topped hills but near to streams to construct their habitations. The study sites selected occupied the lower and middle parts of hillside slopes and were relatively close to one another, on average 21 km apart and with ages ranging from approximately  $395 \pm 65$  to  $485 \pm 65$  years. That means the various sites may be the remains of contemporaneous occupations and accordingly part of the same regional settlement system.

This paper reports on the first studies to be carried out in small scale sites located in the northern region of São Paulo state. In that light it offers contributions and addresses questions that assist in the formulation of hypotheses about societies that inhabited the region in the past.

ORAL

## 10. GUARANI SETTLEMENTS ON THE RIGHT BANK (SÃO PAULO STATE) OF THE PARANAPANEMA RIVER VALLEY, BRAZIL

*Barrocá Faccio, Neide - (Faculdade de Ciências e Tecnologia, Universidade Estadual Paulista (FCT/UNESP) nfaccio@terra.com.br*

*Rocha Luz, Juliana Aparecida (Faculdade de Ciências e Tecnologia, Universidade Estadual Paulista (FCT/UNESP) juli-luzz@yahoo.com.br*

*Barrocá, Diego - (Universidade de Santo Amaro) diego.barroca@agronomo.eng.br*

In the Paranapanema River valley region, on the São Paulo side (right bank), which is the object of this study, archeological research has been going on since the 1960s. This study sets out an analysis of seven sites located in the lower Valley of the Paranapanema River. They are the sites of indigenous settlements of Guarani groups dating back from  $700 \pm 160$  to  $900 \pm 180$  years. We sought to study the elements of material culture to be found at the sites with a special focus on pottery material – the main identifying feature of Guarani culture.

The archeological investigations made use of geo-technology including Global Positioning Systems to construct a Geographic Information System (GIS) enabling effective analysis of the data and their reproduction in graphic form.

The state of Sao Paulo was densely populated by Indians and up until the beginning of the 20th century they were notably present in the valley of the Paranapanema River. The stretch of land where the archeological sites are located lies on the right bank of the river (São Paulo state) and to date has revealed itself to be the area where the sites are most closely grouped, given that all seven lie in a stretch of land only 10,800 metres long. Only parts of the sites were accessible to our study and it is unknown how much of each of them lies submerged in the waters of the Capivara Hydroelectric Dam reservoir. Even in the dry season when the water level drops 10 meters, they do not completely emerge. In the classification proposed by Moraes, the regional settlement was done by agricultural peoples and that is the methodological theoretical framework we adopt to contextualize this study. At most of the sites, considerable amounts of pottery, flaked stone and polished stone artifacts can be found, as well as funeral urns, black patches on the ground and ornaments fashioned from the resin of the South American locust tree (*Hymenaea courbaril*)

Man's considerable technological progress has failed to curb the progressive degradation of the environment and the cultural heritage. While on the one hand such progress has made it possible to perfect many work processes with the use of highly efficient equipment, on the other it has contributed to serious environmental degradation and that is especially true of hydroelectric plant installations and associated land use management. Such interference and failure to preserve the environment includes the archeological heritage that lies within it. That heritage does not always find support for its preservation in spite of its being nominally an asset under Federal Government protection.

Despite the Constitutional Provision for such protection, in reality the protection of archeological sites depends on the existence of an efficient protection policy designed to make conservation feasible, on the existence of the will to preserve them on the part of the government bodies and other entities that finance archeological research, and on the active engagement of a greater number of professional archeologists.

ORAL

### 11. AS THICK AS NEEDED? POTTERY THICKNESS AND THE CONSOLIDATION OF AGRICULTURAL PRACTICE

*Vidal, Aixa (UCM/INAPL) aixavidal@gmail.com*  
*Pérez, Martina (UBA-FFyL/INAPL) martinainesperez@hotmail.com*

Due to its cultural nature, pottery is the material expression of the many dimensions of the society responsible for its creation and use. Hence, its analysis can provide useful information for the characterisation of the life context they participated in. In the same way, this context may explain the presence of certain features in the ceramic object.

The materials considered in this analysis cover a sample from different sites in the archaeological area of Antofagasta de la Sierra (Catamarca, Argentina). They represent two clearly distinctive periods, locally known as Formative and Late Period.

The Formative is defined by the introduction of agriculture and mainly herding to the subsistence repertoire of the local inhabitants. It is also a moment when residential bases or small villages are settled in a system which relates locations in different altitudinal areas. In this analysis, pottery sherds from Casa Chávez Montículos (a vil-

lage site), Real Grande (temporary mountain bases) and Cueva Cacao (a symbolic-laden rockshelter) are selected. In the case of the Late Period, the samples came from Bajo del Coypar (agricultural terraces) and La Alumbra (large village). They represent the main spatial functional-related divisions distinguished for the period, which is also characterised by the consolidation of agricultural practice and large demographic growth.

Amongst the several attributes identified in these samples, the study will focus on wall-thickness. It is a straightforward measure which does not demand more sophisticated equipment than a calliper. However, it can be highly informative when the materials from different provenance are compared, due to the lack of ambiguity in the measurement regardless of the material and the variability it may present.

A clear increase in the number of sherds with rather thick walls (>10mm) is noted throughout the two time periods considered. On the other hand, the sherds collected in the different locations did not report such a large difference in representation as in the case of the temporal axis. In this sample, thickness seems to be consistently related to the general dimensions of the vessel, as seen in the reconstructions from the sherd profiles.

In the case of the pottery produced in Antofagasta de la Sierra, wall thickness may be considered a highly time-sensitive variable, although minor variations in thickness representation are also noted amongst different functional sites of the same period.

It may be interpreted that this increase is related to a different conception of pottery in the two periods considered. Probably highly connected to a change in the appropriation of the landscape due to the increasing dependence on agricultural returns, the technological process regarding pottery-production needed to be re-adjusted. The new economic strategy demanded containers to store the surplus they generated for a relative long time, as well as the smaller vessels in use from previous times as temporary recipients. It triggered a change in the potter's strategies as well, as the increase in wall thickness demands restructuring the chaîne opératoire and the ability of the potter.

ORAL

### 12. BIFACIAL SHAPED TOOLS FROM CERAMIC GROUPS: THE CASE STUDY OF PRAÇA DE PIRAGIBA SITE

*Machado, Juliana - (Université Paris Ouest Nanterre La Défense) ju.drmachado@hotmail.com*

*Rodet, Maria Jacqueline - (Universidade Federal de Minas Gerais) mjrodet.ufmg@gmail.com*

*Fernandes, Luydy Abraham - (Universidade Federal do Recôncavo da Bahia) luydyabraham@gmail.com*

The consolidation of archaeology as a scientific discipline was a late process in Brazil. In the middle of the 20th century, archaeologists have engaged in establishing an overview of archaeological cultures in order to trace routes of diffusions and migrations. In this way, pottery studies were largely emphasized. Recently, research of flaked-stone industries with assemblages from the Late Holocene period increased. Given these developments, our study is about the lithic collection from the *Praça de Piragiba* site, located in the west of *Bahia* state. The large collection available is characterized by the presence of bifacial shaped tools and pottery recipients used in burial.

The database for this study comprises 279 tools and 719 *débitage* remains. These originated from a field season accomplished by the *Universidade Federal do Recôncavo da Bahia* in collaboration with the *Universidade Federal de Minas Gerais*. Technological analysis was adopted as the main methodology in order to understand the *chaîne opératoire* involved and its technical evolution. Therefore, the technical condition concept is an important methodological tool in this study.

Using blocks and flakes of sandstone and silexite, both of median quality, tools were bifacial shaped by hard hammer percussion. Afterwards, flanks and the proximal part were intensely pecked. They present themselves in different technical conditions: beginning, middle and end of technical life; with intentional fractures or not; restructured, or even transformed in other tools. The evolution of the wire edge, the reduction of the reserve of raw material and probable macro traces of use are fundamental elements to understand the technical evolution of these objects.

Prehistoric groups who frequented the *Praça de Piragiba* site were concerned with perpetuating the usefulness of these objects. They evolved technically until being abandoned (due to exhaustion) or transformed. In fact, the region encompassing the west of *Bahia* state, the north of *Minas Gerais* state and the northeast of *Goiás* state presents objects that are morphologically very similar. Although frequently associated with a specific archaeological pottery "tradition", these objects are also found in relation with other pottery "traditions".

ORAL

### 13. CHRONO-CULTURAL VARIABILITY IN THE SERRA DA CAPIVARA REGION (PIAUI, BRAZIL): NEW ADVANCES

*Pagli, Marina - (UMR 7041 Archéologie et Sciences de l'Antiquité - Equipe «Anthropologie des Techniques, des Espaces et des Territoires au Pliocène et au Pléistocène») marina.pagli@gmail.com*

*Lourdeau, Antoine - (Muséum National d'Histoire Naturelle) a.lourdeau@gmail.com*

*Guidon, Niède - (Fundação Museu do Homem Americano) guidon@fumdam.org.br*

We present recent advances about the archaeological sequence of the Serra da Capivara Park (Piauí, Brazil) based on new studies of lithic industries from this region, and their implications for the reconstitution of the human settlement in the region. This area witnesses a dense and continuous prehistoric occupation, starting from Pleistocene period until the Holocene. Nevertheless, detailed lithic analyses have been realized just for few sites until now, with a specific focus on Pleistocene industries. The general techno-cultural characteristics of the successive occupations are still scarce for the whole region.

The analysis of several well-dated archaeological sequences allows an approach of the technical variability through time and shows the technical trends of each period.

Using a technological method to study lithic assemblages and a techno-functional approach of retouched tools, we highlight that different techno-cultural groups are attested in the region.

These results allow a preliminary outline of the changes in lithic production during the prehistoric occupation of the Serra da Capivara region, and can be discussed and integrated in the framework of the settlement of North-East Brazil.

ORAL

**14. HUMAN OCCUPATION IN THE SOUTH-WEST REGION OF GOIÁS (BRAZIL) FROM THE OLD HOLOCENE**

*Viana, Sibeli sibeli@pucgoias.edu.br (PUC Goiás)*

The past occupations in the south-west region of the State of Goiás, remount until this moment to the Old Holocene, with dates around 10 thousand years B.P., represented by archeological sites of Serranópolis region. Sites from Middle Holocene, dated around 6 to 4 thousand years B.P., are found in Serranópolis and in Palestina de Goiás. And, finally, evidences of end Holocene occupations, with the presence of pottery and horticulture also belong to the occupational context of these regions.

The adopted methodology for the analysis of the lytic objects follow the propositions in the way that the objects are conceived and materialized in function of the human environment, that means, being related to subject, that uses and confers the status of instrument to some objects (Rabardel, 1995). In a synchronic perspective, these objects are analyzed from the concept of operative chain (Leroi Gouhran, 1964) and, from a diachronic perspective, building on the concept of technic structure, we'll discuss about the technic of the objects construction over the time (Simondon, 1969 e Boëda, 2013), with the intention of understand their technical transformations.

Based in the available results from the technological analysis, we will reflect about technical insight, knowledges and doings, present between the different occupational periods. By the available data, we observe that the complexity of the lytic industries more remote from Serranópolis is represented by unifacial molded instruments, with elongated and symmetric shape in relation to the longitudinal axis (Lourdeau, 2013), and represent technical changing processes performed over the time in the region. The core exploration system indicates variables technician schemes, related to the production of supports with variable characteristics. About the technical objects from the Middle and End Holocene of Serranópolis and Palestina de Goiás region, the system of core exploration, the system of production and operation of the instruments reveals persistence and important technical ruptures between the sites over the time.

When we bring data about the different spheres of production of the lythic set of the south-west region of Goiás, we intend to contribute with the fruitful discus-

sions in development about the behavior strategies of the human occupations in the South America.

Lapa do Santo is an archaeological site located in the Lagoa Santa karst in eastern Brazil that testify the dynamic nature of the groups inhabiting South America at the beginning of the Holocene. Human occupation in the site starts at 12.7-11.7 cal kyBP and formation process analysis characterizes the Lapa do Santo's deposits as mainly anthropogenic and composed by repeated combustion activities that indicate an intense occupation of

the same locality. The long archaeological sequence of the site offers a unique opportunity for archaeologist to access first Americans' diachronic behavior. The use of Lapa do Santo as an interment ground started between 10.3-10.6 cal kyBP with primary burials. Between 9.4-9.6 cal kyBP the reduction of the body by means of mutilation, defleshing, tooth removal, exposure to fire and cannibalism followed by the secondary burial of the remains according to strict rules became a central element in the treatment of the dead. In the absence of monumental architecture or grave goods, those groups expressed their rituals through the use of the human body as a symbol. Between 8.2-8.6 cal kyBP another change occurred whereby pits were instead filled with disarticulated bones of a single individual without signs of body manipulation. The lithic technology was focused on flakes and cores during the millennia the site was occupied. However, after 9.9 cal kyBP there is an abandonment of allochthonous raw material for lithic production, reflecting some kind of technological shift in those groups. In conjunction, Lapa do Santo's archaeological record reveals dynamic groups in constant transformation with many innovations over a period of centuries, contradicting the view of hunter-gatherers as static a-historic societies. Moreover, funerary rituals focusing in the manipulation of the human body are considered part of a broader system of ceremonies that reflects a high degree of symbolic complexity. In South America this was sometimes assumed to be an Andean phenomenon preceding the rituals arising later with the emergence of complex societies. Lapa do Santo in eastern Brazil changes this scenario and the Chinchorro can no longer be considered "the oldest known rituals in America". The presence of mortuary rituals focusing in the reduction of the body in sites distant thousands of kilometers from each other such as Pampa de los Fósiles, Lauricocha, Huchichocana Cave, La Chimba, La Fundición, Baño Nuevo, Tequendama and Lapa do Santo suggests a possible shared identity in South America dating as far back as the early Holocene.

ORAL

#### **16. A TECHNOLOGICAL APPROACH OF THE LITHIC PLEISTOCENE INDUSTRIES OF THE SANTA ELINA SHELTER (MATO GROSSO, BRAZIL).**

*Vialou, Agueda Vilhena avialou@mnhn.fr (MNHN PARIS)*

The lithic industries of the rock shelter from the level of 25,000 years BP and 10,000 years BP Santa Elina, both associated with extinct fauna brought to the site and explored - *Glossotherium Letsomii*, have their own tech-

niques and morphological characteristics. The choice of raw material in the particular environment of the Serra das Araras and select the support type, blocks or platelets and flakes guided mode of debitage and retouching for the production of the tools.

The Pleistocene occupations are characterized by tools made by tangential retouches on: small platelets in Silicia and limestone, and robust platelets, only on limestone, and also flakes exclusively on limestone. Levels Pleistocene-Holocene transition of 10,000 years BP have taken an industry with more diversified rocks, limestone, flint (opaque red) and sandstone.

In two separate for 15,000 years without noticeable traces of other occupations periods that there is always dealing with a peripheral chip or work plate, without modifying the shape of the support, without Façonnage.

*Boëda, Eric - boeda.eric@gmail.com (Université Paris X Nanterre/La Défense, UMR 7041 CNRS ArScAn – AnTET)*

In this paper we are going to present the results of the functional analysis of the many lithic materials from a number of Pleistocene sites from the Sierra de Capivara: Boqueiro da Pedra Furada, vale da Pedra Furada y Sitio do Meio. A microscopic analysis of the surfaces of the quartz tools has been realized on each one of the 'types' of tools identified on the basis of the technological analysis: "ros-tres" "borers", "denticulated" and other edges prepared as scrapers. The use-wear traces identified have been compared with the experimental program realized, leading us to the identification in the different sites analyzed of: butchering activities, hide working activities, bone/antler boring, wood working and vegetal fiber processing.

Depuis 2008 dans le cadre de la mission archéologique franco-brésilienne du Piauí, 7 séquences archéologiques provenant de contextes géomorphologiques différents ont été datées du pléistocène récent. Chacune de ces séquences présentent une succession de plusieurs niveaux archéologiques comprenant des artefacts lithiques et des restes osseux pour certains d'entre eux. La principale matière première utilisée est le quartz. Mais, uniquement certaines qualités de quartz, les plus aptes à la taille sont utilisées. Deux schèmes opératoires distincts sont réalisés -façonnage et débitage- dans le but de fabriquer plus d'une dizaine d'outils différents. Dans une moindre mesure d'autres matières premières comme le quartzite sont utilisées, servant à la fabrication de certains outils spécifiques peu réalisables sur le quartz. L'ensemble de ces données obtenues aux dépens de plus d'une vingtaine de niveaux archéologiques montrent sur le plan diachronique une variation de faciès technique témoins de connaissances et de savoir-faire différentes et sur le plan synchronique des sites aux fonctions différentes. L'occupation au pléistocène récent au sud du Piauí apparaît comme une réalité bien établie avec une densité de sites qui nous est rendue visible du fait de la conservation des horizons sédimentaires pléistocènes dans de nombreux contextes géomorphologiques aussi différents les uns que les autres.

**Technological analysis of some lithic late-Pleistocene industries from Piauí, Brazil**

Since 2008, within the framework of the French-Brazilian archaeological project in Piauí, seven archaeological sequences, located in various geomorphological contexts,

have been dated from the late Pleistocene. All of these sequences present a series of several archaeological levels, containing lithic artefacts, and osseous rests for some of them. The most used raw material is quartz. But only certain qualities of quartz, the ones most suitable for knapping, are used. Two distinct operating schemas are used – shaping and knapping – in order to make more than ten kinds of distinct tools.

To a lesser extent other types of raw material, like quartzite, are used, to obtain some specific tools hardly obtainable with quartz. All these data, acquired from more than twenty archaeological levels, show, on a diachronic perspective, a variation in the technical facies that testimony of different knowledge and know-how, and on a synchronic perspective sites with different functions. The late Pleistocene occupation in the South of Piauí appears as a well-established reality, with a site density that can be observed thanks to the conservation of the Pleistocene sedimentary horizons in various geomorphological contexts.

## 1. EXPLORING ENVIRONMENTAL IMPACT ON HERD MANAGEMENT AND HUNTING PRACTICES IN PASTORALIST SOCIETIES OF NORTHWESTERN ARGENTINA DURING THE LAST 1400 YEARS

*Yacobaccio, Hugo - (CONICET-UBA) hdyacobaccio@gmail.com*

*Morales, Marcelo - (CONICET-FCEN) marcelomoralesarq@gmail.com*

*Mercolli, Pablo - (IIT-UBA) pablomercolli@gmail.com*

The links between environmental characteristics and climatic change with human subsistence have been the subject matter of research and publications during decades in anthropology and archaeology. This relation was usually studied in a coarse grain in terms of their spatial and temporal resolution in both, extractive and productive societies. The improvement in the resolution of the paleoenvironmental information in the past two decades, and the better understanding of the relationship between climatic signals of different scope allowed the refinement of the questions that currently can be made, and the models which can be built about this topic.

In the recent years a new high resolution paleoenvironmental records have been studied in the South-Central Andes and in Northwestern Argentina as well. This record provided rich and detailed data about the main trends in climate and their impact in the environment during the past 2000 years. Laguna Pululos 1012 core is the only of this record which is located in the Puna or Altiplano of the Jujuy Province, Argentina. It is the more representative source of paleoenvironmental information for the region in order to test some hypothesis regarding particular subsistence strategies carried out by pastoralist societies that inhabited both the Puna and Quebrada de Humahuaca during the past 1400 years.

In this presentation we compare the mentioned paleoenvironmental information with the archaeozoological record from 13 archaeological sites, in order to explore and discuss two particular aspects about the relationship between climate and subsistence in llama herder's societies: a) the links between sustained draught periods and the strategies of herd conservation through differential culling, and b) the relationship between climatic uncertainty and the frequency (i.e. abundance) of the hunting practices on wild camelids.

ORAL

## 2. CLIMATE CHANGE AND HUMAN OCCUPATION IN THE DRY PUNA OF ARGENTINA DURING THE LITTLE ICE AGE

*Oxman, Brenda - (Conicet-UBA) oxmanbrenda@gmail.com*

*Yacobaccio, Hugo - (CONICET-UBA) hdyacobaccio@gmail.com*

*Lupo, Liliana - (UNJu-Conicet) lupolc@yahoo.com.ar*

*Tchilinguirian, Pablo - (INAPL) pabloguirian@gmail.com*

In recent decades climate change has become a central issue for studying pasto societies within and ecosystemic approach directed to understand the complex relationship between people and environment. This paradigm has direct consequences to present complains about global climatic change, and the future of humankind. The objective of this presentation is to advance paleoenvironmental results obtained from a research program carried out in the Dry Puna of the Jujuy Province, through the use of pollen analysis. In this case we will deliver the results from the study of the Lapao 2 profile (1400-1800 calDC). This study seeks to contextualize the environment of the human occupations which inhabited the area in this time-period. The chronology correspond to the period known as the Little Ice Age, considered one of the most recent global climate variations (decreased temperature and increased precipitation) so far historically recorded (1350-1850 DC). Recognition of this period in the Puna of Argentina is still poorly understood, although have been detected in other parts of South America. Disputes over its particular climatic characteristics remain. Some authors postulate a cold-wet period, while others favor an alternate between wet and dry-cold phases. In order to discuss this question for the studied area the results of this presentation are quite important. The Lapao 2 profile measured 1,60 m high, and it has a high resolution chronological sedimentation. Twenty-eight samples for pollen and sedimentary analyses were taken. The results of this study allowed to identify two moments in the composition of vegetation:

1. a mixed steppe with high proportion of Poaceae, accompanied by the expansion of the marsh, that indicate a wetter moment;
2. also a mixed steppe with higher proportion of Asteraceae, that would indicate a drier moment.

In any case, there is no evidence of significant changes in vegetation composition and water availability on a local scale that could have affected the characteristics of the herding groups which lived in the area. These results are interesting in order to evaluate the differential impact of

this global climatic change in particular settings, and the potential of this kind of studies in restricted timescales.

ORAL

### 3. CURRENT VICUÑAS CONSERVATION AND MANAGEMENT. AN APPROACH

Vilá, Bibiana (CONICET-UNLu) [bibianavila@gmail.com](mailto:bibianavila@gmail.com)

Vicuñas (*Vicugna vicugna*) are a wild South American camelid that are being valued since prehispanic times mainly because of their fine fiber, one of the finest in the world. Since prehistoric times this species have been managed as a resource. Wildlife management is the science and art of deciding and acting on the structure, dynamics, and relationships among populations of wild animals, their habitats and people in order to achieve certain objectives. This management can be passive (when the goal is to preserve or protect a natural entity at the mercy of natural processes) or active (involves changes the current situation through direct and planned intervention to increase, stabilize or reduce the population). For a successful vicuña management approach it is crucial to incorporate an ethnozoological view as it necessarily includes the local indigenous knowledge and practices, and an Andean regional cosmovision on the species and its use. Vicuña management is a risky situation that involves uncertainty, has numerous actors and interest in dispute, and the decisions are urgent.

There is an International Convention for the Conservation and Management of the Vicuña signed by Argentina, Bolivia, Chile, and Ecuador. In this convention the right of the local communities for the use of the species is theoretically guaranteed by article 1: "The signatory governments agree that the conservation of the vicuña is an alternative economic production for the benefit of the Andean people and is committed to its gradual use under strict state control". Currently, situations that put in risk the spirit of the Convention are emerging, because foreign textile firms have bought thousands of hectares in the Andes and they negotiate the usufruct of the vicuñas in their area. Some examples of the current discussions on vicuña management, and some concrete management examples will be presented: (a) wild or captive management; (b) ethnozoology approach to the neo-chakus rituals; (c) risk of hybridization; (d) embryo transfer in relation to the need or not, of this technique.

ORAL

### 4. SOCIO-ECOLOGICAL PRESSURES AND HUMAN ADAPTATION IN THE HIGHLANDS OF ARGENTINA: CONTRIBUTIONS OF THE ARCHEOLOGY OF THE PUNA OF SALTA DURING THE MIDDLE HOLOCENE AND BEGINNING OF THE LATE HOLOCENE

López, Gabriel - (CONICET, Instituto de Arqueología, Universidad de Buenos Aires) [gabelope@yahoo.com](mailto:gabelope@yahoo.com)

The aim of this paper is to study the relationship between environmental changes and use of faunal resources and technology during the Middle Holocene and beginning of the Late Holocene in the Puna of Salta, Argentina. During the Middle Holocene and especially toward the end of the Middle Holocene, the high segmentation in resource patches led to human aggregation, increasing the size of the groups, spatial circumscription and competition. These socio-ecological pressures could affect human adaptation. In particular this analysis will focus in the changes in the economic niche and the technology. The materials of analysis of these changes come from different archaeological sites in the Puna of Salta (specially Abrigo Pozo Cavado and Alero Cuevas). The method of study will be based in the analysis of archaeological evidence of these sites (faunal and lithic analysis).

Archaeological record of the Puna of Salta indicates changes related to intensification and domestication. The faunal analysis shows changes in the composition of taxa (domesticated camelids), age profile and processing marks. The lithic technology shows the increase of blades and lanceolate tools known as *saladillenses*.

From models of human behavioral ecology can be predicted strategies aimed at increasing efficiency and minimizing risk by the end of the Middle Holocene. The intensification and domestication of camelids (high ranking resources) were a possible response to socio-ecological pressures. These changes were consolidated in the Late Holocene with a new economic niche.

ORAL

**5. TOCA DA PENA, PIAUI, BRÉSIL : UN SITE ARCHÉOLOGIQUE DATANT DE LA TRANSITION PLÉISTOCÈNE-HOLOCÈNE AVEC DES INDICES D'ACTIVITÉ DE BOUCHERIE SUR DES OSSEMENTS DE MÉGAFAUNE**

Boëda, Eric (Université Paris X) boeda.eric@gmail.com  
Griggo, christophe Griggo christophe - (Université Grenoble 1) Christophe.Griggo@ujf-grenoble.fr  
de Souza, Iderlan (UNIVASF) iderlanz@hotmail.com

Le site de Toca da Pena, découvert en 2008 dans le massif calcaire d'Antero, au sud ouest du parc Capivara (Piauí), est un site mixte, à la fois grotte et abri sous roche. Fouillé sur une épaisseur de plus de 4 mètres, ce site présente en stratigraphie plusieurs couches archéologiques dont la plus récente est datée de 10 000 ans BP. De très nombreux vestiges osseux ont été retrouvés tout le long de cette séquence. L'une des couches archéologiques provenant de la partie supérieure de la stratigraphie indique une interaction directe entre l'homme et la faune. En effet, cette couche a livré des restes d'un paresseux géant : *Scelidodon piauense*, associés à des artefacts lithiques, et dont une partie de la palette costale droite présentait, sur sa face interne, au dépend de quatre côtes successives, des stries de boucherie très courtes, de section en V, caractéristiques de l'utilisation d'un outil. La localisation des stries indique une désarticulation avec les vertèbres thoraciques pour trois d'entre elles et pour la dernière une désarticulation avec la palette costale. Les études taphonomiques excluent toute origine naturelle. D'autres stigmates anthropiques ont été retrouvés sur d'autres espèces dont plusieurs Ongulés. Il s'agit de cassures fraîches réalisées sur des os longs. Par ailleurs, à part quelques os grignotés par des Rongeurs, aucune trace liée à la présence de Carnivores n'a été observée. Ce site, qui permet pour l'une des premières fois de réaliser des analyses archéozoologiques dans cette région du Piauí, atteste donc bien d'une interaction de l'homme sur la Méga-faune, ainsi que sur d'autres espèces, à la fin du Pléistocène récent.

The site of Toca da Pena, discovered in 2008 in the calcareous massif of Antero, in the southwest of Capivara park (Piauí), is a mixed site, both cave and rock shelter. Excavated over a thickness of more than 4 meters, this site presents several archaeological layers in stratigraphy whose most recent is dated 10 000 years BP ago. Numerous skeletal remains were found throughout this sequence. One of the archaeological layers from the upper part of the stratigraphy indicates a direct interaction be-

tween man and wildlife. Indeed, this layer has provided bones of a Giant ground sloth: *Scelidodon Piauense*, associated with lithic artifacts and part of the right rib cage presented on its inside face, on four successive coast, short butchery marks, with V-section characteristic of the use of a tool. The location of the cut-marks indicates the disarticulation with the thoracic vertebrae for three of them and, for the last, disarticulation with the costal palette. Taphonomic studies exclude any natural origin. Other anthropogenic stigmata were found on other species including several Ungulates. These are fresh breaks made on long bones. Moreover, except for some nibble bone by Rodents, no trace associated with the presence of Carnivores has been observed. Consequently, this site that allows for one of the first times to realize archaeological analyzes in this region of Piauí, attests to human interaction on megafauna and other species at the end of the late Pleistocene.

ORAL

**6. PALEO-ENVIRONMENTAL EVOLUTION AND THE FIRST EVIDENCES ON BIG CETACEANS EXPLOITATION IN THE LOW PARANÁ-PLATA BASIN (ARGENTINA)**

Loponte, Daniel - (CONICET) dloponte@inapl.gov.ar  
Voglino, Damián - (Museo de Ciencias Naturales "Antonio Scasso") damianvogolino@yahoo.com.ar  
Liotta, Jorge - (Fundación OGÁ y Museo de Ciencias Naturales "Antonio Scasso") museoscasso@lycos.com  
Acosta, Alejandro - (CONICET) acosta@retina.ar

In the frame of a model which deals with changes in the resources' availability based on paleo-environmental evolution of the Low Paraná-Plata basin, some years ago we proposed a phase of mixohaline-polihaline resources' exploitation by human societies that inhabited the area during Middle Holocene. In this communication we present the first evidences supporting this phase, discussing the bone remains of a cetacean individual recovered in the Arroyo Las Hermanas archaeological site (Ramallo, Buenos Aires). It is located in the right bank of Las Hermanas stream, an affluent which flows into the right bank of Paraná River through a short and wide estuary dated in the Middle Holocene marine ingression.

The archaeological site was excavated in different stages, mapping the exposed material with the aim of testing different taphonomic and cultural aspects, such as the spatial distribution of remains, bones' articulation, and the relationship of osseous material with other anthrop-

ic evidences. The sedimentary sequence of the site was determined on the basis of local geological and paleo-environmental data.

The archaeological site shows a particular stratigraphic sequence. It starts with an actual entisol poorly developed, typical of local low floodplains, which forms an A level sterile in archaeological materials. Below, it develops a 2-2.5 m-thick sequence of fluvial sands without a visible stratification (B level, 1 sub-unity) which is sterile in cultural materials. In the basis of this level there is a 30m thick concentration of alkaline phytosilicates (level B, sub-unity 2) where *Balaenoptera sp.* remains were recovered highly disarticulated. Some specimens show longitudinal marks, which trough macro and microscopical features can be linked to lithic edges. Cervical, toraxical, lumbar and caudal vertebrates were identified, as long with ribs and the cranium (not yet recovered), counting 45 NISP and 33 MNE. Sawing marks suggest processing activities: it is highly possibly that the soft tissue were removed and transported to final consumption loci, leaving *in situ* big and heavy anatomic units (similar behaviors were recorded among other hunter-gatherer groups exploiting mammals weighing several tons). More than 50 lithic fragments were recovered, some of them in direct association with bone remains. Fine grained quartzite of different colors and translucent chalcedony were identified as raw materials. Most of them are micro-flakes and discard flakes result of edges' reactivation made after raw materials from the interior of the Pampa plain.

Arroyo Las Hermanas archaeological site conforms one of the first evidences in the last portion of Paraná basin of human adaptation in the coastal area of the marine estuarial golf of Middle Holocene. It can be interpreted as a *locus* of specific activities of primary processing of *Balaenoptera* (*cf. physalus*). Lithic materials associated suggest it would have been developed by hunter-gatherer groups from Pampean sector which had access to raw material sources located in southern ranges of Buenos Aires.

---

#### ORAL

### 7. HOLOCENE PALEOENVIRONMENTS HUMAN OCCUPATION AND ANIMAL RESOURCES AT SOUTH ANDEA PUNA (25°-27°S), ARGENTINA

Olivera, Daniel Enzo - (CONICET-INAPL y UBA) [deolivera@gmail.com](mailto:deolivera@gmail.com)

Tchilinguirian, Pablo - (CONICET-INAPL y UBA) [\[irian@gmail.com\]\(mailto:irian@gmail.com\)](mailto:pablogu-</a></p></div><div data-bbox=)

The Southern Puna is a morphostructural region which belongs to the Alean Cordillera. It covers 2,000,000 km<sup>2</sup>, and extends from 24° to 27° S and 66.5° to 68° W. It is characterized by extreme aridity with dry conditions (120 mm/yr), and ten year cycles of extreme drought (<10 mm) interrupted by years of abundant rain (200-300 mm). In this kind of environment, risky and uncertain conditions have to be considered in order to analyze economic strategies of the human groups.

The aim of this work is to study the paleoenvironmental evolution in the Southern Puna during the Late Pleistocene and early-middle Holocene, in particular the changes between aridity and humidity, and to link this evolution to human occupation and animal resources management.

Aerial photos and satellite images were analyzed to identify glacial, periglacial and lacustrine landscape geomorphs with the aim of reconstructing the paleogeography from the late Quaternary to a regional scale. Detailed field studies of the Holocene deposits were performed on outcrops exposed over three valleys (Las Pitas (26.015°S, 67.325°W, 3645 m), Miriguaca (25.998°S, 67.388°W, 3471 m) and Confluencia (26.056°S, 67.41179°O, 3360m), and by sediment cores taken from different parts of the Salar of Laguna Colorada (26.032°S, 67.451°O, 3420m). Lithofacies and depositional environments were determined on all recovered units, using visual core descriptions and standard sedimentological facies analytical techniques. Emphasis was placed on the identification of changes in the vertical and horizontal facies indicated by variations in grain size, sedimentary structures, biogenic, pedogenic components and the abundance of organic material. Radiocarbon (AMS) dates (30) were obtained from bulk organic matter or plant debris. Different stable isotopes (<sup>2</sup>H, <sup>18</sup>O and <sup>3</sup>H) were analyzed in Los Colorados River (26.031° S, 67,448 °W, 3421 m) and Las Pitas River (26,028°S, 67.343°W, 3581 m) in order to determine the origin of the recharge, its altitude and age.

The results of these multiproxy analysis has allowed the differentiation of five paleoenvironmental phases, some regional and some local, that developed between 15000 and 4500 yr BP. These phases would be associated to climatic changes due to the obedience of the regional paleohydrological variability of the lakes and desert water courses towards, mostly, the hydric balance originated by the rainfall and evapotranspiration.

Finally, in order of these results we make some obser-

variations about the potential incidence that the different paleoenvironmental conditions could have had for the human groups that inhabited the Puna during early and mid Holocene and the beginnings of the late Holocene considering the available archaeological record.

ORAL

## **8. ECONOMY AND CAMELIDS IN THE PREHISPANIC AGROPASTORAL SOCIETIES OF ANTOFAGASTA DE LA SIERRA (ARGENTINE PUNA) (CA. 3000-500 YEARS BP)**

*Olivera, Daniel Enzo - (CONICET-INAPL y UBA) deolivera@gmail.com*

*Grant, Jennifer - (INAPL) jennygrant62@yahoo.com.ar*

South American camelids have occupied a central role in the economic, social and ritual lifeways of ancient Andean hunter-gathers, herders and farmers, being the only large herd mammals domesticated in the Americas. Their domestication is especially important for highlands areas such as the Argentine Southern Puna where critical resources – water, grass, fertile soils, etc. – are limited for both humans and animals.

When interpreting ancient productive economies it is crucial to differentiate between the presence of wild (*Vicugna vicugna* and *Lama guanicoe*) and domestic (*Lama glama*) camelids in faunal assemblages. This is because the predominance of certain resource acquisition strategies or the presence/absence of some of these strategies could have had repercussions on the logistical organization of the groups. It has been an accepted fact that the expansion of agriculture during the late Prehispanic period had a major impact on group organization. Yet, it is likewise evident that herding and hunting also played an important, though still unclear, role during this period.

Given this uncertainty and with the purpose of further understanding human-camelid relationships our aim here is to compare and contrast the use tendencies of these animals in agropastoral societies from Antofagasta de la Sierra (Argentine Puna) during the Late Holocene – ca. 3000 to 500 years BP.

Our approach highlighted and evaluated different zooarchaeological indicators such as: size variation observed in camelids (osteometry), their assignment to age cat-

egories and different indices of skeletal element abundance (MAU, MNE, PBE). These indicators were applied across a series of different type-sites, distributed across different ecological zones in the region, the results of which were then set against the paleoenvironmental data for the Late Holocene of the area.

Results indicate that wild camelid hunting was important throughout this whole period, even if its characteristic sand intensity varied, with an important peak during the latter part of this timescale. Furthermore, throughout this time, the pastoralist evidence shows a change in type of llama from a more generalized form – ca. 3000 to 1000 years BP – providing meat, fiber and transport, to a more specialized form for the period after this.

In essence, over these ca. 2500 years highlands societies experienced an intensely important and crucial relation with both wild and domestic camelids, although the essential characteristics of this relationship changed over time.

## **9. MID-HOLOCENE CLIMATE CHANGE IN CENTRAL ARGENTINA (35°-40° S): EXPLORING ITS IMPACT ON THE PREDATOR-PREY SYSTEM INVOLVING HUMANS AND GUANACOS (*LAMA GUANICOE*)**

*Barrientos, Gustavo - (División Antropología, FCNyM, UNLP; Centro de Estudios Arqueológicos Regionales, FHya, UNR; CONICET; República Argentina) gustavbarrie@yahoo.com.ar*

*Belardi, Juan Bautista - (UNPA-UARG; CONICET; República Argentina) juanbautistabelardi@gmail.com*

*Catella, Luciana - (División Arqueología, FCNyM, UNLP; Centro de Estudios Arqueológicos Regionales, FHya, UNR; República Argentina) catellaluciana@hotmail.com*

*Morales, Natalia - (División Arqueología, FCNyM, UNLP; Centro de Estudios Arqueológicos Regionales, FHya, UNR.) moralesnatalia@live.com*

In central Argentina (35°-40° S), mid-Holocene warming began about 8.2 cal. Ky BP and lasted for almost 4000 years. During most of this period, the archaeological signal of human populations was exceedingly low. While acknowledging the potential influence of taphonomic and research bias on the general picture, one of the authors (G.B.) previously interpreted this fact as the result of a decline in the demography of human populations subsequent to a climate-induced reduction in the population size of the main animal resource, the guanaco (*Lama guanicoe*). Climate warming beyond the optimum

temperature range for conception and estrual activity can significantly reduce mammalian fertility leading to decrease in population numbers and, eventually, to local extinction. This factor, affecting cycles of prey population contraction and expansion, may impinge upon regional carrying capacity and hence on human demography. To properly evaluate this hypothesis there is much that we need to learn about guanaco physiology and human-guanaco interaction from an ecological standpoint and within the frame of medium to long-term ecosystem and biome evolution. As a first step in this endeavor, we proceeded to assess by indirect means the likely degree of dependence, in our study area, of past human populations on terrestrial game in general and on guanaco in particular. In this paper we present the preliminary results of this research, aimed to model regional hunter-gatherer niche properties and diet composition.

In order to functionally define the ecological niche that was likely available for hunter-gatherers between 35° and 40° of latitude, we constructed an ethnographically-based empirical (statistical) model that relates latitude with the relative dependence on three basic subsistence economies: a) gathering of wild plants and small land fauna; b) hunting, including trapping and fowling; c) fishing, including shellfishing and the chase of large aquatic animals. To assess diet composition, we collected two samples of georeferenced data from the southern cone of South America: a) human  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  measurements on bone collagen ( $n \approx 500$ ) and b) guanaco  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  measurements on bone collagen ( $n \approx 200$ ). Data were graphically represented and processed using GIS technology and statistically analyzed in order to recover information about latitudinal differences in diet composition and trophic level.

On the basis of the quantitative combination of subsistence economies it is possible to identify three main ecological roles: a) "gatherer-hunter-fisher" (G-H-F) at latitudes below 44°, b) "hunter-fisher-gatherer" (H-F-G) between 44° and 51°, and c) "fisher-hunter" (F-H) above 51°. Isotopic data show that below 44° there is a significant representation of low trophic level diets ( $\delta^{15}\text{N} \leq 10\text{‰}$ ) and a greater superposition of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of guanaco and humans relative to that found in more southern regions (*i.e.* Patagonia and Tierra del Fuego).

In combination, our results suggest that dependence of human populations on guanaco was lesser in our study area respective to regions located above 44° S. In Central Argentina the existence of a G-H-F niche may have buffered, to a certain extent, any sudden or progressive fall in the demography of guanaco linked to climate change.

# A8a Lobbying for Archaeology (18th- 21st centuries). Innovative alliances in the establishment of archaeology

## 1. INNOVATIVE ALLIANCES IN THE HISTORY OF ARCHAEOLOGY: INTRODUCTION TO A NEW FIELD OF INQUIRY

Marc-Antoine, Kaeser (Latenium / University Neuchâtel)  
marc-antoine.kaeser@unine.ch

During the last decades, the strong development of the historiography of archaeology has taken advantage of post-processual approaches and postmodern attitudes, which have favoured the questioning of the involvement of our discipline in the legitimization of the main ideological, political, nationalist, and colonial trends of the 19th and 20th centuries.

From now on, we consider that historians of archaeology should concentrate their attention on other forms of lobbying, more strictly economic and technical. It has been observed indeed that since the creation of modern states, archaeologists have often managed to gain the interest of non archaeological organs or institutions in order to establish flourishing alliances and to reinforce their own scientific practices – especially in the context of economical and structural upheavals.

In this introduction to the session A8a, we do not intend to present the materials of a case-study, but rather to set the methodological and heuristic framework of what we consider as a new, promising field of inquiry for the historiography of archaeology's past.

The study of « innovative alliances » offers the opportunity of a better articulation between the history of archaeological ideas and the epistemology of the discipline on the one hand, and the history of archaeological techniques and practices on the other hand. It should also contribute to the development of diachronic perspectives through the history of archaeology, from the beginning of modern times up to the immediate past and the present challenges of our discipline.

Fundamentally, the critical historiography of archaeological « lobbying » should contribute to a reflexive approach on sensitive ethical questions such as the current problems of the financing of archaeological research. Considering archaeology as a scientific, social, cultural, and ideological, but also as a technical, Financial, and economic activity, it could offer the archaeological community some guidelines as to the ways to deal with the new liberal order, especially in the present context of global economic crisis.

ORAL

## 2. THE CREATION OF THE FRONTIERS OF THE TRANSNATIONAL ROMAN EMPIRE WORLD HERITAGE SITE AS AN EXAMPLE OF ARCHAEOLOGICAL LOBBYING

Hingley, Richard - (Durham University) richard.hingley@durham.ac.uk

This paper addresses the context of the debate about the inscription of the Frontiers of the Roman Empire World Heritage Site as an example of archaeological lobbying that has involved various state parties, the European Union and UNESCO. Over the past decade, a sustained campaign has been undertaken to encourage the inscription of the Frontiers of the Roman Empire as a transnational World Heritage Site and the project that spearheaded this initiative received substantial funding from the European Union (D. Breeze and S. Jilek 2008 *Frontiers of the Roman Empire*. Edinburgh). The paper assesses the successes and limitations of this initiative and explores the alliances that have emerged and also the limitations of the initiative.

The paper addresses the ways that archaeologists and heritage managers have led a debate about the inscription of regional sections of this transnational monument into a single World Heritage Site and addresses some of the connotations for the process of definition of a monument that spans western, central and eastern Europe, the Near East and North Africa. It addresses the debates that have identified, defined and interpreted the sections of the Roman frontiers in different regions (cf. D. Mattingly et al. 2013 *Frontier of the Roman Empire: The African Frontiers*. Edinburgh) and also the attempts to write a statement of Outstanding Universal Value for the entire monument and its constituent parts. In particular, it addressed the relationships that are developing between the various state parties along the course of these former frontiers and the role of UNESCO in this debate.

The creation of a unified agenda for the entire monument has led to new forms of co-operation and is also highlighting different regional approaches to archaeology and heritage management. In addition, the initiative has a complex relationship to the contemporary bordering practices of the European Union and also the idea of encouraging tourism. In particular, potential national and regional agendas that appear to divide particular parts of the broader region are defined, exploring the different meanings of former imperial frontier works across various parts of this broad region.

Although highly supportive of the considerable efforts that have been made to create a united agenda, this paper aims to articulate the contrasts in approaches that characterise particular parts of the monument—ideas that help to articulate differing attitudes to the past and to the present. In particular, it emphasises the geopolitics of the global world order in which Roman places are being remade (cf. D. Totten and K. Lafrenz Samules 2011 *Making Roman Places*. Journal of Roman Archaeology Supplementary Series).

ORAL

### 3. LOOKING FOR POWERFUL ALLIES. THE EXAMPLE OF ARCHAEOLOGY AND 14C DATING METHOD

*Delley, Géraldine (Université de Neuchâtel, Institut d'archéologie) geraldine.delley@unine.ch*

After WWII it became necessary for nuclear research to find new applications in civil and pacific domains. Isotopic dating methods like 14C correspond to the kind of applications nuclear research laboratories were interested to develop. Several positive dispositions explain the quick diffusion of the 14C method from the USA to Europe: a clear position of governments regarding the massive supporting of nuclear research from the 1950s onward; the diversity of the domains of application of 14C (archaeology, botanic, geology, climatology, etc.); the supports of politics of sciences to research projects presenting multidisciplinary practices.

This research is based on the analysis of published and unpublished sources (correspondence between scientists, unpublished reports and interviews).

A critical analysis of the introduction of the 14C method in Switzerland reveals that for archaeologists, the potential of method was not only heuristic. Given the attractiveness of nuclear research, archaeologists knew that if they made their collaborations with nuclear physicists visible, they could expect positive effects regarding the position of archaeology in the scientific landscape. On the other hand, such collaborations were perceived positively by physicists as well. Providing archaeologists with absolute dates was a demonstration of the usefulness of nuclear physics even in the domain of humanities.

In the 1950s, the redefinition of the relationship between science and politics encouraged archaeologists to establish alliances with radiocarbonists. These alliances profited directly from the powerful position physics, and in particular nuclear physics, occupied among the

sciences after WWII. Such contextual details, in addition to the modern dimension of the method and its heuristic potentials, explain the power of seduction of the 14C for archaeologists and politics of sciences.

ORAL

### 4. COMPUTING, ENGINEERS AND ARCHAEOLOGY: DISCIPLINE BORDERS AND MIGRATION IN FRANCE (1950-2000)

*Plutniak, Sébastien - (Lisst-Cers, EHESS, France) sebastien.plutniak@ehess.fr*

All along the second half of the 20th Century, both analogical and digital electronic computing technologies encountered a fast and flourishing development. Applications were performed in various civilian, industrial and scientific fields. Scientific applications, more and more unavoidable, led to the creation of specialties and “hyphenated computing” disciplines, following P.-M. Mounier-Kuhn’s word (Mounier-Kuhn, 2010), such as computational linguistics, bioinformatics and more recently neurocomputing and computational archaeology. On this matter we shall distinguish between process of quantification (involving measurement) and process of mathematisation (involving formal abstraction) of a scientific practice: historiographical account of mathematisation have a long-standing tradition, concerning above all physics (Gingras, 2001) and instrumentation (Joerges, Shinn, 2001). Methodological and technological transfers in science are not limited to a cognitive phenomena and can lead to changes in the institutional and social organisation of a discipline: lines and objects of research, legitimacy and recognition can be redistributed, as it was the case between linguistics, computing science and engineering (Grosseti, Boë 2008). These studies offer us a robust framework to investigate the archaeological case, as fewer studies have been led about humanities disciplines.

Contrary to the English-speaking archaeological case, formalisation and computing had a far more restricted role in French archaeology, which has been characterized as a “continental insularity” (Audouze, Leroi-Gourhan, 1981). In this paper we aim to investigate this peculiar situation, relying on a limited set of cases regarding the relationships between archaeology, computing and engineering. This recent side of the history of French archaeology has been less enlightened (Djindjian 2009) and led us to propose a socio-historical account of these developments. The case of Jean-Claude Gardin’s

innovative collaborations will be stressed. Starting from the 1960's he established several contracts, both with inter-governmental and private institutions in order to elaborate archaeological applications of mechanical and electronic computing. The *Centre d'automatique documentaire pour l'archéologie* he set up in Marseille in 1964, recruited mathematicians and engineers: both in order to develop methodological innovations and to offer computing services to archaeologists (and, in fact, to various scientific communities).

Issues related to disciplines' forms and dynamics and to boundary-objects underlie this case. What kinds of positions had these engineers reached and occupied in the archaeological and scientific fields? What were their professional trajectories and their influences on the archaeological discipline? We will emphasize the determination of social relations in these innovative collaborations. Doing so, we aim to contribute to the issues related to "lobbying" by exposing the variability related to the relationships between archaeological and engineering communities.

ORAL

## 5. THE AUSTRALIAN RESEARCH COUNCIL AND THE ARCHAEOLOGY OF THE MODERN CITY IN AUSTRALIA

*Murray, Tim (Faculty of Humanities and Social Sciences, La Trobe University, Melbourne) t.Murray@latrobe.edu.au*

From the late 1990s the Australian Research Council radically reformed its grant schemes in order to underwrite a significant expansion in research funding through developing close links between the academy and industry. Two schemes in particular (SPIRT - Strategic Partnerships Industry Research and Training; and Linkage) provided a framework within which the strategic value of archaeology to industry, especially in the resources sector and in prorty development, was significantly enhanced. In the 20 years that have followed Australian archaeology has been transformed by these new connections, especially those related to the re-development of building stock in the cores of fast-growing cities such as Sydney and Melbourne. Not only has a great deal of archaeology been done, the financial requirements of industry have led to developments in excavation, recording and analysis methodologies practiced across all fields of archaeology.

ORAL

## 6. LOBBYING FOR ARCHAEOLOGY IN THE ITALIAN "FIRST REPUBLIC"

*Guidi, Alessandro (università roma tre) alessandro.guidi@uniroma3.it*

Nowadays, the period between the Liberation from Fascism (1945) and the explosion of scandals that characterized the chronicles of 1992 is defined, in Italy, as the "First Republic".

The paper will examine, in this period, three examples of political lobbying finalized to an (economic) advantage of the major political party, the Democrazia Cristiana (DC) and, from the late 1970s onwards, of their preferred partner, the Italian Socialist Party (PSI)

- the history of the Cassa del Mezzogiorno, a sort of State Bank created to stimulate with massive sums of money the economy of the underdeveloped South of the Country, an organism that specially in the 1950s and in the 1960s allowed many excavations of the most important Greek and Roman cities and/or monuments and the consequent creation of modern Museums and Archaeological Parks;

- the promanation, in the late 1970s, of a law for the creation of young people cooperative societies in the field of Cultural Resource Management (legge 285; many of the young archaeologists, historians of art and architects were later absorbed in the State Antiquity Offices [Soprintendenze]);

- the metaphor, in the 1980s, of Cultural Resources as our "oil" (hence the name "cultural reservoirs"), with the creation of societies whose first aim was the computerization of the cultural patrimony ("Beniculturali").

In all these study-cases archaeologists exploited for their researches the relevant quantities of money that were at the same time the first incomes (and sometimes a real access to stable occupation) for many generations of young practitioners, creating a sort of patron-client relationship with political or academic authorities.

## **7. INNOVATIVE ALLIANCES IN THE TWENTIETH-CENTURY HISTORY OF SPANISH ARCHAEOLOGY.**

*Díaz-Andreu, Margarita (ICREA-Universitat de Barcelona)  
m.diaz-andreu@ub.edu*

The Fons Pericot (Pericot Archive) contains an amazing number of letters received by Prof. Luis Pericot (1899-1978), mainly after the Spanish Civil War, as well as other items.

Although a complete study of the material is yet to be undertaken, the selection of the correspondence so far studied reveals some alliances that archaeologists were establishing at the time with administrations and non-archaeological institutions in order to strengthen their scientific practices.

Alliances with non-archaeologists included members of the diplomacy, wealthy sponsors and touristic offices. Other alliances were established with archaeologists from major powers of the time, a novelty which reported great benefits for Spanish archaeology.

## **8. LOBBYING FOR ARCHAEOLOGY: AN OVERALL ASSESSMENT**

*Marc-Antoine, Kaeser (Latenium / University Neuchâtel)  
marc-antoine.kaeser@unine.ch  
Géraldine, Delley - (University Neuchatel) geraldine.delley@unine.ch*

In view of the novelty of the field of historiographical inquiry into the « Lobbying for archaeology », this contribution aims at a general synthesis of the teachings of the session A8a.

The different contributions to the session A8a will be taken into account. The synthesis will focus on the identification of similarities and possible permanent features – as well on the thematic level as on geographical, regional/national/international, political, chrono-historical levels.

The generic role of « innovative alliances » will be the subject of an overall assessment, evaluating their contribution to the establishment of the archaeological discipline.

## 1. FROM FAR AWAY: MUSEUMS, COLLECTIONS AND SCIENTIFIC RESEARCH

*Chichkoyan, Karina Vanesa - (IPHES- URV) karinavch@gmail.com*

Nineteen century was of movements and immigration of large contingents of people. But this also included the extrapolation and storage of fossil materials in different museums, like happened with South American paleontological collections that were translocate to Europe. In an era where crossing frontiers was easier, objects moved along with peoples, and control over the exit of national territory and entrance into a new one was generally celebrated. This contrast with nowadays situation, were patrimonies are reclaimed and increasing controls are done in order to stop the illegal contraband of archaeological and paleontological pieces.

Today we found these collections distribute in several museums and institutions, miles away from its original point. A reflection about this situation is useful after one hundred years of this event: shall they return to their home countries or shall they stay away. Although the importance in housing material in its original places, a different point of view is taken here: material housed outside allows the diffusion of the own patrimony to citizens that perhaps will never travel to those countries, and encourages intercultural knowledge, but also they provide useful material to realize new studies in international programs which imply an extension of the institutional ties. This material can be focus with the application of methodologies that are not used in the original country, so in an indirect way, this patrimony provides to the research developed there. These conditions also allow integrating and contrasting different theoretical frameworks and data that improve interregional/intercontinental comparisons.

The experience realized in the Natural Science of Valencia, Spain where the Rodrigo Botet collection is housed, is an interesting example case. This is the most important collection of South American fossil megafauna in Europe and was studied by Boscá Casanoves, first curator of the museum. It was part of the first Paleontological Museum in Europe and it is characterized by the diversity and the large amount of material. The same was donated by Rodrigo Botet at the end of the XIX Century and it is the result of non-systematic excavations done by Enrique de Carles at the north-eastern sector of the Pampas Region in Argentina. It also has important human remains, as

the "Samborombon skeleton", that unleashed in Spain the polemic about the antiquity of the first American peopling, as was postulated by Ameghino at that time. This collection was studied under the Erasmus Mundus Master in Quaternary and Prehistory program and currently is part of a PhD. thesis that will include material from this country housed in different museums in Europe and were translocate to this continent in the Nineteen century.

This kind of experiences can only developed because of the political situation the world was passing thought more than one hundred years ago. Thanks to that flow of goods, today, investigation outside the country can be realized and this allows the application of different methodologies, provides new data, and, contrary to what it is supposed, it broaden scientific research from far away.

ORAL

## 2. BRITISH IDEAS IN A FRENCH WORLD. VICTORIAN ANTHROPOLOGISTS AND THE CREATION OF THE "PALAEOLITHIC ART" CONCEPT (1890-1906)

*Palacio Pérez, Eduardo - (Instituto Internacional de Investigaciones Prehistóricas de Cantabria (Universidad de Cantabria) eduardo.palacio@unican.es*

The concept of "Palaeolithic art" changed completely in the late nineteenth and early twentieth century. A concept based on naive realism and the decorative nature of the representations changed into one founded on an evolutionist explanation of the artistic form and in the symbolic-religious meaning of the different motifs. This change was determined by the introduction of a series of ideas developed by British evolutionists in the field of French prehistory. This took place within a complex scenario marked by tension between each country's own archaeological traditions and a clear trend towards the international transmission of ideas. The French researchers Salomon Reinach (1858-1932) and Henri Breuil (1877-1961) played a vital role in this process.

Papers, monographs, conference and congress proceedings, autobiographical diaries and correspondence of the main actors.

The traditional concept of "Palaeolithic art" which appeared in the early twentieth century was the result of the transfer of ideas from British evolutionist anthropology to French prehistory.

### 3. THE "FIRST DOCTOR OF CASTILLO": NELS NELSON AND TRANS-ATLANTIC ENGAGEMENT IN PALEOLITHIC ARCHAEOLOGY IN THE 1910S

*Snead, James E. - (Department of Anthropology California State University, Northridge) jsnead@csun.edu*

Because of the cultural primacy of Old World history and prehistory for scholars in the in the 19th century United States, engaging this past through programs of field-work and scholarship were a deep concern to American intellectuals. Limited resources were available, however, and for much of the century such interaction was limited to exchanges of letters and specimens, with modest programs of classical research, occasional tours of European museums, and meetings with specialists. The turn of the 20th century ushered in new ambition for more direct involvement. The American Museum of Natural History in New York sought to establish a European presence that would extend its curatorial expertise in mammalian paleontology into the realm of human prehistory. Opportunities to develop such a program, however, were scarce, so when a personal visit to France and Spain provided museum president Henry Fairchild Osborn with a range of new contacts, he quickly responded by dispatching a junior colleague, Nels Nelson, to Spain. Nelson's experience at Castillo, where he worked under Hugo Obermaier with an international team, was influential for all concerned. The experience of the "first doctor of Castillo"—as he was humorously designated by Obermaier—thus documents a formative episode of trans-Atlantic engagement in Paleolithic archaeology.

### 4. INTERNATIONAL RELATIONS WITHIN EARLY MESOLITHIC RESEARCH IN NORTHERN SPAIN

*Fano, Miguel Ángel - (Universidad de La Rioja) miguel-angel.fano@unirioja.es*

*Cubas, Miriam - (IIIPC - Sociedad de Ciencias Aranzadi) mcubas@aranzadi-zientziak.org*

The relationship between researchers, at both local and international levels, is a key factor in the historiographical evolution of any research topic. In this paper, the work of the pioneers of Mesolithic research in northern Spain (1914-1930) is described within the framework of scientific and personal relationships at that time. The goal is to analyze their impact on the early research on the period

and its subsequent historiographical development.

The study examines monographs and excavation reports, as well as other documents (diaries, correspondence and biographies) directly related with the scholars involved in prehistoric research in northern Spain during the first third of the twentieth century: Count of la Vega del Sella, Hugo Obermaier, José Miguel de Barandiarán, Henri Breuil, Lorenzo Sierra and Jesús Carballo, among others.

As in the case of Palaeolithic studies, the first research on the Mesolithic in the region did not take place in isolation from European prehistoric studies at the time. The study of the Mesolithic in Cantabrian Spain began within a historiographical context marked by the existence of relationships between local pioneers in Prehistory and a number of foreign archaeologists. These relationships fostered, for example, Obermaier's collaboration in some of Vega del Sella's excavations. In this way, the German prehistorian was witness to the start of Mesolithic research, and he also took part in it. However, the available information reveals that relationships between Spanish archaeologists were rather lukewarm, in general.

The feedback between Spanish and foreign archaeologists sometimes had a significant impact from the historiographical point of view, such as the early location of the *Asturian* culture in its European context. At the same time, the cooler relations among Spanish researchers meant that no debates took place about matters that still remain open, such as the existence of "different Mesolithic facies" in Cantabrian Spain.

---

ORAL

### 5. THE CHICAGO CONNECTION IN SPANISH PALEOLITHIC PREHISTORY

*Straus, Lawrence - (University of New Mexico) lstraus@unm.edu*

A half-century has passed since anthropological archeologists from the University of New Mexico began collaborating with Spanish prehistorians and paleontologists in the study of the Paleolithic of central and northern Spain. While international politics may have provided the initial background for work at Torralba, Ambrona and Cueva Morin in the mid-late 1960s, the long trajectory of interdisciplinary cooperative research has been mutually fruitful for the development of our understanding of Pleistocene hominin adaptations as a result of pro-

ductive, amicable, mutually respectful cooperations that continue to this day. This presentation reviews and indeed celebrates the work and interactions of Clark Howell, Emiliano Aguirre, Leslie Freeman, Joaquin Gonzalez Morales, Karl Butzer, Jesus Altuna, and a whole generation of their students, including the present author and his Spanish and American colleagues, as well as their current and recent students.

The author was a student of Howell, Freeman and Gonzalez Echegaray and has conducted research in Spain with both G.A. Clark (another Freeman student) and M.R. Gonzalez Morales (an Echegaray disciple, while also collaborating with J. Altuna and many other Spanish specialists).

The interactions and mutual influences that developed during the course of excavations at Torralba, Ambrona, Cueva Morin, La Riera, El Juyo, Altamira and Cueva del Miron are analyzed in the light of the development of both the practice of prehistoric archeology in Spain as it turned toward a more anthropological (and less culture-historical) direction and in light of the vast increase in substantive knowledge and practical experience for American researchers, including students. Field experiences, analyses of materials (both cultural and "ecofactual"), participation in meetings and congresses in the U.S., Spain and internationally, joint publications, research/teaching visits in host institutions, scholarships/fellowships, service on thesis/dissertation committees, etc. all contributed (and continue to contribute) to a rich synergy of mutually fruitful professional and personal relationships that changed the course of prehistoric research both for Spain and for certain American prehistoric archeologists.

The overall balance (from my admittedly biased viewpoint) has been positive, and as a participant, the author wishes to make this point in the significant venue of Burgos, not far from Atapuerca, and about mid-way between Soria and Cantabria, where the Chicago connection has had its main impacts on the development of paleoanthropological science in Spain.

ORAL

## 6. AN INFLUENTIAL OUTSIDER: GEORGES LAPLACE IN ITALY

*Plutniak, Sébastien - (Lisss-Cers, EHESS) sebastien.plutniak@ehess.fr*

*Tarantini, Massimo - (Soprintendenza per i Beni archeologici della Toscana) massitarantini@gmail.com*

French prehistorian Georges Laplace defended his thesis in 1961 and published it in 1966. Entitled *Recherches sur l'origine et l'évolution des complexes leptolithiques* this work has been of crucial importance in the field of Upper Palaeolithic studies. Beside its methodological insights with regards to the quantitative approaches of the lithic industries, this work gathered data from an unusually broad area. He studied assemblages from North Africa to Central Europe, passing by Spain and before all France (75 assemblages) and Italy (38 assemblages). However, this innovative study was unequally received, discussed, and extended in these countries. It became very influential in Spain and particularly in Italy.

In this paper, we aim to come back to this formative period of Georges Laplace's scientific life: the period he spent in Italy, doing his doctoral thesis. Social and historical studies of science proposed several ways to account for spatial and social mobility as a critical feature of the scientific activities and their dynamic (Ben-David, Collins 1966; Daryl 1976). Grounded on sociological frameworks regarding migrations in science we scrutinize the Italian years of Georges Laplace. In order to go beyond a biographical account we consider his stay and his researches in Italy in relation to their intellectual and institutional environments. How Laplace got the opportunity to reach Italy? What role played his French supports (as l'Abbé Breuil) and the contemporary policy of the *École française de Rome*? How was structured the prehistoric field in Italy and how Laplace succeeded to manage his own research while taking benefit from his outsider position? How its methodological and interpretative approach was received and reprocessed in Italy?

Our paper aims to answer these questions, drawn upon archives kept at the *Musée National de la Préhistoire* (Les Eyzies-de-Tayac, France), l'*École française de Rome* (Italy), the *Muséum national d'Histoire naturelle* (Paris) and at the *Istituto Italiano di Paleontologia Umana* (Anagni, Italy) and numerous interviews performed with prehistorians who were close to Georges Laplace.

ORAL

**7. AFRICANISM AND INTERNATIONAL RELATIONS OF THE SPANISH PREHISTORIC ARCHAEOLOGY (1939-1956)**

*Gozalbes Cravioto, Enrique (Universidad de Castilla -La Mancha) enrique.gozalbes@uclm.es*

After the Spanish Civil War, a struggle for control of Archaeology broke out. One of the elements of that struggle was precisely the outer extension in the nearest territories through the doctrines of the Africanism. In particular the participation in Morocco was of paramount importance, as it allowed the Commissioner General of Excavations, J. Martínez Santa-Olalla, try to check his thesis about the Spanish origin of the North African cultures. However, he was displaced by Luis Pericot in the African context.

Documentation of the Archaeological Museum of Tetouan. Analysis of Bibliography and official Acts and other materials of the First Archaeological Congress of the Spanish Protectorate in Morocco (1953).

In the context of this time, the presence of the Spanish prehistoric and archaeological research in the Protectorate allowed the contact with European and American prehistorians.

In our contribution we have analyzed these contacts. Especially in the final part of our paper we have paid attention to the collaboration developed between M. Tarradell and L. Balout around the celebration of the Archaeological Congress in Tetuan in Spanish Morocco and after the synthesis of Maghreb prehistory of Balout, documentation from the Archaeological Museum of Tetouan.

ORAL

**8. ARCHAEOLOGICAL CONNECTIONS: TRACKING AND TRACING INTERNATIONAL RELATIONS THROUGH PORTUGUESE COLONIALISM**

*Conde, Patrícia - (Tropical Research Institute, Lisbon, Portugal) patricia2conde@gmail.com*

*Martins, Ana Cristina - (Tropical Research Institute, Lisbon Portugal) / Uniarq-Centre for Archaeology, University of Lisbon, Portugal) ana.c.martins@zonmail.pt*

Amongst studies on the History of Archaeology, colonialism has become one of the main topics. Although still recent in Portugal, the research concerning archaeological practices conducted in and about the former Portu-

guese colonies has brought to light, on one hand, the case of the Board of Geographical Missions and Colonial/Overseas Research (Junta das Missões Geográficas e de Investigações Coloniais/do Ultramar) (1936-1951/1952-1973), within which "Anthropological Missions" encompassed the knowledge of the remote past of those territories and, on the other hand, the surveys led by personal enterprises and local entities which contributed to the production and circulation of archaeological and prehistoric knowledge.

From the confluence of these two axes of analysis it also emerges a growing approach which bring new data and insights into this field of studies. That is the case of regional and international scientific networks that shaped ideas, terminologies and methodologies. Indeed, not unrelated to other colonial contexts and agendas in which Archaeology was becoming institutionalized within scientific research centers and museums, different protagonists and institutions, either from the Portuguese metropolis or its colonies, engaged in a wide dynamic that took shape in congresses and conferences, internships abroad and fieldwork conducted in collaboration with other leading figures of African Archaeology, often resulting in the publication of studies and reports.

In addition to these more noticeable features, correspondence between individuals and institutions from within the country and abroad comprises less detectable aspects regarding the diverse manners Archaeologists addressed questions about Africa's past, enclosing a wealth of information over a broad range of issues which provide a valuable frame to locate Archaeology in different political, economic, social, cultural and geographical contexts during colonialism in the twentieth century.

Under the scope of the Project *Archaeology and Portuguese colonial agenda*, funded by the Portuguese Foundation for Science and Technology, we intend to track and trace the multiplicity of international relations that emerge from the scrutiny of Archaeology conducted during Portuguese colonialism as well as its role in the History of Archaeology.

To discuss about the role and the many forms of international relations in the History of Archaeology that emerge from the scrutiny of Archaeology conducted during Portuguese colonialism we will practice an historical approach. In doing so, we will use mainly both written and iconographic primary sources from public and private archives, namely the documentation in the custody of the Tropical Research Institute (Instituto de Investigação Científica Tropical) (Portugal), the current

successor of the Board of Geographical Missions and Colonial/Overseas Research.

The tracking and tracing of regional and international scientific exchange related to Archaeological research conducted during Portuguese colonialism enables the mapping of a worldwide connection involving different contexts, actors and typologies.

The links between Archaeology and colonialism provide undeniable contributions to the historicization of the discipline. In this framework, we hold that a study on the History of Archaeology cannot fail to consider the many international scientific relations about African Archaeology and Prehistory that took place during the 20<sup>th</sup> colonialism.

ORAL

### **9. FUNDING INTERNATIONAL STUDY TRIPS IN EARLY TWENTIETH CENTURY EUROPE: THE JAE GRANTS AND THE PRESENCE OF SPANISH ARCHAEOLOGISTS IN ITALY (1907-1936)**

*Sánchez Salas, Francisco - (Universitat de Barcelona) francisspr@gmail.com*

The Junta para la Ampliación de Estudios e Investigaciones Científicas (JAE, Spanish Council for the Expansion of Study and Scientific Research) created in 1907. The purpose of this official institution was "to train the future teaching body and to give to the present one the means and facilities to follow closely the scientific and pedagogical movements of the most cultivated nations". Grants for study trips were one of the initiatives that the JAE had in order to reach its aim.

As a result, a large number of Spanish scholars were able to travel to different locations in Europe and also North America. There is information about the selection process and the activities of the grantees in the JAE annual reports. In addition, other type of documents such as reports that the grantees sent to the JAE are now stored in the archive of the Residencia de Estudiantes in Madrid.

This paper will focus on the archeologists who chose Italy as a destination country for their grants. This group was an important one because Italy was selected by more than 40% of archaeology grantees. This preference for Italy, and especially for Rome, can only be partly explained by the founding of the Spanish School of Rome for Archeology and History in 1910. In this paper the impact of these study trips will be analysed

ORAL

### **10. INTERNATIONAL GEOGRAPHIES OF ARCHAEOLOGICAL KNOWLEDGE ? RELATIONS BETWEEN SPANISH AND BRITISH ARCHAEOLOGISTS**

*Díaz-Andreu, Margarita - (ICREA-Universitat de Barcelona) m.diaz-andreu@ub.edu*

This paper will explore the impact of geography in the production, consumption and circulation of knowledge. The analysis will be divided into two major subjects: the geographies of production and reception. The questions to be asked are, on the one hand, whether it matters where archaeological knowledge is produced and whether the archaeologists' locations can influence the content and nature of their scientific production and have an effect on the national and international networks they form. On the other hand, an assessment will be made of the existing conditions and means by which the transmission of knowledge takes place and whether this affects reception.

These different approaches will lead us to a discussion about the perception of academic authority and credibility.

These issues will be discussed in the context of the relationship between Spanish and British archaeology in the twentieth century on the basis of the information found in the Fons Pericot.

ORAL

### **11. INTERNATIONAL RELATIONS IN THE HISTORY OF ARCHAEOLOGY WHEN THE MODERN IS TOO NEW – ON HANNA RYDH AND HER FRENCH CONTACTS.**

*Arwill-Nordbladh, Elisabeth (Department of Historical Studies, University of Gothenburg, Sweden) E.Nordbladh@archaeology.gu.se*

In the 1920ies the Swedish archaeologist Hanna Rydh (1891-1964) spent 6 months at Musée des Antiquités Nationales in St-Germain-en-Laye near Paris, to study Palaeolithic issues. Leader of the archaeological department was the prominent professor Henri Hubert, a disciple of Emile Durkheim and close friend and co-worker of Marcel Mauss. A few years after her French sojourn, Rydh published two articles, one on symbolism in mortuary practices and the other on seasonal fertility and death

cult in Scandinavia and China, themes that were not familiar in Scandinavian archaeology. Here I propose that Rydh was influenced by Durkheimian ideas. The reception of the articles was however very harsh, and a conclusion is that Swedish archaeology was not ready for these continental ideas.

ORAL

## 12. THE INTERNATIONALIZATION OF SWISS WETLAND ARCHAEOLOGY AFTER WWII

*Delley, Géraldine - (Université de Neuchâtel, Institut d'archéologie) geraldine.delley@unine.ch*

In the 1950s, the position of prehistoric research in Switzerland is very unstable. Wetland archaeology, a popular topic, appeared to be a very attractive domain for renewing and reinforcing the perspectives of Swiss prehistory. However wetland archaeology was also problematic: the nationalist dimension of this field of research – responsible of its great visibility at the end of the 19<sup>th</sup> and at the beginning of the 20<sup>th</sup> centuries – was no more bearable after WWII.

This research is based on the analysis of published and unpublished sources (correspondence between scientists, unpublished reports and interviews).

International collaborations in the domain of wetland archaeology during the 1950's brought an opportunity for Swiss archaeologists to renew and thus modernize their practices, reviving the traditional question of the prehistoric lake-dwellings in a methodological perspective. The competences of Scandinavian and Dutch specialists in the domain of natural sciences – sedimentology and palynology – applied to archaeology were particularly decisive.

International collaborations in the field of Swiss wetland archaeology after WWII yielded to the diffusion of innovative tools and new *savoir-faire*. The internationalist dimension of these collaborations was also a means for Swiss archaeologists to turn the debate of this traditional field of research onto new perspectives.

ORAL

## 13. PORTUGUESE ARCHAEOLOGY AND ITS INTERNATIONAL NETWORKS DURING THE 60IES: PROTAGONISTS AND PROJECTS

*Martins, Ana Cristina - (Tropical Research Institute / Uniarq-Center for Archaeology, University of Lisbon) ana.c.martins@zonmail.pt*

In 1958, Lisbon hosted the 1<sup>st</sup> National Congress of Archaeology. Postponed, in contrast to analogous meetings organized in other countries, it intersected generations of Portuguese archaeologists. Predominantly, between those born in late 19<sup>th</sup> century, and young ones looking for new theoretical models. But, to achieve this intention, it was essential to reduce the internal traditional proximity to Spanish and French academicism, in search of new archaeological and anthropological schools. This process became indispensable so as to find new paradigms, visions and synergies. That is why they were largely enthusiastic with the *Wheeler-Kenyon* stratigraphic method, while discovered and learned about *New Archaeology* (1958).

Nevertheless, geographical closeness, individual interests and friendships, alongside with institutional - public and private -, agendas and shared topics, justified a long-standing collaboration between Portuguese and Spanish archaeologists. Fact made clear by several individual and institutional correspondences kept in diverse archives, such as the ones belonged to the National Museum of Archaeology (1893) and the Association of Portuguese Archaeologists (1863).

It is, consequently, our intent within the Spanish research project *Archaeology without frontiers. The international contacts of 20th-century Spanish archaeology*, to reconstruct networks of Portuguese making, circulation, reception and dissemination of archaeological knowledge within international context, identifying head names, organizations, and research projects. Lastly, we will estimate their influence on the establishment of Portuguese archeology, from the late '50s to the early '70s.

To discuss about the ways and the many forms of international networks of Portuguese archaeology during the 60<sup>ies</sup>, we will practice an historical approach. In doing so, we will use mainly both written and iconographic primary sources from public and private archives, namely the documentation in the custody of the National Museum of Archaeologists and the Portuguese Association of Archaeologists, together with several secondary sources

published by Portuguese archaeologists between the end of the 50ies and the beginning of the 70ies.

Evaluating the many ways and forms of international networks of Portuguese archaeology during the 60<sup>ies</sup>, we will be able to understand the relevance of these connections on the establishment and development of scientific projects inspired in *New Archaeology*, institutions and university courses, when comparing to coeval examples, naming protagonists, institutions, outcomes and outputs.

The links between particularities of Portuguese archaeology and the many ways and forms of international networks of Portuguese archaeology during the 60<sup>ies</sup> *New Archaeology* in the country, provide undeniable contributes to the historicization of the discipline. In this framework, we hold that a study on the History of Archaeology cannot fail to consider the significant role of international scientific networks in the establishment and development of archaeology.

whose practicans had be in a more narrow contact with improvements in the north of the continent.

The late arrival of the processual archaeology advances to our country contributed to these improvements coming somewhat weakened and already affected by the radical critique of 'post-processual' or 'post-modern' archaeology in the anglo-saxon realm. As a result, its effect was less important than expected and this fact could possibly explain that a great part of spanish archaeology nowadays still follows, only with a light 'scientific' bar-nish, culture-historial paradigms.

### 14. LEARNING TO BE SCIENTIFIC: THE INTRODUCTION OF THE 'NEW ARCHAEOLOGY' IN SPAIN, 1975-1990

*Fernández, Victor M. - (Universidad Complutense De Madrid) victormf@ucm.es*

Around 1975, in coincidence with the end of Franco dictatorship and the renewal of Spanish culture and politics, archaeology began to receive influences from abroad, the most important being that from the then called 'new archaeology' in USA and great britain. Up to that moment, spanish archaeology was mainly descriptive and had an culture-history orientation that hampered any attempt of theoretical or methodological advances.

The paper consists of a survey of the publications between 1975 and 1990 in the most important archaeological journals of the country, combined with personal interviews with some of the key actors at the moment, now approaching retirement and whose information requires to be collected before it is too late.

The novelties of the new archaeology were two-sided, methodological and theoretical. The first were easily and fastly adopted among us, especially those related to 'spatial archaeology' implemented from the Teruel congresses on this topic since 1984. The second had a far less impact, mainly confined to the field of americanist archaeology

## 1. LE MAMMOUTH DANS TOUS SES ÉTATS

*Vercoutère, Carole - (Département Préhistoire du MNHN / CNRS UMR 7194) cvercout@mnhn.fr*

*Patou-Mathis, Marylène - Département Préhistoire du MNHN / CNRS UMR 7194) patmath@mnhn.fr*

*Demay, Laëtitia - (Service d'archéologie préhistorique de l'Université de Liège / Département Préhistoire du MNHN / CNRS UMR 7194) laetitia.demay@student.ulg.ac.be / ldemay@mnhn.fr*

*Le mammouth dans tous ses états* est une réflexion sur le statut du mammouth laineux (*Mammuthus primigenius*) au sein des sociétés de chasseurs-cueilleurs du Paléolithique supérieur.

Présent à la fois dans la sphère domestique (consommé, source de matières premières), le domaine symbolique et l'imaginaire collectif, ce proboscidiien demeure pourtant peu visible dans les études archéozoologiques *s.l.* des sites d'Europes occidentale. Ce constat est-il en lien avec des questions d'ordre méthodologique? Cette faible représentation du mammouth dans les listes fauniques est-elle une réalité archéologique? Si oui, signifie-t-elle pour autant que les Hommes ont peu interagit avec cet animal? En d'autres termes, les caractéristiques propres au mammouth (*e.g.* très grande taille) et les pratiques de chasse et de boucherie qui lui sont spécifiques sont-elles les seules causes de la rareté de ses ossements dans les sites anthropisés? Cette sous-représentation, particulièrement effective en Europe occidentale, ne pourrait-elle pas s'expliquer par une position à la marge de l'aire d'expansion du mammouth ou/et par des traditions culturelles tournées préférentiellement vers d'autres espèces/matériaux (*e.g.* renne/bois)?

L'étude comparative des résultats d'analyses archéozoologiques menées sur des matériels issus de sites contemporains, mais de contextes environnementaux différents, nous permettra d'apporter des éléments de réponses à ces questions et également d'engager une réflexion naturaliste approfondie sur le statut du matériau ivoire. Par exemple, le choix d'utiliser l'ivoire se fait-il en fonction de la destination de l'objet ou/et du statut accordé à l'«animal ressource»? Quant à l'examen typotechnologique des pièces en ivoire, qui permet de restituer les savoir-faire techniques des artisans, autant que la fonction des objets, il définira la place de l'ivoire non

seulement dans l'économie, mais aussi dans l'imaginaire collectif des sociétés paléolithiques.

ORAL

## 2. LEVALLOIS POINT PRODUCTION IN SOUTHERN SIBERIA AND EASTERN PART OF CENTRAL ASIA: TECHNOLOGICAL VARIABILITY, GEOGRAPHICAL DISPERSAL AND CHRONOLOGY

*Rybin, Evgeny - (Institute of Archaeology&Ethnography, Russian Academy of Sciences, Siberian Branch, Novosibirsk, Russia) rybep@yandex.ru*

*Slavinskiy, Vyacheslav - (Institute of Archaeology&Ethnography, Russian Academy of Sciences, Siberian Branch, Novosibirsk, Russia) slavinski@yandex.ru*

Occurrences of Levallois reduction technology in Siberian assemblages has been widely considered as an integral part of Middle and Early Upper Paleolithic of this region. This paper draws on the results of the studying of data about distribution of characteristic features of Levallois reduction strategy – predetermined triangular and subtriangular spalls, examined through the studies of typical and atypical Levallois pointed artifacts and refits founded in assemblages from Altai Mountains throughout Southern Siberia towards Mongolia determined as the easternmost region of distribution of Levallois point technology. Resulting discussion allows underlining the similarities and differences in the Levallois methods variability in the Middle and Early Upper Paleolithic and giving a broader picture of continuity and/or discontinuity during the “transition” between these epochs.

## 3. UPPER PALEOLITHIC OF CENTRAL ASIA: KULBULAK CULTURE

*Kolobova, Kseniya - (Institute of Archaeology & Ethnography SB RAS) kolobovak@yandex.ru*

*Krivoshapkin, Andrey - (Institute of Archaeology & Ethnography SB RAS) krivoshapkin@mail.ru*

The paper focuses on the descriptions and analyses of the lithic industries recovered from the Upper Paleolithic strata at the Kulbulak site in Uzbekistan, one of the most important sites in western Central Asia. Archaeological studies at this site along with the studies of Kyzyl-Alma-2, Dodekatym-2 and Shugnou in the western and north-western parts of the Pamir –Tien Shan Mountain Range

allows us to propose the identification of Kulbulak cultural-technical tradition. It is characterized by the bladelet technique and represents an original technocomplex of small tools including backed artifacts and triangular microliths. The established trend in the lithic tradition development, the stages of emergence, development, flourishing and replacement of the artifacts fashioned through the carinated technology. The noted features of this technical tradition are typical for the Upper Paleolithic technocomplexes of this region.

Obi-Rakhmat (Uzbekistan) is one of the most important paleolithic archaeological site in Central Asia. Located in the Tien-Shan Mountains, over 1.000 m of elevation, the important 10 meters thick stratigraphical sequence of Obi-Rakhmat delivered rich archaeological deposits from the Middle Palaeolithic to the Upper Palaeolithic. The lithic industry presents original features characteristics of Laminar Middle Palaeolithic. Furthermore, this site yielded 156 human remains with a datation around 70 ky.

In this paper, we present the results of the zooarchaeological study of the 22 archaeological layers of this site, which totalize more than 80,000 skeletal remains.

The behavior of the earliest human occupations attributed to Neanderthals will be compared to the occupations attributed to anatomically modern humans from the upper layer.

Finally, we will discuss the involvement of Obi-Rakhmat site in the understanding of the peopling of Central Asia.

ORAL

#### 5. THE ROSTAMIAN, AN EARLY UPPER PALEOLITHIC BLADELET INDUSTRY OF THE SOUTHERN ZAGROS MOUNTAINS OF IRAN

*Ghasidian, Elham - (Department of Early Prehistory and Quaternary Ecology, University of Tuebingen, Germany) elham.ghasidian@uni-tuebingen.de*

*Conard, Nicholas - (Department of Early Prehistory and Quaternary Ecology, University of Tuebingen, Germany) nicholas.conard@uni-tuebingen.de*

Fieldwork in the Dasht-e Rostam-Basht Region at the southern Zagros Mountains of Iran provides key record of cultural evolution during the Late Pleistocene. The 41,000 cal. BP. radiocarbon dates obtained from Ghar-e Boof Cave, associated with Rostamian tradition place this industry within the Upper Paleolithic. This tradition stone knapping was widely spread in Ghar-e Boof and the other caves and rockshelters of the Dasht-e Rostam-Basht Region. There are several features that distinguish the Rostamian as one of the cultural entities of the Upper Paleolithic. The main characteristic is the focus on unidirectional bladelet production, from both cores and flakes, and the production of the main tool types on these bladelets, including Rostam bladelet. This concentration on bladelet production distinguishes the Rostamian from the other Upper Paleolithic industries, the Baradostian and the Zagros Aurignacian. The Rostamian documents an innovative cultural tradition of restricted spatial distribution. Understanding the situation of the innovative Rostamian tradition during the beginning of the Upper Paleolithic underlines the applicability of the *mosaic polycentric modernity* model. In the Zagros Mountains the patterns of cultural and behavioral evolution during the early Upper Paleolithic appear to be more mosaic in nature and include different cultural entities within distinct ecological zones of the Zagros.

Hublin, Jean-Jacques (Department of Human Evolution, MPI EVA, Leipzig, Germany) [hublin@eva.mpg.de](mailto:hublin@eva.mpg.de)

The Early Upper Palaeolithic (EUP) of Europe is often equated with the appearance of symbolic behaviour in Europe and the dispersal of anatomically and behaviourally modern humans into and within Western Eurasia. These historical processes are heavily debated in the palaeoanthropological and archaeological research communities. In order to contribute to a better understanding of the chronology and environmental context as well as of human behaviour during this critical time period, we present here first results of our new fieldwork at the EUP site of Beregovo I (Transcarpathian Ukraine).

Beregovo I is located approx. 1 km south of the town of Beregovo. In the regional record of the EUP (e.g., Korolevo I and II, Sokirnitsa I-A) the stratigraphic sequence of Beregovo I is of key importance because its upper part covers deposits absent on other EUP sites in Transcarpathia. Previous fieldwork (1969 and 1975) at Beregovo I has classified the archaeology as late/developed Aurignacian and placed it around 26/23 ka uncal BP.

Our research at the site includes fieldwork and archaeological, geological palynological and chronological studies. Fieldwork includes piece-plotting of all objects (lithics, charcoal, tuff) >10mm using a totalstation and wet-sieving of all excavated sediment. The total collection including the small fraction recovered during wet-sieving accounts for more than 28,000 objects.

In our fieldwork we documented two archaeological horizons at Beregovo I. Here we present archaeological horizon (AH) I, which represents the vast majority of the material excavated so far. The AH I is located 2.10-2.45m below the surface in geological units C2 to C4. The majority of the lithics is located in geological unit C3; the overlying unit C2 and the underlying unit C4 contain only a smaller number of artifacts. The main distribution of AH I in unit C3 is overlain by a paleosol (unit C2) rich in conifer charcoals. Several pieces of charcoal have been AMS dated to 27/26.6 ka uncal BP, providing a minimum age for the AH I.

A special focus of our analysis is the study of lithic technology. For lithic reduction different raw material types including flint, local silicified tuff, Carpathian obsidian (3 types), andesite, quartzite, etc. were utilized. An interesting feature is the bladelet/microblade production from specific cores, including double-platform cores and cores with narrow working surface. The cores show that the bladelet/microblade reduction was separated from unidirectional blade production. The retouched tools are dominated by Dufour bladelets subtype Dufour (more than 40 samples made on microblades) with alternate retouch. Other tools include carinated and nosed end-scrapers and Aurignacian retouch on blades. Taking technological and typological observations together, the assemblage can be classified as Proto-Aurignacian. Further, lithic refitting analysis has connected artifacts of our recent excavations with those of 1969 and 1975 suggesting that they belong to the same archaeological horizon.

The identification of a Proto-Aurignacian at Beregovo I, AH I, opens a new discussion of the EUP of the Western Ukraine. Potentially, Beregovo I overlap chronologically with the EUP horizons at Korolevo I, Korolevo II and Sokirnitsa.

## ORAL

### 7. SUNGIR: SZELETIAN OR AURIGNACIAN?

Gavrilov, Konstantin - (The Institute of Archaeology, Russian Academy of Sciences) [k\\_gavrilov.68@mail.ru](mailto:k_gavrilov.68@mail.ru)

The stone industry of Sungir traditionally associates with thin bifaces – triangular and leaf points. This feature pulls together Sungir with final szeletian sites of the Central Europe. Nevertheless, G.P. Grigoryev and M.V. Anikovich stated the point of view about orinyakoid character of the Sungir industry. The problem consists in, whether so

radical revision of cultural specifics of Sungir is possible. How the ratio of Sungir and sites of streletskaya culture can be characterized?

The Sungir collection of flint products which was analysed, consists of 2403 items, including – 1624 tools and 779 flakes with an irregular retouch. This communication is devoted to typology of morphologically expressed tools. Besides, the database on spatial distribution of flint tools was made. The archival materials and field documentation of Sungir excavation contain information about the location of items in squares and the horizons of cultural layer. Unfortunately, exact information on a ratio of these horizons and the real stratigraphy of the buried soil in these materials is absent. The obtained data on spatial distribution of stone tools of Sungir were compared with results of their typological analysis.

Typological features of the Sungir stone tools are connected with several indicators. First of all, it is thin bifaces. Secondly, the Sungir industry differs from the classical streletskian by a number of signs. There are a considerable share of the pieces ecaille, large number of burins, prevalence of the items with the subparallel not retouched edges among scrapers, and presence of the aurignacian types of tools. There are core-burins and core-scrapers, retouched points on micro-blades and asymmetric notched Aurignacian blades among the last ones. Sungir collection contains edge-faceted cores for micro-blades and the numerous micro-blades. The percentage of the tools made on blades is quite high (30,7 %).

The analysis of spatial distribution of stone tools of Sungir allows to conclude that the cultural layer of this site was formed in some stages. The most ancient of it is connected with the lower part of the buried soil (28000-25000 BC). The latest stage associates with the basis of the loams blocking this soil. It is necessary to emphasize rather late stratigraphical position of the points made on micro-blades. However thin biface – triangular point of streletskaya-sungir type, and also asymmetric notched Aurignacian blade were recorded already at the earliest level on the layer.

Thin bifaces, series of the side-scrapers, convergent scrapers and transverse scrapers, mainly flakes splitting testify in favor of szeletoid character of Sungir complex. This conclusion isn't contradicted by existence of aurignacian types of tools. The same feature is also typical for final szeletian sites of the Central Europe, and for some sites in Russia (Zaozer'e, Kostenki XII-1) and Ukraine (Mira, Stinka, Vis).

At the same time, it should be noted well expressed specific features both streletskaya culture and Sungir. The regional specifics of streletskaya culture are shown most brightly in morphology of triangular bifacial points. It differs from the morphology of bifacial points of Central European sites.

ORAL

## 8. NEANDERTHALS, MODERN HUMANS, AND THE ARCHAEOLOGICAL RECORD OF EASTERN EUROPE

*Hoffecker, John - (University of Colorado) John.Hoffecker@colorado.edu*

Across Europe, it is widely assumed that Neanderthals produced all artifact assemblages classified as Middle Paleolithic, as well as some early or "transitional" Upper Paleolithic assemblages. Although the majority of Middle Paleolithic assemblages lack associated human skeletal remains, archaeologists believe that there are a sufficient number of sites with identifiable Neanderthal remains to extend the observed pattern to all of them. There is reason, however, to question the attribution of some European assemblages classified as Middle Paleolithic to the Neanderthals, and this applies especially to Eastern Europe, where a significant proportion of Middle Paleolithic sites may have been occupied by *Homo sapiens*.

There is growing evidence that modern humans developed a Levallois blade and point industry in the Near East roughly 50,000 years ago. The appearance of similar assemblages in Central Europe (i.e., Bohunician) may represent an archaeological proxy for modern human movement into Europe at this time. Eastern Europe contains a large number of assemblages with Levallois blade technology, and most of them appear to date to 50,000 years ago or less. Unlike the Bohunician sites, most of these assemblages contain few typical Upper Paleolithic tools, ensuring their classification as Middle Paleolithic. They are widely distributed across Eastern Europe, including the southwest plain (e.g., Molodova 5), central and southern plain (e.g., Khotylëvo 1, Shlyakh), Crimea (e.g., Shaitan-Koba), and northern Caucasus (Monasheskaya Cave). Most may be firmly or tentatively dated to MIS 3, and—where they are found in an archaeologically stratified context—they consistently occur at the top of the Middle Paleolithic sequence. Until Neanderthal authorship of these assemblages can be confirmed with diagnostic skeletal material or aDNA, they must be considered problematic.

Many archaeologists doubt that the assemblage at Byzovaya in northern Russia—despite the lack of blade technology and typical Upper Paleolithic tools—was produced by Neanderthals, because it appears to post-date their presence in Europe. The same logic might apply to Betovo on the Desna River and there are other sites that: (a) yield independent evidence for activities that could account for the absence of blade production and typical Upper Paleolithic tool forms (i.e., taphonomic evidence for the killing and butchery of large mammals); and (b) may postdate the first appearance of modern humans in Europe. Two examples are Starosel'e, Layer III (Crimea) and Il'skaya 1 (northern Caucasus).

Some or all of the sites mentioned above might have been occupied by modern humans rather than Neanderthals, and this alternative possibility has the potential to alter significantly the perceived pattern of human settlement in Eastern Europe during the late Pleistocene. The Neanderthals might not have occupied the East European Plain during MIS 3 (and might never have occupied the central plain) offering modern humans an empty niche. Modern humans might have rapidly colonized Eastern Europe roughly 50,000 years ago during a period of pronounced and sustained warmth (i.e., GI 12) and without some of the complex and innovative technology that is associated with later movements into higher latitudes (e.g., tailored clothing).

### 9. CULTURAL AND ENVIRONMENTAL CONTEXT FOR THE EAST EUROPEAN UPPER PALAEOOLITHIC FORMATION: KOSTENKI SCENARIO AND EXPLANATORY MODELS.

*Sinitsyn, Andrei - (Inst.for the History of Material Culture RAS) andrei.sinitsyn@gmail.com*

Cultural and environmental context for the East European Upper Palaeolithic formation: Kostenki scenario and explanatory models.

The problem of the Upper Palaeolithic, more ancient than Aurignacian and than local East European "transitional" Streletskian arose in Kostenki due to field works of last decade.

Principal argument in favor of this hypothesis has Kostenki 14 (Markina gora) where three cultural layers of non-Aurignacian and non-Streletskian attribution were put in evidence under Aurignacian layer connected with

CI-Y5 tephra. Most ancient of them (IVb) provided a numerous and various archaeological materials included rich lithic and bone assemblages together with personal ornaments and of art objects.

Aurignacian and Streletskian in Kostenki are dated by 35-36 ka (~40 cal) that put them inside Greenland Interstadial (GI) 9, according to stratigraphic position, connections with CI volcanic ash, and series of radiocarbon dates, including obtained with modern methods of pre-treatments.

Available radiocarbon dates for more ancient cultural layers provide a much closed series at 36-37 ka (~41 cal). Stratigraphic basis for its more ancient age is the position of cultural layers under (Kostenki 14-IVb) and at (Kostenki 17-II) the level of Lashamp magnetic excursion.

The archaeological basis for their separation as a distinct periodization unit is:

- impossibility to be classified both as Aurignacian and as "transitional";
- both assemblages have no recognized predecessors in a more ancient (mid.palaeolithic) stage nor do they have successors in more recent stages;
- distinguished as IUP-stratum they appear to be the manifestation of very variable cultural tradition or a number of cultural entities.

The most probable they existed in the framework of relatively short times.

Supposed model based on Kostenki materials seems to be useful for the large territory owing to including in IUP-stratum such sites as: Sokirnitsa in trans-Carpathians, Zaozerie1 in Mid-Ural, Buran-Kaya 3-C in Crimea. The reason is the same: they are the most ancient manifestation of Upper Palaeolithic at their areas, and cannot be identified nor Aurignacian neither "transitional".

IUP-stratum for the moment appears to be real East European very variable sub-cultural entity; the most probable existed at the frame of Greenland Interstadial (GI) 10 or a bit more ancient times.

Three explanatory models for the IUP phenomenon may be considered:

- a pioneering pre-Aurignacian wave, as suggested by W. Davies, on the basis of some isolated Aurignacian features in each IUP assemblage;
- the initial (starting) point of new cultural unities, the

development of which was interrupted by the Aurignacian expansion;  
- the undeservedly forgotten theory of the syntheotype of G. Laplace.

The last explanatory model seems the most probable at present, as it accords well with the archaeological data and does not require postulated migrations.

In any case, the IUP seems to be a real entity, at least in Eastern Europe, with uncertain temporal and spatial boundaries.

ORAL

## 10. KOSTENKIAN - THE PROLONGATED STORY OF EASTERN GRAVETTIAN OF THE RUSSIAN PLANE.

*Lev, Sergey - (Institute of Archaeology RAS) zaraysk@yandex.ru*

For a long time Kostenkian considered to be a short episode of so called "Eastern Gravettian" presence on the Russian plane. As a part of this wide cultural unity Kostenki-Avdeevoo archaeological culture was limited in time and area. The sites were mostly dated between 23 000 – 21 000 BP.

After Zaraysk site was discovered, the distance between the main sites has increased to 500 km. And what happened to dating? The answer is tightly linked to methodological approach that has been applied to investigations of the cultural deposits by prof. H. Amirkhanov and the crew. It became clear that it is not one but a few sites placed nearby and sometime overlaying each other. Under the term of "archaeological site" we consider the area of continuous distribution of cultural deposits containing a more or less continuous distribution of artefacts and features of similar typological character within a given stratigraphic unit.

Zaraysk actually represents a complex of closely related inter-stratified sites. Four sites, titled Zaraysk A, B, C and D may be identified with total area excavated about 500 sq.m. On Zaraysk A the cultural remains are contained in a sequence of four stratified occupation levels deposited in two geologic units – the upper buried soil and an underlying sandy loam. Zaraysk B located 50 meters to the north of the first site. At this locus, the cultural remains

are deposited only in the upper buried soil and at the contact between this soil and an underlying loam. The layer of sandy loam is absent. It corresponds well by stratigraphy with the upper layer of Zaraysk A. This one-level site gives a perfect opportunity for spatial analysis. Locations C and D are slightly investigated.

Cultural layer is considered as the structural unity of artefacts, features and other remnants of human activity occurred in geological context. Micro- and cryostratigraphic method, pollen and geomorphologic analysis allowed dividing occupation loci usually having no sterile layers on Zaraysk A. The main difference of cultural layers (well divided by frost structures and interstratification) is in a global change of living structure organization strategy. Typical Kostenki settlement with line of big hearths, earth-dwellings around and deep storage pits doesn't exist on the two upper layers (19 000, 16 000 years B.P.). Types of all features, including dwellings, hearths and pits changed as well as inter spatial distribution.

Zaraysk A gives the most important information about the evolution of cultural traditions. Though living structures, types of dwellings and other features changed, material culture and lithic technology stays without any global changes and distinctive for kostenki-avdeevoo culture. Zaraysk B is a short stay camp site with clear spatial distribution. It is related to the upper buried soil and correlated to the layer 4 on Zaraysk A. Both of them as well as the soil humus horizon are dated about 16 000 years B.P. This fact makes real a prolonged chronology of "Gravettian episode" on the Russian plane. And its origins could be searched to the West in the Central Europe.

---

ORAL

## 11. NORTH BY NORTHWEST: LAST GLACIAL PALAEOGEOGRAPHY AND ARCHAEOLOGY OF THE BANAT AND THE BALKAN PENINSULA

*Chu, Wei - (University of Cologne) wchu@uni-koeln.de*  
*Hauck, Thomas - (University of Cologne) Thomas.Hauck@uni-koeln.de*  
*Leonard, Ine - (University of Cologne) ileonard@uni-koeln.de*  
*Richter, Jürgen - (University of Cologne) j.richter@uni-koeln.de*

The initial settlement of Europe by anatomically modern humans from an African source population is now well-acknowledged, but the timing, trajectory and conditions of this migration is still poorly understood. Current paradigms suggest that anatomically modern human migra-

tions likely started in the Levant and may have occurred along two discrete routes, either following a costal path along the Mediterranean basin and/or an inland route through the Danube River valleys. Here, we investigate the importance of the second route for the migration of Palaeolithic populations by focusing particularly on the Timi catchment of the Middle Danube in the Banat regions of Hungary, Romania, and Serbia.

Preliminary results of our investigation suggest that the Banat and indeed the larger Balkan region played an important role in the expansion of anatomically modern humans into the Eurasian continent and may constitute a "Contextual Area," a region where adaptive relationships between natural and socio-cultural factors formed a discreet human habitat.

Understanding how these early settlers exploited this landscape has important implications for the spatial patterns of early anatomically modern human populations in Europe. In addition, this research may shed light on various "transitional industries" of the area (i.e. the Szeletian) and on the impact of this initial colonization on local Neandertal populations.

ORAL

## 12. NEW INSIGHT INTO MIDDLE TO UPPER PALAEO-LITHIC TRANSITION IN THE BALKANS

*Mihailović, Dušan (Faculty of Philosophy, University of Belgrade) dmihailo@gmail.com*

Balkan Peninsula was in the direction of spreading of anatomically modern human toward Europe and is one of the regions where various interactions of the Neanderthals and anatomically modern humans could be expected. In order to comprehend even better the role of the Balkans in the transition period many international projects have been started recently. The investigations continued in northern Serbia at Aurignacian site Crvenka-At near Vršac and of Aurignacian layers in Šalitrena cave, while early Upper Palaeolithic has been confirmed at many sites (Tabula Traiana Cave, Baranica) in the Carpathian Mountains. Aurignacian sites on the other hand have not been encountered in the areas of central Balkans and in the Adriatic zone, while late Mousterian has been confirmed at Pesturina, Hadzi Prodanova cave, Bioe and Crvena Stijena.

Preliminary results of those investigations indicate, beside already known facts, that Upper Palaeolithic spread

from east toward west of the peninsula simultaneously with the withdrawal of the Middle Palaeolithic groups. The Danube valley obviously had an important role as the earliest Upper Paleolithic sites have been confirmed just in that area and the Aurignacian actually has not been ascertained to the south of the Sava-Danube corridor. There is for the time being no reliable evidence for settling of Adriatic-Ionian zone between 40<sup>th</sup> and 30<sup>th</sup> millennium BP. Therefore, the question arises how much that could be explained as result of Campagnian Ignimbrite eruption and how much as result of insufficiently investigated region.

ORAL

## 13. LEVELS OF FLINT KNAPPING EXPERTISE AND APPRENTICESHIP DURING THE EARLY AND MIDDLE UPPER PALAEO-LITHIC: SEVERAL ILLUSTRATIVE EXAMPLES FROM THE EARLY AND LATE AURIGNACIAN AND MIDDLE GRAVETTIAN

*Klaric, Laurent - (CNRS, UMR-7055, PRETEC, Université de Paris-Ouest-Nanterre-La Défense, 21 allée de l'Université, 92023, Nanterre) laurent.klaric@mae.u-paris10.fr*

Excavations at the site of Picardie (Indre-et-Loire) was the starting point for a revision of industries assigned to the second half of the Middle Gravettian. Continued work with material recovered from this site has reveal several indications of knapping apprenticeship, particularly the acquisition of an original bladelet production system – the Raysse method.

Support from the Fyssen Fondation made it possible to develop a research method focused on differing skill levels evident in bladelet production during certain phases of the Early and Late Aurignacian at Corbiac-Vignoble II and Tercis, respectively, and the Middle Gravettian with Raysse burins from the sites of Picardie and Solvieux.

Here, we present a communication focusing on recognising varying skill levels for the different types of bladelet production (*carinated* versus *Raysse*) typical of these periods. Moreover, on at least three of these sites, other indications of apprenticeship are evident, primarily independent attempts at bladelet production or the unskilled or clumsy reuse of abandoned cores. These elements represent a body of corroborating evidence reinforcing conclusions drawn from the bladelet production. In addition, the 'visibility' of these different lines of evidence for apprenticeship are discussed in contextual terms.

Finally, this study provides us a better understanding and a more accurate techno-cultural diagnosis of lithic assemblages of Early and Mid-Upper Palaeolithic. It also brings interesting paleosociological perspective to think about technical knowledge and know-how transmission modes on a large timespan.

#### **14. LE PALÉOLITHIQUE SUPÉRIEUR ANCIEN DE LA GROTTÉ BOCCARD (CÔTE D'OR) DANS LE CONTEXTE DES PREMIERS PEUPELEMENTS DU PALÉOLITHIQUE SUPÉRIEUR DE CÔTE D'OR EN BOURGOGNE (FRANCE)**

*Djindjian, François - (Université de Paris 1 Panthéon Sorbonne & CNRS UMR7041 Arscan) francois.djindjian@wanadoo.fr*

La grotte Boccard à Créancey (Côte d'Or) est un site en grotte de réseau karstique et terrasse s'ouvrant dans une falaise de calcaire bajocien à 500 mètres d'altitude. Le site est situé sur la ligne de partage des eaux entre la vallée de l'Armançon (bassin de la Seine) et la vallée de l'Ouche (bassin de la Saône).

La grotte est profonde d'une douzaine de mètres dans une orientation plein Sud. Les fouilles programmées ont été conduites par l'auteur de 1974 à 1980 et ont concerné les restes de remplissage sur environ 2m<sup>2</sup> à l'intérieur de la grotte et 10 m<sup>2</sup> sur la terrasse.

Un remplissage karstique lacunaire de deux mètres de puissance a été trouvé à l'intérieur de la grotte décrit par une douzaine d'unités stratigraphiques. Il a été vidangé sur la terrasse.

- les couches supérieures post-glaciaires qui ont livré des vestiges remaniés d'occupations ponctuelles et de foyers établis sur un plancher d'effondrement qui a scellé le remplissage sous-jacent,

- un niveau gravettien dans les couches 5/1 et 5/2, bouleversé par l'occupation des ours de cavernes,

- un niveau de paléolithique supérieur ancien, qui a livré un fragment de pierre gravée, dans la lentille 6/2,

- un niveau moustérien ayant livré plusieurs dents néanderthaliennes qui témoigne d'une occupation sur le plancher de la grotte, enrobé dans la couche 6/5

La faune contient le mammouth, le cheval, le renne, le bovidé. Elle est dominée par la faune de cavernes, l'ours dominant, l'hyène, le loup, le renard polaire. La marmotte, le lièvre et l'hermine sont présents.

L'industrie du Gravettien est caractérisée par l'abondance de l'industrie en matière dure animale (bois de renne, ivoire) et la rareté de l'industrie lithique composée essentiellement d'outils abandonnés, de nucléus intacts et d'esquilles de retouche.

L'occupation de la grotte est un bivouac occupé occasionnellement et périodiquement lors des déplacements des chasseurs entre Seine et Saône. La grotte Boccard fait partie des rares sites de Bourgogne attribuable au paléolithique supérieur ancien en Côte d'Or (grotte de la Garenne, Genay, Poron des Cuèches) entre Côtes chalonaises (Saint-Aubin, Saint Martin sous Montaigu, Germolles) et Yonne (Arcy-sur-Cure).

#### **15. LA TRANSICIÓN EN EL BERGERACOIS: DATOS PARA UNA REFLEXIÓN SISTÉMICA.**

*Ortega, Iluminada - (Inrap) iluminada.ortega@inrap.fr*  
*Rios, Joseba - (CENIEH) jorios76@gmail.com*  
*Bourguignon, Laurence - (Inrap) laurence.bourguignon@inrap.fr*

En primer lugar queremos remarcar el hecho que las poblaciones humanas del paleolítico medio y superior, forman sociedades sujetas a los fenómenos típicos del cambio histórico, la idea de que la organización de las sociedades y sus cambios depende de la gestión social que define y satisface las necesidades y que la tecnología de las sociedades, en nuestro caso de la industria lítica, refleja aspectos importantes de esta gestión social de las necesidades. Este planteamiento es importante cuando se abordan los presupuestos teóricos de un periodo como el fin del Paleolítico medio y el principio del Paleolítico superior en el que las explicaciones pueden estar influidas por planteamientos de tipo Biológico.

El proceso de Transición entre el Paleolítico Medio y el Superior debe entenderse por tanto como un proceso histórico en el que las relaciones entre grupos humanos, las relaciones con el medio y las dinámicas propias de cada sociedad son las que provocan las transformaciones que observamos en el registro arqueológico. Por consecuencia, los procesos de cambio se traducen en

variaciones en la forma en la que las sociedades se organizan económica y socialmente.

La industria lítica es la principal evidencia disponible para la comprensión de estas sociedades. Es especialmente informativa porque además de las informaciones de orden técnico y territorial, interacciona con otras esferas de la sociedad paleolítica.

Además de esta complejidad material cronológicamente podemos percibir si observamos las diferentes regiones, un solapamiento más o menos significativo entre el Paleolítico medio y Paleolítico superior inicial. Esto nos incita a centrarnos en un marco más regional para poder más tarde emitir hipótesis de orden histórico.

La región seleccionada, el Bergeracois en su parte central, es un territorio rico en ocupaciones situadas en este momento de cronológico (5 ocupaciones Musteriense finales, 8 Auriñaciense y 4 Chatelperroniense, sin contar con un número importante de incidencias. Este territorio cuenta con un marco geográfico excepcional: región rica en sílex (de gran calidad y tamaños excepcionales), recursos hídricos, entre otros.

Se trata por tanto de un marco ideal para tratar de comprender los cambios en la organización social a finales del Paleolítico Medio y a inicios del Paleolítico Superior a partir del estudio de la industria lítica.

En este contexto, bien particular, nos ofrece nuevas perspectivas para establecer la existencia durante este periodo de la Prehistoria de procesos de imitación, emulación, transferencia de conocimientos, invención y/o rupturas.

*Ricard Marlasca Martín - ricard.marlasca@hotmail.com (Posidònia S.L.)*

The central area of the Iberian Mediterranean has a high concentration of sites linked to Gravettian. Sites as Parpalló, Les Malladetes, Barranc Blanc or Ratlla of Bubo, have provided information about the technological complex, as well as an approach to its economy. However, data from some of these or other sites are limited both by the nature of the collections and the age of the excavations, and the absence of specific taphonomic studies.

Nevertheless, among them, Cova de les Cendres (Teulada-Moraire, Valencia, Spain) provides a fairly complete sequence that from the available datings can be placed between 25,850 and 20,800 BP. It has a rich Gravettian industry and a taphonomic study of the bone remains. Now we present here a larger sample that defines better the occupations of this settlement.

The material of the sample comes from fieldwork in 2010 and 2013 where the original survey of 2m<sup>2</sup> was extended. In this years a surface of about 2 m<sup>2</sup> with a depth of 30 cm, was excavated by natural levels, corresponding to the top of the Gravettian filler, specifically to level XVIIA with two dating of 23929 ± 100 and 23860 ± 100 Bpa. We have analysed both bone remains through a taxonomic, anatomical and taphonomic study, and the lithic and bone industry, defining their techno-typological characteristics.

The lithic and bone industry provides useful information for the characterization of the end of the Gravettian on the Mediterranean side. The component is laminar and backed points and marginal retouches are presented. In relation to the bone tools it has been documented some double point of bone. Also highlights some ornaments using both teeth and molluscs remains.

In relation to the fauna analysis, has been determined taxonomic and/or anatomical 1143 remains, which correspond to a wide range of preys: herbivore such as red deer (NR 404), Spanish ibex (NR 71), horse (NR 13) and aurochs (8); carnivores like lynx, wild cat and monk seal (NR 64); and small prey such as leporids (NR 2462), various birds (NR 187), and a species of tortoise (NR 16). The study of skeletal representation, mortality patterns, morphology fracture, and bone surface modifications (cut and dental marks and fire alterations) allow us to relate the sample to human activities.

Moreover, the mollusc remains both terrestrial and marine, and its high spatial concentration suggests a human consumption. This circumstance had not been observed so clearly in the sequence of the site until now.

Cova de les Cendres is one of the few Gravettian sites that not only provide information on the industrial characteristics of the occupations, but a considerable amount of data regarding subsistence. Available materials also suggest that in the central part of the level, which has the highest density of remains, the Gravettian occupations present subsistence patterns that differ from other sites so far known. It is characterized by a wide range of prey, not just in relation to terrestrial mammals, but aquatic resources such as turtles, fish, or both terrestrial and marine molluscs.

ORAL

### 17. THE TRANSITION FROM MIDDLE TO UPPER PALAEOLITHIC AT LA VIÑA ROCK SHELTER (ASTURIAS, SPAIN)

*Santamaría Álvarez, David - (Universidad de Oviedo) santamariadavid@uniovi.es*  
*de la Rasilla Vives, Marco - (Universidad de Oviedo) mrasilla@uniovi.es*

The Cantabrian region has recently become a key scenario to understand some important questions related with the transition from Middle to Upper Palaeolithic in Europe, such as the appearance of Anatomically Modern Humans, the emergence of human cognition and rock art, the coexistence of neanderthals and *sapiens* populations and the extinction of *Homo neanderthalensis*: when, where, how and why?

La Viña rock shelter is located in the middle valley of the Nalón river in the western cantabrian region. It was excavated by J. Fortea between 1980 and 1996. The excavation took place in two different sectors (western and central) and they unearthed an important cultural sequence ranging from Middle Palaeolithic to Holocene. The stratigraphic sequence of the western sector includes several Mousterian and Aurignacian levels related with the demise of Mousterian populations and the emergence of Upper Palaeolithic cultures.

Water erosions were common in this sector involving all Mousterian levels and the first Aurignacian one. The last erosive event occurred after the formation of XIII basal that constitutes the last Mousterian unit and before the deposition of the first Aurignacian level (XIII inf.). This erosion was very important because it removed part of the Mousterian layers reaching the bedrock in some places. The gap between the Mousterian and Aurignacian levels has been radiocarbon dated in more than 20.000 years old. Consequently, Aurignacian people settled on a very

irregular floor formed by patches of all previous Mousterian levels, well after of the disappearance of the last Mousterian populations.

As a result of these erosions the interstratigraphic movements of archaeological items occurred frequently in the site, generating a gradual transition from Mousterian to Aurignacian whose origin is instead postdepositional and unanthropic.

The analysis of the lithic artifacts has enabled to determine some archaeological contaminations between both cultural complexes: carinated and nosed scrapers, Dufour bladelets, sidescrapers and some handaxes.

After discarding these contaminations the technological traits of each complex agree with previously assumed: a Mousterian without "modern cultural traits" and Aurignacian fully formed from the basal levels. What we observe between Mousterian and Aurignacian complexes is a stratigraphic, chronological, and cultural rupture.

ORAL

### 18. THE EARLY UPPER PALAEOLITHIC IN NORTHERN SPAIN REAPPRAISED

*Arrizabalaga, Alvaro - (Universidad del País Vasco) alvaro.arrizabalaga@ehu.es*  
*Iriarte-Chiapusso, María-José - (IKERBASQUE/ Universidad del País Vasco) mariajose.iriarte@ehu.es*

The topic of the EUP in northern Spain has become a matter of great interest in Archaeology, at least since the late 1980s, when the dates obtained for Level 18 at El Castillo Cave suggested a very old chronology. In the 25 years since then, a large number of studies, analyses, dates and papers have been published about the Middle to Upper Palaeolithic transition in the region. New paradigms and interpretative models have been proposed and, in unprecedented activity, numerous interdisciplinary teams have been involved in answering the main questions that have been posed. Our understanding of the period now is significantly better than in 1989 and some problems have been solved (at the cost of excavating practically all the good sequences in the region with relevant levels). This communication will reappraise the current situation in the interpretation of the Early Upper Palaeolithic in northern Spain, while taking into account the different variables and the explanatory effects of the human factor in this process, as in any important historiographic milestone.

ORAL

**19. CHRONOLOGY OF THE EARLIEST UPPER PALEOLITHIC IN CENTRAL PORTUGAL: OLIVAL GRANDE AND RESOLVING THE OPEN-AIR "AURIGNACIAN"**

*Thacker, Paul (Department of Anthropology, Wake Forest University) thackep@wfu.edu*

For over two decades, the archaeological assemblage from the Vale de Porcos site in central Portugal has been an anomaly. The presence of very large blades (for the UP in Portugal) coupled with an EUP toolkit without backed elements led to a controversial Aurignacian designation. The lack of absolute dates for the deposits as well as significant historical assemblage recovery biases by Heleno's team including discard of most debitage added to contemporary interpretive difficulty.

The recently discovered site of Olival Grande in the lower Rio Maior drainage resolves most of the controversies attached to the Vale de Porcos assemblage. A very large lithic assemblage has been recovered from the locale with marked technological and typological similarities to Vale de Porcos. The site has yielded absolute dates that demonstrate the assemblages (and by extension Vale de Porcos) are greater than 30,000 years old. This paper details the depositional history of Olival Grande and explores the technological organization of recovered EUP lithic assemblages. The resolution of the dating of these industries has significance for understanding the technological discontinuity that is evident between late Middle Paleolithic and earliest Upper Paleolithic adaptations in Portugal.

**20. L'APPORT SCIENTIFIQUE DE LA COMMISSION 8 DE L'UISPP (PALÉOLITHIQUE SUPÉRIEUR DE L'EURASIE) À LA CONNAISSANCE DU PALÉOLITHIQUE SUPÉRIEUR EUROPÉEN (DE 1976 À 2014)**

*Iakovleva, Lioudmila (1 Institut d'archéologie NAS Ukraine (Kiev, Ukraine) et CNRS UMR7041 Arscan) - i.iakovleva@wanadoo.fr*

*Desbrosse, René - CNRS), Janusz Kozłowski (Université Jagellon de Cracovie, Pologne) rene.desbrosse@wanadoo.fr (*

La commission 8 de l'UISPP fut fondée en 1976 à l'occasion du IX<sup>e</sup> congrès UISPP de Nice (France). Elle a rapidement regroupé en quelques années un panel représentatif des spécialistes du paléolithique supérieur européen,

originaires quasiment de tous les pays européens. En 39 ans d'activités, elle a organisé des colloques sur un rythme quasi annuel dans le cadre des congrès mondiaux de l'UISPP, de Nice (1976) à Burgos (2014), et aussi entre les congrès. Ces colloques ont tous été publiés en langue française principalement dans les actes des congrès, dans les BAR et dans la collection ERAUL (Liège). Elle a également publié sept bilans quinquennaux des fouilles et des recherches sur le Paléolithique supérieur européen, pays par pays. Les travaux de la commission ont permis de réaliser en moins de trente ans une synthèse sur le paléolithique supérieur européen unique dans le cadre de l'UISPP. Le propos de cette communication est de parcourir depuis 1976 et de les illustrer les temps forts de ces travaux.

POSTER SESSION

POSTER

**21. THE BEGINNING OF THE UPPER PALAEO-LITHIC IN NORTH-WEST EUROPE**

*Flas, Damien (F.R.S.-FNRS/University of Liege) damienflas@yahoo.com*

The Middle to Upper Palaeolithic transition is still a highly debated topic as it concerns several important questions: the timing and cause of the disappearance of the Neanderthal population/dispersal of anatomically modern humans, the cause of the appearance or widespread adoption of certain technical and symbolic behaviours, the role of "transitional industries" during this period and their association with the different biological populations.

In recent years, reappraisal of old collections, new discoveries and up-to-date radiocarbon dates enabled a more precise interpretation of the Middle to Upper Palaeolithic transition in North-West Europe. These new data are notably related to human remains that permit to tackle the issue of the last Neanderthals (Goyet and Spy Cave) and earliest *Homo sapiens sapiens* (Kent's Cavern) in the region. These recent works also permit to have a new look on the different industries present during the Middle to Upper Palaeolithic transition (various late Middle Palaeolithic industries, Lincombian-Ranisian-Jerzmanowician, Aurignacian) and their chronology.

This talk will thus provide an up-to-date synthesis for the beginning of the Upper Palaeolithic in North-West Europe, even if this region remains still poorly known compared to other European areas.

POSTER

**22. THE ORIGIN OF THE ULUZZIAN: THE UPSETTING OF A PARADIGM?**

*Moroni, Adriana - (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - University of Siena, Italy) adriana.moroni@unisi.it*

*Boscato, Paolo - (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - University of Siena, Italy) paolo.boscato@unisi.it*

*Ronchitelli, Annamaria - (Department of Physical Sciences, Earth and Environment - R.U. Prehistory and Anthropology - University of Siena, Italy) annamaria.ronchitelli@unisi.it*

In the past few years one of the issues of greater interest and debate among Prehistorians has been the shifting from the Middle to the Upper Palaeolithic in Europe, namely the replacement of Neanderthals by Anatomically Modern Humans. In order to define this extremely complex phase, the nature of the makers of the so-called transitional techno-complexes plays a pivotal key-role. Recently, scholars' attention has been focused, in particular, on the French Châtelperronian and on the Italian Uluzzian as these two techno-complexes, previously considered as the evidence of Neanderthals' trend towards "modern behaviour", have been the core of a reconsideration which has generated (and is still generating) new hypotheses, data and debate. While the attribution of the Châtelperronian to Neanderthals has been questioned on the grounds of a possible stratigraphical contamination at Châtelperronian sites such as Arcy-sur-Cure and La Roche-à-Pierrot, in the case of the Uluzzian the results of recent analyses on the two deciduous teeth from the undisturbed Uluzzian layers of Grotta del Cavallo have supported the involvement of *Homo sapiens*. Meanwhile a new set of dates from the same site (45-43 ka BP) allowed to infer that the Uluzzians were the early AMHs who reached Italy (and perhaps Europe). The Uluzzian lithic tool kit is primarily featured by the occurrence of a specific tool: the lunate which is connected to the introduction of the innovative concept of composite implement. Moreover a techno-functional revision of lithic assemblages from the main Uluzzian sites (still in progress), is highlighting that no connections can be detected between the final Mousterian production systems and the Uluzzian ones, confirming the allochthonous origin of this latter techno-complex. On the basis of the strong similarities with the transitional techno-complexes of the African Continent, we suggest a possible early origin of the Uluzzian from Eastern Sub-Saharan Africa. A hypothetical southern route across the Bab-el-Mandeb straits to Arabia, mov-

ing northward into the Near East and then along the Adriatic coast is proposed.

Debates surrounding possible mechanisms underlying the mosaic of bio-cultural changes implicated in the so-called 'Middle to Upper Paleolithic' transition' and their possible connection with the emergence of 'behavioral modernity' in Western Europe remain at the forefront of research concerning modern human origins and the fate of the Neanderthals. The small rockshelter of La Roche à Pierrot, St. Césaire in the Charente-Maritime department of Southwestern France has played a central role in these discussions given the 1979 discovery of a partial Neandertal skeleton in one of the site's Châtelperronian levels. Twenty-five years after Francois Lévêque's initial work, we began new multi-disciplinary excavations at this important site following a substantial project of re-conditioning the original archaeological collections. Here we provide some preliminary results from our ongoing work at the site, including new human remains, investigations of site formation processes, raw material use, new micromorphological analyses, and topographic models.

**Important: at the end of this session will be project the video "Gontsy: 20 years" present by François Djindjian and Ludmila Iakovleva (realized for the commemoration of the 20 years of excavation at the archeological site of Gontsy in Ukraine - 1993-2013)**

**1. THE MAGDALENIAN OCCUPATION OF LEVEL IX OF LAS CALDAS CAVE (ASTURIAS, SPAIN): A SPATIAL APPROACH**

*Corchón Rodríguez, M<sup>o</sup> Soledad - (Universidad de Salamanca) scorchon@usal.es*

*Ortega Martínez, Paula - (Universidad de Salamanca) ortegap@usal.es*

*Rivero Vila, Olivia - (CREAP- TRACES UMR 6508) oliviariver@hotmail.com*

Las Caldas Cave is located in the middle valley of the Nalón river, in a setting widely occupied from the end of the Pleistocene until the Late Glacial Maximum.

The mouth of the Cave opens onto the bottom of a sheltered valley, lateral to the main valley of the Nalón River. The Nalón River Valley and its network of tributaries constituted a shelter-context during the Upper Palaeolithic, favoured by the many streams of thermal waters and the variety of ecosystems near the cave, including high mountains, medium-sized hills, plains and valley areas. This landscape brought together ideal territorial conditions that explain the repeated occupation of the cave, even during the Glacial Maximum (UMG). For this reason Las Caldas Cave shows one of the broadest series of stratigraphic sequences in the Cantabrian region. It includes a total of 19 Solutrean levels in *Sala I*, and 14 Magdalenian levels in *Sala II*, with a time bracket that ranges from ca. 21600 to 12900 cal BC.

Level IX, which has been preserved in *Sala II*, constitutes the first occupation of the Middle Magdalenian, in a very cold and humid phase of the climate at the end of the Older Dryas, with datings from 14347±436 cal BC. These extremely hard climatic conditions can be seen in the material register, explicitly in the presence of reindeer among the fauna consumed, and in representations of fauna typical of the cold steppes in the movable art, the most outstanding being a series of engraved *plaquettes* of sandstone or limestone with representations of reindeer, mammoths, and woolly rhinoceros. In addition, on this same level approximately two hundred engraved *plaquettes* have been recovered showing representations of anthropomorphs, as well as different herbivores (horses, deer, goats, bison and aurochs, among others), with a large variety of morphotypes and a technical quality that is special. The bone industry that accompanies the mobile art shows similarities with other levels of the early middle Magdalenian (levels IX to VI), the presence of Pyrenean elements standing out, such as *contour découpée*,

decorated bone discs and sculptures, as well as engraved protoharpoons, half rod, and antler point. The lithic industry, massively carved in flint, shows a high number of burins, higher than that of the grattoirs, numerous retouched blades, and a high percentage of backed bladelets.

The random distribution of the material register over the surface of the excavated area (H2-G2, H3-G3, H4-G4, G5), as well as the wealth and relevance of the materials recovered, require analysis of the floor of occupation from a spatial perspective in order to reveal the interrelations among the different elements comprising the whole archaeological floor. In addition, a study was made of the lithic and bone industries from a techno-functional perspective, with a view to approximation of the activities carried out by the hunter-gatherer groups of the Cantabrian middle Magdalenian.

ORAL

**2. ASSESSING EXPECTATIONS AND LIMITS OF INTRA-SITE ANALYSIS: FROM THEORY TO PRACTICE (AND VICE-VERSA) IN THE PALEOLITHIC SITES OF LA GARMA CAVE (OMOÑO, CANTABRIA, SPAIN)**

*Maximiano, Alfredo - (IIIPC. University of Cantabria.) maximianoam@unican.es*

*Arias, Pablo (IIIPC. University of Cantabria.) pablo.arias@unican.es*

*Ontañón, Roberto (Museo de Prehistoria y Arqueología de Cantabria. IIIPC. University of Cantabria.) ontanon\_r@cantabria.es*

*Bárcia, Camilo (IIIPC. University of Cantabria.) camilobarciagarcia@gmail.com*

This communication introduces a comparative study of two cases which are so close in *space* (distance each other no more than 200m), and *time* (both were calibrated in Magdalenian: approx 14.4k BP), but are radically different in archaeological formative processes in the way it has been able to preserve/modify the material evidence of social and natural actions: Archaeological remains.

So, in the first of these sites - *Garma A*- numerous episodes of occupation are stratified in continuity succession of sedimentary layers (Arias *et al.* 2005). The second case, in the *Lower Gallery* -ZoneIV- (Ontañón. 2003; Arias *et al.* 2011) where the original cave access was collapsed and cut off all natural and anthropogenic interactions (no sedimentation process). This fact caused that archaeological remains and structures *ante quem* Magdalenian time are on surface, which it would represent an arche-

type of *living occupation floors*.

Since empirical perspective, these two cases is a great opportunity because we have two archaeological records which respond us to the same casuistic/social dynamics, but far away from archaeological formation process. Consequently, the first intra-site issue we must consider is: *How could affect the differential formation process in terms of interpretation spatial distributions?*

As a solution, we characterize a wide range of spatial trends (i.e. inside-outside of structures, segregation and specialization areas...) with it, we'll analyze each other distribution and compare spatial tendencies at inter-site level (*Garma A v. Zone IV*) base upon:

Robust archaeological data collections and information levels, which draw statistically significant trends around:

1. Spatial structure of each observed distributions, and
2. Analyze the type of spatial relationship between distributions to establish an interpretive discourse about spatial variability.

Engage a holistic and integrative perspective sidewalk phenomenology under study: *the social organization of space*. Understanding occupation floors as a dynamic system in which both, the principle of *equifinality* (i.e. same final state from different initial conditions and continuing different routes) (Von Bertalanffy 1968:137); and the *multifinality* (i.e. similar condition states, can lead to different final states) (Buckley 1967:98). These are plausible solutions but different significantly and implications in understanding *how* managed/organized the space, it was modified by social and natural agents.

Thus, characterizing certain sets of special attributes of each archaeological site, and assessing the degree of affinity and/or dissimilarity of these sets between the two sites, - taking into consideration that these were the result of very different formative contexts (and preservation) - we could be closer to the potential implications of *equifinality* and *multifinality* in these archaeological record, which it would leads us to calibrate expectations and limits of *intra-site* analysis.

ORAL

### 3. AN APPROACH TO SOCIAL BEHAVIOUR IN THE MAGDALENIAN AT LA PEÑA DE ESTEBANVELA (AYLLÓN, SEGOVIA, SPAIN)

*Ortega, Paula - (Universidad de Salamanca) ortegap@usal.es*

*Cacho, Carmen - (Museo Arqueológico Nacional) carmen.cacho@mecd.es*

*Martos, Juan Antonio - (Museo Arqueológico Nacional) juanantonio.martos@mecd.es*

*Yravedra, José - (Universidad Complutense de Madrid) joyravedra@hotmail.com*

*Martín, Ignacio - (Universidad de Murcia) ignacio.martin@um.es*

The Rock-shelter of La Peña de Estebanvela, in the south-east of the River Douro basin, is located in a montane environment, bounded to the south by the foothills of the Central Range and to the north-east by the southern edge of the Iberian Range. It contains a sequence dated at the end of the late Upper Pleistocene, where six levels have been differentiated, attributed chrono-culturally, from bottom to top, to the Middle Magdalenian (Levels VI and V), Upper Magdalenian (IV and III) and Late Magdalenian (II and I). Radiocarbon determinations situate these stratigraphic units in three main spans of time, between the dates of 17,700 and 17,190 cal BP; 15,150 and 13,890 cal BP; and 13,720 and 12,610 cal BP. The association of micromammal and herpetological samples indicate a temperate humid climate, similar to modern conditions. They are the characteristic taxa of an environment with a water-course and dense vegetation, with woodland and areas of transition towards more open terrain with shrubs on the edge of the woodland, and dry and humid pastures. The archaeozoological study has determined the exploitation of several ecological niches: open areas (*Equus ferus*, *Equus hydruntinus*), woodland (*Capreolus capreolus*, *Cervus elaphus*) and mountain areas (*Rupicapra pyrenaica*). The consumption of these ungulates was complemented by fishing, evidenced by finds of vertebrae of *Salmo trutta*.

This paper presents the spatial study of Stratigraphic Unit III, carried out with the assistance of a Geographical Information System.

This study has detected accumulations and dispersions of materials that, together with the detailed techno-typological, traceological and taxonomic analysis of the archaeological record, reveal the presence of activity areas (for lithic reduction, butchery and hide-working).

These results are eloquent of the social behaviour of the magdalenian groups living at La Peña de Estebanvela.

ORAL

#### 4. CREATING MOBILE PATCHES: LOWER MAGDALENIAN LITHIC CONVEYANCE SYSTEMS IN CANTABRIA (SPAIN)

*Lisa M. Fontes - (University of New Mexico) fontes.lisa.marie@gmail.com*

Vasco-Cantabrian Spain is an ecologically diverse coastal region with gradationally distributed lithic raw materials: the highest quality flints are located in the eastern Basque provinces, while coarser grained materials are prevalent in Asturias and western Cantabria. Numerous lithic studies have demonstrated the varying effects of raw material availability on human settlement, assemblage composition, and technological organization. This paper contributes to archaeological landscape studies by evaluating lithic conveyance during the Lower Magdalenian (c. 20.5-17.5 kya cal BP) in central and eastern Cantabria and demonstrating that scalar differentiation in tool stone transport was used during this period to safeguard lithic assemblages as stable, yet mobile, resource patches.

Lithic debris and tools from seven Lower Cantabrian Magdalenian (LCM) contexts at four sites (Altamira, El Juyo, El Mirón, and El Rascaño) were analyzed. A lithic raw material collection was populated with samples from the four sites and used for inter-assemblage comparisons.

Each LCM lithic assemblage contained: 3-5 high to very high-quality flint materials that represented the majority of lithic artifacts at the site; numerous flints in trace amounts; and lower quality mudstones, limestones, quartzes, and/or quartzites. Analyses indicate three principal lithic conveyance systems: local, extra-local, and distant. Local conveyance at El Mirón was of principally lime- and mudstone materials, while at central Cantabrian site low-quality flints were reduced using bipolar techniques. Both behaviors were supplementary, employing poorer quality resources in a lithic assemblage through different means, and conserving the highest quality tool stones. Extra-local conveyance occurred among the four sites: trace flints of various--usually medium to high--qualities were found in all contexts. Some

trace flints were used for blade(let) production. The overlaps in minor flints indicate that strategic material transport kept assemblage patches stable, especially for armature manufacture. Finally, while high-quality Basque region flints appreciated varying amounts of each assemblage--decreasing in quantity as outcrop distance increased--they remained consistent among blade(let) tool assemblages regardless of site location (~30% of raw material), indicating these sources' importance in manufacture of weapons technology. Evidence of tool rejuvenation increased in assemblages located further from Basque country sources. Local and distant conveyance strategies were complimentary, amplified in central Cantabria where Basque flint outcrops were further distant, and diminished at Mirón (c.50-70 km from the outcrops), where these flints were a principal raw material group. The distribution of high quality materials and corresponding supplementation of low quality stones show the importance of flint quality on economic strategies, and that strategies co-varied with resource distribution.

Raw material availability played a significant role in LCM lithic strategies. LCM raw material conveyance was part of a scalar system that combined procurement tactics (direct, embedded, exchange) to furnish lithic assemblages that were portable, stable resource patches with sufficient tool stone suitable to the myriad tasks completed using reductive technology. This systemic combination would have allowed LCM hunter-gatherers access to a variety of lithic resources and informed their ability to maintain adaptively stable toolkits as mobile stone resource patches in the diverse Cantabrian environment.

---

ORAL

#### 5. PALAEOOLITHIC SITES IN THEIR LANDSCAPE: TWO CASE STUDIES FROM NORTHERN SPAIN

*Fano, Miguel Ángel - (Universidad de La Rioja) miguel-angel.fano@unirioja.es*

*García, Alejandro - (Monrepos Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM & IIIIPC, University of Cantabria) garcia@rgzm.de*

Research on Palaeolithic societies has traditionally been based on the study of archaeological deposits. This paper stresses the importance of information related to the location and characteristics of the sites containing these deposits. If an understanding of a site involves knowing its local and regional context, as the mobile nature of

hunter-gatherer societies requires, it is obviously necessary to obtain precise knowledge about the places where archaeological deposits are preserved. This will strengthen our hypotheses about the role played by the different sites. However, a study of this kind is necessary not only within the framework of a materialistic approach, as the choice of a certain place may be influenced by much more subtle factors, connected with the significance or symbolism of certain elements in the landscape, or with the archaeological sites themselves. For example, the potential amount of information that Palaeolithic rock art sites are capable of providing is evident.

This paper presents the preliminary results of our work in the Asón and Nalón River basins (northern Spain) to illustrate the type of observations that can be made through the application of a particular methodology, and their relevance within a regional approach to the study of Late Magdalenian societies in Cantabrian Spain. Eight sites from each valley are considered. The methodology applied is based on the definition of a series of indicators that describe the area where they are situated. These indicators can be divided into *Parameters*, which are obtained by direct observation and measurements in the field (absolute and relative altitude, topography...) and *Variables*, which require the use of a GIS to be modelled and quantified (viewshed, slope of terrain...). This methodology allows a comparative study of the sites being studied.

The sample of Magdalenian sites shows significant similarities and differences regarding their location. For instance some of them are situated in relatively similar locations: valley bottoms, with a very low relative altitude allowing more direct access to their surrounding areas and in general with limited visibility (El Valle, El Horno, Sofoxó...). Other sites are located on hillsides, in prominent positions within the landscape (El Mirón, La Viña, Peña de Candamo...), and their viewsheds are in general much larger than those of the sites in the valley bottoms. Probably these similarities and differences must have been significant in connection with the role played by each site in its social context. However for a real understanding of the meaning of these data the integration of all the archaeological information is required. Only then will the type of analysis being proposed be fully applicable in terms of inference.

ORAL

## 6. TERRITORY AND ABIOTIC ECONOMY BETWEEN 33 AND 15,6 KA AT VALE BOI (SW PORTUGAL)

*Pereira, Telmo - (ICArEHB) telmojrperreira@gmail.com*

*Bicho, Nuno - (ICArEHB) nbicho@ualg.pt*

*Cascalheira, Joao - (ICArEHB) jmcascalheira@ualg.pt*

*Infantini, Leandro - (ICArEHB) leandroinfantini@gmail.com*

*Marreiros, Joao - (ICArEHB) jmmarreiros@ualg.pt*

*Paixao, Eduardo - (ICArEHB) eduardo.paixao88@gmail.com*

The environmental shifts occurred during the Late Pleistocene had major influence in the landscape and, consequently, in the available resources. This had direct impact on human behavior and ecology, demanding from people to constantly adjust to new economical conditions. In coastal areas, this impact tended to be even greater since along with continental transformations, coastal populations had also to deal with the retreat of marine resources during the harsher times.

However, such retreat might have made available former underwater rich cobble and bolder beaches, especially in areas with rocky cliffs eventually making it easier to gather lithic raw materials.

In this paper we present our preliminary results on the diachronic variability of raw materials in Vale Boi. Vale Boi is a coastal site, located at 2,5 km from the present coast line, in the margins of a freshwater stream, has three different loci, all rich in lithics, fauna (including marine), bone tool, adornments, charcoal and ocher and has a continuous human occupation from 33 to 15,6 ka. Such chronostratigraphic record makes it a perfect study case for the understanding of coastal populations behavior and economy throughout the Upper Paleolithic.

Our objective is to infer territory of resources exploitation, landscape, economic patterns and social networks. Raw material sources are usually fixed points on the landscape (by opposite to other resources such as fauna and flora) and, therefore, are one of the best ways of understand how people moved in the landscape and, consequently, to infer past human behavior. We used a set of methods to approach both the archaeological and the geological record in order to correlate sources and artifacts. Our results show that the hunter-gatherers that occupied Vale Boi during the Upper Paleolithic not only used several raw materials but also a variety of sources for the same raw material. This happened both diachronically and synchronically, showing that the sequence as well as each archaeological layer is very complex.

The Upper Pleniglacial, between 23 000-20 000 BP, is characterized by the intensification of cold climate and the maximum extent of ice sheets. There is a little information about the human activities during this period. New archaeological excavations in Ukraine permit to evidence data about behavioural human adaptations. These sites are on the one hand Doroshivtsy III in the Dniester valley and on the other hand Pushkari I (excavations VII), Pogon and Obollonia in the Desna valley.

In order to better understand the subsistence strategy we carried out zooarchaeological studies, including paleontology, taphonomy and palethnography, which allow us to reveal the strategy of fauna exploitation by the human groups.

These sites are distinguished by atypical lithic industries made on local flint related to the Gravettian but containing Epigravettian or Aurignacoid elements. All these sites are characterized by a restricted faunal spectrum with the presence of reindeer, horse, mammoth and carnivores (fox [*Vulpes vulpes* and *Alopex lagopus*] and wolf). The settlements are recurrent camps with little de-

velopment occupied during varied seasons oriented to hunting and butchering activities. The particular status of woolly mammoth is noticeable in Doroshivtsy III (layer 6), Pushkari I, Pogon and Obollonia. Indeed it was used as food resource, as raw material to make tools and as artistic support. Ivory was used to make grooved points; this is the oldest occurrence of this kind of artefacts in these regions. Moreover two engraved tusks presenting more or less figurative pictures were found in Doroshivtsy III/6 and Obollonia. The other large herbivores were also consumed. The reindeer is predominant in the layers 5, 4, and 3 of Doroshivtsy III. Carnivores were exploited for their pelts in all these sites.

Some similarities can be noticed between the Dniester and Desna valleys through the use of ivory artefacts which tend to decrease thereafter. These sites demonstrate the continuity of human occupations within the Eastern European plain, with the persistence of hunting methods and the relative diversity of animal exploitation, during the Upper Pleniglacial.

**8. GESTION DU TERRITOIRE DANS LE BASSIN MOYEN ET SUPÉRIEUR DU DNIÉPR PENDANT LE MÉZINIEN (15 000 - 14 000 BP)**

*Iakovleva, Lioudmila - (Institute of Archaeology NAS Ukraine (Kiev) and CNRS UMR 7041 Arscan) l.iakovleva@wanadoo.fr*

*Résumé*

Entre 15 000 et 14 000 BP, dans le bassin moyen et supérieur du Dniepr, en Europe orientale, les groupes de chasseurs-cueilleurs du Mézinien ont peuplé un territoire d'environ 500 000 km<sup>2</sup>.

Les sites archéologiques découverts et fouillés depuis la fin du XIX<sup>e</sup> siècle sont :

1) des habitats résidentiels de longue durée dans le cycle annuel avec des cabanes construites en ossements de mammoths, provenant principalement de grandes accumulations d'ossements de mammoths situés à proximité des habitats et largement exploités par le groupe humain.

2) des sites de passage, d'occupation courte, dédiés à des chasses spécialisées, ou des bivouacs à l'occasion de déplacements à la recherche de matières premières

3) des sites de matière première (coquillages fossiles du Sarmatien, coquillages de la mer noire, silex, ambre fossile), exploités systématiquement par le groupe humain.

4) Des accumulations d'ossements de mammoths, ex-

exploités de façon variable par le groupe humain.

Les fouilles de sites résidentiels du bassin moyen et supérieur du Dniepr (Méziine, Gontsy, Mejiriche, loudinovo, Timonovka, Elisseevichi, Kiev-Kirilovskaia) et des sites de passage (Semenivka, Jouravka, Fastiv, etc.) permettent de reconstituer une économie du mammoth, qui pourvoit aux ressources alimentaires (avec le renfort ponctuel du renne et du cheval), au combustible (os frais pour l'alimentation des foyers), à la matière première des outils (ivoire, os) et comme éléments de constructions des cabanes. La chasse aux animaux à fourrure (carnivores, lièvre, marmotte) joue également un rôle important. Les approvisionnements des coquillages, des silex et de l'ambre permettent de reconstituer des circulations jusqu'à près de 600 km.

#### Abstract

Between 15 000 and 14 000 BP, in the middle and upper Dnepr basin, in Eastern Europe, hunter-gatherer groups of the Mezinien have peopled a territory of about 500,000 km<sup>2</sup>. The archaeological sites discovered and excavated since the end of the 19th century are:

- 1) Residential settlement, long-term lived in the annual cycle, with mammoth bone huts, mainly built from large accumulations of mammoth bones located near the settlement and widely exploited by the human group.
- 2) circulation sites, having a short occupation, dedicated to specialized hunts, or bivouacs at the occasion of travel for raw material sites (Sarmatian fossil shells, Black Sea shells, flints, fossil amber), systematically exploited by the human group.
- 3) Accumulations of mammoth bones, exploited in a variable manner by the human group.

Excavations of residential sites in the middle and upper Dnepr basin (Meziine, Gontsy, Mejiriche, loudinovo, Timonovka, Elisseevichi, Kiev-Kirilovskaia) and circulation sites (Semenivka, Jouravka, Fastiv, etc.) allow to reconstruct an economy of the mammoth, which provides food resources (with punctual reinforcement of reindeer and horse), fuel (fresh bone for hearths), raw material for tools and weapons (ivory, bone) and as elements of constructions of the huts. The hunting of fur (carnivores, hares and marmots) also plays an important role. The procurements of shells, flints and amber allow reconstructing travels up to nearly 600 km.

## 9. BOTTLENECK AND CORRIDORS AND THEIR IMPACT ON PALEOLITHIC SUBSISTENCE AND LANDUSE IN THE COMPLEX TOPOGRAPHY OF THE ZAGROS MOUNTAINS OF IRAN

*Heydari-Guran, Saman - (Department of Early Prehistory and Quaternary Ecology, University of Tuebingen, Germany) saman.heydari@ifu.uni-tuebingen.de*

*Märker, Michael (Heidelberger Akademie der Wissenschaften Forschungsstelle: The role of culture in the early expansions of humans) michael.maerker@geographie.uni-tuebingen.de*

*Conard, Nicholas (Department of Early Prehistory and Quaternary Ecology, University of Tuebingen, Germany) nicholas.conard@uni-tuebingen.de*

Intensive survey conducted by the Tuebingen-Iranian Stone Age Research Project (TISARP) team in the Dasht-e Rostam-Basht Region of the Southern Zagros Mountains resulted in the identification of 111 caves, rockshelters and open air sites, mainly associated with Upper Paleolithic lithic artifacts. Based on the complex topographical situation of the Dasht-e Rostam-Basht habitat area, this region is classified into 13 microhabitats. The analysis of lithic artifacts from each microhabitat demonstrates variation in the quality and quantity of the assemblages, which reflect specific patterns of landuse. This new method of quantifying landscape structure, site topographical positions and archaeological data permits the assessment of terrain features in facilitating Paleolithic landuse, including hunting, gathering, mobility and resource acquisition. Our work at the Dasht-e Rostam-Basht Region and comparisons with other areas within the Zagros Mountains suggest that the complex topography of this vast geological zone provides many bottleneck corridors which facilitate early human monitoring the movements of animals. These features in the landscape also provide places to camp and easy access to the prey and other resources during Late Pleistocene.

ORAL

## 10. TERRITORIALITÉ ET MOBILITÉ DES GROUPES DE CHASSEURS CUEILLEURS PENDANT LE DERNIER MAXIMUM GLACIAIRE EN EUROPE OCCIDENTALE, CENTRALE ET ORIENTALE

*Djindjian, François - (Université de Paris 1 Panthéon Sorbonne & CNRS UMR7041 Arscan) francois.djindjian@wanadoo.fr*

### Résumé

Au dernier maximum glaciaire, les groupes humains du Gravettien refluent vers le sud de l'Europe dans les péninsules : ibérique, italienne, balkanique et dans les golfes : tyrrhénien, adriatique, égéen et autour de la mer Noire. Ils s'y différencient : Solutréen en Europe occidentale, Epigravettien en Europe centrale et en Europe orientale. Les groupes humains, contraints dans leur nouveau territoires méridionaux, vont revenir à des territoires petits et une mobilité faible, qui les oblige à changer à la fois de système de ressources alimentaires (chasse aux mammifères grégaires remplaçant celle aux troupeaux migrants), de sources d'approvisionnement en matières premières (réutilisation des quartzites), et en conséquence de technologie (retour au débitage d'éclats, importance du débitage lamellaire) et d'outillages. Nous avons appelé ceci, la *stratégie opportuniste locale*, avec des territoires de moins de 1000 km<sup>2</sup> et une mobilité faible à l'intérieur de celui-ci. Les variations climatiques du dernier maximum glaciaire, font apparaître deux épisodes plus humides, bien visibles dans les séquences de loess d'Europe centrale et orientale et dans les enregistrements non anthropiques vers 20-19 000 BP et vers 18,5-17 000 BP. Durant ces deux épisodes, les groupes humains vont se déplacer vers le Nord pendant l'été, système que nous avons appelé *stratégie de mobilité saisonnière*, où ils vont retrouver la chasse aux animaux migrants et les gîtes de bon silex. L'objet de cette communication est de montrer que ces deux systèmes ont existé pendant le dernier maximum glaciaire à la fois en Europe occidentale, centrale et orientale, où, malgré des différences typologiques dans les assemblages, des caractéristiques communes peuvent être soulignées.

### Abstract

At the last glacial maximum, the Gravettian human groups flow back to southern Europe in the Peninsulas: Iberian, Italian, Balkan and the gulfs: Tyrrhenian, Adriatic, Aegean and around the Black Sea. There, they differentiate: Solutrean in Western Europe, Epigravettian in Central Europe and in Eastern Europe. Human groups, constrained in their new southern territories, go back to a system of small territories and low mobility, which requires them to change both of food resource system (gregarious mammals hunting replacing migratory herd hunting), of sources of raw materials procurement (reuse of quartzite), and, as a result, of technology (return to the flake knapping, importance of the lamellar knapping) and of industry. We called this, the *local opportunistic strategy*, involving territories of less than 1000 km<sup>2</sup> and a low mobility within it. The climate variations of the last glacial maximum, reveal two wetter episodes, clearly visible in the sequences of loess of Central and Eastern

Europe and in non-anthropogenic records around 20-19 000 BP and 18,5-17 000 BP. During these two episodes, human groups will move northward during the summer, system we called *seasonal mobility strategy*, where they will find again the hunting of migratory animals and outcrops of good flint. The purpose of this communication is to show that these two systems have existed during the last glacial maximum both in Western, Central and Eastern Europe, where, despite typological differences in assemblages, common characteristics may be highlighted.

#### 11. LANDSCAPE AND HABITAT - THE CÔTE CHALONNAISE (BUGUNDY, FRANCE), A PALAEOOLITHIC MICRO REGIONAL CASE STUDY

Hoyer, Christian Th. - (Universität Tübingen) christian.hoyer@uni-tuebingen.de

Herkert, Klaus - (Universität Tübingen) klaus.herkert@student.uni-tuebingen.de

Frick Jens Axel - (Universität Tübingen) jens-axel.frick@ifu.uni-tuebingen.de

Siegeris, Markus - (Universität Tübingen) markus.siegeris@student.uni-tuebingen.de

Floss, Harald - (Universität Tübingen) harald.floss@uni-tuebingen.de

Since the second half of the 19th century, Southern Burgundy has constituted as an important region for the transition from Middle to Upper Palaeolithic in France. Containing remains from the Middle Palaeolithic, the Châtelperronien, the Aurignacian and the Gravettian, the position of this region is strengthened not only diachronically but also geographically for the overlap of these different complexes in time and space compared to neighbouring regions.

Beginning in the middle of the 1990s, a research team from Tübingen University directed by H. Floss has been investigating this area, building on a research tradition started by A. Arcelin and H. Breuil and carried on by J. Combier and H. Delporte. In spite of the long history of research in this region, it is clear that more detailed information in the form of absolute dates, chronostratigraphic studies, and technological reassessments of the different assemblages are required. Through ongoing excavation, survey, and collection analysis of different cave and open-air sites and surface collections, the Tübingen research team is attempting to fill gaps in the current knowledge of the region as palaeolithic habitat.

As basic parameters for the Côte Chalonnaise region, which is geographically situated in the Jurassic mountain chain bordering the Saône-river-plain in the west, the availability of main resources (game, water, silex) in very proximity of all of the major archaeological sites is attested.

The reconstruction of the Palaeolithic relief helps to understand Palaeolithic procurement patterns as well as the visibility of the landscape and the sites in the environment might play an important role in the organisation of the habitat and the space occupied.

The aims of the current projects are, among others, building up an occupation model for the early and middle Upper Palaeolithic in the area. GIS based mapping and modeling, datings, supported by raw material provenience-analyses, as well as chaîne opératoire studies and especially technological comparisons of the lithic and organic industries will provide a deeper insight in the complex long-term settlement patterns and resource economy strategies in the Côte Chalonnaise in the years to come.

### 12. FIRST EUROPEAN ANATOMICALLY MODERN HUMANS AND THE ROUTE OF SHELLS: CHRONOLOGICAL AND QUALITATIVE EVIDENCE FROM THE VENETO PLAIN REGION SITES

Romandini, Matteo - (Università di Ferrara) [matteo.romandini@unife.it](mailto:matteo.romandini@unife.it)

Falcucci, Armando - (Università di Ferrara) [armando.falcucci@student.unife.it](mailto:armando.falcucci@student.unife.it)

Gurioli, Fabio - (Università di Ferrara) [fabio.gurioli@unife.it](mailto:fabio.gurioli@unife.it)

Broglio, Alberto - (Università di Ferrara) [alberto.broglio@unife.it](mailto:alberto.broglio@unife.it)

The use of marine shells as ornamental and symbolic objects is widespread among early AMH. This practice is also attested in those areas that are located at great distance from the sea (Taborin, 2004; White, 2004). Sometimes the lack of sea shells was compensated by the collection in freshwater (Romandini, 2012). Even if a few species can be surely associated to a particular environment, the collection areas can be supposed through the geographical distribution of the finds. In this work we take particular attention to two Northeastern Italian sites, Grotta di Fumane (Monti Lessini, Verona) and Riparo del Broion (Colli Berici, Vicenza).

Taphonomic microscopic analyses of the shells surfaces were carried out using Leica S6D Green Ough (L.A.T. of Ferrara) stereomicroscopes with 20-220 magnification range.

The assemblage from Fumane plays an important role as for the great number of shells (838 samples) as for the variability of the taxa represented (around 60). Furthermore the 3 *Dentalium inaequicostatum* and the *Theodoxus danubialis* found in Broion are both attested in Fumane.

It is difficult to circumscribe the ecological area of the species: some of them are typical of rocky substrates, other of sandy bottoms. Some specimens are now exclusive of the south-eastern part of the Mediterranean Sea (*Nassarius circumcinctus*), while others (*Gibbula pennanti*, *Gibbula cineraria*, *Littorina obtusata*) are particularly common along the coasts of the Atlantic Ocean and scarce in the Mediterranean Sea. Many of the species found in Fumane are also attested in the Italian Aurignacian sites close to the French Mediterranean coast.

The taxa present in these two sites represent a rare example of the little known fauna of the Mediterranean during the Würm Interpleniglacial, both the Tirrenian and the Adriatic Sea, when the sea level was 80-90 metres (Djindjian *et al.*, 1999) lower than today and the coastlines were about 200 kilometers southwest and 400 kilometers south-east from them. Although the paleoecological

studies of the shells are still in progress it can be brought an hypothesis of the possible collection areas based on the inter-site analysis and landscape reconstruction.

The two important sites considered, Grotta di Fumane and Riparo del Broion, have yielded striking archaeozoological and taphonomical bodies of evidence that reveal special attention to some species of marine shells that could have been carried from the beaches to the caves through apposite expedition or through exchanges between different groups.

Within the current studies is reasonable to hypothesize that the species of both sites have a Mediterranean origin and that the links between the chronological data and the hypothetical line passing through Fumane and Broion, compared with others guidelines coming from the Ligurian sites (Riparo Bombrini and Riparo Mochi), may represent a rare proof of the movements and/or exchange networks of the early Aurignacians in Europe.

In southwest France, from the Late Solutrean to the Badegoulian, lithic industries witness deep technical and economical changes. Between 23.5 and 20.5 ky cal BP, a general reconfiguration of the lithic technical system occurs, and might be evidence of a broader reorganization of the society.

The "SaM" collective research project builds upon this evidence and aims at a better characterization and quantification of these changes, by putting together data from different technical and symbolic domains. This paper will present the work undertaken within this project, which includes researchers from different disciplines. This diversity and complementarity allow project members to go beyond mere typological and technological approaches and address technoeconomic and socioeconomic issues – especially group organization on the spatial and temporal levels, territory management, and hunting practices.

Our first results show that these technoeconomic evolutions are likely accompanied by changes on a broader scale ("sociological overhaul"). However, the impact of environmental changes on these groups living at the beginning of the Last Glacial Maximum remains to be evaluated. In this perspective, this paper will offer an at-

tempt at correlating our results with the available environmental data, thanks to a radiocarbon dataset that has been partly renewed within the "SaM" project.

ORAL

**2. THE EARLY TIMES OF THE MAGDALENIAN AS SEEN THROUGH LITHIC AND BONE EQUIPMENT. NEW DATA (ARCHAEO-STRATIGRAPHIC, HISTORICAL AND TECHNO-ECONOMIC) IN THE SOUTHWEST OF FRANCE**

*Sécher, Anthony - (UMR5199 PACEA) anthony.secher@hotmail.fr*

*Langlais, Mathieu - (UMR5199 PACEA) mathieu.langlais@u-bordeaux.fr*

*Pétillon, Jean-Marc - (UMR 5608 TRACES) petillon@univ-tlse2.fr*

*Chauvière, François-Xavier - (Office du patrimoine et de l'archéologie de Neuchâtel, section archéologie. Laténium) francois-xavier.chauviere@ne.ch*

In South-West of France, new analyses of lithic and bone equipment and a series of <sup>14</sup>C dates allow us to address the question of the genesis of the Magdalenian.

For the Lower Magdalenian, the re-examination of lithic and bone assemblages of the lower levels of Saint-Germain-la-Rivière (Trécolle excavation), Gironde, clarifies the techno-economic behavior of these groups. Comparisons are made with other sites such as Gandil shelter in Bruniquel or Scilles cave in Lespugue.

This "first" Magdalenian is dated between about 21 and 19 ky calBP. New results in the MAGDATIS project also clarified the definition of an "Early Middle Magdalenian" in Gironde, dated between 19 and 18 ky calBP. Assemblages from this period include Roc-de-Marcamps and Moulin-Neuf (Gironde) but also the upper levels of Saint-Germain-la-Rivière (Trécolle excavations) and those of the ongoing excavations at Petit Cloup Barrat (Lot; Castel and Chauvière excavations). Data from these sites shed a new light on the early days of the Classic Magdalenian, including the so-called "facies" with Lussac-Angles points, antler "shuttles" or scalene bladelets.

Between Lower and Early Middle Magdalenian, techno-economic characterization of antler working, direct dating of diagnostic objects and research on lithic equipment all show technical changes. These data lead to specify the rhythms of transformation of the Lower Magdalenian and the slow genesis of Classic Magdale-

nian through new behaviors, both technical, economic and symbolic.

ORAL

### 3. EL ORIGEN DEL MAGDALENIENSE: UNA CUESTIÓN CONTROVERTIDA. EL REGISTRO DE LA CUEVA DE LAS CALDAS (ASTURIAS, NORTE DE ESPAÑA)

*Corchón Rodríguez, M<sup>o</sup> Soledad - (Universidad de Salamanca) scorchon@usal.es*

*Ortega Martínez, Paula - (Universidad de Salamanca) ortegap@usal.es*

La cueva de Las Caldas está situada en un entorno de pequeños valles, aledaños al curso principal del río Nalón, en el tramo medio de la cuenca. El lugar, intensamente habitado a finales del Pleistoceno, constituye un lugar privilegiado para la habitabilidad humana en el Paleolítico. El valle alberga una veintena de cavidades y abrigos con ocupaciones que se extienden desde el Auriñaciense al Aziliense, muchas de ellas con grabados y pinturas parietales. Aunque no es una cueva de grandes dimensiones, conserva uno de los registros estratigráficos más importantes del Suroeste de Europa, en lo que se refiere al Solutrense y Magdalenense. En Las Caldas, las características orográficas determinan la existencia de una amplia variedad de ecosistemas, tanto de alta montaña, cerros y planicies a media altura, como en valles abrigados. Esta variedad de recursos disponibles, unido a la abundancia de fuentes termales y minero-medicinales en el entorno de la cueva, determinaron que el lugar constituyera un entorno-refugio para los grupos sociales que ocuparon el valle.

El yacimiento muestra una amplia secuencia estratigráfica, con una horquilla temporal que abarca unos 10.000 años ( $24185 \pm 370$  calBP, nivel 15, sala I;  $14936 \pm 342$  calBP, nivel I, sala II). La sala I conserva un depósito arqueológico de 17 niveles solutrenses, que representan la secuencia completa del Solutrense cantábrico. La Sala II, en cambio, sólo ofrece un nivel, Solutrense final, reposando sobre el piso calizo y subyaciendo a un extenso depósito de 16 niveles magdalenenses. En esta sala II también está representada la secuencia magdalenense completa (inferior, medio antiguo y medio reciente, superior y final), que se extiende desde la Oscilación de Lascaux al Alleröd. Para la datación de estas series de niveles, se dispone de 26 dataciones  $^{14}\text{C}$ .

Este trabajo se centra en el estudio de los depósitos del final del Solutrense, y su relación con los más antiguos

niveles magdalenenses. Se presta especial atención a la secuencia de niveles XIII y XIV de la Sala II, con materiales del Magdalenense inferior y Solutrense final, respectivamente. Y se analizan las características de otras ocupaciones del Magdalenense inferior, así como la distribución espacial de los restos arqueológicos con metodología SIG.

Por otra parte, algunos de los niveles de Las Caldas han sido objeto de diferentes interpretaciones culturales, en relación con el final del Solutrense cantábrico y su sustitución por los primeros grupos sociales magdalenenses. Por ello, se estima que un examen crítico y comparativo de los diferentes tipos de restos materiales recuperados en los niveles, objeto de controversia, puede arrojar algo de luz en relación con el origen del Magdalenense en la Región cantábrica.

*Santamaría, David (Área de Prehistoria. Universidad de Oviedo) santamariadavid@uniovi.es*

*Duarte Matías, Elsa (Área de Prehistoria. Universidad de Oviedo) eduarda@gmail.com*

*Jordá Pardo, Jesús F. - (Lab. de Estudios Paleolíticos. Facultad de Geografía e Historia, UNED Madrid) jjorda@geo.uned.es*

*Pérez Ripoll, Manuel - (Universitat de València. Dept. de Prehistòria i Arqueologia) Manuel.perez@uv.es*

*Sanchís Serra, Alfred - (Museu de Prehistòria-SIP, València), Yolanda Carrión Marco (UNED, Valencia) alfredsanchis@gmail.com*

*Wood, Rachel - (The Australian National University, Canberra (Australia) rachel.wood@anu.edu.au*

In the first proposals of H. Breuil the “plus vieux Magdalénien” is identified in the Cantabrian (cf. Castillo) and Mediterranean regions (cf. Parpalló), whilst F. Jordá suggested that the Solutrean persisted in Iberia longer than elsewhere. Both have had a profound effect on the analysis of the final Iberian Upper Palaeolithic. Excavations during the second half of the twentieth century and the first radiocarbon dates ratified these relationships, limiting one chronostratigraphic framework and archaeological items marked regional characterization (cantabrian “de-solutreanized” process and mediterranean solutreo-

gravettian). This background led the Peninsular data to lie outside the “Badegoulian issue”. However, it is clear that the Archaic Cantabrian Magdalenian and the Ancient Mediterranean Magdalenian (Badegoulian facies) need to be incorporated into this discussion.

The aim of this presentation is to assess whether archaeological contexts available for analysis of “Solutreo-Badegoulian chronological transition” in Cantabrian and Mediterranean regions. This information will allow us to reconsider the Solutrean persistence and the beginnings of the “plus vieux Magdalénein” in Iberia from an evaluation of the stratigraphic, radiocarbon and archaeological data.

As the Badegoulian in Iberia is poorly-dated, we obtain new radiocarbon dates have become available, from Cueva Llonín (Asturias) and Cova del Parpalló (Valencia). After the consideration of the archaeological-stratigraphic data, the dates have been incorporated into Bayesian models using OxCal calibration.

The “Solutreo-Badegoulian-Magdalenian Transition” appears to coincide with the end of the Late Glacial Maximum, with high energy sedimentary episodes that have affected its conservation in most lithostratigraphic sequences and may have disturbed a significant part of the available dates. Finally, the dates and archaeological contexts that offer greater resolution pose different scenarios in approaching the study of this process.

Analysis of the radiocarbon dates shows that the taphonomic processes linked to LGM, coincide with regional features. The discussion on the chronological convergence requires a comprehensive assessment of the archaeological contexts to advance the construction of explanatory hypotheses. Our goal is to encourage reflection on one of the significant processes for the understanding the Iberian Final Palaeolithic.

## 5. THE ARCHAIC MAGDALENIAN (A. K. A. BADEGOULIAN) IN SPAIN

*Utrilla, Pilar - (University of Zaragoza) utrilla@unizar.es*

This communication studies lithic and osseous industries from the sites attributed to the Archaic Magdalenian in the Cantabrian Coast (Rascaño, Castillo, Río-Lloseta, Cueva de la Mina, Riera, Llonín, Cova Rosa, Mirón, Caldas and Aitzbitarte) and compares them to others belonging to

the Mediterranean basins (Parpalló, Volcán de Faro, Gato-2). We meditate about its diffusion East-North through the Ebro Valley if we consider the C14 dates. We argue the existence of different *facies* based on the presence or not of some significant tools such as raclettes, single-bevelled sagaies decorated with spikes patterns, pseudoexcise engraving in curve motifs... We also propose some chronological phases, such as the classic Magdalenian 0 characterised by coarse tools that precedes Magdalenian I and appears well documented in some Cantabrian sites (i. e. Mirón cave). We will discuss the opportunity of adopting the term “Badegoulian” for what we have been calling early phases of the Magdalenian and, if so, if we must apply it in a restricted or an ample way.

## 6. THE SETTLEMENT IN EASTERN ASTURIAS AFTER THE LGM. THE BADEGOULIAN LEVEL OF LLONIN CAVE (ASTURIAS, SPAIN)

*de la Rasilla Vives, Marco - (Área de Prehistoria. Universidad de Oviedo) mrasilla.vives@gmail.com*

*Duarte Matías, Elsa (Área de Prehistoria. Universidad de Oviedo) eduardma@gmail.com*

*Rodríguez Otero, Vicente (Arqueólogo. Villaviciosa. Asturias) vicente.correo@gmail.com*

The Llonin cave has an important archaeological sequence accompanied with a varied chronologically long rock art. It is represented the Mousterian, Gravettian, Solutrean, Badegoulian, Middle and Upper Magdalenian and some remains from the Azilian and Bronze Age. In rock art we have figurative (deer -mainly females-, bison, goat, horse, reindeer, aurochs, bear, feminine antropomorphic) and nonfigurative (rectangular or meanderlike signs, groups of points and lines) using different techniques: painting (black or red colour, few of them using the tampon technique), and engraving (simple or multiple lines with modelling striate technique). This cave is the best example in the rock art of the Spanish and French geography of the last engraving technique mentioned.

We have studied a statistically significant sample of level III archaeological records (Galería Area) from a technological and typological point of view.

In that level we have found an unusually associated lithic and bone collection: raclettes, Placard type bone points, the pseudo-excise carving technique and the use of local raw materials. In addition, we have a broad number of notches, denticulates, splintered pieces, a low blade-

let production, and a noted quantity of lithic artifacts made in quartzite and in local flint.

New <sup>14</sup>CAMS datations that will be exposed and analysed in other paper in this Congress situate the Llonin level III around 18.000 years BP (uncalibrated). This will be compared with dates of similar levels and with the immediate Solutrean data just to see the quality of the transition between Solutrean and Magdalenian.

Finally, we also propose to include this level in the Badegoulian because it adapts better with the characteristics offered in those named sites in France and in the Iberian peninsula.

## 7. THE END OF THE SOLUTREAN IN THE EASTERN CANTABRIAN REGION. FEW DATA FOR A COMPLEX PROBLEM

Rios-Garaizar, Joseba - (CENIEH) joseba.rios@cenieh.es  
San Emeterio Gómez, Aixa - (III PC) aixitaseg@gmail.com  
Garate Maidagan, Diego - (Université de Toulouse le Mirail) garatemaïdagandiego@gmail.com

Investigations about the Solutrean-Magdalenian transition are highly dependent on the radiometric chronologies and on the cultural classifications of archaeological assemblages. The situation in SW France seems quite ordered with a Badegoulian technocomplex (ca. 23.6-20.5 kyr Cal BP) situated between recent Solutrean and Lower Magdalenian (Ducasse, 2012). Some authors have claimed the presence of Badegoulian assemblages in the Cantabrian Region (Aura et al., 2012) but, by now, there is no clear proof for that (Rios-Garaizar et al., 2013). On the contrary, in the Cantabrian region there is a characteristic late Solutrean with rare foliates, high percentages of backed bladelets and some raclettes, which extends until ca. 20.0 kyr cal BP. This represents a probable local transition to Lower Magdalenian, which, from a technological point of view, is mainly characterized by the use of multicomposite hunting weapons. Despite this situation could be an artifact of archaeological research development in both sides of Pyrenees, we propose that it could be the result of the coexistence of more or less permeable cultural traditions (Badegoulian and Late Solutrean) in SW France and N Spain. We will discuss these hypothesis taking in account the available environmental and archaeological information for the Late Solutrean in Eastern Cantabrian Region and Western Pyrenees.

---

ORAL

## 8. THE INITIAL MAGDALENIAN OCCUPATIONS OF EL MIRON CAVE (RAMALES DE LA VICTORIA, CANTABRIA, SPAIN)

Straus, Lawrence Guy - lstraus@unm.edu (Department of Anthropology, University of New Mexico, Albuquerque, NM 87131 USA)

González Morales, Manuel R. - moralesm@unm.edu (Instituto Internacional de Investigaciones Prehistóricas, Universidad de Cantabria, 39005 Santander, Spain)

Our excavations since 1996 in El Mirón Cave on the northern edge of the Cantabrian Cordillera, between Santander and Bilbao, have revealed a sequence of Initial, Lower, Middle, Upper and Epi- (i.e., Azilian) Magdalenian occupations of varying degrees of intensity. The Initial Magdalenian levels overly a series of Solutrean ones and represent a change in the nature of human use of the cave, from short-term, limited-function Solutrean visits (probably by warm-season hunting parties) to massive, organic matter- and artifact-rich layers, whose character as palimpsest deposits from major, repeated, long-term, multi-purpose, residential episodes continues throughout the overlying Lower Magdalenian levels.

Radiocarbon assays for the Initial Magdalenian levels (119.3-117) range between ca. 17.6 – 17.0 uncal. BP (ca. 20.7-20.3 cal. kya), with considerable continuity in the lithic (non-projectile point) and osseous artifact assemblages and the presence of a few Solutrean point fragments in the Initial Magdalenian assemblages. The Initial Magdalenian assemblages are devoid of classic Badegoulian lithic artifact types (*raclettes*, transversal burins), but are characterized by large numbers of large flakes, tools on flakes of “archaic”/Mousteroid aspect (denticulates, notches, sidescrapers) made on local non-flint raw materials (mudstone, quartzite, limestone). However, there are also numerous unretouched and backed bladelets made on excellent-quality flint from coastal *flysch* outcrops of Upper Cretaceous age (40-60 km from the site), continuing a “bifocal” kind of composition typical of many Solutrean and Magdalenian assemblages in Cantabrian Spain. There are mainly undecorated antlers *sagaies* of diverse cross-sections, but most characteristic seem to be very large (robust), round-section points.

The pattern of fundamental technology continuity, but with the gradual replacement of one class of weapon tips (Solutrean foliate and shouldered points) by another (antler points armed with bladelet elements), seems to be the chief characteristic of the Solutrean-Magdalenian transition in this site, though it is acknowledged that, while similar in some aspects to other early Magdalenian

assemblages from the region (e.g., El Rascaño, La Riera), there were diverse kinds of assemblages in both the Cantabrian region (e.g., Las Caldas) and throughout Iberia (e.g., El Parpalló in Valencia) in general, some indeed with *raclettes*, although generally centuries more recent than the origins of the Badegoulian culture in France.

Subsistence evidence, still very preliminary, suggests that El Mirón inhabitants (like those throughout the region) continued the Solutrean pattern of heavy dependence on hunting red deer and ibex in this montane setting within a very open landscape dotted only by a few scattered pines and junipers. Late survival of Solutrean technology and essential technological, settlement and subsistence continuity were the hallmarks of human adaptations as the environment slowly and tentatively moved from the conditions of the LGM into those of early Oldest Dryas (GS2a).

---

ORAL

## 9. EARLY MAGDALENIAN PALEOECONOMIC BEHAVIOR IN THE CANTABRIAN REGION, NORTHERN SPAIN

*Geiling, J.M. - (Instituto Internacional de Investigaciones Prehistóricas de Cantabria-Universidad de Cantabria) jeanmarie.geiling@unican.es*

*Marín-Arroyo, A.B. (Instituto Internacional de Investigaciones Prehistóricas de Cantabria-Universidad de Cantabria) anabelen.marin@unican.es*

*González-Morales, Manuel R. (Instituto Internacional de Investigaciones Prehistóricas de Cantabria-Universidad de Cantabria) moralesm@unican.es*

*Straus, Lawrence Guy (Department of Anthropology, University of New Mexico; Instituto Internacional de Investigaciones Prehistóricas de Cantabria-Universidad de Cantabria) lstraus@unm.edu*

This research aims to recognize the driving factors of human behavioral change on subsistence in Upper Paleolithic hunter-gatherers during the Last Glacial, a period of rapid climate fluctuations. Throughout the Last Glacial Maximum advancing ice-sheets substantially reduced hunting territories. In this scenario, northern Iberia acted as a refugium. Evidence of the refugium is shown in recent aDNA studies and the increase on archaeological sites, especially during the Solutrean. These factors may indicate an influx of migrants in southern European refugia resulting in a population expansion across northern Iberia. By studying subsistence strategies carried out during and after the Last Glacial Maximum we have identified

two periods of major changes: one during the transition from Solutrean to Early Magdalenian and the other during the Early to Middle Magdalenian. The current study focuses on the Early Cantabrian Magdalenian (17-14,5 ka BP), using an extraordinary rich archaeological deposit from El Mirón cave, located in the upper Ason valley at the eastern Cantabrian Cordillera. The archaeozoological results from Level 15 and 16, date around 15-15,2 ka BP, are presented here.

The palaeoeconomic behavior achieved for those hunter-gatherers is reconstructed based on identification of taxa consumed, age of the individuals, carcass transportation, variety of butchering process, extent of logistic mobility and site use. The taphonomic modifications were classified to identify the accumulating agents and the diagenetic processes affecting the assemblage.

The results show how the Early Magdalenian economy at El Mirón cave was mainly based on red deer and ibex, which were hunted seasonally. According to the taphonomic results, the archaeological levels studied were formed under warmer and more humid climatic conditions.

Comparisons between the Early Magdalenian faunal assemblage and the Middle Magdalenian assemblage at El Mirón indicates continuity in selected hunted species, seasonality of occupation at the site and of butchering activities practiced. However, a decrease in animal bone density in the later levels indicates a change in site occupation.

The archeozoological data presented throughout this study suggests that paleoeconomic behavior in the Cantabrian region during Magdalenian was intrinsically affected by climate changes. These had a great effect on the settlement pattern and economic decisions of Iberian Late Glacial human populations.

ORAL

## 10. INITIAL MAGDALENIAN PENDANTS BELONGING TO LEVEL 17 MIRON CAVE (CANTABRIA): ANALYSIS AND EXPERIMENTATION.

*Varela Neila, Ángela - (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) angelavarelaneila6@hotmail.com*

*González Morales, Manuel R. - (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) moralesm@uni-*

*can.es*

*Straus, Lawrence G. - (University of New Mexico) lstraus@unm.edu*

Miron Cave is a cavity located in the valley of Asón, located in Monte Pando, which also Covalanas cave is. The entrance to the cave faces west, converging slightly below it the Gándara, Calera rivers and Asón.

It is 20 km away from the present coastline, and 260 meters above sea level. The proportions of the site are quite impressive, as the hall is 30 meters deep, between 6 and 14 wide and about 13 high. Within an upward jutting slope about 100 meters to the heart of Monte Pando is. The chronology covers the field is wide, from the Mousterian to the Bronze Age, and is divided into three distinct areas : cabin , barnyard and trench.

The present case is the so-called cottage, where all traces in this set were extracted .

The level 17 has been chronologically classified as belonging to the lower Magdalenian, with some dating to about 17,000 years.

This is a stratigraphic level characterized by intense chocolate color in which a large amount of lithic and bone industry were found. Associated with this chronological time was found in 2010 the first Magdalenian burial of the Iberian Peninsula as a secondary burial. Furthermore, these residues linked to a block schematic with deep engravings are found.

The material in this study is based on two groups: the teeth and marine molluscs.

On one side are two teeth of deer with different types of drilling or suspension, an atrophic canine and incisor. Conversely, the number of punched molluscs is quite superior. Seventeen seafood items are divided into two subgroups: scaphopods and gastropods.

The analysis of the parts has been made with binocular magnifier, while experimentation was made from existing marine mollusks.

In some human action parts are observed regarding boreholes or manipulations.

The comparison between the parts of the archaeological record and the experimental objects sheds some similarity, it just looks blurred by poor maintenance of some hanging by depositional processes.

As far as possible it has been observed that some of the pieces have marks from the use in necklaces or clothing. Conducting suspension and using these as decorative object is a fact level 17 Miron Cave. On one hand a variety of drilling techniques based on different types of molluscs and dental pieces obtained by these groups of checks. Thus, the techniques of making pendants are adapted to the characteristics of each object.

## 1. PINIONS TO EAT?. AGAIN?

Badal García, Ernestina - (Universidad de Valencia) Ernestina.badal@uv.es

Vidal Matutano, Paloma - (Universidad de Valencia) Paloma.vidal@uv.es

Sanchidrián Tortí, José Luis - (Universidad de Córdoba) gt-1satoj@uco.es

Jordá Pardo, Jesús Francisco - (UNED) jjorda@geo.uned.es

Aura tortosa, Emili Juan - (Universidad de Valencia) Emilio.aura@uv.es

There are known accurately the faunal resources consumed during the European Upper Paleolithic, but the plants resources are virtually unknown. This may be due to its nature, conservation features and archaeological methods employed in their recovery. Even today archaeological excavations are made where systematic sampling is not done looking for plant resources. Precisely because of the fragility of the plants and the lack of archaeobotanical results efforts should be made at all sampling sites.

Southern Iberia has provided some of the earliest references to the use of plants during the Middle and Upper Paleolithic European (cf. Gorham's and Nerja caves). Recent data indicate that plant resources had a significant place in the human diet long before the "broad spectrum revolution" proposed by Flannery. Ohalo II is perhaps the best example for the Eastern Mediterranean (Weiss et al., 2004). Our communication tries to demonstrate that a systematical and sustainable management of the vegetable resources during the Upper Paleolithic has taken place in the Western Mediterranean too, from the archaeobotanical results of a Solutrean level Cueva de Nerja (Málaga, Spain).

In the "Sala del Vestíbulo" at Nerja's Cave, a domestic fire was brought to light in A7 square, belonging to the level NV 8s. In this paper we present the botanical identification of over 5000 plant remains from the fireplace and the level that encompasses. The methods of analysis are purely mechanical. We used a Nikon Optiphot-100 dark/bright field incident light microscope for taxonomic identification of wood charcoal and Hitachi 4100 Scanning Electronic Microscope. Later, the material was selected for radiometric datation.

Two kinds of remains are presented: processed vegetables for human consumption and the charcoal used as

firewood. From the total of charred remains, 96% are from *Pinus pinea* cones and only 4% are wood charcoals. This ratio indicates the hearth's specificity in the pine-cones processing with the aim to obtain the pine nuts.

1 - Results of this fireplace show the importance of plant resources in the communities of the Upper Paleolithic in southern Europe. Moreover, these resources were also consumed in other regional sites even in earlier periods (Badal 1998, Mestcalfe 1950).

2 During the LGM umbrella pine (*Pinus pinea*) remained in the south of the Iberian Peninsula and was managed sustainably by hunter-gatherers owing to its firewood scarcity. Their presence in this context indicates warm climatic conditions in southern Iberia.

3. The wood used for fuel comes from other taxa that have not nutritional value as *Pinus nigra* / *P. sylvestris*, *Fabaceae*, *Cistus*, etc.

## 2. UPPER PLEISTOCENE - HOLOCENE VEGETATION CHANGES IN NAVALMAILLO ROCKSHELTER (PINILLA DEL VALLE, MADRID, SPAIN)

Ruiz-Zapata, Maria Blanca - (UAH) blanca.ruiz@uah.es

Gil García, María José - (UAH), Enrique Baquedano (MAR) mjose.gil@uah.es

Arsuaga, Juan Luis (UCM-ISCI) jlsuaga@isciii.es

Pérez-González, Alfredo (CENIEH) alfredo.perez@cenieh.es

Navalmaillo Rockshelter pollen data are presented, in order to know de vegetation and climate changes during Upper Pleistocene (levels: NVP-fluvial, NVP-H, NVP-F and levels  $\beta$ ,  $\alpha$ ), dated in  $71.685 \pm 5.082$  -  $77.230 \pm 6.016$ ), and Holocene (NVH), formed previously  $3690 \pm 60$  BP ( $4.170$ - $3.860$  cal BP) (Fig.1). The site is located at 1.114 mns, in the center of the high Lozoya valley; was formed by fluvial action (Lontaneres and Navalmaillo, tributarios of Lozoya river) that eroded Late Cretaceous dolomite outcrops. Vegetation point of view (Peinado Lorca y Rivas Martínez, 1987), the area is located in Guadarramense section, Supramediterraneo bioclimatic level, in *Luzulo forsteri-Querceto pyrenaicae* range (Fernández, 1988) with deciduous forest (*Quercus pyrenaica*) development under supramediterranea climate, subhumid continental. The pollen extraction followed the standard established protocols (acids and alkalis). The residuals were pollen-enriched through flotation in the Thoulet's dense liquor being later preserved in glycerin in eppendorf tubes. The

number of pollen grains in the samples oscillates between 300 pollen grain number; when the number was low (10-20) that they are figured in the pollen diagram as "presences". The statistics was made using TILIA® and TILIA-GRAPH®. In the samples with statistically significant number of pollen grains the AP/NAP logs were built as well as the rarefaction analysis, to determine the vegetation diversity. In order to make easier the data reading a synthetic pollinic diagram has been built including the most significant taxa (Fig.2).

Pollen data show a vegetation, from Pleistocene formed under climate conditions dry Mediterranean (NVP-river), which pass through a phase with a more moderate climate, with variations in the rate of moisture (NVP-H); progressively are installed more dry conditions (NVP-F) ending in other more severe and with lower temperatures ( $\beta$  levels and  $\alpha$ ). During the Holocene, the trend observed, within a Mediterranean climate, is toward the installation of conditions with increasing water scarcity, which define the progressive increase of excellence in the study area. The development of nitrophilous taxa and of the NPM coproflora affinity, show the existence of fauna in the territory, which alter the conditions food webs of the east. The relationship between AP and the NPM type 207 (cf. *Glomus fasciculatum*) curves, show the processes of deforestation of the territory, which favoring the reactivation of the erosive processes (*Concentricistes* or *Pseudoeschizaea circura*), especially on the basis of the 860 BP (910-690 cal BP).

Six-phase have been detected as a response to climate change, which, in general, express the transit towards the installation of cooler conditions during the upper Pleistocene. During the Holocene, the vegetation is defining the Mediterranean increased in the study area (Fig.2)

ORAL

### 3. THE LAST GLACIAL MAXIMUM CHARACTERIZED BY THE SMALL-MAMMAL ASSEMBLAGES IN SOUTHWESTERN EUROPE

López-García, Juan Manuel - (Università degli Studi di Ferrara) [lpzjmn@unife.it](mailto:lpzjmn@unife.it)

Bañuls-Cardona, Sandra - (Università degli Studi di Ferrara) [sandra.banulscardona@unife.it](mailto:sandra.banulscardona@unife.it)

Blain, Hugues-Alexandre - (IPHES, Institut Català de Paleocologia Humana i Evolució Social) [hablain@iphes.cat](mailto:hablain@iphes.cat)

Lozano-Fernández, Iván - (IPHES, Institut Català de Paleocologia Humana i Evolució Social) [ivanlozano@gmail.com](mailto:ivanlozano@gmail.com)

Cuenca-Bescós, Gloria - (Universidad de Zaragoza) [cuenca@unizar.es](mailto:cuenca@unizar.es)

We presents here a palaeoenvironmental and palaeoclimatic approach to the end of the Last Glacial Maximum (LGM) in the Iberian Peninsula on the basis of the small-mammal assemblages (insectivores, bats and rodents). The LGM is an important period in our climate history defined by the maximum extension of ice sheets between ca. 22 and 19 ka BP. In the Mediterranean region the LGM is characterized by humid conditions, which allow for the development of arboreal vegetation.

The small-mammal remains described in this study were recovered from five different archaeological sites within the Iberian Peninsula: El Mirón cave (Ramales de la Victoria, Cantabria), Valdavara-1 (Becerreá, Lugo), El Portalón (Sierra de Atapuerca, Burgos), l'Arbreda cave (Serinyà, Girona) and Sala de las Chimeneas (Maltravieso, Cáceres).

These studied sites shows a non-analogue association represented by species associated with mid-European climatic conditions, such as the voles *Chionomys nivalis*, *Microtus arvalis*, *Microtus agrestis* and *Microtus oeconomus*, together with species associated with Mediterranean requirements, such as *Iberomys cabreræ* and *Microtus (Terricola) duodecimcostatus*. These assemblages reveal that our ancestors lived in those moment under harsher climatic conditions than today in the vicinity of the studied sites, though not as rigorous as elsewhere in Europe, with mean annual temperatures lower than present and an environment dominated by wet open meadows.

Our results have been compared with other environmental and climatic proxies, such as, global isotope curves and palynological, anthracological and palaeoherpetological studies, showing that our data coincide with these previously published results, providing a scenario for the palaeoclimatic and palaeoenvironmental conditions that occurred during the LGM in the Iberian Peninsula.

ORAL

### 4. HUMAN SOCIO-NATURAL RELATIONS IN CENTRAL PORTUGAL AT THE LAST GLACIAL MAXIMUM

Haws, Jonathan (University of Louisville) <http://bit.ly/1rmDzmG>

During the Last Glacial Maximum, abrupt climate changes created highly variable paleoenvironments inhabited by human populations across the Iberian Peninsula. Pollen and sedimentary analyses from deep-sea cores off Portugal provide records of regional-scale paleoenvi-

ronmental responses to the climate shifts that punctuated the LGM. Archaeological assemblages from caves and rockshelters offer a more local-scale understanding of human-environment interactions during this period. One site in particular, Lapa do Picareiro, has yielded a continuous, stratified sedimentary sequence that provides a diachronic record for MIS 2 human occupation and environmental change.

Here I present data from the ongoing excavation including results of artifact, faunal, and sedimentological analyses of the Late Gravettian and Solutrean (Levels U-O). The taphonomic study of the faunal remains informs on local paleoenvironments and human diet choice during the LGM. Sedimentological analyses including magnetic susceptibility link the cave deposits with global scale records of LGM climate from the Greenland ice cores.

The mammalian taxa represented in the assemblage agree with those identified in other sites in the region. The large mammals represented show only very general changes through time due to their adaptive plasticity. The abundant and ubiquitous rabbit remains allow for quantitative comparisons with other sites for a more fine-grained analysis. In particular, they can be used as an independent test of Davis's (2007) "rabbit paleothermometer" hypothesis. The avian taxa are highly diverse, especially in Levels T and U. Amphibians are also well represented in these levels. The taphonomic analyses suggest inputs by humans, the Iberian lynx and raptorial and scavenging birds. Humans and lynx were likely responsible for most of the large mammal and rabbit as well as some birds. Raptorial birds likely preyed on the rodents, especially voles, amphibians and small birds. Vultures and carrion crows are present and also likely contributed many mammal remains. The fauna therefore derive from multiple sources and provide a balanced paleoenvironmental record. The magnetic susceptibility results agree with SST estimates derived from deep-sea records that suggest relatively warm, mild conditions during the LGM.

The results are used here to understand human responses to long-term environmental change in central Portugal. The spatial distribution of artifacts, animal bones and charcoal concentrations suggest sporadic, short term visits to the cave prior to and during the LGM. Inferences drawn from modern analogues of species ranges and habitat preferences of the faunal species suggest periods during which conditions may have been similar to the present, especially during the Late Gravettian.

ORAL

## 5. TECHNOLOGICAL ORGANIZATION AND SOCIAL NETWORKS DURING THE SOLUTREAN IN SOUTHERN AND WESTERN IBERIA

*Cascalheira, João - (Universidade do Algarve) jmcascalheira@ualg.pt*

*Bicho, Nuno - (Universidade do Algarve) nbicho@ualg.pt*

Geographically limited to the westernmost regions of Europe and with a relatively short chronological range when compared to other pan-european technocomplexes, the Solutrean has been traditionally regarded as one of the first examples of human refugia during the Late Pleistocene. Clusters of sites in particular regions of SW Europe seem to reveal that, similarly to what has been argued for animal and vegetal species, Solutrean settlement patterns form a scenario of isolated refugia that may have contracted and expanded their cultural influence as climate fluctuated.

In southern and western Iberia, during the later phases of the technocomplex, similarities between each of these niches have been long argued, based on the distribution of specific types of lithic weaponry, like shouldered and stemmed projectiles. However, these patterns of apparent cultural convergence have never been evaluated based on a detailed technological analysis of lithic assemblages that would permit to better understand between-region variability and, from a paleoanthropological perspective, shed some light on the systems of cultural transmission and the operation of hunter-gatherer information networks during the Last Glacial Maximum in Iberia.

This paper presents the results of a study of lithic technological organization during the final stages of the Solutrean in southern and western Iberia, drawing evidences from a total of five sites located between the Valencian region and the Portuguese Estremadura (Cova Parpalló, Cueva Ambrosio, Vale Boi, Vale Almoinha and Olival da Carneira). Statistical procedures are used to demonstrate patterns of variability across space and time, and help to define in which specific technological particularities the various eco-cultural niches were closer or further apart. Some similarities and dissimilarities between the contexts were identified which showed that: (1) when present, the similarities across regions are mostly visible in the size and type of the lithic blanks produced and, very rarely, in the specific technological attributes of their production; (2) some of these associations are supported by a solid chronometric framework, which shows on

one hand, that the industries that are similar from a typological point of view are contemporary and, secondly, that the traditional subdivision of the Mediterranean Solutrean in phases cannot be proven with the currently available data.

From a paleoanthropological standpoint, the results obtained show that the human adaptive system to the Last Glacial Maximum worked at two different, but complementary, scales. One that is essentially local, formed by several, well established eco-cultural niches, where communities have shared, and maintained, in the form of cultural traditions, techno-economic schemes that are best adapted to the particularities of the respective ecological contexts.

The other, suprarregional, related mainly with broad geographical social ties, maintained as an extra factor of the adaptive response to the impact of climate and landscape modifications, and functioning through sharing behaviors of stylistic concepts and typological elements.

*Baptista, João (UTAD) jrbaptist@utad.pt*

The construction of a dam in the region of Trás-os-Montes, Northeastern Portugal, gave origin to a project of archaeological excavation and survey which began in 2008. The work done is now bringing to light important data about the settling of this territory during the upper Paleolithic, which was known until now in the Côa valley area only.

Here we present the archaeological results obtained through the study of the quaternary deposits of the left bank of the Medal stream, located in the Sabor river valley which is one of the main tributaries of the Douro (Duro) river.

The lithic assemblage proceeded from a trench of 16 m<sup>2</sup>, in two separated layers originated from the remains of the same moment of settling during the Upper Paleolithic. The technological and typological study revealed an intensive use of low-angle covering retouch applied to the reduction of blanks thickness on a numerous of raw-material like quartz or flint, probably in the making of leaf points as shown by the presence of a fragment of a laurel leaf point. The blanks are reduced through a variety of technological strategies using several types of raw materials. We have recognized an unidirectional on quartzite strategy with cores presenting use wear traces on difference surfaces, mainly in the edge between the platform and the front of the core, which proofs the multi-functionality of these cores. In another hand there is evidence of other more complex strategies using cherts (both sedimentary and hydrothermals) aiming the production of specific shaped bladelets from prismatic cores, carinated cores or through bipolar technique using anvil cores. The absence of backed barbs from the assemblage is also an important fact to note.

Not being yet in possession of absolute dating results which can give us more secure data about the chronology collection, from the technological and typological study we can predict and attribution to the Solutrean complex.

The importance of the solutrean occupation documented on the left bank of the Medal stream is high having in mind that the archaeological remains in this context are scarce in Northwest of Iberia, largely due to the geomorphological processes during the Last Glacial Maximum. The left bank of the Medal stream is subsequently one of the most relevant solutrean stratigraphical contexts known in this region.

---

ORAL

## 7. UNRECOGNIZABLE: THE ICE AGE WORLD OF THE SOLUTREAN

*Straus, Lawrence Guy - lstraus@unm.edu (Department of Anthropology, University of New Mexico, Albuquerque, NM 87131 USA)*

The geographical success of the diverse Aurignacian cultures was consolidated by an apparently more unified network of Gravettian societies that stretched from Wales to Russia and that accomplished the repopulation of southern Iberia by *Homo sapiens sapiens*. Ironically, the appearance of characteristic Gravettian technologies to-

gether with iconic burial practices and (less widespread) "Venus" figurines, seems to have coincided with the climatic deterioration that marked the onset of MIS 2. This downturn became particularly sharp during the Heinrich 3 Event, which in turn was followed shortly by Heinrich 2 and the beginning of the Last Glacial Maximum. While humans were able to deal with conditions in the upper-middle latitudes of southern Britain, northern France, the Low Countries, Germany, southern Poland and the former Czechoslovakia in early MIS 2 by means of a creative cultural explosion ranging from mammoth bone houses to eyed needles to careful settlement choices and elaborate mobility strategies to an overarchingly cohesive belief system and network of social relations, this geographic success was not to last as conditions worsened. Cold and aridity south of the advancing ice sheets led to landscapes ranging from polar desert to steppe-like environments so poor in fodder as to become bereft of game and hence humans.

Although the ecological frontier between these glacial barren grounds and the far richer tundra-grasslands of the middle latitudes fluctuated during the course of the LGM (and with the fluctuations came brief, ephemeral northerly re-advances of human territories in unglaciated areas of Germany and Switzerland), fundamentally by the end of the Gravettian (ca. 24-25 cal kya) the human population of western Europe was reduced to unevenly distributed territories mainly in SW and SE France and peripheries of the Iberian Peninsula. Similarly, in central Europe, the progressive Gravettian abandonment of the North European Plain resulted in an LGM situation in which human populations survived in refugia in the Italian and Balkan peninsulas. Despite the pleniglacial cold, the amount of insolation at the middle latitudes provided a growing season long enough, especially in more humid coastal and near-coastal regions, for there to be ample and highly diverse game, which was the critical factor in human survival, although even some southern regions (Les Landes, the high *mesetas* Old Castile) were often largely unsuitable for human habitation and thus were empty. In SW Europe, the technologies of the human survivors of the LGM are known as "Solutrean" and, in Italy and the Balkans, as Early Epigravettian.

This paper will examine the environments in which the Solutrean technologies and adaptive strategies developed the indications for the selection of local settlement concentrations in the most favorable settings, the evidence for regional cultural identities, and hints of inter-regional social relations driven, no doubt, by demographic imperatives under possible population "bottle-neck" conditions.

ORAL

## 8. THE DAWN OF THE LAST GLACIAL MAXIMUM IN THE CANTABRIAN REGION (NORTHERN SPAIN): THE PALEOENVIRONMENTAL DATA IN ITS CHRONOLOGICAL AND CULTURAL CONTEXT

*Prieto, Alejandro - (Universidad del País Vasco) alejandro.prieto@ehu.es*

*Calvo, Aitor - (Universidad del País Vasco) aitor.calvo@ehu.es*

*García-Ibaibarriaga, Naroa - (Universidad del País Vasco) naroa.garcia@ehu.es*

*Iriarte, María-José - (Universidad del País Vasco) mariajose.iriarte@ehu.es*

*Castaños, Jone - (Universidad del País Vasco) jcastanosdlf@yahoo.es*

*Castaños, Pedro - (Aranzadi) pedrocastanos@yahoo.es*

The transition between the Gravettian and the solutrean in the Cantabrian Region still has several open questions of various kinds. Among them is particularly relevant the relationship between the beginning of the Last Glacial Maximum (c. 23 to 16 kyBP, between H2 and H1 events) and this important cultural change. This work aims to delve into this issue, building a multidisciplinary reference framework based on the interrelationship of paleoenvironmental, chronological and cultural data available for the period between 22.5 to 17.5 kyBP

For this work, we have used as a basis the chronological framework recently developed (Calvo and Prieto, in press) and based on the OxCal 4.2 software. From this, we have integrated the information available from paleoenvironmental proxies (microfauna, macrofauna, sedimentology and palynology) and various techno-complexes. This will allow us to approach to the paleoenvironmental evolution of the Cantabrian Region over this period and to observe his possible link with the technological changes that took place in it. Collaterally, also will allow us to reflect on the correspondences or differences between the paleoclimatic evolution of the Cantabrian coast and the global paleoclimatic framework based on marine isotopic stages. Finally, this work represent the continuity and combine different jobs presented in the II International Congress on the Solutrean (Velez Blanco, Almería, 25-28 June 2012)

ORAL

## 9. LIVING IN THE EDGE? COVA GRAN AND HUMAN PRESENCE IN THE SOUTHERN PYRENEES IN THE LGM

*Mora Torcal, Rafael - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UAB) rafael.mora@uab.cat*

*Benito Calvo, Alfonso - (CENIEH) alfonso.benito@cenieh.es*

*Martínez Moreno, Jorge - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UA) jorge.martinez@uab.cat*

*Vega Bolibar, Susana - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UA) susana.vega@uab.cat*

Human presence in the southern Pyrenees during the Late Glacial Maximum (LGM) was poorly known until recent years, however this situation is changing rapidly. New sites excavated in the core and periphery of the Pyrenees are opening new perspectives to analyze human adaptations in this area along this critical climatic period. Cova Gran de Santa Linya (Southeastern Prepyrenees) contains large but fragmentary LGM sequence. Detailed analysis of contextual, techno-typological and radiometric data contributes to characterize hunter-gatherer lifestyle in the Southeastern Pyrenees.

We analyze the stratigraphy and LGM archaeological resolution in Cova Gran. The contextual attributes lead us to discuss the role of syn/post-depositional processes and their impact on the archaeological record. We also present technological and radiometric trends in the excavated areas.

Human presence in Cova Gran during MIS2 is documented in all excavated areas. Cova Gran confirms the presence of hunter-gatherers post-date the Maximum Late Glacial, but recent discoveries suggest previous human settlement during the LGM.

Syn/post depositional processes played an important role affecting the configuration of the archaeological record. These observations can help to understand the apparent scarce human presence during the LGM in the Southeastern Pyrenees.

Contextual discussion and their comparison of the archaeological data from other sites in the Southeastern Pyrenees, suggest that Cova Gran was repeatedly visited along the LGM. The identification of different techno-complexes in the site implies diverse cultural traditions over a long time scale in a landscape usually considered inhospitable, or with scarce human presence. These new data increase our knowledge of this process, opening

interesting perspectives for analyzing the human presence at the southern Pyrenees in the LGM.

ORAL

## 10. CENTRAL IBERIA AROUND THE LAST GLACIAL MAXIMUM: HOPES AND PROSPECTS

*Alcaraz-Castaño, Manuel - (Universidad de Alcalá) mac0088@hotmail.com*

Historically, the inner territories of the Iberian Peninsula, dominated by the upland regions of the Central Spanish plateau and the Central System range, have been depicted as a nearly depopulated area during the Late Pleniglacial or Marine Isotopic Stage 2, and especially during the Last Glacial Maximum. This is in contrast with the common consideration of the Iberian coastal areas as part of a southwestern European ecological refugium during the harshest periods of the last glacial cycle. This model has been affirmed in recent surveys, and only very recently has faced some important challenges, coming from new field data. Here we discuss these new data and propose new hypotheses and avenues of research on the human-environment interactions in Central Iberia around the LGM.

The aforementioned data come basically from 2 sites located in the Tagus River basin: (1) *Las Delicias*, a classic open-air site in the Manzanares valley (Madrid) that has been recently re-excavated, and (2) *Peña Capón*, a rock shelter close to the southern foothills of the Central System range (Sorbe valley, Guadalajara), where recent analyses of lithic and bone materials have been developed. Geoarchaeological, chronometric and palaeoecological information coming from these sites allow positioning preliminary hypotheses concerning the settlement of Central Iberia during MIS 2, and namely during Solutrean times.

Las Delicias hosts a Middle or Upper Solutrean lithic workshop, and the Peña Capón rock shelter functioned as a hunting camp during several moments within MIS 2, including at least Protosolutrean and Middle Solutrean times. These data, together with other Solutrean findings in the region, imply the existence of territorial organization, and hence some degree of stable settlement. Therefore, they call into question the classic model of the *Meseta* as a depopulated or crossing area during the Late Pleniglacial. In contrast, we hypothesize that the human occupation of Central Iberia during MIS 2 was more stable than previously thought, and probably included

the settlement of some areas during the LGM and other harsh climatic and environmental events of the last glacial cycle.

It is soon to conclude whether these human occupations (1) were related to relatively favorable episodes around or within the LGM, (2) were favored by the existence of ecological refugia, or (3) reflect the adaptability of hunter-gatherers to harsh environments. Although current data does not allow to decide on such possibilities, future field work, planned to be done very soon, will contribute to investigate these and other key topics related to human-environment interactions around the LGM. This research will focus on site formation processes, both at the macroscopic and microscopic level, and also on gaining more chronometric and palaeoecological data at Las Delicias and Peña Capón.

Current information is still insufficient for building solid models on human-environment interactions during the LGM in Central Iberia. However, it allows, for the first time in the discipline's history, to propose hypotheses based on valuable empirical data. Our imminent new field research on the Late Pleniglacial of this area will contribute to increase our knowledge of a long-standing underestimated archaeological record.

ORAL

**11. THE SOLUTREAN SITE OF LA CUEVA DE AMBROSIO. NEW PERSPECTIVES OF THIS CULTURAL TECHNOCOMPLEX IN THE SOUTHEASTERN OF THE IBERIAN PENINSULA.**

*Ripoll López, Sergio - (UNED) sripoll@geo.uned.es*  
*Muñoz Ibáñez, Francisco Javier - (UNED) fjmunoz@geo.uned.es*  
*Jordá Pardo, Jesús Francisco - (UNED) jjorda@geo.uned.es*  
*Yraverdra Sainz de los Terreros, José - (Universidad Complutense) jyavedr@ghis.ucm.es*  
*Martín Lerma, Ignacio - (Universidad de Murcia) ignacio.martin@um.es*

The last investigations made during the excavation of the different levels at this important site to study the solutrean in the southeast of the Iberian Peninsula, have permitted us to make some precisions on its chronostratigraphic position in the Upper Pleistocene.

The calibration of a new radiocarbon date for the level IV (Upper Solutrean) and other six new dates (5 of them AMS) for the level II (Final Upper Solutrean) allows us to

place this two cultural phases between the Greenland Stadial GS3 (end of OIS 3) and the end of the Greenland Intersadial GI 2, with a greater occupation of level II after the Heinrich Event H2, agreeing with the intersadial that come just before the last glacial maximum (GS 2). This new data modify clearly the before existing dates, making the whole record very much older. On the other side, the discovery of decorated panels with engravings and paintings, recovered by Upper Solutrean sediments, allow us to place these representations, with great precision, in the Medium Solutrean (level VI) that must be placed between the GI 5 and the G 3. The excavation of the area that we call the microstratigraphy, included in level II (Final Upper Solutrean or Evolved Upper Solutrean), has provided 21 double layers of hearts, one of them with a stone structure and thousands of very typical solutrean flint implements that includes the characteristic barbed and tanged points, shouldered points and leaf points.

The investigations carried out in the Laboratorio de Estudios Paleolíticos with this arrowheads, shows that they must be thrown with a bow. The results show that are morphologically and metric well suited to be thrown by a bow. The replicas had a perfect ballistic behaviour, so we can think that the origin of bow can be earlier than traditionally thought.

Along all the solutrean levels the hunting strategies are kept stable enough: goat, horse, deer and rabbit. Provided that significant changes are observed neither in the received species nor in his percentage the appearance of new types of projectile points might be related to new systems of hafting and propulsion, which in turn they would be a part of an adaptive strategy to the new environmental conditions that believe themselves in western Europe with the LGM and that would have as aim assure or increase the possibilities of receiving the pieces of hunt.

ORAL

**12. BEYOND SOLUTREAN POINT TYPES: TECHNOLOGICAL ORGANISATION AND BEHAVIOURAL IMPLICATIONS**

*Schmidt, Isabell - (Institute of Prehistoric Archaeology, University of Cologne) isabell.schmidt@uni-koeln.de*

Most researchers concerned with hunter-gatherers of the Last Glacial Maximum agree that the pace in which characteristic Solutrean technologies – bifacial shaping and pressure retouch as well as related heat treatment

of raw materials – appear in the record is well beyond the resolution of available archaeological data. Similarly, the observed appearance of regionally distinct Upper Solutrean point types on the Iberian Peninsula remains an unresolved phenomenon, although recent modelling of ecological and cultural data indicates that some geographical patterns correspond to environmental variables.

The present study intended to look at Solutrean points from a different perspective – that is the technological organisation and technological strategies involved in the production, design and use of these tools – to illuminate variability and reasons for the synchronic variability beyond the final tool design and point type distribution. More than 1200 points from almost 80 sites on the Iberian Peninsula were studied, covering all main settlement areas and point types dated to 25.-20.000 calibrated years BP. The analytical methods applied to the material were organized within a biography model and comprised the analysis of raw material, production sequences and technological strategies, morphometrics and shape as well as macroscopic fractures and use-wear. To trace and structure technological organisation of acquisition, production and use, the study draws from the conceptual framework of risk and cost in the study of lithic technological organisation. It explores technological strategies applied during individual life-histories of the functionally similar, but typologically distinct tools. They touch upon aspects of behaviour, technology and tool design. The results obtained by the multi-stranded set of analytical methods were summarised into point-type profiles and subsequently compared within and between environmentally distinct regions.

This comparative approach allowed identifying adaptive strategies within the processes of making, using and re-using these specific tools that clearly distinguish functionally similar tools from northern and southern Iberia. The obtained data suggest that synchronic variability of Solutrean points does not merely relates to stylistic variations in final tool design, but that regional differences are deeply rooted in distinct technological strategies of tool making and tool using behaviour, reflecting distinct subsistence- and mobility patterns among hunter-gatherer groups of the Last Glacial Maximum.

*Kageyama, Masa - (LSCE) masa.kageyama@lsce.ipsl.fr*

*Vrac, Mathieu - (LSCE) mathieu.vrac@lsce.ipsl.fr*

*Ramstein, Gilles - (LSCE), Team HDRG (FQRSC) gilles.ramstein@lsce.ipsl.fr*

This paper explores the impact of climate variability on the spatial behaviour of human populations. Climate variability is an important component of environmental risk and one of the most important challenges our species will face in the near future. We focus on the Last Glacial Maximum in Western Europe, examining how past populations reacted to this challenge.

High-resolution climate simulations are produced using outputs from the IPSL-CM5 and a downscaling method (GAM). The distribution of known archaeological sites is used as a proxy for the distribution of human populations.

The results help us better understand the spatial distribution of human population during the Last Glacial Maximum and demonstrates the rich potential offered by the archaeological record as a means of testing the sensitivity of human systems to different thresholds of environmental risk.

### 14. POPULATION DYNAMICS IN WESTERN EUROPE DURING THE LAST GLACIAL MAXIMUM

*Maier, Andreas - (Friedrich-Alexander-Universität Erlangen-Nürnberg) and.maier@fau.de*

*Kretschmer, Inga - (State Office for Cultural Heritage Baden-Wuerttemberg) inga.kretschmer@rps.bwl.de*

*Schmidt, Isabell - (Institute of Prehistoric Archaeology, University of Cologne) isabell.schmidt@uni-koeln.de*

*Zimmermann, Andreas - (Institute of Prehistoric Archaeology, University of Cologne) a.zimmermann@uni-koeln.de*

Knowledge on demographic developments is vital for the understanding of social processes and cultural

change. To shed new light on this crucial aspect, we present current research – carried out within the framework of the CRC 806 “Our Way to Europe”, funded by the German Research Foundation (DFG) – on population dynamics in Western Europe during the Last Glacial Maximum. We use an upscaling approach based on site density and raw material catchments for our estimations. A consistent set of GIS-methods is used to delimit regions of intensive settlement activities against areas which were visited only in an ephemeral way or were avoided completely. Most important for the identification of these regions is the distance-based statistical analysis of site density and its visualisation by isolines. Information on raw material catchments is used to deduce foraging areas. Overlapping or mutually exclusive foraging areas and the collective or non-collective exploitation of raw material sources provide insights into interaction patterns of the people involved. Extensive overlaps of foraging areas indicate a joint exploitation of resources by the same group of people, whereas mutually exclusive foraging areas suggest exploitation by different groups. These foraging areas are – with regard to ethnographic observations – thought to represent annually aggregating groups consisting of several smaller groups living dispersed throughout a certain time of the year. Based on habitat and subsistence, several ethnographically known hunter-gatherer populations are selected and the median number of persons per aggregated and dispersed group is calculated. Applying these numbers to the case study at hand, population densities are calculated for different scale levels and for both the number of people only within the populated areas as well as within the whole of Western Europe. By doing so, we estimate regionally differentiated population densities and absolute numbers of people from a regional up to a continental scale. A spatial and diachronic comparison with equivalent data for the periods of the preceding Gravettian as well as for the succeeding Magdalenian allows identifying changes in the patterns of population dynamics. Based on these observations, we set up hypotheses about sources, trajectories and sink-areas of dispersal processes and discuss pull- and push-factors of migratory events in the context of the Last Glacial Maximum. Thereby this study contributes to our understanding of the social and cultural development as well as human-environment interactions during this period of cold climatic conditions in Europe.

POSTER

## 15. POSSIBLE CAUSES OF THE DISAPPEARANCE OF LARGE CARNIVORES IN THE IBERIAN PENINSULA, HUMANS VS CLIMATE

Sauqué, Víctor - (Universidad de Zaragoza)  
vsauque@gmail.com

Rabal-Garcés, Raquel - (Universidad de Zaragoza) rrabalg@gmail.com

Cuenca-Bescós, Gloria - (Universidad de Zaragoza)  
cuenca@unizar.es

The Iberian Peninsula (IP), due to its geographical configuration, displays two distinct climatic geographic ranges, the Eurosiberian and the Mediterranean (González-Sampéiz et al., 2010), this coupled with the rich paleontological record makes it an exceptional area for the study of Late Pleistocene. During this period the IP present a high number of climatic changes but only some climatic changes might have left signal in the archaeological and paleontological record. This is why we focus in the faunal changes during MIS3-MIS2, and also in the transition Middle to the Upper Paleolithic where IP plays an important role, as the southern part of the last refuge for Neanderthals with anatomically modern humans existing in the north. Through a comparative study of the fauna composition will be defined the causes which conducted to the disappearing of large carnivores.

We have built up a database collecting the faunal lists from 116 localities in the IP. For the present study, only sites with NISP greater than 100 and radiometric dates and/or archaeological record have been considered. We have divided the deposits by geographical and climatic situation and age. For age, we consider each of the following time periods of the Late Pleistocene: MIS3 (Middle Paleolithic) (60-40 ka), MIS3 (Early Upper Paleolithic), (c.40–26 ka), MIS2 LGM (Last Glacial Maximum) (c.26–16 ka), Gravettian–Solutrean and MIS2 post-glacial (c.16–11,5 ka), Magdalenian. Also we use NISP as abundance/scarceness indicator, and compare the percentages of NISP for each taxon and for each region and period.

In the Eurosiberian region *Ursus spelaeus* is the most abundant carnivore during MIS3. Large carnivores were not greatly affected by the change of humanity, from neandertals to early homo, during the transit MP–EUP and in this region the main change of carnivore composition was observed in the LGM when the *U. spelaeus* disappeared and *Crocuta crocuta*, *Panthera pardus*, and *Cuon alpinus* increased. In the Mediterranean region carnivores were common during MIS3 (MP) and they began

to decrease in the transition MP-EUP, this process continued and in the LGM the large carnivores were completely missed.

Large carnivores have a different story in each climatic region of IP and the change to UP affect the carnivores in a different way in each region. Eurosiberian region acted as a refugial for large carnivores until MIS2 Magdalenian.

Three Neolithic sites from Northern Morocco, Ifri Oudadane, Khil and Kaf Taht El-Ghar, have been studied as part of the AGRIWESTMED (ERC) project on the origins and spread of agriculture in the Western Mediterranean. The systematic recovery and flotation of sediments in these three sites has provided a broad assemblage of seed and pollen remains of domestic plants (both cereals and pulses) of Southwest Asian origin since Early Neolithic levels.

The plants that have been identified are: free threshing wheat (*Triticum aestivum/durum*), hard wheat (*T. durum*), einkorn (*T. monococcum*), emmer (*T. dicoccum*), naked barley (*Hordeum vulgare* var. *nudum*), hulled barley (*Hordeum vulgare* subsp. *vulgare*), broad bean (*Vicia faba*), lentil (*Lens culinaris*), pea (*Pisum sativum*) and grass pea (*Lathyrus* sp.). A set of radiocarbon dates on those seeds has allowed confirming the onset of agriculture in this region since at least the second half of the 6<sup>th</sup> millennium cal BC.

There are strong similarities with the Iberian Peninsula in both radiocarbon dates on seeds and the range of culti-

vated plants identified suggesting that both areas were probably part of the same process of agriculture spread.

Benchernine, Redha (*CNRPAH, Algeria*)

Hachi, Slimane (*CNRPAH, Algeria*) [slimhachi@yahoo.fr](mailto:slimhachi@yahoo.fr)

GLD1 cave belongs to the large karst network of Adrar Gueldaman limestone ridges of the northwestern Babor Mountains of the Tellian region (Northern Algeria). Recent excavations conducted by the Centre National de Recherches Préhistoriques, Anthropologiques et Historiques, Algeria (CNRPAH), since 2010 have provided a rich archaeological material. Eight samples of wood charcoal from the excavated sectors were radiocarbon dated by AMS giving median dates ranging from 1484 cal BP to 17031 cal BP.

This paper presents the results of archaeozoological studies on the vertebrate remains from Neolithic levels situated around the VI and VII millennia BP. Morphological and biometric analyses reveal the presence of domestic mammals, such as sheep and goat, at VII millennia BP. This evidence is particularly important and will bring new insights into the emergence and development of the Neolithic in North Africa.

*Zoughlami, Jamel (Institut National du Patrimoine, Tunis)  
jamel.zoughlami@yahoo.fr*

Au Maghreb oriental, le développement des groupes de chasseurs-cueilleurs épipaléolithiques et le passage d'une économie de prédation à une économie de production commence à être mieux connu grâce aux recherches récentes acquises sur plusieurs sites tunisiens. La séquence d'occupations capsiniennes mise récemment en évidence à SHM-1, sur la côte orientale de la Tunisie, montre, au cours des trois derniers niveaux (première moitié du 6<sup>e</sup> millénaire cal BC), l'acquisition d'une série d'innovations techniques, généralement associés au Néolithique, avec le maintien d'une économie de prédation dans le cadre d'occupations sédentaires. Dans la dorsale tunisienne, plusieurs établissements localisés autour de Doukanet el Khoutifa (Makhtar) montrent l'émergence à partir de la deuxième moitié du 6<sup>ème</sup> millénaire cal BC d'une économie pastorale, avec des influences marquées, continentales et méridionales. Ces premières données préliminaires permettent de proposer des pistes de réflexion inédites pour la néolithisation de la Tunisie et de la Méditerranée centrale.

#### **4. OXEN WITHOUT HERDSMEN. ANIMAL AND HUMAN BEINGS IN THE PREHISTORIC ROCK-ART OF THE WESTERN SAHARA**

*Soler, Joaquim (Universitat de Girona) joaquim.soler@udg.edu*

*Soler, Narcís (Universitat de Girona) narcis.soler@udg.edu*

Among the different periods defined in the Western Saharan rock-art it is hard to find a clearly pastoral stage. Although it is common to detect human beings in relation to animals, those are usually wild ones (giraffes, rhinoceros, elephants, antelopes...). Only a few examples represent scenes involving oxen and men, and not always in a pastoral way. Being generally admitted that all the Saharan rock-art begins in the Neolithic, the Western Sahara seems an intriguing place to test the real existence of an art of hunters followed by an art of herdsmen during the Holocene.

In 1995, after the cease-fire of 1992, the Universitat de Girona, in cooperation with the Ministry of Culture of the Sahrawi republic, started over the research on the Western Sahara. Because the research has been conducted in areas not well known during the colonial era, the materials can contribute with new data to the discussion. Hun-

dreds of painted rock-shelters and engraved slabs have been recorded and reproduced. The stylistic methods employed in the study have proved useful to define and order chronologically new regional styles, which now provide information about the technological, economical, ideological and ecological change on the western edge of the Sahara.

If we focus on the Western Sahara data, it not seems possible to clearly define an art of herdsmen because most of the scenes should be attributed to hunter-gatherer communities. On the other hand, our surveys and excavations show that abundant and old ceramic Neolithic traditions were present all along the Western Sahara. Therefore if we pretend to maintain such analytical categories, we should be also prepared to accept that some of the prehistoric Saharan rock-art could be older than what is generally believed. Or to accept that the Western Saharan rock-art, in contrast to some styles from Central Sahara, is not directly mirroring the daily life of their authors.

In our opinion in Western Saharan the iconographic evidence is not a solid argument to infer the economical basis of the authors. The characteristics and chronology of the Western Sahara Neolithic must be found through archaeological excavation.

ORAL

#### **5. DE L'ART AU CONTEXTE : FAUNE DOMESTIQUE DES REPRÉSENTATIONS RUPESTRES DE L'ATLAS SAHARIEN EN ALGÉRIE**

*Amara, Iddir (Université d'Alger) amara\_iddir@yahoo.fr*

*Roubet, Colette (MNHN-IPH) croubet@mnhn.fr*

En Algérie septentrionale, sur les parois gravées et peintes de l'Atlas saharien les faunes sauvages (éléphants, rhinocéros, carnivores, *Pelorovis*, équidés, mouflons, gazelles, antilopes, sangliers, autruches etc.) et domestiques (Caprinés : moutons, chèvres ; bovins) et sont présentent ensemble, durant la période pré-Holocène et Holocène. Les sites d'occupations ne sont que des haltes au pied des parois.

Les parois situées en plein air couvrent, d'est en ouest, les massifs atlasiques des Némencha, Aurès, Ouled Nail, du djebel Amour et des monts des Ksour. Des passages sud-nord et est-ouest isolent chacun de ces massifs et permettent de relier les régions sahariennes aux hautes plaines. L'eau y est partout abondante (sources,

oueds et plans d'eaux (douce et salée) L'analyse des représentations a consisté à isoler le bétail domestique des scènes de la vie sauvage. Les restes osseux résultant de consommation alimentaire ne sont actuellement connus que dans les grottes de la partie orientale atlasique.

Pour la faune sauvage, les scènes gravées signalent : l'agressivité, l'affrontement, la poursuite, la mobilité, etc. Pour la faune domestique on n'a relevé aucune scène de troupeau, pas d'isolement des caprinés par rapport aux bovinés, peu de chiens et pas de porcs, pas d'enclos et pas de rassemblement communautaire. L'attitude statique du bélier porteur d'un ornement sur la tête et d'un collier tressé au cou, précédé ou suivie d'un berger sert de trait d'union, d'est en ouest, entre ces massifs et la culture pastorale qui s'est répandue dans l'Atlas saharien. Ces représentations non datées, se singularisent de celles observées sur les massifs sahariens durant l'Holocène.

L'Atlas Saharien en Algérie porte des manifestations d'une faune sauvage et domestique, mal ou pas du tout attestée dans les sites de plein air. Elle est réduite à une faune domestique dans l'Aurès et les Nemencha. Le registre domestique est indissociable du registre sauvage. Et le pastoralisme primitif qui s'est répandu prend en compte l'incertitude et les dangers d'un milieu sauvage agressif. C'est durant cette période Holocène que se manifestent les remontées sahariennes des populations nomades atteintes comme les faunes par les modifications climatiques (aridité).

## 6. THE BONE INDUSTRY FROM THE CAPSIAN AND NEOLITHIC CONTEXTS OF EASTERN MAGHREB: A TECHNOLOGICAL AND FUNCTIONAL APPROACH

*Petrullo, Giacomina (Università degli studi di Roma La Sapienza e Université Paris X Nanterre La Defense) minapetrullo@libero.it*

The work I am going to present was carried out within the framework of my Ph.D. research. I have investigated the exploitation of hard faunal materials coming from some pre-pastoral and pastoral contexts of the Eastern Maghreb, defined as Capsian and Neolithic of Capsian Tradition. The specific focus of my analyses is on material from excavations carried out by J. Morel and T. Rivière during the first half of 20th century in the regions of Tébessa and Aurès. For the first time, these collections have been investigated from a technological and functional perspective.

The multidisciplinary approach I have applied involved the identification and characterisation of the technological scars on débitage and comparison with those visible on artefacts from an experimental reference collection.

Each element underwent a progressive scale of observation, from the naked eye up to 130X magnification under a stereomicroscope. This allowed the identification of specific manufacturing techniques, processes of matrix partition and manufacturing methods for the production of certain

morpho-types. In parallel, the study of the deformation of the tool's active edge and the observation, under reflected-light microscope, of the microwear allowed a better understanding of the types of materials with which some of the tools came in to contact.

The reconstruction of the *chaîne opératoire* and, more generally, of the production processes of hard faunal materials coming from the analysed contexts, yielded a new contribution to the definition of the Eastern Maghreb food-producing communities. The synchronic analysis of the pre-pastoral contexts highlighted a certain degree of homogeneity in the technical and economic choices of groups of people in the Eastern Maghreb. At the same time, the diachronic analysis has highlighted the element of continuity and discontinuity between pre-pastoral and pastoral contexts.

I believe that the application of this approach to other collections of worked bone artefacts coming from the Maghreb would provide new insights to the still-open debate about the relationship between groups of the pre-pastoral Capsian and the pastoral Neolithic of Capsian Tradition.

POSTER

## 7. AAARC - AFRICAN ARCHAEOLOGY ARCHIVE COLOGNE, AN OPEN ACCESS ONLINE ARCHIVE ON THE ARCHAEOLOGY AND ENVIRONMENTAL HISTORY OF AFRICA

*Lenssen-Erz, Tilman (University of Cologne) lenssen.ertz@uni-koeln.de*

For more than 50 years the African Archaeology at the University of Cologne has conducted field research in various parts of Africa, particularly in the Eastern Sahara and in Namibia. The focus was on environmental history

and on rock art, with internationally renowned projects like B.O.S. (settlement history of eastern Sahara), ACACIA and "Rock Paintings of the Upper Brandberg". In the projects after 1990 there was close cooperation with the Heinrich-Barth-Institut (e.V.) which so far published six voluminous catalogues of rock art and 26 monographs on African archaeology.

Most of the materials accumulated in the research projects are not digital in origin and are now digitized and made openly accessible in the new digital online archive AAArC (African Archaeology Archive Cologne). Besides being a repository for tens of thousands of pictures, also whole documentations of excavation are made accessible here and the entire catalogue of the surveys in the Eastern Sahara by the pioneering project B.O.S. in the 1980s.

ORAL

## 8. THE EXPLOITATION OF WILD PLANTS IN THE MID HOLOCENE CONTEXTS OF NORTH AFRICA. USE-WEAR AND RESIDUE ANALYSIS ON GRINDING STONES FROM THE HAUA FTEAH CAVE, LIBYA

*Lucarini, Giulio (McDonald Institute for Archaeological Research - University of Cambridge) [gl374@cam.ac.uk](mailto:gl374@cam.ac.uk)  
Radini, Anita (University of York) [ar611@york.ac.uk](mailto:ar611@york.ac.uk)  
Barton, Huw (University of Leicester) [hjb15@le.ac.uk](mailto:hjb15@le.ac.uk)  
Morales, Jacob (independent scholar)*

The North African region offers up essential data for the study of the origins of the earliest forms of plant exploitation. Data available from several Saharan and coastal areas in the region have revealed that the arrival of domestic wheat and barley from the Levant during the Mid Holocene did not replace the exploitation of autochthonous wild plants, especially grasses. Studies have shown that only in rare cases did domesticated and wild plants integrate with each other. The Neolithic layers of the Haua Fteah cave, in Cyrenaica (Northern Libya), have so far produced archaeobotanical assemblages exclusively made up of wild species.

The appearance of grinding stones in the Neolithic layers of the cave may indicate a certain level of behavioural change and the adoption of new economic strategies, relying more strongly on plant exploitation. It is generally presumed that a direct link exists between stone tool morphology and its function, for example, plant processing in the case of grinding stones. However, this assumption still needs to be tested using the most innovative

methods for the functional analysis of stone tools. These methods may allow us to obtain significant new information as to how tools were originally used.

Traces of use-wear on the grinding stones from the Haua Fteah have been studied with low power microscopy to help clarify their function. Moreover, residue analysis, and in particular starch analysis, only rarely applied in North African contexts, was carried out on a sample of tools, in order to determine the types of plants processed by the Holocene communities in the cave.

The importance of wild plants in the economy of North African prehistoric groups has often been underestimated, especially after the Levantine domesticated crops were imported. Here we confirm their role as a primary food source in Cyrenaica during the Mid Holocene.

ORAL

## 9. THE NEOLITHIC OF CYRENAICA (NORTH-EAST LIBYA): NEW ENLIGHTENMENTS FROM RECENT RESEARCH

*de Faucamberge, Elodie (UMR 7041) [elodie.de-faucamberge@mae.u-paris10.fr](mailto:elodie.de-faucamberge@mae.u-paris10.fr)*

With the support of the Department of the Antiquities of Libya, the recent research undertaken in Cyrenaica these last years by the University of Cambridge (Cyrenaican Prehistory Project) on one hand, and by the French archaeological mission in Libya on the other hand, have substantially improved our knowledge of the beginning of food production in this north-eastern African region. Due to the lack of prehistoric research in the second half of the 20<sup>th</sup> century, little information on the Cyrenaican Neolithic is available (only two complete excavations with absolute datings) and restricted to a narrow area (the northern coast).

In the Haua Fteah cave, the first results obtained by C. McBurney in the 1950's have shown a Neolithic sequence starting around 6 800 uncalibrated BP with domesticated animals and pottery. Nearly fifty years later, the CPP reexamining McBurney's excavation has provided a new set of datings for the Holocene period and achieved unprecedented botanical studies. The rock shelter of Abu Tamsa, studied by a French team since 2006, has delivered another stratigraphic sequence for the Neolithic period.

If plant domestication up to now has not been re-

corded with certainty for prehistoric times, it remains highly probable owing to the huge agricultural potential of northern Cyrenaica. Abu Tamsa's assemblage has confirmed with the new data from Haua Fteah that ovicaprins husbandry started in the area during the first half of the 6<sup>th</sup> millennium cal BC therefore indicating a rapid diffusion of the Near-eastern flocks from Egypt to North-east Libya. Its sequence has also displayed a slightly earlier beginning of pottery production, i.e. in the second half of the 7<sup>th</sup> millennium cal BC, and similarities in the flint assemblage with western Egypt. This deeply contrasts with the position of C. McBurney who was convinced of strong links in the Haua Fteah's industries with the western Caspian culture.

As the Neolithic of Cyrenaica will have to be better documented and defined, the relationship between this zone and the neighboring areas (Egypt, Maghreb and the Sahara) will also have to be clarified by future field research.

ORAL

### 10. THE PATTERN OF NEOLITHIZATION IN DAKHLEH OASIS IN THE EASTERN SAHARA

*McDonald, Mary M. A. (Dept. of Archaeology, University of Calgary) mmcdona@ucalgary.ca*

A review of the evidence from a large oasis in the Egyptian Western Desert concerning the origin and spread of Neolithic traits across North Africa. Relevant information from Dakhleh Oasis includes a pattern of increased sedentism starting in the Early Holocene, the degree of borrowing of artefact traits from the Near East, data from faunal and palaeobotanical remains, and from rock art. The evidence suggests that neolithization in Dakhleh was largely attributable not to migrants from the Near East, but to local groups selecting from the 'Neolithic Package' a few elements particularly suited to their needs, specifically cattle and caprines.

### 11. THE INTRODUCTION OF NEOLITHIC RESOURCES IN NORTH AFRICA ? A DISCUSSION IN LIGH OF THE LATEST HOLOCENE RESEARCH BETWEEN LIBYA AND EGYPT

*Barich, Barbara E. (ISMEO-International Ass. for the Mediterranean and Orient) barbara.barich@mclinknet.it*

The dynamics affecting coastal areas of North Africa,

especially the rise of Neolithic economies, remained largely unexplored until a few years ago. Hitherto all the Holocene sites cited in the literature, starting from the Neolithic layers of the Haua Fteah Cave in Cyrenaica and others in Tunisia etc., have been generically associated with the Caspian tradition through the "Neolithic of Caspian Tradition" affiliation.

There are no definitive answers for questions about how groups belonging to a very well-documented late Palaeolithic tradition developed locally, and if and how these changes resulted from outside influences that may have affected the region during the middle and late Holocene. This is especially true of the provenance and success of the main domesticates, in other words the plant (wheat, barley) and animal species (sheep/goat, cattle, pigs) which constitute the North African Neolithic complex.

Studies have so far shown a predominantly interest in the morpho-typological aspects of the different traditions thinking to deal with the theme of change through the analysis and the comparison with the previous Late-palaeolithic and Epipalaeolithic substrate. In this way, little interest has been addressed towards a more comprehensive interpretation of North African societies by first dealing with issues of changes in the economic and social development. In this respect, one recognizes a clear gap between the coastal area and the Saharan regions about which for a long time reconstructions and interpretation models based on firm chronologies and palaeobotanical and archaeozoological data have been available.

Based on this finding, the paper focuses in particular on what has recently emerged from important investigations in Egypt (Western Desert) and Libya (Jebel Gharbi plateau). The analysis of precise palaeoenvironmental reconstructions and, as regards Egypt, secure archaeozoological data, make us confident in defining the paths of penetration and diffusion of the animal and botanical species underlying the Neolithic transformation of these areas.

On the other hand we cannot ignore the relationship with the southern regions in the Sahara, where ceramic societies of the Saharo-Sudanese tradition with an initial form of food production are well attested from the earliest phases of the Holocene. Although there are some parallels between the two spheres in terms of the type of relationship established with the environment and the adaptations preceding food production, it is clear that the coast of North Africa followed an independent path,

separate from that of the transaharan area between the Sahara and the Nile.

The paper puts an emphasis on these themes and takes into account especially the areas that have allowed palaeoclimatic and geo-archaeological reconstruction in a broader perspective which includes changes in the settlement pattern and in the economic system.

## 1. THE CHRONOLOGY OF PALAEOOLITHIC CAVE ART: NEW DATA, NEW DEBATES

*Ontañón, Roberto - (Museo de Prehistoria y Arqueología de Cantabria/Cuevas Prehistóricas de Cantabria) ontanon\_r@cantabria.es*

*Utrilla Pilar - (Universidad de Zaragoza) utrilla@unizar.es*

After several decades in which the evolution of Palaeolithic art seemed a settled scientific matter, new findings have called into question the soundness of this construction apparently well founded. Obtained by increasingly refined and precise radiometric dating techniques, new data have shaken the interpretive building constructed on the postulates of A. Leroi-Gourhan and which had stood, virtually unchanged, over the last quarter century.

Indeed, by accepting in a generalized way the proposals of stylistic evolution from H. Breuil to Leroi-Gourhan and his followers, most of the researchers involved in this specialty have tried to situate the parietal evidence within the established cultural-historical sequence. The dissonant events ("aberrant" dates, some "rare" old and new sites) were relocated within the broad outline or have been relegated to the limbo of the data difficult to interpret. However, from the 90s of the XXth century, new evidence with a robust probative capacity has come to light, generating strong reactions and a deep controversy within the research of Palaeolithic art.

The first major debate is about the discovery, study and dating of the Grotte Chauvet, with an astounding parietal ensemble whose Aurignacian ascription clashes against the waterline of Leroi-Gourhan's stylistic evolution. In the present day, several scholars discuss the acceptance of that attribution, including criticism on the dating method.

The second main impact on the prevailing paradigm has arrived a little bit after, in what some call the "post-stylistic era". The recent developments of radiocarbon dating with the introduction of the ultrafiltration techniques and, moreover, several results of indirect dating of rock art by means of the U-Series method, would permit to backdate the beginning of cave art even beyond Aurignacian times. This has allowed some colleagues to claim the possibility of a Neanderthal cave art that could deprive our first ancestors of what until recently was thought one of his most significant hallmarks.

This paper aims to recapitulate the latest developments in this field and has as its main objective to constitute

an introduction to what we expect shall be a good discussion both on the methodological aspects and their historical and anthropological implications, considering radiochronological data obtained on rock art but also gathering information from the archaeological sites where these representations are situated, that can provide interesting information for proper contextualization of the graphic evidences.

Villotte, Sébastien - (Université Bordeaux - PACEA) s.villotte@pacea.u-bordeaux1.fr

Suite à la découverte de la grotte ornée et à restes humains (dépôts mortuaires probablement sépulcraux) de Cussac (Dordogne) en 2000, une des premières questions posées par Norbert Aujoulat et collaborateurs était la contemporanéité entre l'art pariétal et le dépôt de corps humains. Plusieurs échantillons avaient été prélevés et datés. L'un des trois restes humains échantillonnés (locus 1) a permis d'avancer un âge  $^{14}\text{C}$  contemporain du Gravettien.

Depuis la mise en place d'un programme collectif et pluridisciplinaire fin 2008, nous avançons progressivement vers un questionnement plus ambitieux et la confrontation de différentes approches et méthodes de datations, relatives ou numériques. Les principaux points de problématiques ou disciplines impliquées sont : la mise en place et l'âge des formations sédimentaires et des spéléothèmes scellant soit des vestiges (restes humains) soit le secteur d'entrée, les restes humains, les charbons en paroi ou au sol, les rares silex taillés, les éléments de bois de renne travaillés, les vestiges de faune et, bien sûr, l'art pariétal ce dernier presque uniquement représentés par différents types de gravures.

Nous présenterons les premiers résultats obtenus par champs disciplinaires (datations numériques et âges relatifs).

S'ils ne permettent pas de répondre à toutes les interrogations (par exemple la question de l'entrée et l'âge de la fermeture du porche) confirment jusqu'à présent, toutes disciplines confondues, une fréquentation probablement très resserrée dans le temps, centrée sur le Pléistocène supérieur et le seul Gravettien.

---

#### ORAL

### 3. ABOUT THE SIMULTANEOUS PRESENCE OF THE MEGALOCEROS AND THE REINDEER ON THE WALLS OF THE CHAUVET'S CAVE

Martin, Michel - mic.martin586@orange.fr

We take the census of the art of ornate caves in the superior Paleolithic, called "Reindeer age" between 32000 BP and 11000 BP, 49 Megaloceros (13 in Spain, 36 in France) and 165 Reindeers (30 in Spain, 130 in France). Among these figures, Chauvet cave contains 7 Megaloceros and 12 Reindeers.

Comparative study between sites with archaeology dates and available  $\text{C}^{14}$  dates, with techno-stylistic including study of cephalic details (like eye and nostril, or absence of ear for reindeers at Chauvet and Gabillou, two caves sharing out many common points), corporal details, level of insertion of foots, animation degree (like run never translated on Megaloceros, from II/III style, which is only walking in the «Gallery of Megaloceros» at Chauvet), cut out lines («despieces»), perspective (horns, feet) and figurative and abstract subject of which predominance of cold fauna attending Reindeer.

The chronology shows that only Chauvet cave offers dating Megaloceros at 32000 BP. Every one of them are minimum gravettians, or solutreans : 31 from II style, 17, from III style, any from IV style (tab 1). Non-existent animation is usually (28) on unfinished figures often without foots. The Reindeer, always from IV ancient style (included Chauvet) and also from the recent IV style, appears everywhere between IV and III Würm, at the transition Solutrean with Magdalenian, or at middle Magdalenian. Entire, provided with complex animation, it is present right to the end of Magdalenian, substituting for Megaloceros because it becoming scarce and under the peyorative climatic influence, more favorable to Reindeer (tab 2). Their simultaneous presence probably exists in Spain, at La Lloseta (Asturies) where, without radiometric dates, one megaloceros and one reindeer are identically treated by the same filling (black for megaloceros, red for reindeer) and at La Pasiega (Cantabria), where one megaloceros and two reindeers red ochre are ascribed to the same cultural period.

Megaloceros and Reindeers have few luck to be contemporaneous at Chauvet. First, such is the case exceptionally elsewhere, because Reindeer appears on the wall when Megaloceros leaves it and the graphic comparison (included animation) between the two species takes away each other by style. Secondly, the megaloceros dated by AMS radiocarbon date offers a spotted animation by Leroi-Gourhan like indicative of III style, unknown at first glance into Aurignacian. At last, the absolute date of megaloceros comprises a mix with clay from a stump, with contaminating power, that is untrustworthy and the measurement of "13 delta" is incompatible with only that charcoal can do it and also by disqualification of Tandétron which has worked out computation.

ORAL

#### 4. AURIGNACIAN ROCK ART COMPLEXITY IN CANTABRIAN REGION: THE CASE OF ALTXERRI B

Ruiz-Redondo, Aitor - (*Instituto Internacional de Investigaciones Prehistóricas de Cantabria (IIIIPC), Avenida de los Castros s/n, 39005 Santander, Spain*) aruizredondo@gmail.com

Our understanding of the beginnings of Palaeolithic graphic activity has advanced considerably in recent years. Twenty years after the discovery of Chauvet, the number and diversity of Aurignacian ensembles has been increased.

In this communication we present the analysis of the parietal ensemble of Altxerri B (Northern Spain). In this site, we have studied the paintings and their archaeological and geological context. One of the main objectives of our research was to determine the chronology of the pictorial phase in the cave. The impossibility of taking direct painting samples for dating force us to search other evidences for the chronological context of art.

Archaeological, geological and stylistic evidence, together with radiometric dates, suggest an Aurignacian chronology for this parietal ensemble (*ca.* 39000 cal BP). These results, joined to other researches developed lately in Cantabrian Region, are outlining a new panorama for the oldest graphic activity in this region. Well studied examples are still rare, but the discoveries in the last years invite to be optimistic that maybe in a close future our knowledge about the origins of figurative expression could be increased. In this context, the site of Altxerri B can be added to the small but growing number of sites dated in this period in Europe, corroborating the hypothesis of more complex and varied figurative art than had been supposed in the Early Upper Palaeolithic.

ORAL

#### 5. INDIRECT DATING OF PALAEOOLITHIC CAVE ART IN THE LOWER GALLERY OF LA GARMA (CANTABRIA, SPAIN) USING THE U-SERIES TECHNIQUE

Arias, Pablo - (*Universidad de Cantabria*) pablo.arias@unican.es

Ontañón, Roberto - (*Museo de Prehistoria y Arqueología de Cantabria*) ontanon\_r@cantabria.es

Pike, Alistair - (*University of Bristol*) alistair.pike@bristol.ac.uk  
Hoffmann, Dirk - (*Max-Planck- Institut*) dirk.hoffmann@eva.mpg.de

García-Díez, Marcos - (*Universidad del País Vasco*) diez.garcia.marcos@gmail.com

Pettitt, Paul - (*University of Durham*) paul.pettitt@durham.ac.uk

Zilhão, João - (*iCrea-Universitat de Barcelona*) joao.zilhao@ub.edu

The research project at the Archaeological site of La Garma, co-directed by two of the signatories (PA and RO), included in 2000 sampling and analysis for absolute dating of calcite formations associated with Palaeolithic cave art. Two methods were used in combination, the U-Series and Thermoluminescence. The results yielded new data on the chronology of pre-Magdalenian representations forming part of a characteristic style in the central sector of the Cantabrian region (depictions composed with dotted lines). These data were significant because they showed a trend, now confirmed, to an older chronology than it was assumed for these cave paintings.

Following with this ongoing research, in 2012 new exploration, selection and sampling of calcite crusts connected with Paleolithic cave art have been made, in cooperation with the team of the "U-Series Dating of Palaeolithic Art" Project. It has been considered appropriate to address this second phase of sampling and dating, given the substantial advances observed in these methods, i.e. higher resolution and less impact on the conservation of parietal supports.

The method of U-Series is based on the differential decay of isotopes of natural radioactive series of uranium and thorium. For the dating of secondary calcium carbonates, the degree of disequilibrium between U-238 and Th-230, along with the imbalance of U-234 and U-238, is calculated by iterative methods to determine the age at which calcite precipitation occurred. If the calcite formation is overlying a painting, the date obtained from this speleothem will be then a *terminus ante quem* for the artistic event.

The results of this second phase of dating are presented and discussed in the context of the cave art of La Garma (especially in relation to the data previously obtained by using these techniques) and within the general framework of Palaeolithic rock art in the Cantabrian region.

ORAL

## 6. REFLECTIONS IN THE EARLY ART OF CAVE OF "EL CASTILLO"

*Bernaldo de Quiros, Federico - (Universidad de Leon) fberg@unileon.es*

The recent dating of a series of "dots" from the painted interior of cave of "El Castillo" bring us the opportunity of present some of the discoveries from the "Transitional Aurignacian" levels of the cave. Also we present a decorated cobble from level 21 who is marked with a straight row of four evenly spaced, incised points which are positioned above a fifth incised dot situated directly in the middle of the upper row. The cultural behavior represented by this decorated stone develops and continues without a gap through El Castillo's earliest Aurignacian levels, where possible evidence for figurative representation is found.

Here we simply wish to stress the increasing and robust evidence for local roots of symbolic behavior in the local Middle Paleolithic of Cantabria, and to note that the cave of El Castillo illustrates the development, without any gaps, from the Mousterian through to its Upper Paleolithic levels. If, as many researchers have proposed, such symbolic behavior is linked, at least in part, to greater desires for inter and intra-group communication, spurred by demographic pressure or by shifts in social morphology, then this small pebble from Level 21a provides elegant evidence of the elaboration of such social expression in the Cantabrian Middle Paleolithic. This development of social expression must also be reflected in the settlement dynamics of the Cantabrian Middle Paleolithic.

The relation between this "dots" and those dated in the cave is also an interesting theme because as the dates are "ante quem", a possibility is open to be considered as being manufactured by the same authors.

ORAL

## 7. LA VIÑA ROCK SHELTER (ASTURIAS, SPAIN): RELATIONSHIP BETWEEN THE STRATIGRAPHY AND THE PARIETAL ENGRAVINGS

*González-Pumariiega Solís, María - (Consejería de Educación, Cultura y Deporte. Asturias) maria.glez-pumariiega@asturias.org*

*de la Rasilla Vives, Marco - (Universidad de Oviedo) mrasilla@uniovi.es*

*Santamaría Álvarez, David - (Universidad de Oviedo) santamariadavid@uniovi.es*

*Duarte Matías, Elsa - (Universidad de Oviedo) elduarma@gmail.com*

*Santos Delgado, Gabriel - (Universidad de Salamanca) gsd@usal.es*

La Viña rock shelter is the easternmost of the thirteen well-lit sites with rock engravings spread along the Nalón river basin. It is located ~150 m above the river level, facing S-SE. Its UTM30 ETRS89 coordinates are: X=270739,95; Y=4799489,80; Z=212 m.a.s.l. La Viña is the largest settlement in that valley and contains the most extensive archaeological sequence, from the Middle to the Holocene. There is also an important group of engravings, clustered along the rock face into six different areas with diverse levels of preservation. The two main groups of engravings border the sectors where the archaeological excavations were made.

Great part of the engravings were partially or completely covered by the palaeolithic layers and, as the shelter is widely opened, some others were covered by thick masses of calcareous formations developed over the wall. Moreover, some of the oldest carvings played a role in the rock front natural evolution, guiding the run-off parietal water and consequently creating a calcareous formation, not only over the walls surface but also over the stratigraphic sequence. In addition, some fallen fragments of engraved wall took part of the archaeological deposit.

As archaeological excavation progressed (1980-1986) and the occupation layers were removed, great part of the hidden engravings appeared. J. Fortea organised those engraving into two successive cultural horizons, while recognisable features in the other shelters along the Nalon valley. The oldest period is made up of deeply engraved vertical lines, regularly arranged along the western half of the rock front. The only similar ensemble is found at El Conde cave. On the other hand, the second cultural horizon spreads in different areas of the rock front and it is mainly made up of a tangled mess of non-

figurative deep engravings, although there are some individual depictions. Here the animal figure appears. This horizon is identical to the rock art of other sites in the Nalón valley.

Fortea posed a chronology based on archaeological sequence. Thus, his arguments were the paleolithic deposits covering the decorated wall, the hand-height above the occupation layers, the pieces of wall fallen to the corresponding level and some geological features. Archaeological research carried out in La Lluera I, La Lluera II and El Conde did not contradict his hypothesis: the oldest horizon would have been engraved from the Aurignacian layers while the second horizon would have been done during Graveto-Solutrean periods. Recent topographical surveys of the parietal engravings have supported those proposals and have released new data about the topographic organization of the engravings.

ORAL

**8. CHRONOLOGY OF PALAEOLITHIC ROCK ART AT FUENTE DEL TRUCHO: STYLE, U-SERIES DATES AND COMPARISON WITH CANTABRIAN SITES.**

*Hoffmann, Dirk - (Max-Planck- Institut) dirk.hoffmann@eva.mpg.de*

*Pilar Utrilla - (Universidad de Zaragoza) utrilla@unizar.es*

*Pike, Alistair - (University of Bristol) alistair.pike@bristol.ac.uk*

*Bea, Manuel - (Sacner 3D Patrimonio) manubea@unizar.es*

*Baldellou, Vicente - (Museo de Huesca) vbaldellou@aragon.es*

*García-Díez, Marcos - (Universidad del País Vasco) diez.garcia.marcos@gmail.com*

*Zilhão, João - (iCrea-Universitat de Barcelona) joao.zilhao@ub.edu*

Nine different calcite samples overlying cave art at Fuente del Trucho (Asque-Colungo, Huesca) have been dated by U-series. The U content in the calcite is high and therefore it has been possible to date very small samples. The detrital component is almost negligible, so the uncertainties of the results are small. Interestingly, the initial  $^{234}\text{U}/^{238}\text{U}$  activity ratio is unusually depleted. The results are quite consistent so far and all fall between 24 and 31 ka. These dates are expressed in solar years before the time of measurement and, therefore, must be interpreted within a regional Upper Paleolithic chronostratigraphic framework expressed in calibrated radiocarbon years before present.

The oldest results obtained are for samples associated with red dots. These results place the execution of the underlying motifs in a time range beyond the Middle Gravettian (i.e., beyond 30 kcal BP, or  $\sim 25 \text{ ka}^{14}\text{C BP}$ ). These results are not as old as the dates obtained at El Castillo, but it should be borne in mind that, in the Cantabrian site, the oldest motifs are disks, not dots.

Calcite overlying a red horse in panel VIII (sample FT5) yielded a minimum age of 29 ka that implies execution minimally in the Middle Gravettian. Stylistically, this motif is comparable to a horse figure from La Pasiega (c2) and also bears resemblance to horse representations found among the engraved plaques of Parpalló.

Samples FT8 and FT9 provide minimum ages of  $\sim 26.5 \text{ ka}$  for two hand stencils. These results are consistent with the Gravettian age obtained by radiocarbon for the black pigment used in hand stencils from Cosquer ( $\sim 27 \text{ ka}^{14}\text{C BP}$ , i.e.,  $\sim 30\text{-}32 \text{ ka calBP}$ ) and for the date on a bone sample archeologically associated with similar motifs at Gargas. At Fuente del Trucho, however, none of the dated hands have missing or truncated fingers. In the Cantabrian strip, minimum ages for hand stencils ranging from 24.2 to 37.3ka have been obtained at El Castillo. Overall, these results remain consistent with two chronological hypotheses: (a) if, given uncertainties and inconsistencies, the Cosquer radiocarbon dates are taken to represent minimum ages only, that hand stencils at these sites are, in all cases, of an Aurignacian-or-older age; or (b) that such motifs span an extended range, some having been made as late as the time of the transition from the Gravettian to the Solutrean ( $21.0\text{-}21.5 \text{ ka}^{14}\text{C BP}$ , i.e.,  $\sim 25\text{-}26 \text{ kcal BP}$ ).

An age of 25.7 ka was obtained for calcite overlying a "trilobate" sign in panel V, placing it minimally in the Late Gravettian; a similar chronology may therefore apply to motifs similarly designated in panel XXII. On the grounds of their identical style, such a minimum age can also be proposed for an ibex figure from the Fuente del Trucho and the engraved, trilinear-headed hind on a pebble from Antoliña.

Fuente del Trucho is confirmed to be a major site of the Paleolithic artistic cycle. Minimally, its art is of Gravettian age. In the case of the dots and hand stencils, their execution can be further constrained to the Early Gravettian or older.

ORAL

**9. PALEOLITHIC ROCK ART FROM COMTES'S CAVE (PEDREGUER-SPAIN), AND ITS AECHAEOLOGICAL RECORD.**

*Boronat Soler, Juan de Dios - (Museu Arqueològic Soler Blasco) Mvsev.xabia@gmail.com*

*Martínez, Enric - (Fundació Cirne) cirne2@gmail.com*

The recent discovery of a new cave with paleolithic rock art in Valencian Country, led a research project to document the artistic expressions, and their contextualization through archaeological excavation of the site.

Comte's cave opens in the middle-upper stretch of the ravine Parra, in the town of Pedreguer, just over nine kilometres from the Mediterranean sea. Its a long cave consist of two rooms, connected by a narrow passage. Fifteen sites with painted or engraved paleolithic rock art have been found in the deepest of the cave, that coming to increase the scarce regional record.

We have made the topographic research of the cavity. The panels were scanned in 3D high resolution, and it has made a detailed photographic research, from which we have obtained the digital tracings.

The excavation in the inner room, has found paleolithic layers under study. Harris methodology has been used, and different layers have recorded with referenced 3D photography.

Excavation results are still processed. The anthracological research and radiocarbon dates are almost finished. It seems that the only layer completely excavated, must belong to a warm period of Tardiglacial.

Both lithic and bone artifacts, and faunal remains suggest that the cave was occupied similar way to other nearby settlements. Deer and goats hunting is the origin of the most of the protein intake, although differential intakes are described for each species. Juvenile phalanx of *Homo sapien* with flint marks and human bites that suggest an episode of cannibalism is also documented.

For the time being the bestiary is reduced to nine copies. Zoomorphs show stylistic features that bring us to the early stages of pre.magdalenian art. The triangular shape of a quadruped's legs (perhaps a goat) and the snout making of a horse are like lower solutrean stone flats from Parpalló cave.

The repertoire of signs is also very interesting. Especially we have found three remarkable good size spirals, the only parallel we meet its again on the stone flat number 16726 from Parpalló, that researchers attribute to upper and middle solutrean.

The U-Th method, based on the radioactive disequilibrium between  $^{230}\text{Th}$  and its parent isotopes  $^{238}\text{U}$  and  $^{234}\text{U}$  has been used in a number of recent projects to date calcite precipitates above and occasionally below cave paintings to constrain their age. Initial results from Spain have shown that the earliest dated paintings date at least to the Early Aurignacian period and present a far longer chronology that that based so far on radiocarbon dating. Here we outline our methodology and the steps we take to demonstrate the reliability of U-Th dates, and present some recent results of our ongoing U-Th dating programme.

Garate, Diego - (CREAP-Toulouse) [arkeologimuseoa.teknikari1@bizkaia.net](mailto:arkeologimuseoa.teknikari1@bizkaia.net)  
Rivero, Olivia - (CREAP-Toulouse) [oliviariver@hotmail.com](mailto:oliviariver@hotmail.com)  
Tosello, Gilles - (CREAP-Toulouse) [gilles.tosello@wanadoo.fr](mailto:gilles.tosello@wanadoo.fr)  
White, Randall - (New York University) [randall.white@nyu.edu](mailto:randall.white@nyu.edu)

Dramatic progress has taken place in  $^{14}\text{C}$ -dating with the introduction of accelerator mass spectroscopy (AMS) that has made possible the direct dating of prehistoric artworks drawn with charcoal. However, in the case of engravings, mineral-based black and/or red paintings, we are limited to using only indirect methods that allow the dating of deposits that have covered the works over time (e.g. TL, U/Th, oxalates, etc.).

The uranium/thorium dating method (U/Th) gives reliable and relatively precise results when dating massive speleothems, because the sampling is carried out at the heart of the material where the hypothesis that it is a *closed system* (no exchange with the outside environment) can be verified in most cases. Unfortunately, the situation is quite different in the case of thin layers of calcite overlying Palaeolithic cave drawings. The conditions under which calcite forms depend largely on the hydrologic activity that has varied to a great extent during the Upper Palaeolithic and the Holocene. Consequently the ages obtained are minimum ages (*terminus ante quem*) that are frequently much younger than the real ages of the underlying artworks.

However, a much more serious source of mistake, rarely discussed, yields results in the opposite direction. With thin layers of carbonate deposits that are in a damp medium, the uranium incorporated in the calcite during its crystallization may be partly eliminated because of its solubility in water. The consequence of uranium leaching leads to an artificial increase of the age that may reach considerable proportions (e.g. a negative hand print in a cave of Borneo was dated to 27.000 years by U/Th whereas its age determined by  $^{14}\text{C}$  was only 8-10,000 cal BP; Plagnes *et al.*, Cross dating (Th/U-14C) of calcite covering prehistoric paintings in Borneo. *Quaternary*

*Research*, 2003, 60 (2): 172-179) and this can be also the case for some of the dates recently obtained in Cantabrian caves (Pike *et al.*, U-Series Dating of Paleolithic Art in 11 Caves in Spain. *Science*, 336, 15 June 2012, 1409-1413).

Owing to these two contradictory sources of error, the dates given by the U/Th method may appear younger or older with deviations much larger than the standard deviations given by laboratories. It is thus almost impossible and very dangerous to base an archaeological interpretation on the ages of Palaeolithic artworks as determined by U/Th, *if not confirmed by an independent method*. The most reliable independent method would be the  $^{14}\text{C}$ -dating of the carbonates in the same samples. At present, the application of the U/Th method for dating prehistoric rock art should be regarded as experimental, but improvements are in progress (for instance, the separate dating of ultra thin layers taken in the depth of the deposit by laser ablation; cf. Aubert *et al.*, Uranium-series dating rock art in East Timor, *J. Archaeological Science*, 34: 991-996).

## 1. WHY PAINT HERE? THEORETICAL THOUGHTS ON THE DOCUMENTATION OF CONTEXT IN ROCK ART ARCHAEOLOGY

*Lenssen-Erz, Tilman - (University of Cologne) lenssen.ertz@uni-koeln.de*

Rock art as an immovable, usually highly visible source of information, by its longevity is prone to new interpretations and appropriations whenever a new social group gets into contact with it in the course of history. The intangible, ephemeral context changes and its specific meanings will probably always remain cryptic for us. But the physical context of rock art usually remains unchanged in its spatial relations, topography and geology. Other contextual elements which never undergo substantial change are the basic human needs (after Abraham Maslow). Through an assessment of the relationship between human needs and physical context in terms of space and resources in a given area we are able to refer to matter that can be grasped empirically. But it also opens an avenue to collect data on intangible issues, relating to religion, symbolism, identity or communication. With a specific format of site data it is possible to construct an Idealised Elementary Site. This represents the 'average' site in which are combined the most common patterns of use in a given rock art region. Eventually this allows reconstructing mental maps which people in the past may have entertained in relation to 'their' landscapes, as will be demonstrated here with the Holocene rock art of the Daureb (Brandberg) in Namibia.

ORAL

## 2. IS PROCESSUALIST THE SHAMANIC INTERPRETATION OF PALAEOLITHIC ART? EPISTEMOLOGICAL APPROACH TO THE POSSIBLE RELATIONSHIP BETWEEN INTERPRETATIONS OF PALAEOLITHIC ART AND ARCHAEOLOGICAL THEORIES

*Fernández Quintano, José - (Independiente) beroso@hotmail.com*

### PRECEDENTS

Some of the principal proposals of Paleolithic Art interpretation:

Mid - nineteenth century. Artistic activity in a society of abundance

Early twentieth - century. (Influence of anthropology).

Magic: concern for fertility and hunting.

Mid - twentieth century. (Influence of structuralism). Structuralism: importance of the panel (rock art). Study your situation in the cave, and their motives.

Late twentieth - century. (Influence primitive cultures). Shamanism: special relationship between consciousness (altered states) and art.

Some of the major archaeological theories:

- From the second half of the nineteenth century to the second half of the twentieth century. Diffusionism, Evolutionism, Cultural-historical.

- From the second half of the twentieth century to the present. Processualism, Postprocessualism, Systemic, Landscape archaeology.

No interpretations of Palaeolithic Art, no archaeological theory, have the support of the entire archaeological community. There are archaeologists who give more importance to the chronology and technological research of the materials.

### QUESTIONS OPEN TO DEBATE

Is there a direct relationship between the proposals on the Paleolithic Art and archaeological theories? Or, any proposed interpretation of Palaeolithic art may be related to any archaeological theory?

Interpretation of Palaeolithic Art is independent of archaeological theory? So one interpretation of Palaeolithic Art processualist is possible?

### APPROACH

A first approach would be: Processualists are the interpretations of Paleolithic art initially developed with assumptions from other sciences (such as anthropology); Postprocessualists are the interpretations that are made only from the direct study of Paleolithic art.

### PROPOSAL

Some archaeological theories are methodological (precede the work of the archaeologist), leaving more open cultural conclusions (archaeologists work more freely, but this raises the problem of the influence on his work as scientists, of their ideological values ??as individuals or as members of a corporation). Other archaeological theories, from the start, bind method and culture. This affects the development and research findings.

As for the proposals on Paleolithic art, some of these proposals tend to give more importance to cultural conclusions that a methodological procedures. By having more importance the final conclusions are not clearly perceive

the ideological values that researchers introduced at first.

ORAL

### 3. THE PALAEOLITHIC ART OF TITO BUSTILLO CAVE (ASTURIES, SPAIN) IN ITS ARCHAEOLOGICAL CONTEXT.

*Balbín Behrmann, Rodrigo de - (Area de prehistoria. Universidad de Alcalá) babubera@movistar.es*

*Alcolea González, José Javier (Area de Prehistoria. Universidad de Alcalá) javier.alcolea@uah.es*

Over the last four decades, the research conducted in the cave of Tito Bustillo (Asturies, Spain) has provided us with a comprehensive view of the site's archaeological content. The works carried out in the 1970's and 1980's consisted essentially in the excavation of the Magdalenian deposit of the cave's first room, and in the analysis of the Palaeolithic rock art located all along the cave. During the last 15 years we have completed the documentation of the cave's rock art, and we have also valued some little known aspects of its archaeological reality.

Recent works in the cave of Tito Bustillo have included both a review of all the rock art locations in the cave, and an intensive survey of the entire underground area. The review of rock art has been undertaken using new technical means in lighting and photographic recording, and it has also included a program of direct and indirect dating by <sup>14</sup>C AMS and uranium series. Survey works have been accompanied by specific test-pit excavations in different parts of the cave, aimed at contrasting some ideas on the human frequentation of the cavity.

Our research has allowed us to better understand the prehistoric structure of the cave, and especially its settlement by its prehistoric inhabitants throughout the Upper Palaeolithic. We have discovered new decorated galleries, and also new traces of human presence in the form of archaeological structures and portable art objects. The dating program, which has been extended to some structures discovered near the entrance and in the cave's deepest area, has allowed us to frame the chronological development of the human occupation of Tito Bustillo, as well as to better understand the role of the graphic elements in the whole palaeolithic habitat.

The evaluation of all data available at present points to the characterization of the Palaeolithic graphic ensemble of the Tito Bustillo cave as a major factor in the humanization of the underground space. It also points to the consideration of this space as an important part of

the Upper Palaeolithic habitat.

ORAL

### 4. THE SALLE DU FOYER IN LES TROIS-FRÈRES

*Bégouën, Robert - (Association Louis Bégouën) robert.begouen@wanadoo.fr*

The Salle du Foyer is in the deep part of Les Trois-Frères. Numerous engravings were found there in 1964. From the cave's discovery in 1914, the finders noted a lithic structure in the center of this gallery from around which emerged bone splinters and charcoal suggesting a hearth.

During the excavation of Enlène, we undertook an exhaustive study of this part of the cave (parietal art, excavation, deposited objects, sedimentology, dating etc.). Oval in shape, this small gallery measures 7 m long and 5 m wide. Taking into account the preservation of the cave and it being secure, the remains uncovered were left in situ. Thus, with one glance, it is possible to observe the remains in their entirety just as they were abandoned by the Magdalenians. This strategy did not make their study easy as some of it had to be done on site.

Several activities were carried out by the Magdalenians in this deep part of the cave, at 640 m from the light of day. Excavation confirmed the human origin of the lithic structure, composed of large limestone blocks, stalagmites and a large fragment of sinter bassin. Around it the space was adapted and fires made, survived by pits dug into the clay floor where bone clearly served as a combustible. Two of the pits contain various objects, such as sandstone slabs brought in from the exterior. Fauna was eaten on the spot, particularly reindeer.

The mobiliary material recovered is poor, with no art. The flints are above all local but with the presence however of several distant imports (Bergerac, grey Perigordian and Chalosse from Gascony). Certain were worked on-site to produce blades and splinters, while other blades were imported already worked. With the notable exception of two nuclei deposited on a wall, all the others were imported. The tools from the site suggest alimentary activities and a use in creating parietal engravings.

Finally, the gallery's walls harbor deposits, mainly lithic, and a quite large piece of jet carefully hidden in a secret crevice.

#### The parietal art

The Salle du Foyer is surrounded by walls completely

polished by the passage of bears in earlier times, which gives them a marbled appearance. This particularity attracted the Magdalenians' attention and they took advantage of this quality background for very fine engravings. These engravings are in fact so fine that their study by classic methods is impossible. Molds were therefore taken and their reconstitution in resin has revealed all their richness and diversity.

This study makes it clear that we are in the presence of a place for the Magdalenian engravers where the well-preserved archaeological context allows us a close encounter.

---

ORAL

**5. THE SOLUTREAN CAVE ART OF LA CUEVA DE AMBROSIO (ALMERÍA, SPAIN).**

*Ripoll, Sergio - (UNED) sripoll@geo.uned.es*  
*Muñoz Ibañez, Francisco J. - (UNED) fjmunoz@geo.uned.es*  
*Martín Lerma, Ignacio - (Universidad de Murcia) ignaciomartinlerma@hotmail.com*

In the solutrean site of La Cueva de Ambrosio several engraved and painted figures dated on the Upper Palaeolithic, have been found during the field works of 1992 and 1994. In The panel I we have identified an excellent representation of a horse, a bird, one bovidae and another protome of a horse. Below this surface there are many red ochre wallpaintings covered by a calcitic path and for the time being we are unable to give any interpretation for it. In the second panel we have discovered more tone splendid red painted horse, two more engraved horses and a little head of one other black painted horse. There are many engraved lines and pictural rests that must be studied in the future.

The exceptionality of this discovery is that we can interrelate perfectly these rock art paintings with the archaeological levels clearly defined chronologically and culturally (ca. 20.000 B.P.), Middle Solutrean and Upper Solutrean from the same site.

More than twenty years ago, we find the first figures traits in La Cueva de Ambrosio. During these long years we have spent countless hours in front of the various panels and many others in front of the computer monitor to try to decipher those unconnected strokes that were watching and not got to define. The advance of computer technology, reflection and maturation of some ideas that already we knew some time ago, they have enabled us to significantly enlarge the iconographic corpus

of this surprising season. In this site, in which we have been working for more than 30 years, we have found the more complete and interesting sequence for the Spanish Mediterranean Solutrean period. According to the investigations carried out so far, it seems to this shelter was not a permanent camp, but rather a place that is used to go at certain times to renew the lithic tools (Ripoll et alii, 1988) and where, despite the brevity of their stays, found through the low thickness but high extension of the fire places and little osseous remains to have constituted a food they had time to paint and engrave samples of Palaeolithic parietal cave art on its walls.

*Jaubert, Jacques - (Université de Bordeaux, PACEA, UMR 5199, PPP, F-33615 Pessac) jjaubert@pacea.u-bordeaux1.fr*

The Gravettian cave of Cussac well-known for its art and human remains contains numerous traces of human and animal incursions covering the whole cavity. Most of them include, for instance, static or dynamic footprints, hand or finger marks, lithic and bone industries, slides, scratch marks, wallows, charcoal deposits, red or black traces (colorant?), broken concretions, moved speleo-

thems.

Since 2009, a team incorporated in the *Projet Collectif de Recherche "Grotte de Cussac"* directed by J. Jaubert is engaged in the identification, inventory and study of these Activity Traces (TrAcS). The objective is to study the interaction of humans and animals with the subterranean environment and understand how Gravettians perceived this complex space, by crossing data on these different traces with information provided by other disciplines (parietal art, anthropology, geosciences, ichnology, pigment analysis, etc.). To our knowledge, Cussac is the first cave where a comprehensive inventory is carried out by a specific team. This new approach is due to the discovery conditions of the cave, which was left almost untouched since the Palaeolithic and to the policy of conservation. The team prospects with non-invasive methods, respecting the limits of the path and records, describes, photographs the accessible TrAcS.

The areas that are currently inventoried show that human TrAcS are more frequent and diverse than that of animals and mostly composed by the red and black traces (including snuffing torches also revealed by the presence of charcoal on the ground, wall friction, etc.), and breakage and movement of speleothems. Industry evidences are rare but there are three lithic artefacts (two blades and one laminar flake) and one (maybe two) bone artefact that are the subject of specific studies by specialists (technology, traceology, petrography, etc.). Animal TrAcS are for the most part produced by bears, and mainly characterized by scratches on large areas. Chronologically, bear traces always predated the human activity. We are only at a preliminary stage of our research and even though we can already reconstruct the actions of bears and Gravettians on small areas of the cave, there are still TrAcS that need to be inventoried and interpreted for better understanding of their appropriation of the symbolic space of the cavity in its entirety. New imaging technology, such as 3D scanner and photogrammetry, already used at Cussac by the parietal art (dir. V. Feruglio) and anthropology (dir. D. Gambier) teams, will be principally used for the footprints study. The interest of 3D scanning is twofold. Firstly, footprints can be the subject of morphometric and dynamic studies. Secondly, it ensures a perfect conservation of walls and floors, while reaching areas that are distant from the walkways.

The presence of TrAcS, art and human remains shows a complete and intense appropriation of the subterranean environment by humans and bears. Our study constitutes a fundamental step for the understanding of the

cavity, and more generally, of the identity of Gravettians, their culture, behavior, activities, movements or occupations in the context of a complex site with monumental engraving.

ORAL

## 7. CUSSAC CAVE: THE INFLUENCE OF THE SUPPORT ON ART WORKS DISPOSITION, TECHNICAL CHOICES AND TRACE RECORDING

*Ferrier, Catherine - (Univ. Bordeaux-UMR PACEA 5199) c.ferrier@pacea.u-bordeaux1.fr*

*Konik, Stéphane - (Ministère de la Culture et de la Communication-CNP Périgueux-UMR PACEA) stephane.konik@culture.gouv.fr*

*Ballade, Marie - (UMR PACEA-Univ. Bordeaux) marie.ballade@etu.u-bordeaux1.fr*

*Bourdier, Camille - (UMR TRACES) camille.bourdier@univ-tlse2.fr*

*Feruglio, Valérie - (UMR ArScAn) feruglio@free.fr*

*Chapoulie, Rémy - (UMR IRAMAT-CRP2A, Univ. Bordeaux Montaigne) Remy.Chapoulie@u-bordeaux3.fr*

*Jaubert, Jacques (UMR PACEA-Univ. Bordeaux) - j.jaubert@pacea.u-bordeaux1.fr*

The parietal art of Cussac cave, a major ornate site for the parietal art of the Gravettian period, is characterized by the dominance of engraving. The lithological characteristics of the limestone banks from the Upper Campanian have somehow influenced the localization of representations. The surface states of the support - which were acquired by alteration before human beings first used them - influenced the choice of the engraving technique and permitted the conservation of traces whether they were intentional or not.

The approach uses sketches realised with different scales, both in 2D and 3D, as well as physico-chemical analyses of the limestone banks by comparing their unaltered and altered features:

- mapping of the lithology and the surface states of the walls (downhill branch). Representation of the signs of alteration corresponding to a heap sand which resulted from the disintegration of the rock.
- taphonomic sketch of the Triptych's panel
- study of a wall fragment which had fallen to the ground next to the Great panel and the sand: petrography, granulometry, mineralogy by XRD and Raman spectrometry, analyses of chemical elements by SEM-EDXS and EDXRF. The walls show two lithological features :

- at the bottom, the first one is made of decimetric banks which contributed to the formation of irregular profiles, in the shape of stair steps.

- at the top, the second feature corresponds to metric banks which form large subvertical or horizontal surfaces with smooth morphologies. The analyses demonstrate that the rock suffered from superficial, millimetric dissolution. That was reflected by the almost complete disappearance of the sparitic and microsparitic cement. That phenomenon had several consequences:

-increase in porosity, leading to much lesser cohesion in the rock;

-release of millimetric grains which progressively heaped up on the walls or at their foot;

-relative concentration of iron hydroxydes which maybe caused the yellow-earth colour of the rock patina.

Because of the dimension and shape of the surfaces available, it was the massive banks which were preferred. That type of support enabled the realization of large works on panels which sometimes reach several metres in length. The fragility of the surface means that the technique of finger-engraving was preferred, giving more or less large and deep traces. Soft and hard tools were also used. Hence the fact that the rock which had been altered on several millimetres could be easily cut, as far as the healthy part, whose clearer aspect than that of the patina makes it easier to see the representation. Moreover the surface's crumbly consistency seems to have been used to overcome the issue of the curvatures and use a relief effect thanks to the asymmetry of the inclination of the stroke edges (Egyptian relief). The support also bears light and fortuitous traces of the hands that rested on it and which enable the understanding of the artist's gestures on certain outlines.

## ORAL

### 8. NATURAL TO CULTURAL: THE DIFFERENT CONTEXTS OF ROC-AUX-SORCIERS (ANGLES-SUR-L?ANGLIN, FRANCE) ROCK ART

*Bourdier, Camille - (Université Toulouse Le Mirail ? UMR TRACES 5608) camille.bourdier@univ-tlse2.fr*

Localized between the Aquitaine and the Parisian Basin, Roc-aux-Sorciers rock shelter was occupied and abundantly decorated – engraved, painted and sculpted – during the Middle Magdalenian (19 000-16 000 cal. BP). Our researches tackle the function of this site and, thus, question the social role of rock art. These issues require not only the analysis of the graphical productions,

but also the examination of the contexts in which they were made and used. This broader reasoning process considers three contexts: the natural context (topography of the site), the internal archaeological context (nature of the occupation) and the external archaeological context (nature of the other “contemporary” decorated sites). Each context provides complementary information about the public that could have had access to the decorated walls and about the activities that were associated to the rock imagery.

Roc-aux-Sorciers rock art lies in the walls of a huge shelter opening on the bank of a river, i. e. in a visible and accessible place with a collective accommodation. Three archaeological layers show an intense occupation of the site during the Middle Magdalenian. The abundant and varied material (lithic industry, bone industry, fauna, portable art, personal ornaments) underlines the diversity of activities carried out: domestic, hunting and symbolic. The scale of the shelter, the profusion of material and the reoccupation of the site seem to indicate that Roc-aux-Sorciers was an aggregation site. In this perspective, this public rock art could have participated in reinforcing the social cohesion of the people gathered there. In this particular context, rock art could have acted as an affiliation pattern, with an imagery expressing and transmitting a common system of values and beliefs. Finally, Roc-aux-Sorciers is not isolated; it is part of a group of decorated sites, about forty kilometres away. Numerous links have long been noticed with the cave of La Marche which occupation contained several hundreds of engraved slabs. The industries and the personal ornaments are very similar, so is the iconography, especially through the abundance of human realistic representations. However, the bestiary of La Marche is more varied and the formal variability is wider. These techno-stylistic differences raise the hypothesis of distinct practices: a collective expression in Roc-aux-Sorciers, performed by one or a few specialists, against a more individual practice in La Marche.

Therefore, studying the multiple contexts of Roc-aux-Sorciers rock art, both natural and cultural, opens new perspectives on the likely diversity of functions of the decorated sites in the Middle Magdalenian and, beyond, on the all the more probable symbolic plurality of this rock art.

ORAL

**9. FIRES IN THE MEGACEROS GALLERY (CHAUVET-PONT-D'ARC, ARDÈCHE) : CHRONOLOGY AND LINK WITH THE ROCK ART**

*Ferrier, Catherine - (Univ. Bordeaux-UMR PACEA 5199)  
c.ferrier@pacea.u-bordeaux1.fr*

*Debard, Évelyne - (Université Lyon 1-Laboratoire de Géologie de Lyon-UMR 5276) Evelyne.Debard@univ-lyon1.fr*

*Kervazo, Bertrand - (CNP Périgueux-UMR PACEA) bertrand.kervazo@culture.gouv.fr*

*Lacanette, Delphine - (I2M-Université de Bordeaux) lacanette@enscbp.fr*

Researches on the taphonomy of the rock art walls of the Chauvet cave led to detailed study of fire marks: pink and grey color of the rock, flakes due to the heat, and soot deposits. This thermal wall state was observed in the first rooms, where the main red paintings are located, as well as the deep rooms where most of the wood coal paintings were found.

The Megaceros Gallery, located in the deep area, comprises the most widespread marks of this wall state. They are divided in five zones and are associated with artefacts and prints on the ground (fire places, charcoals, pieces of wood prints, thermoclasts).

The study lies on :

- the description and the cartography of the thermal wall state and of the artefacts on the ground ;
- fire experiments in an underground quarry (LaScArBx IThEM program).

The chronological data (C14 datings of the charcoals and relative chronology with the rock art) links the fire to the Aurignacian. Two major periods are distinguished, according to the results of the study of the Panneau du Mégacéros, where several realisation phases can be observed. Considering the narrowness of the gallery and the number of identified hearths, the contemporaneity of the fires is non conceivable.

The cartography, the fire experiment results and the modelling of the combustion gases flow, show the great size of the fires and their location on the axis of the gallery. The smokes were evacuated at the ceiling, which allowed the palaeolithic man to maintain the fire and to breathe in the lower part. This results has been confirmed by 3D numerical simulations of the burning of a fire in a simplified geomery of the Megacros Gallery.

The functions of the fires keeps unknown: lighting, getting the torch going again, protection from the bears who were present in the cave at the same period...

In the Megaceros Gallery, other hypothesis can be considered:

- colourant production, given the great quantity of charcoals uncollected on the ground and, in one case, gathered under one of the paintings ;

- markings, for two small rubefied areas, located above a rock step, in the medial part of the gallery ;

- or, in a more hypothetical way: smoke, heat or light production, without reason other than symbolic ; modification of th wall state, in particular its colour and maybe its consistence.

*Espejo, Maria del Mar - (Cueva de Ardales) mariadeespejo@gmail.com*

The Ardales Cave is located in a mountain area near the village of Ardales about 50 km North of Malaga. It was Henri Breuil who recognized first its rock art in 1918. Ardales cave is outstanding in Southern Spain for its numerous examples of paintings and engravings from the Upper Palaeolithic. To date 1010 pictorial artefacts from 252 panels have been described. They probably represent three chronological phases from the Gravettian, the Solutrean and the Magdalenian. Apart from the rock art an important number of non-pictorial artefacts have been conserved. These are stone and bone tools placed near the panels, paste of red and yellow pigment, stone containers used as pigment palettes and stone lamps used for artificial lightning. The talk will present latest results of the spatial distribution of the non-pictorial artefacts and their possible relation to human movement in the cave and to the position of the rock art panels.

The artistic and symbolic expression in the Late Epigravettian of Northern Italy consists essentially of the mobiliary art found in residential and funerary contexts. An exceptional case is represented by Dalmeri rock shelter, an hunting seasonal camp located at about 1240 m asl on the Asiago-Sette Comuni Plateau (Trento). This site not only has played a key role in revealing the socio-economic dynamics of settlements and resource exploitation of Late Epigravettian hunters, but also has provided unique evidence of symbolic activities.

The earliest human occupation of the site, dated to 13,400-13,100 cal BP, is characterized by the presence of hearths, a dwelling structure, and rich cultural components such as a lithic industry and faunal and charcoal remains (Montoya, 2008; Tagliacozzo and Fiore, 2009). In addition, these layers revealed a total of 267 stones painted with red ochre that have zoomorphic, anthropomorphic, and geometric motifs (Dalmeri et al., 2006; 2009; 2011).

The spatial distribution of the stones indicates that a fan-shaped area of ca. 30 sq m and more than 4 m wide

oriented east-west towards the rock wall was reserved for ritual activities. Most of the stones were found with the decorated side facing down and were often in small piles (Dalmeri et al., 2009). This distribution suggests the intentional concealment of the painted images.

Another interesting discovery made just outside of the rock shelter involves three pits that were filled with different materials. The structures (and substructures) contained an abundant selection of ibex cranial parts with horns and single horns with more than 8,000 remains, particular objects, polishers and stones painted with ochre. The stratigraphic and taphonomic analyses of the filling revealed the intentional deposition of the materials and the utilization of the ibex horns for filling up the pits.

A direct connection between the painted stones and the ritual pits is supported by the stratigraphic data, the spatial organization and the C<sup>14</sup> dates. This evidence, moreover, suggests the hypothesis of a complex ritual activity that involved a large parte of the living space, including significantly the entrance area of the shelter. The presence of ochre marks applied to the upward-facing sides of the painted stones, probably finalized to recognize them, associated to the evidence of a gradual filling of the pit 1, suggests a dynamic ritual, repeated and renovated over time in a relatively short period.

ORAL

**12. DETERMINING NATURAL VERSUS CULTURAL COLOURED ROCKS (?PIGMENTS?) AT NAWARLA GABARNMANG, A 48,000-50,000 YEAR OLD ABORIGINAL SITE IN NORTHERN AUSTRALIA**

*Castets, Géraldine - (Laboratoire EDYTEM) geraldine.castets@univ-savoie.fr*

Western Arnhem Land's rock art is world famous yet very poorly dated. One of the key challenges facing researchers is establishing how old the rock art is, since, unlike other archaeological materials, art is not straightforward to date because of the mineralogical nature of most pigments used by Aboriginal people in the past. In some sites, considerable numbers of coloured nodules of uncertain cultural status are excavated in painted caves and rockshelters, offering the potential to better understand the antiquity of the painted art itself by chronostratigraphic associations with buried pigments. To do so requires matching the chemical properties of buried pigments with on-wall paints. Yet a critical challenge is

to first weed out non-cultural buried pigments: that is, to recognize what constitutes earth pigments brought to a site by people, as opposed to non-cultural coloured rocks that have naturally formed within a site. To distinguish between the two requires understanding the geomorphological and chemical processes that cause the diagenesis of pigmentation on buried rocks.

This study reports on the earth pigments excavated from Nawarla Gabarnmang (Jawoyn country, western Arnhem Land, Australia), at 48,000-50,000 cal BP one of the oldest known cultural sites in Australia. The shelter's ceiling and many of its rock pillars are literally covered in multiple layers of paintings. Excavations have revealed numerous coloured rocks, some clearly natural, some clearly cultural, with various degrees of uncertainty in-between.

Using a range of techniques including macroscopic observations and chemical analyses (XRF) coupled with structural techniques (XRD, Fourier Transform Infrared, Raman micro-spectroscopy), we present initial results aimed at determining which objects are natural, which are cultural, and what kinds of diagenic processes have resulted in the colouration of the natural pieces.

ORAL

### 13. EXPLORING THE ORGANIZATIONAL STRUCTURE OF CAVE USE THROUGH PHYSICAL CONTEXT ANALYSIS

*Villeneuve, Suzanne - (Simon Fraser University) suzanne\_villeneuve@sfu.ca*

A century of hypotheses concerning Paleolithic cave use has focused either on individual activities (such as vision quests or shamanistic visits) or group activities such as initiations. Resolving this issue provides an important foundation for examining more complex questions such as the exclusivity/inclusivity of groups using caves and their possible roles in the development and maintenance of inequalities in the Upper Paleolithic. The basic research problem that I have attempted to address is whether any of the decorated Upper Paleolithic caves were used for group rituals? If so, what was the nature of the group activity (at least in general size of groups), and what types of social groups might have been involved? A sample of caves from the Perigord Region of Southwest France was examined to test a systematic approach to examining these issues. An activity area approach (as applied in other domains of archaeology) was adopted

in the analysis of the spatial distribution of cave images, to explore what the immediate contexts of images may reflect in terms of associated activities or group sizes and how different portions of caves may have been used. It was important to document the physical and visibility conditions surrounding images, and to understand image patterns according to these contexts. Thus, variation within caves (and between caves) in the physical contexts of images and the way space was used are central concerns of this work.

A number of subgroups of cave spaces resulted from this analysis that potentially reflect subcomponents of activity. Their distribution appears to hold insight into the overall organizational structure of cave use, and implications for similarities in activity between some caves. These results take into consideration: 1) the size of the physical space, wall topography and visibility conditions to understand possible group sizes; 2) clustering or distribution of images to understand where activities may have concentrated and what type of movement may have been involved, and 3) image characteristics within this context (although further effort is required when attempting to interpret intentionality in terms of audiences).

Thus, when viewed from an activity area (or social context) perspective, with attention to physical contexts and visibility in examining image distributions, a similar organizational structure to cave use seems to emerge. This is different from most past explanations and something that would perhaps not emerge when focusing on the symbolic content of the images themselves. If there is a similar organizational structure to the use of some caves, symbolic content of the images might more profitably be examined within this context, at least at the level of animals, anthropomorphs, and geometric shapes.

The transformations or maintenance in Upper Paleolithic beliefs are undoubtedly reflected in some way in the caves. The painted caves may in fact be an ideal place from which to better understand the development of complexity during the Upper Paleolithic, and the emergence of inequalities, if examined in terms of a social context perspective in a dynamic temporal and regional model.

ORAL

#### 14. PLAQUETTES DECORATED AS A HISTORICAL SOURCE OF PALEOLITHIC

*Clavijo, López Juan - (UNED) j.clavijo@lacroixnorte.com*

The work aims to conduct an overview of the phenomenon of plaquettes decorated Palaeolithic.

There have been various methods used to achieve this goal, first a literature review of research results, including the most recent, and assumptions of the most important authors, and on the other hand has made several visits to museums to see documentation.

As a result the paper develops different hypotheses: Petrifaction art, why art towards 35000BP might appear, usually called full, fully developed; Natural message communication system, the art in response to a communication system between two species graph; From the board to the wall, the more complex societies need a more expressive communication; Technical variability of the performing arts, traditions that established the operational chain to create art were discontinued with the death of specialist.

In conclusion we can say that Paleolithic plaquettes decorated were not made for one reason, but there were different situations that led to its realization. I mean, probably a result of a variety of uses. Furthermore iconography represented why did not maintain the same meaning throughout the period, could evolve in content, is able to adopt the same but with different meanings signs and therefore need not be a single explanation for implementation.

ORAL

#### 15. THE IMPORTANCE OF HISTORIOGRAPHY IN THE PALEOLITHIC CAVE ART CONTEXT STUDIES

*Ochoa, Blanca - (Universidad del País Vasco UPV/EHU) blanca.ochoa@ehu.es*

In the course of the last decades there has been new cave art discoveries such as La Garma, Chauvet-Pontd'Arc, Le Réseau Clastres in the Niaux Cave, Cosquer or Cussac, these have allowed researchers to advance in context and spacial studies. This has been due to the fact that the decorated chambers were intact in the moment of the discovery and soon after that protocols to protect these invaluable records were developed.

The problem is that these types of caves are a minority. Most of the discoveries were made at the beginning of the 20<sup>th</sup> century and a few years after the first studies were published, the caves were modified to a great extent to prepare them for touristic visits. This altered the space of the cave to a great degree and destroyed evidences that could have existed. In these cases, we have lost invaluable information for the majority of the Palaeolithic cave art. However, the study of historiographical documents can provide information regarding the context and the original space distribution of the caves. In this poster we will introduce available data from different historiographical sources such as pictures and descriptions available in publications but also in unpublished materials. These documents are invaluable for the reconstruction of the space and the context in the moment of the discovery of the caves because they will allow us to reconstruct, to some extent, the spatial configuration that existed before the modifications were made on the caves.

#### 16. TRACKING IN CAVES ? FIRST DECIPHERMENT OF PALAEOLITHIC HUMAN FOOTPRINTS IN PAINTED CAVES BY TRACKERS FROM THE JU/'HOANSI-SAN (NAMIBIA)

*Pastors, Andreas - (Neanderthal Museum) pastors@neanderthal.de*

*Lenssen-Erz, Tilman - (University of Cologne) lenssen.ertz@uni-koeln.de*

Human hand- and footprints from prehistoric times along with human bones are the most personal remains left from an individual. Under ideal conditions a short lapse of time of a single person may be recorded in a plastic surface. No other findings (stone tool, artwork or other) are so clearly linked to a short individual moment. Prehistoric foot- and handprints are known from different continents and periods. Among them the most spectacular ones are footprints from Laetoli and Koobi Fora. No less fascinating are footprints left by Pleistocene humans in decorated caves in South-western France. The extraordinary status of such fragile remains stands in stark contrast to the scientific interest during the last 100 years because only three researchers have seriously studied small parts of the known footprints. This imbalance is perhaps owed to the cultural alienation to this kind of remains and the potential means to interpret them.

This experiment aims to test the feasibility of such an integration of two knowledge systems and the benefit for archaeological science but not to test the reliability of indigenous tracking skills. Even if the concrete method of tracking is still unknown and study in process, the precise and plausible results are worth to be presented to a wider public.

To stimulate the research on human footprints three professional trackers from the Ju/'hoansi-San from Tsumkwe (Namibia) - once known as "Bushmen" -, Ciqae, Thao and Kxunta, were directly confronted with the original footprints in four French caves: Niaux, Pech-Merle, Fontanet and Tuc d'Audoubert. For perhaps the first time, indigenous knowledge (IK) was integrated into archaeological data-gathering without the detour of ethnographic analogy or as mere confirmation of previous results.

In all four caves visited, the old interpretations of human tracks are now flanked by alternative readings which imply several necessary revisions. Most spectacular may be the identification of toe-imprints at the track that hitherto was present in literature as the only print of a shod foot. If pointed out by an expert, the impressions of the toes are even recognisable to an untrained observer, so that the hypothesis of a moccasin can hardly be upheld. For none of the tracks that formerly had been interpreted as 'ritual dance' or similar ceremonial behaviour was there any corroboration by the trackers. All footprints seem to be generated by ordinary stride with few exceptions of a faster pace, thus leaving no space for hypotheses regarding extraordinary behaviour. In none of the caves investigated was there any proven or even potential connection between spoor and the parietal art of the caves. In three cases the hitherto assumed number of acting people was either augmented (Pech-Merle) or diminished (Niaux, Tuc d'Audoubert).

Human tracks constitute a source that is comparatively obvious and unambiguous, though replete with information. They are equally accessible to various kinds of knowledge systems and therefore may be an ideal prototype for the integration of IK into archaeological sciences, not as an exotic add-on but as a serious interdisciplinary liaison method.

## 1. THE ROLE OF GRAPHICAL DOCUMENTATION IN THE STUDIES ON PREHISTORIC GRAPHIC EXPRESSION

*Teira, Luis - (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) teiral@gestion.unican.es*

If we analyse the publications related to the documentation of prehistoric rock art, especially if we refer to moments before the impact of computers, we will probably agree that the imagery shown in them acts as an "illustration", understood as a specific category that speaks of images that accompany a text. The relation between these two elements in this type of papers is vastly varied and methodologically dark. In fact, unlike text, images can hardly be placed in the argumentative structure of the studies. Do they belong to data submission or are they part of the development of interpretations? Taking the words of P. Ucko on methodology in the analysis of rock art, "most publications seem to assume we all know what we are doing and we have good theoretical basis to do so" (Ucko, 1989, *Subjectivity and the study of Paleolithic rock art*). In this communication we analyse the role of graphics –understood as scientific images– in the documentation of Prehistoric Graphic Expression; the impact of digital technology on a renewed and vain use of the terms "objective" and "subjective" and also the use, often contradictory, of technical terms such as 2D, 3D, image, photo, tracing... In this sense, we will try to expose the defining keys of the image generation process in a subject as peculiar as Prehistoric Graphic Expression.

## 2. L'ART PARIÉTAL DE CUSSAC (DORDOGNE, FRANCE) : MÉTHODOLOGIE ET PREMIER BILAN

*Feruglio, Valérie - (PCR Cussac) feruglio@free.fr*  
*Bourdier, Camille - (Université Toulouse Le Mirail - UMR TRACES 5608) camille.bourdier@univ-tlse2.fr*  
*Aujoulat, Norbert*  
*Delluc, Marc - (Spéléoclub de Périgueux, SCP, Bergerac) marc.delluc@sfr.fr*  
*Portais, Jean-Christophe (CRMH Aquitaine)*  
*Jaubert, Jacques (Université de Bordeaux, PACEA) jjaubert@pacea.u-bordeaux1.fr*

En 2008, un collectif (Projet collectif de recherche sous l'égide du Ministère de la Culture) a été constitué pour

étudier la grotte ornée et sépulcrale de Cussac (Dordogne) découverte par M. Delluc en 2000. Nous présenterons un bilan de 5 années de terrain (2009-13) consacrées, pour l'art pariétal, à une reprise de l'inventaire et à l'étude des principales caractéristiques techniques, thématiques, stylistiques et iconographiques qu'avait commencée Norbert Aujoulat et dont il avait livré des résultats préliminaires (Aujoulat *et al.*, 2001, 2002).

Nous confirmerons d'une part l'extrême homogénéité qui sous-tend ces productions, et d'autre part leur cohérence au sein du répertoire graphique du Gravettien moyen.

Pour des raisons d'accès, d'équipement et de programmation, l'étude ne porte que sur une partie du réseau représentant cependant la quasi-totalité de la branche Aval, de l'entrée actuelle au Panneau du Passage, soit près de 400 m de linéaire de la longue galerie de Cussac. Cette zone est la plus densément ornée de la cavité, concentrant les panneaux majeurs (Panneau de la Découverte, Grand Panneau). Au-delà, le Panneau du Fond, conclut ce secteur et ne peut être étudié pour l'heure faute d'équipements difficiles à mettre en œuvre.

Pour l'étude de l'art pariétal, quatre principaux objectifs ont été programmés : 1) Reconnaissance topographique des panneaux ou figures isolées ; 2) Inventaire systématique et établissement d'une base de données déclinée en panneaux et entités graphiques reportée sur un SIG ; 3) Approche taphonomique de la paroi ornée par une analyse interdisciplinaire avec des géoarchéologues et des informaticiens sur un support 3D (étude de cas pour le Panneau du Triptyque) avant de procéder au dernier volet qui est prévu sur le moyen ou le long terme : 4) Relevés sur support 3D dont la première tranche vient juste d'être livrée.

Compte tenu de la richesse et de la densité iconographique de la Branche Aval, une analyse, même préliminaire, autorise une vue d'ensemble fiable et représentative de ce sanctuaire d'exception.

La présentation de ces divers volets méthodologiques, faisant largement appel aux nouvelles technologies nourrira la réflexion sur les approches actuelles et les nouveaux outils de l'étude de l'art pariétal dans un souci de compréhension, mais aussi de conservation et de diffusion de ce patrimoine.

ORAL

### 3. NEW STUDIES AT THE GENOVESE CAVE, SICILY, USING A PORTABLE XRF

*Vianello, Andrea - (independent researcher) a\_vianello@hotmail.com*

*Tykot, Robert - (University of South Florida) rtykot@usf.edu*  
*Giglio, Rossella (Soprintendenza per i Beni Culturali e Ambientali Trapani) - giglioro@libero.it*

The so-called Genovese Cave in Levanzo has been the subject of new studies with a non-destructive portable XRF. The cave is very important because of its geographical location at the western end of Sicily and its parietal art, both carved and painted. There are both human and animal figures depicted in the cave. The painted art includes black and red figures in separate panels. Past excavations in the cave have revealed a long occupation that spans from the Palaeolithic to the Bronze Age.

The phenomenon of Palaeolithic cave art is widespread in Europe, but it appears concentrated in Iberia and France, with very few sites found in Mediterranean areas at the crossroad of future development. This study intends to briefly compare some of the art from these 'marginal' sites with the better studied and more famous European art.

In this study, we present the data from a portable XRF, which has been used to analyse the elements of the painted art and distinctive areas of the geology of the cave. From such data, we can reconstruct the materials used to paint the figures. A fresh look at the archaeological evidence from the Genovese cave provides much needed contextual information on the use of the cave itself. We have also begun exploring the contexts of other caves in the area for comparative purposes, though no other cave in Sicily contains all types of figurative art as in the Genovese Cave. The portable XRF has been used on many types of materials.

We have also initiated a new study of the parietal art taking into consideration new discoveries of figurative art from across Sicily. In particular, Sicilian ceramic idols seem very similar to those depicted in the cave, suggesting that cave art and portable art stemmed from the same beliefs but were not used together in the same contexts. The number of carved and painted figures is also much higher than any assemblage of figurines. These differences and the scientific data that we are producing will form the basis for a new re-interpretation of the cave. Here, we discuss some of the empirical data and review some of the constraints that they place for future interpretations.

We aim to differ from past interpretations of cave art that consider only art itself and rather recognise the art as one of the long-lasting manifestations of a group of people that used the cave habitually.

ORAL

### 4. EPHEMERAL HERITAGE: THE ROCK ART MOULDS OF THE TAGUS VALLEY (PORTUGAL) AND THE APPLIED PHOTOGRAPHY TO ARCHAEOLOGICAL MATERIALS.

*Garcês, Sara - (Universidade de Trás-os-Montes e Alto Douro - FCT PhD scholarship; Instituto Terra e Memória; Grupo de Quaternário e Pré-História do Centro de Geociências) sara-garces.rockart@gmail.com*

*Joaquim, Flávio Nuno - . (Instituto Politécnico de Tomar, Estrada da Serra 2300 Tomar, Portugal; Instituto Terra e Memória) flavio.joaquim83@gmail.com*

*Oosterbeek, Luiz - (Instituto Politécnico de Tomar, Estrada da Serra 2300 Tomar; Instituto Terra e Memória (ITM, Mação); Grupo Quaternário e Pré-História do Centro de Geociências (u. ID73 - FCT) loost@ipt.pt*

*António Ventura - (Instituto Politécnico de Tomar, Estrada da Serra 2300, Tomar, Portugal) aventura@ipt.pt*

An innovative protocol between the Earth and Memory Institute (Instituto Terra e Memória) and the Master's Degree in Applied Photography of the Tomar Polytechnic Institute (Portugal) has brought forward a reliable record of the latex moulds of the Tagus Valley Rock Art Complex engraved rocks. This material is the result of a tracing technique of the rock engravings used in the early 70's in the Tagus Valley, when the discovery of the thousands of engraved rocks was made at the same time as the imminence of the construction of the Fratel dam.

Latex moulds were the object of an ambitious registration and documentation project, in the scope of the project *Ruptejo*, which culminates with the necessity of recording exactly and objectively this material, whose state is still pretty good, though fragile, after four decades. It is, however, one of the few materials that certify the importance of the rock art collection of the Tagus Valley, which is now submerged.

The Master's Degree in Photography has been responsible for the systematic photographic registration of the moulds and has suggested a study to find out how can photography contribute to new forms of visualizing and perceiving rock art engravings, which are today regis-

tered by the moulding process. Applied Photography is, thus, an extremely important tool for the construction of continuous and reliable evidence of an ephemeral heritage.

## 5. NEW TECHNOLOGIES APPLIED TO PREHISTORIC ROCK ART STUDIES.

*Bayarri Cayón, Vicente - (Gim-Geomatics) vicente.bayarri@gim-geomatics.com*

*Ripoll, Sergio - (UNED), José Latova - latova@asfimagen.es (ASF-Imagen) sripoll@geo.uned.es*

*Municio González, Luciano - (Junta de Castilla y León) luciano.municio@gmail.com*

The present paper shows the project *Development of a Management System for the protection, enhancement and dissemination of Prehistoric Rock Art and Stations (SIGAREP I and II)* which has advanced the promotion, protection and dissemination of cultural heritage and archaeological sites comprising stations rock art in the mountains of Central System in the provinces of Madrid, Guadalajara, Segovia and Avila. This art, due to its characteristics is not easy to guard or be displayed in museums, through the implementation of a common transverse project for the institutions belonging to different Autonomous Communities. The scope was promoting the use of new information technology systems and the most innovative 3D documentation systems of the heritage for preventive conservation that contribute to the maintenance and recovery of this art so difficult to guard. Later through the use of new information technologies it should be available to museum visitors.

## 6. THE CAVE OF FUENTE DEL TRUCHO (ASQUE-COLUNGO): THE GEOMETRIC DOCUMENTATION 2005-2014

*Angas, Jorge - (3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza.) j.angas@3dscanner.es*

*Bea, Manuel - (PostDoc Researcher "Torres Quevedo", 3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza & MINECO. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza.) manubea@unizar.es*

*Utrilla, Pilar - (Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro.") utrilla@unizar.es*

*Baldellou, Vicente - (General Direction of Cultural Heritage. Government of Aragon. Group "Primeros Pobladores del Valle del Ebro.") vbaldellou@aragon.es*

During the last few years, new techniques for surveying applied to Rock Art have been developed. Nowadays the apparent rate of development of technology, together with social immediacy, often does not allow the establishment of an entire process of technologies and procedures necessary in all types of archaeological documentation projects. Deciding how to focus the latest survey techniques applied to archaeological sites, aimed at a didactic application, is a complex process. The development of this purpose must balance the research process with the social spreading of scientific knowledge.

We present a proposal of a geometric documentation methodology to apply in Palaeolithic caves. The experience carried out in the cave of Fuente del Trucho (Asque-Colungo, Huesca), from 2005 to 2014, has allowed us to outline a systematic and accurate registry for the physical reality of the cave. The application of different geometric documentation systems (laser scanner, structured light scanning, microphotogrammetry) makes it possible to obtain three-dimensional models at different scales as well as ortho-rectified and point clouds of high density for certain areas.

Combining different methodologies, for a global geometric documentation of the cave and on selected reduced surfaces, we have as a result a high density and high resolution point cloud to rebuild the tri-dimensional panels for the study, those that, for conservation reasons, must be analysed in greater depth.

All the techniques mentioned allow us to obtain a tri-dimensional mesh from which it is possible to incorporate measurements based on the point clouds by extracting the 2D and 3D characteristics to be measured. Comparison between point clouds of the same area captured at different times will give us the necessary data to have a better comprehension of the diachronic behaviour of the wall and rock art motifs and, with them, to determine and orientate the best manner of conservation.

Cave of Altamira is located in Santillana del Mar, in northern Spain. It is one of the most prominent examples of human symbolic creation and is recognized as one of the landmarks of the World Prehistory. Therefore, the Cave of Altamira is included in the World Heritage List since 1985.

The cave of Altamira has different maps, made over time and since its discovery in 1879, and that have evolved together to the development of geomatics techniques. Since the first sketch freehand which was published in newspaper *El Impulsor* in 1880, plane of Harlé in 1881 until 1942 maps made by Francisco Fernández Montes, FOESTRA series in 1975, cartography of *Instituto Geográfico Nacional* between 1998 and 2002, and many others. Such maps often do not match due to the unreliability of the methods used and the complexity of the cavity. They have served instead as a fundamental tool for different preservation art studios of the cave and tourist use.

The importance historically given to cartography within the caving and the study of prehistory is that any subsequent study after discovery of a cavity requires a plane on which to base it. Hence surveying is one of the first tasks performed and it is essential to provide support to different multidisciplinary information from other sciences.

The new data capture techniques allow resolution and detail information ranging from the centimeter to micron. Traditional maps and planes have evolved to 3D mapping, from which implicit information can be derived such as heights of gallery and thickness of the roof maps usually very difficult to represent. This model can be used for climate simulations and calculations of all kinds to become the base map or essential support of multiple data enabling the creation of a GIS. Nowadays it is also possible to document painting and engraving or

microbiological monitoring processes with a reliability of microns.

This article shows the process followed for the new cartography of Cave of Altamira by generating comprehensive 3D documentation using different techniques, both Cave of Altamira and its external environment, with reliability from several millimetres to micron depending on the different elements represented.

The presentation will compare the new cartography with other historical surveys and the new values that can be drawn from the model as the surface area and volume of the rooms, geological setting, etc.

Also it will be analyzed using the new cartography, measured facts from previous studies and possible lines of future work to exploit the potential of the new data.

## 8. NEW DOCUMENTATION AND ART STUDY IN THE WALLS ROOM AND RED SMALL ROOM OF THE CAVE OF ALTAMIRA

*Bayarri Cayón, Vicente - (GIM Geomatics, S.L.) vicente.bayarri@gim-geomatics.com*

*Latova, José - (ASF Imagen, S.L.) latova@asfimagen.es*

*Lasheras, José Antonio - (Museo Nacional y Centro de Investigación de Altamira) Investigacion.maltamira@mecd.es*

*De Las Heras, Carmen - (Museo Nacional y Centro de Investigación de Altamira) Investigacion.maltamira@mecd.es*

*Prada, Alfredo - (Museo Nacional y Centro de Investigación de Altamira) Investigacion.maltamira@mecd.es*

The Cave of Altamira Cave is located in Santillana del Mar, in northern Spain. It is one of the most representative examples of Paleolithic art and is a reference in the history of art.

It was the first cave in which was described what we now call rock-art and therefore the origin of other discoveries of this kind of expression of man. It constitutes one of the most prominent examples of human symbolic creation and is recognized as one of the landmarks of World Prehistory. Therefore, the Altamira Cave is included in the World Heritage List since 1985.

The study of its rock-art is still partial and presents some obsolescence in part based on an unequal iconographic documentation. The study of art has focused on the famous Hall of Polychrome, vast canvas on which

the artists painted and recorded for over 20,000 years. However, Altamira has a lot of artistic performances spread along its 270 meters long, that have not been studied in detail and, in many cases, not published. The conservation of the Cave of Altamira and its artistic representations requires a comprehensive inventory and technical documentation and knowledge according to what we have available today for these representations.

Therefore we have initiated a project to revise and update the catalog of cave art. The development of the method and protocols work is being developed on panels of called *Sala III*. This space was originally part of a continuous area which integrated Polychrome room and that extended to the entrance of the cave. Here are located several artistic ensembles of various technical characteristics.

In this study, it was analyzed a panel painted in black with representations on the vertical wall and series of signs painted in red within a narrow chamber formed in a diaclast.

This article shows the results obtained by applying the latest documentation methods based in photogrammetry and terrestrial multispectral remote sensing along with the mathematical analysis of different digital files which provide new documentation of parietal art sets. We will also introduce a historical analysis comparing the different ways in which have been documented and represented these sets to try to understand the evolution that over time has suffered its understanding and see how the evolution of the different methods of representation has made vary our understanding of these signs and figurative representations. Things are as we represent them.

The integration of some geomatics methods permit to document rock-art in a rigorous, safe and detailed way. These techniques offer 2D and 3D results that can be used in any study. The new amount of information can change the way to understand them.

ORAL

**9. LA LLUERA I CAVE (SAN JUAN DE PRIORIO, OVIEDO, ASTURIAS, SPAIN): ART AND GIS OF THE MORE FIGURATIVE AREAS OR "NICHE AREAS" OF A SANCTUARY.**

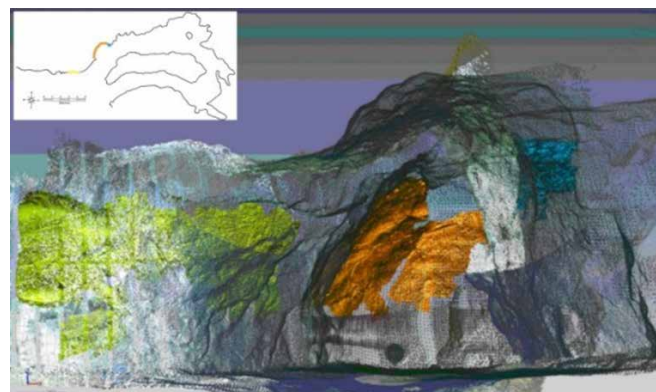

Rodríguez Asensio, José Adolfo - (Universidad de Oviedo)  
adolfo@uniovi.es

Aguilar Huergo, Eugenio - (Universidad de Oviedo)  
e.aguilar.0@hotmail.com

---

Since the beginning of the rock art until today, the study of prehistoric art has been done with different tools (drawings, photos, tracings...). The study of the engravings in La Lluera I cave (San Juan de Priorio, Oviedo, Asturias, Spain) is a good example. Since its discovery in 1979, by the Polyphemus group for the study of his engravings have been done all kinds of photos, drawings and tracings. Thanks to these early studies, his engravings were framed as belonging to the Solutrean (Fortea Pérez, 1990). In 2008, we proceeded to the scanning of his engravings (4 areas: niche, bison's area, left entry and right entry). Today, everything can be integrated into the appropriate tool: GIS. The engravings are the peculiarity to destroy a portion of the surface rock leaving a hole made with an object or even by hand (Sanchidrián, 2001). This hollow drawn in 3D is the sketch. It is known as sketch to the delineation that is formed with the design or plant of anything.

3D scanning engravings - Lluera I cave. Yellow: entry's horse, orange: niche and blue: bison's area.

The present study focuses on the more figurative areas or "zones niche" the cave of Lluera I: the niche (379 sketches), the entry's horse (22 sketches) and the bison's area (111 sketches). Thanks to this study is achieved:

- The representation of every sketch or engraving in 3D. Which allows us to: observe and take information of its Length, Width, Depth; if it is made: in V, in U, etc.
- Encode all the information of each sketch and artistic manifestation: measures, direction taken by the artist in making each sketch, etc.
- Create a catalog of the artistic manifestations of these three areas.
- Create all kinds of analysis and consultations, and view them immediately in 3D. The realization of the same in the three areas leads us to a working hypothesis: Is pos-

sible, good starting from planning or from the margin of improvisation that in every work of art is, the artist used sketches in dry skin as a visual support by making them? A thing is clear: it is not any hand that engraved, and much has drawn on dry skin and in the full light of day before making these three areas.

Catalogue of figures: the niche. Scale: 30 cm

The creation of a 3D GIS of the sketches has been, thanks to the technical advantages posed by GIS, a revision to the art of these three areas, and a face wink to the future: GIS, thanks to augmented reality and interactivity, may be the best didactic support for a virtual visit.

Elaboration's phases: the niche. Phase 1- Red. Phase 2- Blue. Phase 3- Green. Phase 4- Purple. Phase 5- Orange. Phase 6- Black. Phase-7 Brown. Without phase- Yellow. Scale: 30 cm.

ORAL

## 10. PHOTOGRAMMETRY AND PCA APPLIED TO THE TRACING OF ROCK-ART PAINTINGS. A CASE STUDY FROM THE PRECORDILLERA REGION (NORTHERN CHILE).

Cerrillo Cuenca, Enrique - (CSIC, Instituto de Arqueología)

*enrique.cerrillo@csic.es*

*Sepúlveda Retamal, Marcela - (Universidad de Tarapacá)*

*marcelaasre@gmail.com*

*Ortiz Coder, Pedro - (E-Capture) pedro@ecapture.es*

In the present paper we introduce a computer-aided method for recording rock-art paintings through digital photographs. The aims of the method can be summarised in two: the creation of high-resolution ortho-images and the digital detection of pigments in them.

We present a first advance to an on-going work focused on the digital analysis of rock-art paintings from the precordillera region (Northern Chile). The case illustrated is Mullipungo 1, one of the sites excavated by Schiapacasse and Niemeyer (1996) in the 1980 decade. At that time, they identified 6 panels with depictions of dynamics camelids, anthropomorphic representations and geometric motives. The preservation of paintings is currently poor and its recording is greatly hampered. Comparative approach and stylistic analysis regarding to other sites are complex.

Photogrammetry is becoming the standard for archaeological documentation tasks, and is especially advantageous in the case of rock art. We have obtained a 3D model and high-resolution ortho-images from the panels by using 4e software, a powerful and precise solution for photogrammetric restitution.

Complementarily, we have developed an experimental software platform called PyDRA for improving the recognition and documentation of paintings through photograph that allows a fast and efficient processing of data. The resultant ortho-images are transformed into three matrices (one per image channel) and statistically analysed. Among the several methods that PyDRA implements, we have selected the Principal Components Analysis (PCA). This method projects the matrices from the original image into a new space, whose representation usually splits in different channels the information about pigments and the background.

The application of photogrammetric techniques to the site of Mullipungo 1 has served to produce a new tracing of the site, in a totally digital way. More than 200 images were used for the photogrammetric restitution, whereas the general ortho-image of the site was divided in 6 images for a faster and efficient analysis. Once processed by PyDRA, the statistics showed a high correlation between the RGB bands and how the depicted motifs were clearly visible when transforming into images the 2<sup>nd</sup> and 3<sup>rd</sup> components (matrices).

Several authors have described or designed different procedures for simplifying the documentation and digital tracings of rock-art paintings. As it can be stated, the choice of the software used for the digital processing can play a noteworthy role when presenting the final results. The use of our own software allows a more accurate choice of the parameters requested during both photogrammetric restitution and analytical processes, as the high resolution and precision of the 3D model and the enhancement of pigments can show.

Different kinds of improvements can be outlined on the newly obtained tracings from Mullipungo 1: 1) the recording of new figures; 2) additional details of some depictions; and, 3) more information about the use of the rock surface. The proposed methodology decreases the time spent during the fieldwork, as well as the equipment used, which is especially important when working in a mountainous region, as the precordillera is.

*D'Hulst, Dominique - (GEConseil, 30 rue de la République, 09200 St Giron, France) dominique.dhulst@free.fr*

During the last 150 years, many prehistoric decorated caves suffered from growing touristic exploitation and invasive archeological operations. This resulted in irreversible destructions and in uncontrolled degradations of the remains, associated with permanent or temporary destabilization of cave microclimates. We propose remediation strategies able to restore satisfactory conservation properties in these sites.

Multisite, multiparametric monitoring in cave and at the surface provides information on karst dynamics and cave microclimates. These data are compared with in situ observations of the evolution of the remains and of their rock support. The identification of multiple buffering mechanisms responsible of stable condition in karstic caves and former work in Chauvet cave led to define underground confined state, which possesses optimal conservation properties.

In le Mas d'Azil and Marsoulas caves, exchanges conditions with outside had been dramatically changed by modifications of the entrance and even internal geometry of the cave, resulting in open microclimatic conditions expanding to most of the decorated zones. Restoration of confined zones in le Mas d'Azil reduced the thermal impacts due to visits and to the outside climate influence, preventing condensation on parts of the decorated walls. Further improvements are needed in this site. In Marsoulas, remediation is expected in the future with a double door structure whose buffering properties will mimic those of the initial scree removed by archeologists in 1931. In Pech Merle tourist cave, recurrent painting fading was related to natural seasonal drying of walls. Comparing microclimate studies achieved 30 yrs ago and present ones lasting since 1998, allows to assess the effects of improvement of the cave closure system which restored a confined state insuring a permanent stable and optimal visibility of the paintings. In Gargas, starting from a completely open state with documented degradations, optimization of the closure and of the lightning system as well of the number of visits, allowed to reach gradually a semi-confined state that improved the conservation properties of the cave.

Remediation operations in decorated caves have to be based on the identification of regulation processes that should be re-established. A particularly important point is to refer to a realistic "initial state" of the cavity, which often has to be reconstructed from documents, archeology, geology, or geomorphology. Remediation consists of restoring progressively natural buffers or introducing new ones, and should be assessed by monitoring physical and chemical parameters of the cave atmosphere especially near archaeological remains.

**12. MANAGING THE CLIMATE OF CAVES WITH  
ROCK-ART THROUGH COMPUTERIZED MODELING**

*Bayarri Cayón, Vicente - (Gim-Geomatics)*

*vicente.bayarri@gim-geomatics.com*

*Ontañón-Peredo, Roberto - (Museo de Prehistoria y Arqueología y Cuevas Prehistóricas de Cantabria) ontanon\_r@cantabria.es*

*Castillo, Elena - (Universidad de Cantabria) castille@unican.es*

One of the key aspects in the management of the caves with rock art is maintaining the balance -or, at least, "a" balance- in the environmental conditions of underground spaces. The reason for the conservation of this magnificent heritage from about 40,000 years ago to the present is the maintenance of a marked climatic stability fostered by the isolation, absolute or relative, of this subterranean environment.

The main purpose of this paper is to promote sustainability and conservation of the caves with rock-art, by increasing and improving the capacity of the managers of these sites through the design and implementation of a powerful analysis tool that allows us to base the decision making process on solid quantitative data, not on inferences more or less consistent derived from methodologically limited studies. In the framework of the project, the climate of the caves, the influence of the impact of human presence in the underground environment and possible changes in cave's management system are studied.

The methodological basis of the research is founded on numerical simulation in fluid mechanics. This relates to the study of the air flows, the energy and mass transfer and transport of particles, all phenomena involved in the configuration of each cavern climate (Lacanette et al. 2006, 2007; Malaurent et al. 2006).

The work program includes 3D scanning in order to have the models of the caves; location and geo-referencing of the sensor's network; determination of the conservation equations of the fluid environment and running of computerized simulations: Different hypothetical scenarios are being implemented, depending on the issues that arise for conservation and the specific requirements of each cave.

The paper describes the considerations to take into account and the results obtained when analyzing the configuration of the climate in the cave, the influence of cli-

mate configuration on the movement of air, the impact of human presence and the analysis of the attenuation of parameters altered by this presence.

**13. THE PHOTOGRAPHY APPLIED IN ARCHAEOLOGY - THE CASE OF COBRAGANÇA ROCK ART SITE**

*Joaquim, Flávio Nuno - . (Instituto Politécnico de Tomar, Estrada da Serra 2300 Tomar, Portugal; Instituto Terra e Memória) flavio.joaquim83@gmail.com*

*Garcês, Sara - (Universidade de Trás-os-Montes e Alto Douro - FCT PhD scholarship; Instituto Terra e Memória; Grupo de Quaternário e Pré-História do Centro de Geociências) sara-garcês.rockart@gmail.com*

*Borralheiro Pereira, Anabela - belaborralheiro@gmail.com (Museu de Arte Pré-Histórica e do Sagrado do Vale do Tejo, Mação, Portugal)*

Photography is a cross-discipline, which demands specific knowledge of words and things. It crosses from the surface of an image for semantic depth of the visual field (optical). Archaeology processes knowledge in the inverse way, from the depth to the surface by contact (the haptic). Both deal with the darkness in emergency and revelation, respectively, of the image and the layers.

In both the awareness of time and duration is a crucial dimension. These two processes of (re) construction of knowledge and reality are deficient. Together, they complement and potentiate each other. It would say that would constitute a third discipline that detects the material and immaterial dimensions of the environment, what surrounds us, it brings to mind the past time, who summons the memory trace as the union of continuity, the transmission of a heritage and cultural heritage.

The application of photography in archaeological work was once considered only as a descriptive technique for knowledge of the monument, with a highlight on its historical value. The photography used in a systematic way, as a support for cooperation of notes and observations made during excavation work, complement the visual perceptual information and aesthetics of archaeologists during the intervention process and study of the archaeological sites.

The work presented here is intended to illustrate the photographic methodological development in archae-

ology, with the highlight of the rock engravings from the Cobragança site located in Mação, Portugal.

These are two engraved quartz countertops with representations of concentric circles, squares, lines, rectangles, and that seems to suggest a zoomorphic figure. The history of this rock art site accompanies various times of the evolution of the use of photography in archaeology. It has been proved as indispensable technique in digital preservation thereof having regard to the engravings near-total destruction by the action of a forest fire a decade ago.

Illustration connects these two concepts of memory in different media: photography, the photographic record in its visual support in paper, and the rock engraving, permanent engraved in the rock, both documenting something of different perceptions and different meanings in different media, but both connect up to your visual concept.

#### ORAL

### 14. ANALYSIS AND INTERPRETATION OF A PARIETAL REPRESENTATION USING ADVANCED CAPTURE AND DATA PROCESSING TECHNIQUES: THE ANTHROPOMORPHIC FIGURE FROM HORNOS DE LA PEÑA (CANTABRIA, SPAIN)

*Ontañón-Peredo, Roberto - (Museo de Prehistoria y Arqueología y Cuevas Prehistóricas de Cantabria) ontanon\_r@cantabria.es*

*Bayarri Cayón, Vicente - (Gim-Geomatics) vicente.bayarri@gim-geomatics.com*

*Teira, Luis - (Instituto Internacional de Investigaciones Prehistóricas de Cantabria) teiral@unican.es*

The anthropomorphic figure from Hornos de la Peña is an engraving well known in the Paleolithic cave art of the Cantabrian region. Since its first publication in the early twentieth century has been the subject of several studies that have provided different lectures of the motif involving various interpretations of its relation to other traits present in the same parietal panel.

In an attempt to clarify the reading of this representation, we have chosen to apply innovative technologies for capturing and processing geometric data in order to quantify the operational process, so that the graphic result is a product methodologically verifiable by other observers, and therefore, rigorous in the sense of the scientific procedure.

The circumstances of location of the parietal sector in which the subject is situated complicate its study because of the limitations of the available space. Therefore we chose the use of small size equipment such as the handheld laser scanner ZScanner 700. The reliability of the instrument, 50 µm, and resolution up to 100 µm in depth, make it perfectly useful for scanning engravings. The data were processed using algorithms based on primitive search, adjusting different levels of smoothness, strength, tolerance and curvature of the generated 3D grid. The combined analysis of the results allows us to set thresholds to discriminate statistically similar traits that can be isolated to facilitate the reading and interpretation of the engraving.

The application of this method allowed us to discriminate "families" of traits corresponding to the anthropomorphic figure from other immediate matching other causes (including natural cracks), which had been subject to diverse interpretations by different researchers. In our view, the key interest of this work lies in the presentation of a method that is reproducible by other researchers or by ourselves on successive graphic evidences, within the logic of a scientific procedure, which allow us to quantify the subjective choices implicit in that process.

#### ORAL

### 15. TRACKING BIODETERIORATION PROCESSES BY PHOTOGRAMMETRIC METHODS

*Bayarri Cayón, Vicente - (Gim-Geomatics) vicente.bayarri@gim-geomatics.com*

*Ontañón-Peredo, Roberto - (Museo de Prehistoria y Arqueología y Cuevas Prehistóricas de Cantabria) ontanon\_r@cantabria.es*

*Castillo, Elena - (Universidad de Cantabria) castille@unican.es*

Microbial colonization is one of the main problems in the conservation of prehistoric art. Key factors in the conservation studies are the identification and quantification of microbial populations in caves and the assessment of their interaction with substrata and infiltration water. Geomicrobiological studies reveal that the growth of microbial communities is associated to the partial or total destruction of substratum surface (host rock, speleothems, pigments) as well as to the development of chemical precipitates by microbial activity.

Different methods have been applied by cave research

groups during the last years, varying from visual inspection to photographic coverage and, more recently, models from 3D laser scanner or photogrammetric cameras. The main objective of this project is to get a reliable, accurate and straightforward tool allowing the collection and processing of quantitative data to monitor visual impacts of microbiological communities.

The procedure begins with data acquisition, in form of pairs of images of very high resolution on the study areas. The photogrammetric support is carried out by 3D laser scanner, for georeferencing and increase reliability over other traditional methods such as range finders. Equivalent pixel size can vary, being able to get up to 3.5 microns for details in areas where required. The second step is processing the data to create 3D models comparable among them over time and thereby control the 2D and 3D evolution of the observed biodeterioration processes. Thirdly, in the phase of data analysis a double study of the models is performed: (a) 2D analysis, to determine the variation in length and control surface changes and (b) 3D analysis, to define the volumetric variation or height growth of colonies of bacteria, fungi, algae or other existing item.

This new method intends to be a most optimized technique for recording, as well as for monitoring over time, the visible microbiological or mineral recoveries commonly found on the walls of caves that may have an impact on the appearance of parietal works.

The potential advantages of this method compared with conventional studies performed using photographic scans, are: Collection and management of quantitative data, not semi-quantitative or qualitative; manageable protocol for data collection into the caves; micron accuracies; analysis of the evolution of the microbe colonies not only in surface but also in volume.

---

ORAL

## 16. DISCRIMINATION OF PIGMENTS IN DIFFERENT ROCK FACES THROUGH THEIR SPECTRAL SIGNATURE

*Bayarri Cayón, Vicente - (GIM Geomatics, S.L.) vicente.bayarri@gim-geomatics.com*

*Castillo López, Elena - (Universidad de Cantabria) castille@unican.es*

*Ontañón-Peredo, Roberto - (Museo de Prehistoria y Arqueología y Cuevas Prehistóricas de Cantabria) ontanon\_r@cantabria.es*

Spectral signatures are the specific combination of emitted, reflected or absorbed electromagnetic radiation at varying wavelengths which can uniquely identify an object.

The spectral signature of an object is a function of the incidental electromagnetic radiation wavelength and material interaction with that section of the electromagnetic spectrum.

Different pigments used in rock-art have different spectral signatures. Calibrating spectral signatures under specific illumination collected are needed in order to apply an empirical correction digital images.

The objective of the tests is to distinguish various pigments used in such paintings as well as the possible prints using an Analytical Spectral Device-Full Resolution Spectrometer (ASD-FR). The ASD-FR covers the region between 350 and the 2500 nm; from the invisible to the near infrared.

Most remote sensing applications process digital images to extract spectral signatures at each pixel and use them to divide the image in groups of similar pixels using different approaches. They try to assign a class to each group by comparing with known spectral signatures. Correct matching of spectral signature recorded by image pixel with spectral signature of existing elements leads to accurate classification in remote sensing.

The article shows the spectral signatures both in open-air and in a cave, since the sampling was made in the Shelter of El Cubular and the Cave of Cudón.

It is possible to distinguish pigments based on the spectral signature to later derive more accurate classification maps.

Collect spectral signatures is important since it makes possible to identify different substances, pigments or classes and separate them by their spectral signatures.

---

POSTER

## 17. DECORRELATION STRETCH AND POLYNOMIAL TEXTURE MAPPING - TWO METHODS FOR THE DOCUMENTATION, CONSERVATION AND THE ANALYSIS OF MOBILE ART. EXAMPLES FROM BAVARIA AND BURGUNDY.

*Nadine, Huber - (Universität Tübingen) nadine.huber@student.uni-tuebingen.de*

*Christian, Hoyer - (Universität Tübingen) christian.hoyer@uni-tuebingen.de*

*Harald, Floss - (Universität Tübingen) harald.floss@uni-tuebingen.de*

As part of recent research, regarding decorated objects from the Klausenhöhlen in the Altmühl valley, Bavaria and Solutré, Burgundy, two new methods were used to document and analyze objects bearing traces of pigment or engravings, which were poorly or not published yet.

Decorrelation stretch is a method, which was developed as a tool for aerial photography and, later, the digital improvement of pictograms, but works with all kinds of faded colorants and in all scales of photography. With this method, the painted limestone slabs and pebbles from the old excavations in the Klausenhöhlen Magdalenian were examined to enhance the contrast of partially faded rows of points of red pigment. The advantage of this method is, to deliver precise outlines of pigmented zones, even if they are hard to define with the naked eye. For one of the pieces, we were able to verify the shape of the point rows as they were visible in the 1960ies, when they were drawn for the last time, and faded out strongly over the years. All features considered, this method is not only interesting for documentation and analyzing issues, but also appropriate for the conservation of paintings in a poor condition.

The second method presented, is polynomial texture mapping (PTM). This method, as well as the closely related reflectance transformation imaging (RTI), allows to combine a bulk of photographs from a single object, illuminated from different light directions. As a result, a digital model is created, which enables a virtual review of the object under varying light conditions. PTM or RTI photography can easily be used for the documentation of archaeological objects of most different kinds, for example stone artefacts or engraved objects. For simulating different light conditions, the method is predestined to visualize very fine structures on objects like negatives on stone tools or very fine engraved lines on bone, ivory or limestone.

The method was used by the authors to document a larger amount of decorated objects from Solutré, in very short time, one of the advantages of this kind of documentation is, that objects are accessible for research very comfortably by a computer, when direct access to the original finds is not possible for any reasons.

Summarized decorrelation stretch and PTM or RTI represent two different tools for the documentation, con-

servation and analysis of a wide range of archaeological objects. Both are easy to learn and apply and in the low budget sector compared with many other computer-aided techniques.

**1. CROSSING ICONOGRAPHIC TRAJECTORIES BETWEEN LE ROC-AUX-SORCIERS (ANGLES-SUR-L'ANGLIN, VIENNE) AND LA MARCHE (LUSSAC-LES-CHÂTEAUX,VIENNE): FROM NORM TO IDENTITY CLAIM THROUGH THE TREATMENT OF HUMAN DEPICTIONS.**

*Fuentes, Oscar - (Université Paris I Panthéon Sorbonne - UMR ArScAn 7041 Ethnologie Préhistorique) oscar.fuentes@roc-aux-sorciers.com*

The formal, technical and stylistic study of the art in the Magdalenian sites of Le Roc-aux-Sorciers (Angles-sur-l'Anglin) and La Marche (Lussac-les-Châteaux) unites these two sites of the Eastern Vienne. When this is associated with the study of material culture, it becomes clear that, within a limited territory, the Magdalenian populations shared the same cultural traditions, the same norms. These graphic norms, which were fluid and changing, are established in accordance with the mechanisms of difference and make it possible to tackle the social dynamic of the decorated sites. The numerous human depictions in a realistic style pose the problem of the claim to identity within these social norms. The analysis of these images thus refers us to the construction of these identities during the Magdalenian.

ORAL

**2. ROCK ART AND LANDSCAPE OF ERONGO REGION, NAMIBIA.**

*Nankela, Alma Mekondjo - (University of Trás-os-Montes e Alto Douro- Quinta de Prados, Vila Real, Portugal) amnan-kela@gmail.com/ahamulo@gmail.com*

The Erongo region in western Namibia is a well-established area having one of the largest concentrations and accumulations of prehistoric rock art sites in Southern Africa with principal sites from the Brandberg, Erongo Complex and the Spitzkoppe Mountains in Erongo Region, Namibia. There is, however, a distinctive regional variability for the placement of rock art in this region and such variability is largely driven by physical (geology), social, religious and cultural settings of the region. The content of the rock art varies within the region as well, but there are several themes that are sufficiently widespread

to indicate broad, high-level geographical and temporal continuity within the Southern African hunter-gatherer, herder, and agriculturist belief systems over the period in which rock art were created.

In this paper, I wish to present the rock art of Erongo Region in relation to the elements of landscapes with practical examples from the Brandberg, Spitzkoppe and Erongo Mountains in Erongo Region, Namibia looking at the typology of the figures, traditions, techniques, style, graphic expressions, the relationship between rock art and landscape and their variability. Furthermore, we will explore how hunter-gatherer and herders activities and symbols on the landscapes where form of cultural impressions through manipulation of the surrounding natural environment. This relationship is based on an acute observation and perception of the environment which is part of an integrative cognitive whole. Thus, the spatial distribution in the context of interpretation of rock art is also reflected in the location of mythic events, cosmological structures, wisdom teachings and ritual symbolism within the specific landscape.

This investigation might inform us of the possible reasons behind the placement of the art in the landscape and whether there is a link between the natural world and the rock art to indicates decisions about what was to be incorporated in rock art. The case study approach will be used to understand my research findings within the global landscape of rock art research.

**3. NORM AND INDIVIDUALITY IN ROC-AUX-SORCIERS ROCK ART (VIENNE, FRANCE): DEALING WITH THE « HANDS » IN THE ANIMAL BAS-RELIEFS.**

*Bourdier, Camille - (Université Toulouse 2 Le Mirail - UMR TRACES 5608) ca.bourdier@laposte.net*

*Pinçon, Geneviève - (Ministère de la Culture et de la Communication (France) - UMR TRACES 5608) genevieve.pincon@culture.gouv.fr*

Occupied several times during the Middle Magdalenian (18 000-16 000 cal. BP), Roc-aux-Sorciers rock shelter (Vienne, France) is also characterized by a rich rock art, combining bas-reliefs, paintings and engravings that associate geometric patterns and depictions of animals and humans. The stylistic analysis of the animal bas-reliefs reveals the strong homogeneity of the graphical codes together with subtle variations of some anatomical elements. For two successive sets of bas-reliefs have been

identified, part of this formal variability could result from the slight evolution of the codes during the occupation of the site. However, in both sets of bas-reliefs, each animal shows specific formal attributes (ears, nostrils) which then could illustrate the creativity of the author(s). Thus this stylistic analysis questions the respective shares of the individual expression and of the collective norms in the Middle Magdalenian rock art iconography. It also gives the opportunity to discuss our capacity to identify authors or "hands" through formal criteria.

#### **4. PRIMITIVE ENGRAVINGS IN THE MEGALITHIC COMPLEX OF MEZORA (ARCILA, MOROCCO)**

*Gozalbes Garcia, Helena - (Universidad de Granada), Enrique Gozalbes Cravioto (Universidad de Castilla-La Mancha) helenagoga@hotmail.com*

In 1829, during his visit to the megalithic monument Mezora, the British traveler Sir Arthur de Capell Brooke identified several engravings which, due to its characteristics, he considered as parts of a gateway in the circle. Nearly half a century later, Ch Tissot failed to identify the motifs, although he managed to recognize the hypothetical gate. Since then these aspects are lost in the historical-archaeological researches, which mostly pointed out that they had not found the engravings.

Mezora megaliths. Study of the surface of the megaliths, detecting antique engravings.

During the course of an investigation conducted in 2013 we have identified several of the antique prints, the ones which coincide with those mentioned by Capell Brooke, and we have also located the area of the mentioned door, which had to be modified by the moving of some of the monoliths (probably during the diggings developed in 1932-1936). Presence of engravings in certain megaliths of the Mezora Circle.

ORAL

#### **5. STYLISTIC REPRESENTATION AND DISFIGUREMENT OF HUMAN FIGURES ON ROCK WALL: SOCIAL IDEOLOGIES AT STAKE.**

*Vialou, Denis - (Muséum national d'Histoire naturelle, Paris) dviaiou@mnhn.fr*

The common designations of the human prehistoric representations, like "realistic", "naturalistic", "schematic" ..., do not really reveal their own particular stylistic status in relation to animal representations. For the human representations, the styles express an ideological feeling of the societies which produce them.

ORAL

#### **6. GROTTA SCRITTA, AN EXAMPLE OF MEDITERRANEAN PREHISTORIC ART EXPRESSION.**

*Marchetti, Marie-Laure - (Service des Patrimoines, Archéologie, Direction de la Culture et du Patrimoine, Ajaccio) Marie-Laurence.Marchetti@ct-corse.fr*

The Grotta Scritta site contains the only known prehistoric cave paintings discovered to date on the Corsican territory and demonstrate the symbolic thought of this period. These paintings belong to the Iberian Peninsula artistic current called "schematic art". They show evidence of more or less stylized anthropomorphic and anthropozoomorphic, secondary or additional signs (dots and dashes) and geometric patterns very schematic representations. One of the remarkable facts is the organization of paintings on the walls, exploiting significant microtopography. Its date is determined by comparison with similar sites of the Mediterranean area in Provence, Spain and Sardinia between the late third and early second millennium BC (Late Neolithic - Early Bronze Age), for the very first representations and may extend to the 2<sup>d</sup> Iron Age. Grotta Scritta is part of a geographical context including prehistoric areas like Nebbiu and Agriate, both rich of burial and worship sites, often with megalithic expression (statues, tombs) as the site of Monte Revincu.

ORAL

#### **7. FROM INDIVIDUAL STYLE TO COLLECTIVE STYLE. TENTATIVE APPLICATION TO PALAEOOLITHIC CAVE ART.**

*Groenen, Marc (Université Libre de Bruxelles), Didier Martens - dmartens@ulb.ac.be (Université Libre de Bruxelles) - mgroenen@ulb.ac.be*

The practice that consists in determining the date of art works and the place of their production based on a corpus of references firmly anchored in time and space has gained recognition. Of course, such frame of reference does exist for Palaeolithic cave art. Nevertheless, it seems

possible to isolate some stylistic characteristics particular to certain groups, in certain geographical areas, and to determine, within this set of common characteristics, individual ways of doing. This is the course of analysis that we would like to test, by trying to shed some light on the figurative material of the Cantabrian caves of La Pasiega and Covalanas, and of the Perigord sites of Lascaux, Les Combarelles and Rouffignac, with the help of notions such as individual and collective styles.

ORAL

## 8. LE PILIER SCULPTÉ DE LA GROTTE D'ISTURITZ : SYNTHÈSE PLASTIQUE DES IMAGES ANIMALES

*Labarge, Aude - (Aulame - Espace Culturel Isturitz oxocelhaya) aulame@free.fr*

En 1913, le pilier sculpté de la grande salle d'Isturitz est découvert par E. Passemard. Il identifie un potentiel d'une quinzaine d'animaux figurés. Tout au long du XX<sup>e</sup> siècle, les chercheurs ont observé le pilier, infirmant ou confirmant le bestiaire présentés par les chercheurs précédents, jusqu'à la relecture exhaustive du pilier en 2013.

Le pilier sculpté a fait l'objet d'une étude technique, stylistique et plastique. Afin de réaliser l'étude plastique, plus de 200 croquis préparatoires d'analyse ont été effectués, traitant de tous les faits plastiques fondamentaux liés à cinq catégories de traitement plastique : forme, couleur, valeur, matière, composition.

Chaque figuration a été étudiée pour elle-même et mises en comparaison avec la variété des figurations du pilier.

La démarche plastique contribue à une meilleure observation des figurations, notamment sur le plan artistique : les jeux d'illusions optiques, d'anamorphose, des étapes d'élaboration des formes figurées, des reprises et corrections de formes... mais surtout l'étude plastique met en valeur la complexité de la figuration et permet de reconnaître la codification du langage artistique.

Le bestiaire du pilier central de la grande salle d'Isturitz est varié et riche : il comprend près d'une quinzaine de figurations, dont certaines ont été effacées et réexploitées. La plasticité du pilier est complexe et offre tous les savoir-faire fondamentaux artistiques : anamorphoses, narration, ébauche, réexploitation de forme, jeux de volumes variés...

Cette analyse a permis de mettre en valeur le langage plastique, codifié et savamment exploité durant le Magdalénien moyen.

ORAL

## 9. COMPARATIVE STUDY OF THE VALIDITY AND RELIABILITY OF THE MACROSCOPIC

*Apellániz, Juan María - (Universidad de Deusto) juanmaria@apellaniz.biz*

*Amayra, Imanol - (Universidad de Deusto) uanmaria@apellaniz.biz*

**Introduction:** We present a method tested with experimental figures that demonstrates reliability in the attribution of drawings and engravings. This involves comparing the hit rate between the visual inspection method and two methods based on geometric analysis of the shapes of drawings and engravings. The results indicate the usefulness of the application of the geometric/microscopic method in prehistoric figures.

**Material and methods:** Research analyses the predictive value of two main variables: shape and stroke. In the study of shape, two methodologies are compared: a macroscopic attribution of 40 figures made by students and experts versus a geometric analysis of 134 experimental figures and 70 Palaeolithic figures. These last ones are measured with **the 20 variable method** which factorizes contours from the points of maximum negative curvature, minimal positive curvature and inflection into five anatomical parts: neck, trunk, length, internal hindquarter and external hindquarter. In the study of stroke, geometry from the variables width, length and angulation in the grooves of 60 engraved figures and in the width of the stroke of 39 painted figures are analysed microscopically. The following statistical techniques were applied in the aforementioned studies: frequencies, percentages, descriptive statistics, bivariate correlations, confusion matrix, exploratory multidimensional scaling, exploratory factorial analysis and discriminant analysis.

**Results:** Results obtained indicate a greater degree of validity and reliability of the microscopic /geometric method (70% in the experimental painted figures; 82.5% in the Palaeolithic painted figures; 74.28% in the Palaeolithic engraved figures; 78% in the experimental engraved figures) compared to the traditional macroscopic method (59% of the experimental painted figures).

**Conclusion:** It can be concluded that visual examination is more subject to perceptual errors of attribution than

the geometric/microscopic analysis, and that this last method is shown as a valid and reliable technique for the identification of the authorship. It demonstrates that there is an individual graphic formula each person expresses him or herself with consciously or unconsciously. Outline geometry of Ekain or Niaux figures, or from the grooves of the stroke of an engraved work, reflects this formula with a particular and unrepeatable organization.

ORAL

## 10. ARTISTES PALÉOLITHIQUES : AURIONS-NOUS PEUR DES MOTS ?

*Feruglio, Valérie - (equipe scientifique grotte Chauvet) feruglio@free.fr*

Il semble qu'aujourd'hui il soit de moins en moins possible de parler d'artistes pour qualifier les peintres, graveurs, sculpteurs qui ont investi certaines grottes d'Europe occidentale. Cet état de fait s'inscrit-il dans le «politiquement correct» à l'instar des paraphrases institutionnelles qui remplacent les substantifs trop précis qualifiant des handicaps ou des métiers considérés comme peu gratifiants ou ce refus du terme « artistes » réside-t-il dans le constat de la faiblesse de nos outils scientifiques pour le certifier ?

Si nous considérons ces producteurs d'images en tant qu'artistes, des champs d'analyse nouveaux s'ouvrent à nous. Au travers d'exemples pris dans des grottes ornées couvrant différentes cultures du Paléolithique supérieur telles que Chauvet, Cussac, Lascaux ou Les Trois-Frères, nous verrons comment les outils de l'histoire de l'art ou de l'esthétique peuvent nous faire envisager différemment ces expressions graphiques qui, outre les questions qu'elles nous posent, à tout le moins, nous émeuvent encore.

Envisager le travail qui consiste à faire ployer la matière et sélectionner les matériaux pour servir au mieux le message à véhiculer permet d'approcher l'individu, sa part de créativité de même que l'apprentissage qu'il intègre et reformule au fil du temps. Mais tout créateur s'inscrit dans une société en s'y confondant ou en s'en démarquant, qu'on lui impose les choses ou qu'il les déclenche ; conformiste ou novateur il traduit son environnement social. Les contraintes sociales marquent-elles ses limites ou lui permettent-elles de les transgresser ? L'environnement lui est-il favorable ou sent-t-il la nécessité de le transcender ?

Le changement de regard dans l'analyse des graphismes pariétaux tourné vers l'individu peut nous offrir les clés de lecture de sa société et de son environnement.

ORAL

## 11. CONTRIBUTION OF ELEMENTAL AND STRUCTURAL ANALYSIS TO THE INTERPRETATION OF PAINTED AND DRAWN COMPOSITIONS OF EL CASTILLO CAVE (CANTABRIA, SPAIN).

*Groenen, Marc - (Université Libre de Bruxelles) mgroenen@ulb.ac.be*

*Groenen, Marie-Christine*

*Gilles Wallaert - (Université Libre de Bruxelles, Materials engineering, characterization, synthesis and recycling) gwallaer@ulb.ac.be*

*Dille, Jean - (Université Libre de Bruxelles, Materials engineering, characterization, synthesis and recycling) jdille@ulb.ac.be*

*Segato, Tiriana - (Université Libre de Bruxelles, Materials engineering, characterization, synthesis and recycling) tsegato@ulb.ac.be*

*Delplancke, Marie-Paule - (Université Libre de Bruxelles, Materials engineering, characterization, synthesis and recycling) mpdelpla@ulb.ac.be*

At the present day, our census of the painted and drawn motifs of El Castillo cave reaches 1835. Up to now, no analysis of the pigments has been carried out. Such analysis may prove useful to bring closer the various rock art compositions of painted and drawn motifs.

46 samples of coloring materials were taken from the drawings and paintings as well as 6 samples from deposits of Cantabria. They were characterized by various methods. The morphology and elemental composition of the 46 samples were determined by scanning electron microscopy (SEM) coupled with EDX analysis. For the samples containing mineral compounds, a local characterization by transmission electron microscopy (TEM) coupled with EDX and electron diffraction was carried out. Finally, the previous results were confronted to those obtained by micro and macro X ray diffraction.

ORAL

**12. THE PLAQUETTE OF VILLALBA DE ALMAZAN IN THE INTERIOR PALEOLITHIC OF THE IBERIAN PENINSULA.**

*de Balbín Behrmann, Rodrigo - (Universidad de Alcalá, Departamento de Historia y Filosofía) babubera@movistar.es*  
*Baquedano Pérez, Enrique (Museo arqueológico regional de la Comunidad de Madrid) enrique.baquedano@madrid.org*  
*Alcolea González, José Javier (Universidad de Alcalá, Departamento de Historia y Filosofía) javier.alcolea@uah.es*  
*Fernández Moreno, José Javier (Museo arqueológico de Asturias) info@museoarqueologicodeasturias.com*

The Paleolithic art of the Interior of the Iberian Plateau is sparse in demonstrations, dispersed in their situation and poor in material relationships. This is not only because its reality, but also for the lack of focused studies. This failure is softened in recent years. One of the scarce known mobile manifestations is the plaquette of Almazan, published in 1988 and found again without material context. It is an isolated item with very good graphic quality, in which we intend to take full profit using the actual implements we have for study. We possess a 3d scanner and a complete photographic series, which will be useful for that effect. But we want also give a graphical, stylistic and chronological context linking their content with the near known sites in the plateau areas, like the Coa, its excavations, and all the elements that allow us to value completely this unique and fundamental Paleolithic graphy.

ORAL

**13. ANIMATION IN PALAEOLITHIC ART OR DO PALEOLITHIC ARTISTS DREAM OF ANIMATED ANIMALS?**

*Azéma, Marc - (Chercheur associé à l'UMR 5608 du CNRS, TRACES-UMR 5608 / CREAP, Toulouse-Le Mirail) marc.aze-ma@wanadoo.fr*

On the wall and the ground of caves, on the items of daily life, the Paleolithics sought to animate, literally "give life" to their artwork. Several processes and graphical conventions enabled to reproduce the movement of natural models taking account of the physical characteristics of different materials and the influence of external parameters (lighting in particular). The existence of an optical mechanism, like « thaumatrope », shows genius and intentions of artists of our Prehistory.

ORAL

**14. ANIMALS AND SIGNS, FROM REALISM TO ABSTRACTION AT THE END OF MAGDALENIAN. LA MAIRIE CAVE AND MÈGE SHELTER IN TEYJAT (DORDOGNE).**

*Paillet, Patrick - (Muséum national d'Histoire naturelle, Département de Préhistoire, UMR 7194) paillet@mnhn.fr*  
*Man-Estier, Elena - (Ministère de la Culture, Centre National de Préhistoire, UMR 5199-PACEA) man-estier@mnhn.fr*

The animals present in the parietal device of La Mairie cave, or on the mobile supports found in this cave or in the Mège shelter nearby constitute a well-known corpus with its realistic and conventional style as well as extraordinary formal qualities. This triumphing realism is what is remembered. Yet it has to be tempered if not challenged by the presence in the same parietal and portable corpus, perhaps even from the hand of the same artists, many schematic, geometric, almost abstract or in any case very original representations. Very few structured signs similar to the ones prehistorians usually like, but here, next to horses, bovines and classic deers, we find exceptional animals by their zoological origin (seals, swans, reptiles, etc.) and their expressive modality (schematic animals, seen from the front, etc.), fantastic beings and organized patterns whose inspiration we don't know but where the unmoving and living coexists at the same time. Henry Breuil saw in 1905 a "degeneration" of representations towards animal ornaments. The term is somewhat excessive and we do not believe that there is an alteration or regression in this graphic development process, and even less in its symbolical resonance.

Instead, it is for us an evolution in an inexorable artistic expression and reorganization, or an even more radical change, in the semantic content that accompanies the final moments of the Late Ice Age. These representations, with their specific typology and their close relationship with a more conventional art, are forcing us to investigate the symbolic thoughts of the last Magdalenians, at that specific time when deep environmental changes affect their world and society. This symbolic universe from which reality escapes gradually announces the close-by Azilian universe.

**15. PIGMENTS AND PIGMENT MAPS. SOME NON-DESTRUCTIVE APPROACHES TO ESTABLISH RELATIVE CHRONOLOGY OF A SITE.**

*Solodeynikov, Alexey - (Arkus Heritage Preservation Center, Saint-Petersburg) solodey@mail.ru*

The report is dedicated to some digital techniques in painted rock art researching. Being based on composition of the known dyes I am looking for a non-destructive method to differentiate pigments, which had been made of dissimilar input materials, with particular prescription or other process conditions. This gives us an opportunity to separate paintings which were made by different masters in limits of the given site, which means that we obtain possibility to separate different chronological layers of the site. The job is made on Kapova cave materials.

**1. 'GOING BY THE NUMBERS', A QUANTITATIVE APPROACH TO THE GALICIAN PREHISTORIC PETROGLYPHS**

Vázquez Martínez, Alia - (Departamento de Historia I. Facultade de Xeografía e Historia Universidade de Santiago de Compostela) [alia249@gmail.com](mailto:alia249@gmail.com)

Rodríguez Rellán, Carlos - (GEPN - Departamento de Historia I. Facultade de Xeografía e Historia Universidade de Santiago de Compostela) [crrellan@gmail.com](mailto:crrellan@gmail.com)

Fábregas Valcarce, Ramón - (GEPN - Departamento de Historia I. Facultade de Xeografía e Historia Universidade de Santiago de Compostela) [ramon.fabregas@usc.es](mailto:ramon.fabregas@usc.es)

Today, despite the notable progress on the knowledge about Galician's carvings, we still lack an updated census of these and, as a result, we do not have adequate information about the precise number or the geographical distribution of the main groups of motifs that make up this artistic phenomenon. In order to tackle this problem, we have gone through the Xunta de Galicia's Catalogue of the Archaeological Heritage, obtaining a database of 3361 petroglyphs.

By using both GIS and data management programs, we have drawn a series of maps and charts showing the iconographic variability of the panels, correlation patterns of motifs and the dispersion of those across Galician territory.

Preliminary observations confirm that coastal areas have the largest concentrations of carvings, in sharp contrast with the inland districts. On the other hand, geometric motifs tend to associate mostly among themselves, while zoomorphs often share the panel with geometric images. Metallic weapons such as daggers or hallebards have a marked tendency to appear on the same rock and less so with other kinds of motifs. Finally, petroglyphs of clear historical chronology –such as crosses, alphabetic forms, etc– are in clear dissociation with prehistoric carvings.

**2. CVARN- ROCK ART VIRTUAL CORPUS OF THE NORTH-WESTERN PORTUGAL. A MULTIMEDIA TOOL TO INVESTIGATE AND DISCLOSE THE POS-PALAEOLITHIC ROCK ART**

Bettencourt, Ana M. S. - (University of Minho) [bettencourt.ana@gmail.com](mailto:bettencourt.ana@gmail.com)

[ana@gmail.com](mailto:ana@gmail.com)

Abad Vidal, Emilio - (CESGA) [emilio.abad@gmail.com](mailto:emilio.abad@gmail.com)

Rodrigues, Alda - (University of Minho) [aldacrodrigues@gmail.com](mailto:aldacrodrigues@gmail.com)

The purpose of this paper is the dissemination of the Rock Art Virtual Corpus of the Northwest of Portugal (CVARN), a database dedicated to the subject of Pos-Palaeolithic rock art in the Northwest of Portugal that will be available through a website at the end of September 2014.

This software tool is being built and nourished under the ENARDAS project, a scientific project financed by the Operational Programme Thematic Factors of Competitiveness and by the European Regional Development Fund, an ongoing project since 2011, but open to the entire scientific community.

Apart from being a first compilation of different 'styles' of rock art, which occur in the western façade of Iberia between the basins of the rivers Minho and Vouga, it will have both social and scientific functions.

In social terms, the results obtained may contribute to regional development, especially considering the development of tourism.

In scientific terms, it will allow the identification of different stylistic spatial areas (such as the Atlantic Rock Art or Schematic Rock Art); different stylistic groups inside the Atlantic Rock Art (for example); areas with higher or lower density of rock art; the spatial distribution of certain carving motifs, in short, to promote scientific research in this field.

Some examples and considerations will be carried out.

**3. THE ARCHAEOACUSTICS OF MACROSCHEMATIC ART. AN INITIAL STUDY**

Díaz-Andreu, Margarita - (ICREA-Universitat de Barcelona) [m.diaz-andreu@ub.edu](mailto:m.diaz-andreu@ub.edu)

García Benito, Carlos - (Universidad de Zaragoza) [cgb@unizar.es](mailto:cgb@unizar.es)

García Atiénzar, Gabriel - (Universidad de Alicante) [g.garcia@ua.es](mailto:g.garcia@ua.es)

In this paper the results of acoustic tests undertaken in

a new rock art landscape, the macroschematic rock art area of the mountains to the north of Alicante, will be explored.

In the mountain ranges located to the north of the province of Alicante a new rock art style was identified in the early 1980s. This rock art tradition was dated to the Neolithic on the basis of the similarities of some of the painted motifs to some figures impressed onto Cardial impressed ware. The number of sites is not high, twenty shelters in nine sites, and the motifs painted include anthropomorphs, serpentiforms, lines and thick points. A few casual comments had been made about how excellent the acoustics are in one of the major macroschematic group of sites at Pla de Petrarcos, but the literature has remained silent about this.

The paper will describe the results of the of the acoustics tests undertaken at the Pla de Petrarcos, Barranc de l'Infern and Sarga sites. As in our previous studies on acoustics and rock art, we will analyse the results of reverberation and echoes.

We will compare the areas with and without rock art sites in order to identify whether the shelters to be decorated were chosen in the locations with the best acoustic properties. We will also examine whether the places with higher number of motifs have the best acoustics. The results obtained in the Macroschematic sites will then be compared with those of other areas in which only Levantine style is present.

ORAL

#### 4. ROCK ART, SYMBOLIC POTTERY, TRAVELLING AND NOSTALGIA

*Ferraro, Lorena - (Administración de Parques Nacionales) ferrarolorena@yahoo.com.ar*

*Vidal, Aixa - (Universidad Complutense de Madrid) aixavidal@gmail.com*

The connection between rock art and pottery has been traditionally been established either with a chronological intention (i.e. to date the representations) or as a marker of a common cultural background. This idea is based on the conception of the former as a static feature in the landscape, a place where people go to, avoid or live in, a fixed location incorporated in the *habitus* but distant from most of daily activities.

Pottery, on the other hand, inasmuch as a chronologi-

cal marker has been typically considered a utilitarian tool which takes actively participates in everyday life. Thus, notwithstanding its portability, it is also mentally fixed to a specific place, be it the raw material source, the task place or its final deposition. Even when commerce and exchange are considered, pottery is seen just as evidence of trade relations or as an important good which raises the interest of people other than its makers.

However, both rock art and pottery can be interpreted as a key element in the movements of human individuals or groups. People is constantly "in the move", collecting materials and resources, following herds, making visits to relatives, joining places of symbolic interest, exploring. And they do not just go from a place to another one; they go through places as well and they gain meaning not only by their features but also by the values and interpretations people make of them. They turn the landscape into a homely place by marking them with representations which makes them feel safe, at the same time the place acquires domesticity by participating in the voyage.

Similarly, pottery accompanies the traveller along the landscape. It may be argued that it makes part of the baggage because of utilitarian reasons regarding food consumption, or due to its value as a trading good. Nevertheless, the vessels chosen for the trip are not always the most appropriate ones for these functions, but they are usually easily identify as typical of a group, a token of local identity. Hence, they link the travellers with their place of origin, as much as the familiar representations they may read on the walls and caves when passing by. This paper aims at opening new possibilities for interpreting these expressions of human culture as an element needed to recreate the homeland left behind (even if it is temporarily), creating in the traveller a sense of being-in-the-world and copying with the nostalgia of the household and the known world.

Darriba, Xermán (*L'École des Hautes Études en Sciences Sociales (EHESS-CNRS)* <http://www.becariosbarrie.org/node/2354>

Paz, Alexandre

Interpretations of European megalithism have been gradually diversifying in very different ways during the last few years. In the present text we will focus on the contributions of the study protocols of megalithic art which define megaliths as a result of complex stories which include rebuilding, maintenance and, in short, continuous adaptation. The strategy –widespread in the Iberian Peninsula– which consists of an in-depth analysis aimed at the decoration of monuments, has brought interesting innovations: direct C14 dates, decoration in different stages, repainting and reusing of pieces that accurately illustrate the long stages of maintenance and rebuilding of megalithic architecture.

Based on a comparison with other archaeological sites that can be found in different geographical areas, this study proposes a critical analysis of the above-mentioned archaeological items in the north-west Iberian megalithism. We analyse mound and structure alterations, stones with unusual shapes or compositions, certain superimposed artistic techniques, etc.

Therefore, it seems possible to predict hypothesis that have already been established in other European regions, which include megaliths in ancient processes of erection of big stones.

.Among all the possibilities available, the most attractive one is probably the possible existence –widespread and non-extraordinary– of megalithic stelae previous to the chambered architectural structures that have been so well studied in the regions covered in this project. The maintenance of these series of stelae and megaliths along the whole life cycle of European megalithism is another analysis item that has not been previously documented in the Iberian Peninsula.

## 6. BY THE WAY: MOBILITY AND PERCEPTION OF OPEN-AIR ROCK ART.

Rodríguez-Rellán, Carlos - (*Universidad de Santiago de Compostela*) [carlos.rellan@usc.es](mailto:carlos.rellan@usc.es)

Fábregas Valcarce, Ramón - (*Universidad de Santiago de Compostela*) [ramon.fabregas@usc.es](mailto:ramon.fabregas@usc.es)

Open-air rock art and Atlantic Rock Art in particular, have been often considered as an active element in the configuration of the economic and symbolic significance of prehistoric landscapes. Thus, in the last 20 years, the spatial setting of Galician petroglyphs was analysed and repeatedly associated with the control of certain resource-rich areas or the routes leading into them. Nevertheless, such considerations have been frequently based on relatively shallow spatial analyses and the importance of those paths and areas established *ad hoc*. Furthermore, the interaction between rock art and the surrounding landscape was approached in a superficial manner, neglecting the importance of perceptibility of the decorated panels as a main element in determining their agency.

The use of GIS applications and high-resolution cartography (LIDAR maps) together with the implementation of new methods for the analysis of the potential intensity of transit through the landscape will allow us to check the hypothesis of the link between Galician petroglyphs and the so-called “geography of movement”. On the other hand, the use of new methodologies such as the Agent Based Modeling makes possible to study and simulate the processes of perception of rock art sites, comparing their theoretical level of perceptibility with that of other monuments allegedly playing an important role in the configuration of the landscape: the mounds.

Cortón, Natalia - (*Rock Art Conservation S.L.*) [nataliac\\_n@yahoo.es](mailto:nataliac_n@yahoo.es)

Gómez, Carmen - [feito.cg@gmail.com](mailto:feito.cg@gmail.com) (*Rock Art Conservation S.L.*) [javier.goberna@yahoo.es](mailto:javier.goberna@yahoo.es)

Costas, F. Javier - (*Asociación Cultural Amigos do Mosteiro de Oia, Acamo*)

Martín, Esperanza - (*Dolabra Arqueología*) [dolabra@gmail.com](mailto:dolabra@gmail.com)

We offer here some results from an archaeological proj-

ect in A Cabeciña hillfort, northwestern Iberian peninsula, taking into account two little campaigns in 2012 and 2013. This is a small-scale but very fruitful project promoted by the local community and scientifically directed by the Galician School of Conservation for Cultural Heritage.

The Cabeciña hill is a cultural landscape where two different kind of sites live together, apparently apart but, as we know now, completely interrelated. First, some rock art groups, more or less clearly linked to Bronze Age Atlantic style. Second, an Iron Age hillfort, as they are common in Galiza.

Our main aim was to build archaeological knowledge through documentation without "aggressive" archaeological techniques, always bearing in mind the importance of preventive conservation and sustainable local development. We think we do not always need "traditional" and deep digging to bring out new data for prehistorical discussions. In fact we think that kind of "old archaeology", that is, excavation without planned conservation, may imply some important problems related to financial and conservation issues.

Our results offer, for instance, some implications for Galician rock art chronology, recently involved in very interesting arguments. Galician rock art has always been associated as a whole with Bronze Age but nowadays some prefer to think of a long chronology and multiple styles. Our main rock art panel shows some strange typological implications: uncommon motifs in Northwestern Iberia were linked to Atlantic relationships and even Neolithic chronology. Our work was very limited and our results are, obviously, hypothetical, but in many ways we think rock art is in this case completely related with the later hillfort. The chronological debate gets more complicated but still unresolved. The rocky landscape, both natural and cultural, seems to be integrated with the hillfort, maybe during the construction of the impressive masonry walls. This is clearly a place with a very long occupation. Both the landscape and the rock art are adapted and transformed, maybe rethinking its symbolism. Some decorated stones were clearly moved and placed as a sort of "stelae", for example. Apart from that, this site serves also for discussing the natural/cultural character of granitic "panholes" or "basins". Long discussed, this kind of "rock art features" have been considered at the same time religious elements (mainly sacrificial basins), natural eroded depressions or Roman wine or olive presses. Such a radical debate needs some new data and a new approach. Our case is specially important because in the 19th century it was located in the surroundings a proper

sacrificial basin with a Roman inscription, the huge and famous "Pía of Mougás". This context given, we were really surprised by some new discoveries worth publishing and debating.

The research project "SIGAREP II" was centered on rock-art cavities of North Face of the Central System as a continuation of SIGAREP I which was centered in the southern face of the mountainous chain. Both projects have been a real experimental laboratory in which we were able to test a number of methodologies not only dedicated to rock-art, but the entire environment in order to contextualize those art forms in an area riddled with archaeological sites. Emerging technologies such as 3D laser scanning, photogrammetry, remote sensing or high resolution photography, have been some of the tools that we used to conduct this study, which was complemented with a complex relational database in order to set up a GIS of the central Iberian Peninsula. We will not extend on these issues since they are going to be presented in another session (A11F - The role of art in prehistoric societies), and we will here to the findings in the area of Ávila. Rock art in the province of Ávila is not too well known, except for some sets such as *Ojos Albos* or *Raso de Candaleda*, but in recent years has significantly increased the corpus of stations with schematic art. During the work of documentation in *Ojos Albos* site, we attracted attention to a completely exposed area close to the previous shelter in which was appreciated a Phi-shaped anthropomorphous. We proceeded to full document this panel and our surprise was that by applying different digital image processing algorithms, we found that the only figure had become a complex scene that was particularly important due to their stylistic characteristics were similar to other places very remote from this area.

The scene is formed by a set of 20 human figures with a

strong naturalism far from local conventions. Apparently only one is a male and the rest female, associated with three circular ideomorphous with different morphologies. Clearly superimposed on this set is the figure of the discovery which has become three human figures and circulate a sign made of points.

## 9. THE SACRED CANYON. ROCK ART IN THE DURATÓN CANYON (SEGOVIA, SPAIN)

*Ripoll, Sergio - (UNED) sripoll@geo.uned.es*

*Bayarri Cayón, Vicente - (Gim-Geomatics) vicente.bayarri@gim-geomatics.com*

*Latova, José - (ASF-Imagen) latova@asfimagen.es*

*Municipio González, Luciano - (Junta de Castilla y León) mun-gonlu@jcy.es*

Reaching the centenary of the publication of the Marqués de Cerralbo, on the rock art of the Barranco del Duratón (Segovia), they continue to produce new discoveries of great interest for this great set. This research team has proposed to carry out an ambitious interdisciplinary project to document with the appropriate technology, this extensive set of manifestations, in order to pay tribute to all those who have gone before us in the analysis of this canyon in its corresponding interactive monograph.

In 1933 the Abbé Henri Breuil published his monography *Les Peintures rupestres schématiques* of the Péninsule Ibérique, in the first volume, he resumed the relationship of stations published by the Marqués de Cerralbo, incorporating some illustrations and plates. It took 40 years until the Professor Rosario Lucas were faced with the systematic study of the cave representations of the Barranco del Duratón which conducted to his doctoral thesis. From the defense of this work in 1973, some more or less systematic works have been held such as the *Carta Arqueológica* of the province of Segovia, which greatly expanded the number of stations which had inventoried the Dr. Lucas (27) until 59 sites distributed in five municipalities.

The SIGAREP II project (Sistema Gestor de Arte Rupestre y Estaciones Prehistóricas), awarded in competitive call by the Ministry of Education, Culture and Sport, aims to encourage the promotion, protection and dissemination of the cultural heritage composed of archaeological sites and sites of cave art of the Central System in the provinces of (Madrid, Guadalajara, Segovia and Ávila)

and which due to its characteristics is not easy to exhibit in museums.

The scope of the project has been the promote the creation and use of new technologies, creating synergies between the needs of traditional documentation and representation of archaeology and heritage 3D documentation more innovative systems of the time so that this heritage through these technologies is perfectly documented and reach both the research community and the general public developing a set of elements of dissemination of variable complexity.

The relevant territory contains one of the highest concentrations of prehistoric art in the central area of the Iberian Peninsula. And do not stop appearing new stations such as the shelter Remacha discovered just two years ago. Sampling carried out in the framework of the cited project has focused on the station of the Solapo del Águila, in which the Professor Rosario Lucas identified a total of 76 Iconographies. The leading methodology that we have applied, allowed us to expand the inventory until 118 figures and define more precisely some of the analyzed in the doctoral thesis of this researcher.

Here we present the preliminary results of this ambitious project that aims to analyze all of the decorated shelters that reaches the number of 59 stations in an enclosed space such as the Barranco del Duratón, which with this concentration becomes the Sacred Canyon.

## 10. THE DRAWINGS OF "MASKS" AND OTHER

*Sanches, Maria de Jesus - (Research Center in Archaeology, Arts and Cultural Heritage (CEAACP) mjsanches77@gmail.com*

This paper aims to discuss the imagery known as "eye idols" in the context of the Neolithic and Chalcolithic settlement of northern Portugal and particularly its regional graphic traditions dating from the recent prehistory. It is motivated by our recent discovery of several panels with figures of "masks" and anthropomorphic figures of schematic body, both of type "o eye idols" on the rock escarpments of the Serra de Passos / Sta Comba mountain (Eastern Trás-os-Montes).

## 11. ILLUSTRATING SABOR'S VALLEY (TRÁS-OS-MONTES, PORTUGAL): ROCK ART AND ITS LONG-TERM DIACHRONY SINCE THE UPPER PALEOLITHIC TILL THE IRON AGE

Soares de Figueiredo, Sofia - (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) sofia.csf@gmail.com

Xavier, Pedro - (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) pedroxavy@gmail.com

Nobre, Luís - (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) luis\_nobre@sapo.pt

Domínguez García, (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) Isabel - isabeldoga@gmail.com

Neves, Dário - (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) darioneves1@gmail.com

The construction of a major dam in the Trás-os-Montes region, in Northeast Portugal, has led to an unprecedented archaeological survey that included a specific rock art study across a 3,000 hectares area. Over the past four years, the implementation and the development of this study revealed that the number of rock art sites is much higher than initially expected. In addition, the quality and the chronologies of the findings are exceptional, not only in a regional context but also on a peninsular and European scale.

The present paper seeks to explore a specific geographical area within the Sabor valley, an area where we found the highest concentration of rock art sites, with chronologies ranging between the Upper Paleolithic and the contemporary period. However, this paper will only focus on the rock art produced between the Upper Paleolithic and the Iron Age period, meaning, before historical times.

With regards to the Paleolithic era, we will study the Foz do Medal terrace and its exceptional portable art that accounts over than 1500 engraved plaquette fragments. In terms of rock art from the transition of the Holocene and post-Paleolithic period, we will focus our attention on three main sites containing original depictions of caprids and cervids. Finally, we will study almost one hundred Iron Age plaquettes uncovered in the Crestelos archaeological site. We would like to stress the fact that all mentioned sites are located within a radius of less than 2 Km. Due to the concentrated materiality in a single and restricted area, our aim is to approach different continuities and discontinuities in terms of rock art archaeological records. Were the same animals depicted in the Upper Paleolithic and in the post-Paleolithic periods? Why do we find mobil supports both in the Paleolithic and Iron

Age periods and none in the time in between? These are some of the questions we will be addressing.

ORAL

## 12. THE ROCK ENGRAVINGS OF LAGE DOS SINAIS/MONTE DO OLHEIRO (BARCELOS, NW PORTUGAL). DISCOURSING ABOUT PLACE, MORPHOLOGY AND AUDIENCE

Aluai Sampaio, Hugo - (Universidade do Minho) hugoaluai@gmail.com

Cardoso, Daniela - (Universidade de Trás-os-Montes e Alto Douro) danyrest5@gmail.com

It was Sarmiento (1933[1894-95]) who first published *Lage dos Sinais/Monte do Olheiro*, referring a carved rock with a set of circular compositions.

Rejecting rock art sites as mute entities in the landscape and beyond the simple analysis of the depicted motifs, this work aims to present new interpretations taking into account other important features.

Based in Sarmiento (1933[1894-95]), Cardoso (1951) and Coimbra (2004) the first task of the present work was to assemble the available information about the place. Secondly, it implied the observation *in situ* of the carved outcrop during different hours of the day, sometimes using artificial light, allowing the subscribers to specify the description of some motifs and to identify new ones in neglected areas of the outcrop. At the same time consented the contact with the *locus'* physical context (in relation to water, natural passages, visibilities and inter-visibilitys, grazing, mining, etc.) and the carved outcrop's topographic features.

The *Lage dos Sinais/Monte do Olheiro* occupies a platform in the middle Northwestern slope of Mount Saia, near the ridge that separates the hydrographic basins of two major water courses. It is easily accessed from the immediate valleys using two pedestrian tracks connecting with the top of the mount. Medium to coarse grain granite formations of different kinds proliferate. The carved outcrop, in that same type of rock, has an irregular surface leveled with the ground with two protuberances.

Within the carvings occur typical Atlantic Rock Art motifs: concentric circles, cup marks, spirals and a circle with semi circles attached to the outer ring. It also figures a swastika inside a circle.

Aware of the intrinsic chronological problems we accept Atlantic Rock Art manifestations in the Iberian Peninsula since the IV millennium BC (Alves 2003). However, in this specific case the presence of a swastika ratifies the long biography of this place.

We understand the *Lage dos Sinais/Monte do Olheiro* as a place of great importance from Recent Prehistory until historic times, including regional Iron Age. A *locus* that witnessed the creation, the addition and the alteration of meanings, testifying the intertwinement of senses and audiences in its large diachrony. In a micro-scale of analysis it appears to reproduce Mount Saiá's history, functioning as a mnemonic place, reproducing and amplifying the mount's own memory.

*Fernandes, João - (Departamento de Matemática, Faculdade de Ciências e Tecnologia da U. de Coimbra) jmfernandes@mat.uc.pt*

*Ramos, Normando - (Administrador da Metais Jaime Dias, SA) normando.ramos@gmail.com*

This communication presents the results obtained in the framework of a multidisciplinary approach taken to the set of schematic paintings from prehistoric shelter of Pala Pinta, Alijó, in the Portuguese region of Trás -os-Montes in the northwest of the Iberian peninsula.

The aim of this study is to evaluate the performance and applicability in specific contexts involving the rock art of non-intrusive digital methodologies for the detection, chemical analysis, survey, registration and graphic documentation of this art.

The use of digital / multi-spectral photography has allowed us to achieve results that substantially improved

the accuracy with which we can observe the paintings and has led not only to the detection of a novel motif as to reset the contours of other depiction of the composition. Chemical analysis of paintings by the method of X-ray fluorescence allowed the identification of Fe with its colouring element. Furthermore, the 3D scanning has made possible the integration of depictions and rock support in a single three-dimensional interactive platform, allowing us to examine systematically and from multiple perspectives the figurative scheme, improving the possibility of establishing the correct spatial relationship between motives and how to analyze any unintended associations to certain geological features displayed by the support.

The results achieved with the combined application of these methodologies have opened them so the possibility to better understand and support our proposed interpretation for the composition of the shelter.

The presence of several steliforms in the composition has led to a broad consensus interpretation, around the archaeological community, as probable evocations of our star. However, its iconic resemblance to the various aspects that a comet can develop during a sighting, led us to conclude that the differences in configuration, size and arrangement can be related to various stages of development of such an event.

Furthermore, some geological features of the shelter seam to establish a relation between the paintings and the landscape, alerting us to the possibility of the society that decided to make these depictions have intentionally attempted to establish a direct correlation between his astronomical conjectures and the territory of their experiences. Although aware of the low probability of success in finding a comet among those of which we have the orbital parameters, it did not dissuade us from trying to find among them those that, once we reversed their orbits, one could establish a coherent link between their path under the sky shelter and its possible evocation in paintings. This demand, allowed us to find four comets in the period between 5500 BC and the year 0, in which the development of the various stages of their eventual sighting occurred within the field of the sky that can be seen from the shelter

**14. ARCHAEOLOGICAL FIELD SURVEY IN THE ER-  
QUEYEZ SITE (WESTERN SAHARA): NEW DISCOV-  
ERIES OF ROCK ART**

*Muñiz-López, Teresa - (Archaeologist. Lemgasem Research Group) [tmuizlpez@yahoo.com](mailto:tmuizlpez@yahoo.com)*

*Khatri, Ahmed (Archaeologist. Museum of Tifariti)*

*García González, David - (Archaeologist. Lemgasem Research Group) [garcia.gonzalez.jdavid@gmail.com](mailto:garcia.gonzalez.jdavid@gmail.com)*

*López Rodríguez, Carmina - (Andalusian Institute of Earth Science (CSIC-UGR) [karmymem1983@gmail.com](mailto:karmymem1983@gmail.com)*

In the time allotted for an Investigation project and Co-operation in the archeological site of Erqueyez in Western Sahara, an archeological field survey was carried out, the results of which are presented in this work. For various reasons, there are still plenty of areas that have not been explored yet, especially everything on the west slope of the rocky massif where we focus our archeological intervention.

An intensive archeological field survey was carried out in the areas with probability of housing geological formations susceptible to painted motifs. We centered our sampling zone in the west sector of the rocky massif but some areas of the east face and superior platform were covered as well. The cave paintings were documented by digital photography with a high resolution and GPS system which make it possible to localize the small caves and subsequently use these findings to elaborate a GIS. During the work of the survey, some thirty small caves with intact paintings, to this day, were discovered. The majority of them were found in the west face of the massif, the area less surveyed in previous campaigns.

Eight of the documented small caves were selected for their description in this work, for being the one that present the best preserved paintings because they are situated in more protected places from the erosive agents.

The survey has allowed us to amplify the number of known small caves with paintings in different publications at the moment. We have been able to detect certain differences in form, size and motifs represented in the eastern and western sectors, even though we have no known explanation for them at the moment.

The work in this survey provided evidence of the need for the continuation of the line of recognition of the site.

## 1. ART IN PREHISTORY AND THE CULTURAL BACKGROUND OF NON-LITERATE SOCIETIES

Fritz, Carole - (CREAP-TRACES-Toulouse) [carole.fritz@univ-tlse2.fr](mailto:carole.fritz@univ-tlse2.fr)

López-Montalvo, Esther - (CREAP-TRACES-Toulouse) [esther-montalvo@gmail.com](mailto:esther-montalvo@gmail.com)

Sauvet, Georges - (CREAP-TRACES-Toulouse) [georges.sauve@sfr.fr](mailto:georges.sauve@sfr.fr)

In the frame of a program of the French Research Agency (ANR) devoted to creation, we have developed a research project on *the Arts of Prehistory and the Cultural Dynamics of Societies before Writing*. The team includes international specialists of Palaeolithic and Post-Palaeolithic art in different parts of the world (France, Spain, North and South Africa) as well as anthropologists, neuropsychologists and linguists. This communication is presented on behalf of the whole group. The main goal of this research is to better understand the status of art in non-literate societies, going from the elementary actions of the maker to the perception by the whole community and the influence of art on the behaviour of each member.

Artwork can be considered by archaeologists and anthropologists from two complementary points of view: as a manufactured artefact or as a societal indicator, but the two aspects should not be dissociated, because the creative gesture cannot be understood out of its social context. Since the oldest symbolic artwork production in the Upper Palaeolithic (portable and cave art), it clearly appears that the various steps of the operating sequence are carried out by individuals under the control of the group and according to processes of learning. Globally, the production of a graphic item obeys to the same social constraints than flint or bone work. Today, the skill of the engravers can be highlighted thanks to strong magnification devices and the knowhow of the painters thanks to the new technology of non-invasive pigment analyses.

The influence exerted by the society can be also highlighted in many other aspects of prehistoric art, such as formal, stylistic and expressive features, spatial organization and composition. A thorough study of these aspects, in association with the technical gesture and making use of multi-dimensional data analysis processes, provide useful indicators concerning the cultural level

of interaction between groups and the dynamics of exchange networks. The main goal of most rock arts is to inscribe in a long-lasting medium essential stories such as myths. The way these stories are expressed is particularly informative, as well as their frequency and territorial distribution. We have found, thanks to examples taken from various rock arts, that the same narrative devices are used in different parts of the world (Spanish Levantine art, Sahara, Ennedi, Brandberg) and can be tracked down even in the Upper Palaeolithic cave art.

The current trend in prehistoric art research is towards multidisciplinary integrative studies in order to reach an holistic approach. Nothing can be said from a single category of facts, because the most relevant thing is the relationship between data issued from different domains. Crossing the methodologies of various sciences is particularly useful in the case of art, because art encompasses various domains: semiotics, phenomenology of perception, Gestalt psychology, neuropsychology, theory of mind, cognitive sciences, sociology, anthropology, etc. When archaeological data are introduced in this melting pot, a real progress can be expected in the knowledge of a society, intertwining technical, socio-economic and cultural aspects.

ORAL

## 2. THE ORIGINS OF IMAGES BETWEEN PSYCHOLOGICAL PROJECTION AND TRACING INNOVATION

Ego, Renaud - (indépendant) [renaud.ego@orange.fr](mailto:renaud.ego@orange.fr)

The origin of images (as defined by figurative tracings) is still an open question. Through Gombrich and Whitney Davis's hypotheses, we are confronted with fundamental factors in the arising of images during the Paleolithic period.

In *Art and illusion* (1960), E.H. Gombrich proposes the idea of « projection ». According to this psychological approach, images were originally suggested by shapes in natural features, such as cracks and evocative rocks, upon which men imposed semantic values. Men would have discovered horses and bulls in vaguely suggestive rock surfaces and would have highlighted them with colours to make them visible to other onlookers. Whitney Davis reverses this process in *The origins of images making* (Current Anthropology, 1986, 27-3) : objects (as evocative rocks) are no longer perceived as marks ; rather, marks (digitally traced lines) are seen as objects. « Once marks are perceived as things, the full analogical

power of the line is logically derived and even detached from mere experience of perceptual ambiguity.»

Gombrich's hypothesis is paradoxical, as it requires the intellectual ability of « seeing as » - through the previous existence of « natural » images - to explain the birth of such an ability as intentional tracings. But in David's view, the birth of images arises as a happenstance, even considered as a « logical » and necessary possibility inscribed in lines, that keeps tracing activities separated from any intentionality.

If figurative tracings were only a technical development of the power of lines, they would have given form to all kinds of figures instead of being so strictly circumscribed to a limited range, namely animals and sexual emphasized figures. In that sense, images making reveals an expectation, rooted in tracing activities, that emerges through this innovation in tracing activities: the outline. Even in its incomplete state, the outline is a synthesis of the two primary units of tracing: the point and the line. But it overcomes them in deepening their internal dimension. To draw a point allows a « here » which also considers the space that surrounds it; drawing a line is to enter a motion (and time as motion) while also revealing the division of two spaces, shaping the question of limits in an absolute simple form. The outline goes beyond them by encircling this dimension of time, internal to the line, in the spatial unity of a surface. This is a primary symbolization of a living body.

The visual threshold of resemblance arises from this significant shift but still has to be explained as a mental, fundamental process. With the outline, the original question of limits moves to the more dialectic one of the partake present in both animal and sexual themes. The outlined figures embody the limits of time, (death and regeneration) through the sexual theme; and they embody spatial limits, through the animal/ species theme. With these living ensembles of both shared and divided spaces, the question of identity (similar/dissimilar, unity/diversity,) begins to be visually exposed.

### **3. QUANTITATIVE ANALYSIS OF EARLY AURIGNACIAN BEAD MORPHOLOGY: MODELING PRODUCTION ORGANIZATION AND EXCHANGE**

*Heckel, Claire - (New York University) [claire.heckel@nyu.edu](mailto:claire.heckel@nyu.edu)*

In the prehistory of personal ornamentation, the imposition of specific forms on plastic raw materials such as

ivory, soapstone, and amber is a significant development beyond the perforation of naturally-occurring objects, and occurs in several regions of Eurasia during the Early Upper Paleolithic. The morphological standardization of Early Aurignacian beads has been recognised as an important characteristic of these artifacts in their function as social technologies and as symbolic artefacts. Even so, few studies have been performed to quantitatively characterize the standardization and variation of these remarkable artefacts at the site and regional levels.

This study applies software developed in the biological sciences to the morphometric and attribute analysis of over 600 basket-shaped beads from five Early Aurignacian sites in southwestern France (Grotte d'Isturitz, Grotte des Hyènes at Brassempouy, Abri Castanet, Abri Blanchard, and Abri de la Souquette). Evidence on raw material procurement and production stages from each of these sites is also considered.

The results of this study provide data on patterns of standardization at site and regional levels based on several lines of evidence. A newly-developed typology for basket-shaped beads demonstrates that there is spatial variation in bead typologies beyond the general level of "basket-shaped bead." Statistical analysis of the variation of specific shape attributes confirms that certain attributes were consistently more controlled than others. Further statistical analyses determine the importance different factors (such as provenience and raw material) on final bead morphology.

The combined results of these studies confirm the existence of semi-specialized craft production in specific territories during the Early Aurignacian and provide data for the construction of new models for the organization of these activities. They also provide new insights on the production and exchange of these artifacts in Early Aurignacian landscapes, and on the role of standardized ornaments in Early Aurignacian social and economic systems.

### **4. THE IVORY FIGURINES FROM THE SWABIAN JURA IN THE CONTEXT OF THE AURIGNACIAN SOCIETIES IN CENTRAL EUROPE**

*Floss, Harald - (Universität Tübingen, Germany) [harald.floss@uni-tuebingen.de](mailto:harald.floss@uni-tuebingen.de)*

Four cave sites in the Swabian Jura (Southern Germany) have yielded a spectacular array of Aurigna-

cian art: Hohle Fels, Geißenklösterle, Vogelherd, and Hohlenstein-Stadel. From these sites, we know about 50 figurines realized mostly in mammoth ivory. These objects of portable art constitute some of the earliest known representational artifacts in the world. Subjects addressed in this contribution include the possible religious and social foundations underlying the production and use of these objects. New aspects of daily life in the Aurignacian are becoming clearer through ongoing research at these sites that add richness and depth to their study and interpretation. We are particularly interested in the spatial and stratigraphical informations of these figurines in order to create hypotheses about their use. Objects of mobile art often are identified as “non-utilitarian”. Nevertheless, they are strongly linked with social and religious needs and therefore very “utilitarian”. In a period when Neanderthals and anatomically Modern Humans shared partly the same areas of Europe, art production might contribute to find self-conception and identity.

## 5. EARLY SYMBOLISM IN THE LONE VALLEY (SOUTH-WESTERN GERMANY)

*Dutkiewicz, Ewa - (Department of Prehistory, University of Tübingen) ewa.dutkiewicz@uni-tuebingen.de*

*Wolf, Sibylle - (Department of Prehistory and HEP, University of Tübingen) sibylle.wolf@ifu.uni-tuebingen.de*

*Conard, Nicholas J. - (Department of Prehistory and HEP, University of Tübingen) nicholas.conard@uni-tuebingen.de*

The two cave sites, Vogelherd and Hohlenstein-Stadel, located in the Lone Valley in the Swabian Jura, are of particular interest concerning the appearance of early symbolism during the Aurignacian. In the 1930ties Gustav Riek excavated in Vogelherd and Robert Wetzels conducted the excavation at Hohlenstein-Stadel (both University of Tübingen). Recent fieldwork at both sites delivered several hundreds of three-dimensionally carved personal ornaments, made of mammoth-ivory as well as tooth pendants. These sites yielded also the earliest figurative art. The Aurignacian people mostly depicted Pleistocene animals. From Hohlenstein-Stadel we know the tallest Ice-Age-figurine, the famous hybrid “Lion Man”. Numerous marks on these figurines are a distinctive feature within this cultural complex. The ensemble of the signs shows interesting regularities. We use new methods for the documentation and analyzes of the marks. We also show new results of the studies of osseous material. In our talk we will present and discuss the expressions of

symbolic behavior and their meaning for the Aurignacian people in the Lone Valley.

## 6. THE ROLE OF GRAPHIC SIGNS IN PREHISTORIC SOCIETIES

*Sauvet, Georges - (CREAP-TRACES-Toulouse) georges.sauvet@sfr.fr*

*Bourrillon, Raphaëlle - (CREAP-TRACES-Toulouse) r.bourrillon@gmail.com*

*Gárate Maidagan, Diego - (CREAP-TRACES-Toulouse) garatemaidagandiego@gmail.com*

*Petrognani, Stéphane - (ARSCAN UMR 7041 Nanterre) clarkpetro@yahoo.fr*

*Rivero Vilá, Olivia - (CREAP-TRACES-Toulouse) oliviariver@hotmail.com*

*Robert, Eric - (ARSCAN UMR 7041 Nanterre) eric.robert15@wanadoo.fr*

*Tosello, Gilles - (CREAP-TRACES-Toulouse) gilles.tosello@wanadoo.fr*

Prehistoric societies need to be equipped with strongly rooted rules and laws. Most often, the force of these laws rests on founding myths that nobody can contest. Images play an important role in the stability of these societies because they act as a binder. Those who share and understand these images belong to the same cultural community. In Palaeolithic art (as in many other rock art), the main topic is probably related to myths and everybody who knows the myths is able to understand the meaning of the figurative representations. However, non figurative representations (often called “signs”) need a supplementary and specific training. Whereas animals and human images may be understood within a large intergroup area, signs having a more limited diffusion acquire a **distinctive function** in the society.

In traditional societies, each member is defined by his (her) membership to a group (clan, lineage, social status, etc.) and this is shown by marks that may be directly inscribed in the body or drawn on a fix medium such as a rock wall. Corporeal signs (body paintings, tattoos and scars) are **differential markers** linked to a socially ruled practice, obeying to precise rules. External marks drawn on rocks may have a similar meaning to which is often added the function of **territorial marker** (rather than Leroi-Gourhan’s **ethnic markers**). When found very far from their original territory, signs may still recall their “distant” origin and act as a label (**e.g.** in Palaeolithic art, the presence of claviform signs in the Cantabrian Region

might have kept a memory of their “Pyrenean” origin). Some specific motifs in portable art may bear a similar connotation.

In Palaeolithic art, the practice of corporeal signs is impossible to discuss, but the hypothesis of signs used as differential markers may be argued. The case of signs belonging to the same formal family accumulated in narrow recesses will be illustrated with the quadrilateral signs found in Cantabrian caves such as El Castillo, La Pasiega, Las Chimeneas and Altamira. A formal and statistical analysis made with the help of Correspondence Analysis shows that Pasiega and Castillo form distinct groups and that the main distinctive features are independent and freely combinable. A scheme showing the various combinations of features demonstrates that we are dealing with a codified system, which is in agreement with the hypothesis that the whole set of Cantabrian quadrilateral signs was used as *differential markers* of human groups or individuals. A similar hypothesis may be considered for the tectiforms found in four nearby Perigord caves. Many historical and contemporaneous examples of the same behaviour may be found.

Palaeolithic art probably involves different subsets of items, with different purposes and different levels of signification. Figurative items were likely related to essential beliefs shared by a large cultural community, whereas more localized subsystems, mainly based on non-figurative signs, seem to be designed for the purpose of social interactions between local groups.

### 7. SOUTH OF THE GUADALQUIVIR: HANDS, HINDS, HORSES AND SIGNS.

*Sanchidrián Torti, José Luis - (University of Córdoba (UCO))  
gt1satoj@uco.es*

*Medina-Alcaide, M<sup>a</sup> Ángeles - (University of the Basque Country (UPV/EHU))  
mangeles.medina@ehu.es*

*Hernando Álvarez, Clara - (University of Salamanca (USAL))  
clara85@usal.es*

All the Upper Palaeolithic sites in Andalusia are located to the south of the River Guadalquivir, in a geographical area bounded to the north by the river, and to the south by the coastline.

The area is favoured by a number of bioclimatic factors, even in the harshest conditions. In particular, the southernmost section of the Mediterranean coastline, running

from the province of Granada down to the Bay of Algeciras, constitutes a unique niche surrounded by a barrier of mountain peaks (average altitude 1500 m. a.s.l.) which protect it from cold northerly and north-westerly winds and act as a heat screen towards the south. Moreover, thanks to the complex thermohaline circulation off the Bay of Málaga, this local sector of the ocean is highly productive. These optimal bioclimatic factors, also reported for Pleistocene chronologies in the south of the Peninsula, favour human settlement in the area.

The present study focuses on Iberian Gravettian and Solutrean chrono-cultural phases (26.000-16.500 BP), since the parietal art (the main object of the study) and occupational layers belonging to these techno-complexes are the most representative of the study area.

New archaeological data deriving from the excavation of local occupation layers (e.g. Bajondillo, Nerja), together with new dating for the Palaeolithic settlement of caves containing Pleistocene art (Nerja) provide an enriching scenario which prompts a critical reappraisal of the spatio-temporal distribution of graphic morphotypes characteristic of the southern Iberian Peninsula. However, the figurative sequences derived from overlapping parietal art and the direct dating both of the Cueva de la Pileta and of the mobiliary art of the Cova de Parpalló remain essential to any approach to Palaeolithic art in this region. Shared access to the various records reported has ensured significant progress in the sequencing and understanding of Palaeolithic art in the southern Iberian Peninsula.

This study takes a new look at the chronology of certain figurative prototypes (negative handprints, conventional three-line hinds figures, “duck-bill” horses and signs), discerning different stages in the major artistic block known as pre-Magdalenian. Secondly, the spatial and chronological adscription of these prototypes enables some of them to be identified as territorial markers which provide information on changes in population (peaks and troughs) prompted by socioeconomic and palaeo-environmental changes, and also on the relationships within and between the human groups living in this area prior to the Magdalenian techno-complex.

ORAL

## 8. SOCIAL AND CULTURAL INTERACTION IN THE CANTABRIAN-PYRENEAN REGION DURING THE LATE MAGDALENIAN (14500 - 11500 BP): NEW DATA FOR A LONG-STANDING THEORY

Ruiz-Redondo, Aitor - (*Instituto Internacional de Investigaciones Prehistóricas de Cantabria (IIIIPC). Avenida de los Castros s/n, 39005 Santander, Spain*) aruizredondo@gmail.com  
Garate-Maidagan, Diego - (*CREAP Cartailhac-TRACES-UMR 5608, University de Toulouse-Le Mirail, 5 allées Antonio Machado, 31058 Toulouse Cedex 9, France*) garatemaidagan-diego@gmail.com

In the field of graphic activity, the second part of Magdalenian period is characterized for an stylistic homogenization in an extensive territory of southwestern Europe. Some areas that had previously shown a distinctive personality, became in that period part of a common graphic form.

In this communication, we introduce the analysis of the thematic and other technical and stylistic characteristics from Pyrenean and Cantabrian parietal ensembles in the timelapse between 14500 and 11500 BP. We include unpublished data resulting from new findings and recent reviews of already-known ensembles.

The graphic activity from these two regions, which until then had shown great peculiarities, is well integrated into the homogenizing process. The ensembles of both areas show some deep similarities in terms of thematic, techniques and graphic conventions, although some differences are still present. These data could be joined to with others obtained from studies of lithics and raw materials of that period. All of them point to a very strong social interaction between the Cantabrian Sea and the Pyrenees.

The new data reported in this communication confirm the research carried out during the last 30 years about the cultural relationships between human groups in a large territory encompassing the Cantabrian Region, the north side of the Pyrenees and a large part of the southwest of France during the late Magdalenian (see among others Sieveking, 1978, *Trabajos de Prehistoria*, 35:61-80; Bahn, 1982, *Oxford J. Archaeology*, 1-3:247-268; Fortea, 1989, in *Le Magdalénien en Europe*, ERAUL, 38:419-437; Corchón, 2004, in *La Materia del language prehistórico*, p. 105-126; Sauvet et al., 2008, *Zephyrus*, LXI:35-56).

ORAL

## 9. COGNITIVE PROCESSES RELATED TO THE PALEOLITHIC FIGURATIVE DRAWING: EXPERTS OR NOVICES?

Amayra, Imanol - (*Universidad de Deusto*) imanol.amayra@deusto.es

Apellaniz, Juan María (*Universidad de Deusto*) - juanmaria@apellaniz.biz

Experimental studies of neuroscience and cognitive psychology have shown that skilled artists are more analytical in their drawings. Analytical thinking is characterized by decomposing the image into natural parts. Instead, perception of novices is holistic, schematic and less concerned about the relationship of the parts. Another mechanism that differentiates experts from novices is the graphical invariance, ie, the constancy of the proportions in the representations. The artists who perform a large number of representations have higher graphical invariance and are more easily identifiable with mathematical methods of decomposition of images.

In order to investigate whether the behavior of Paleolithic graphic artists is similar to the skilled modern artists, we conducted a comparative study of Paleolithic Figures 70 and 140 experimental figures.

The total sample consists of 70 figures paleolithic horses (from Spain and France), 70 experimental horses made by experts and 70 figures horse made by novices. Experts and novices performed an average of 4 figures. All selected figures had a complete outline. The method of sampling was randomized and single blind. The complete outline of each figure was measured with 20 geometric variables related to the length and width. The variables are related to the contour points of maximum negative curvature, minimal positive curvature and inflection. The exploratory factor analysis was applied to the study of the decomposition of the images into parts. Instead, multidimensional scaling was applied to the recognition of the authors.

Exploratory factor analysis identified a total of five anatomical parts: neck, trunk, length, internal hindquarter and external hindquarter. The total variance explained was 77% (KMO Index = 0.82). This mathematical structure appears mainly in expert and Paleolithic groups. In the novice group, the factor structure is not clear. The factorial components are not discrete, for example, variables of the trunk, hindquarter and external hindquarter presented a correlation greater > 0.40. However, often the correlation is less than this magnitude between vari-

ables within the same anatomic area.

Regarding the criterion of identification of the author was as follows: at least three figures should appear close in three of five multidimensional scalings of the five anatomical parts (neck, trunk, length, internal hindquarter and external hindquarter). The average percentage of identification in the expert group was 75%, 78% in the Palaeolithic and 65% novice.

The anatomical parts of mayor diagnostic validity in the Palaeolithic figures painted were the trunk and the neck; in the engraved Palaeolithic and experts figures the trunk and the hindquarter. In the group of novices is not clearly identified an area of attribution of authorship.

The Palaeolithic authors' graphic behaviour was very similar to the experimental experts: analytic and analogic vision, figure segmentation in parts, and graphic consistency in the dimensions of at least two out of the five parts of the figure. The similarity between the parts dimensions, especially in the painted Palaeolithic figures, is not necessarily correlated to the macroscopic similarity.

ORAL

## 10. SINGULARITY AND SURVIVAL OF ROCK ART AT THE OJO GUAREÑA CAVES (BURGOS, SPAIN)

*Ortega Martínez, Ana Isabel - (CENIEH) anaisabel.ortega60@gmail.com*

*Martín Merino, Miguel Ángel - (Grupo Espeleológico Edelweiss) mamartinmerino@gmail.com*

The Ojo Guareña karst, located in the Cantabrian Range in the north of province of Burgos (Spain) in a relatively isolated area, is far away from the big natural routes of communication in the Iberian Peninsula. The Ojo Guareña Complex is one of the biggest cave systems in Spain, including fourteen interconnected caves with a total length of at least 110 km. The complex has an impressive record of Prehistoric activities, from the Middle Paleolithic to the Middle Ages. Cave art is of special relevance, with sites dating from the Last Upper Palaeolithic to the Bronze Age, including the rock art of Cueva Palomera (with seven main sites) and six other caves, the Cueva de Kaite being of special value.

The Paleolithic of Sala de las Pinturas in Palomera Cave is a unique rock art site which is chronologically and stylistically related to the last Magdalenian culture towards the transition to the Epipaleolithic culture (Pleistocene-

Holocene boundary).

The graphic record of Kaite site is represented by semi-naturalists with deer and goat figures, some of which include young offsprings and surrounding lines and signs which enclose them. This graphic conception seems to have a continuity with local codes of the Paleolithic art, in the transition between the last hunter-gatherers and early farmers in the beginning of Neolithic times.

The Sala de la Fuente in Palomera Cave, near the Sala de las Pinturas, shows a post-Palaeolithic rock art, where the graphic expression of the human figure is persistent. This site presents the same type of wizard ("Brujo") anthropomorphic that can be found in Sala de las Pinturas, Paleolithic, perhaps because they had a special meaning. Interestingly, the same kind of schematic deer design engraved in Kaite Cave is also documented in this site. It is proved that the Kaite sanctuary is from an earlier period in time; however, these schematic designs are frequent in the Iberian Neolithic and Bronze Age art.

The rock art of Sima de Villallana shows geometric signs linked with human remains and tumulus of sandstone boulders. The chronological data allow us to relate this site to the Late Bronze Age phases and the possible continuity with the ritual use of Vía Seca maze, in Cueva Palomera, during the Iron Age.

The graphic analysis and the comparison with different rock art sites from the Ojo Guareña Complex allows us to assess the continuity or the change in graphic activity and the population inside of an isolated territory. Moreover, these concept and space relationships among these rock art sites imply that the artists had to have a complete knowledge of this vast karst system from the Late Paleolithic until the Bronze Age. The use by these prehistoric people of the underground Landscape with symbolic activities is associated with the transformation of this cave-territory in a social and symbolic landscape for the community.

---

ORAL

## 11. SPATIAL ANALYSIS OF ROCK ART IN THE MOUNTAINS OF EL SISTEMA CENTRAL. (MADRID, GUADALAJARA, ÁVILA AND SEGOVIA, SPAIN).

*Bayarri Cayón, Vicente - (Gim-Geomatics) vicente.bayarri@gim-geomatics.com*

*Ripoll, Sergio - (UNED) sripoll@geo.uned.es*

*Latova, José - (ASF Imagen) latova@asfimagen.es*

*Municio González, Luciano - (Junta de Castilla y León) luciano.municio@gmail.com*

The mountain Central System has always been considered as a natural barrier between the North and the South Plateaus. Research Projects SIGAREP I and II, conducted by the signatories of this paper during the years 2011 to 2013, were dedicated to the study and documentation of both Paleolithic and post-Paleolithic rock-art using advanced technologies. The study showed connections between north and south parts.

The paper shows the recording and spatial analysis techniques undertaken in this vast territory, which shows through different patterns designed by the research team that there are clear links between the two sides of this mountain chain from at least 20,000 years to the present. Applied patterns clearly show that our ancestors had no such barrier through which they were traveling incessantly, techniques, themes, ideas, deep thoughts and something as intangible as spirituality.

ORAL

## **12. ANTHROPOLOGICAL INSIGHTS INTO THE SPANISH LEVANTINE ROCK ART: AN APPROACH TO THE IBERIAN NEOLITHIC SOCIETIES THROUGH THEIR IMAGES.**

*López-Montalvo, Esther - (CNRS-UMR 5609 TRACES) esther-montalvo@gmail.com*

The narrative content of scenes and the naturalistic features of depictions of the Spanish Levantine rock art make of this art an useful tool in our goal of digging for a better comprehension of the social and economic organisation of prehistoric societies concerned.

Since these paintings show significant continuities and ruptures in time and territory regarding formal features of figures but also the activities portrayed, their analyse allow us to question if these graphic variations observed in the panels are the reflect of deeper changes in the social structure, and if so, if they can help us to characterise the dynamics of these societies.

Placing the Levantine paintings in time and space axes, we analyse the activities represented in panels paying special attention to those aspects that allow us to discuss the social complexity of these groups – inequalities, gender role, violence, activities of prestige, etc.

The anthropological approach to the Levantine paintings allows us to assess some cognitive aspects with no remains in the archaeological record. Despite of the limits in the reading and interpretation of the prehistoric iconography, we defend that the activities represented in the Levantine paintings are deeply rooted in the behaviour of these groups, so they can be very useful in order to both assess social and economic aspects and to have a better comprehension of the role of these painting in societies.

ORAL

## **13. FEMALE AND MALE: THE NARRATIVE OF LAPA DOS GAIVÕES (PORTUGAL)**

*Martins, Andrea - (Associação Arqueólogos Portugueses) andrea.arte@gmail.com*

The Lapa dos Gaivões (Arronches - Portugal) is a rock shelter with geological features that allows the formation of different scenic spaces used during recent prehistoric as stage of several narratives. The morphologies of schematic figures show a sexual distinction, framed in diverse scenes that reveal daily aspects, symbolic and real, of the communities. The feminine universe is structured in the connection with nature and with the idea of regeneration, birth and community. The Lapa dos Gaivões rock shelter would allow the aggregation of the community, in a large amphitheatre, where the scene would be punctuated in little stories and narratives of the human groups or past actions. These would aggregate the community and give social-culture cohesion. The stylistic analysis of the schematic motives, searching for defining patterns, allows the identification and morphological characterization of members of the same group. The study of singular recurrences in the site makes possible the recognition of a particular community. These typological characteristics are the distinctive element of this community, present in the female and male universes, and display different formal features. We will present the several stories of the site through the technical mechanisms that allowed the execution of an iconographic repertoire and the creation of a narrative expressed in a single moment.

ORAL

**14. BETWEEN « CULTURE OF THE PEACE » AND « ART OF THE WAR » AMONG BOVIDIAN PEOPLE OF THE SAHARAN CENTRAL MASSIFS.**

*Barbaza, Michel - (Université Toulouse Jean Jaurès) michel-barbaza@wanadoo.fr*

Central Sahara establishes, by the quality and the abundance of its rock art, a real conservatoire in the open air where extraordinary evidences of the lifestyle of the Neolithic herdsman are collected. How to understand and to interpret these rock drawings? Why images? Why the bovidian representations illustrating the daily life of the populations of the saharan Neolithic by their surprising realism, do they succeed abstract compositions and stamped with mystery, expressing the existential anxieties of "round heads" people, confronted with a world undergoing profound ecological change.

Crossing back the road of the knowledge and going back up the nature of things, from the decorated wall to its meaning, the archaeologist tries to reach the forming of the myth and to understand the profound nature. The researcher, having elaborated the meticulous surveys of the decorated wall, endeavours to create the internal organization of the sceneries and to put in prominent position the structure of the compositions. Reflection of their essentially, it allows to catch a glimpse of the fundamental explanation of the rupestral art.

Distinguishing the myth, as a trouble of the collective unconscious, from the mythological stories which it engenders, by successive touches the author brings to the foreground the reason of these surprising compositions. Making converge the methods of the prehistoric archaeology, the art history and the social and cultural anthropology, he illustrates the principles of an anthropological study of rock art. At last, confronting the results of these disciplines with the data of the saharan prehistoric ecology, he gives prominence to the possible causes of tension and conflict between the pastoral peoples, whom the art is exactly in charge of resolving.

Before the aridity and desertification work in favour of the advent of a protohistoric society with traders and warriors, the bovidian people set up the conditions allowing the institution and the preservation of a great pastoral civilization. The stories which illustrate it are lost forever; the myth which generated them, sometimes, shows through.

ORAL

**15. DIFFERENTIAL EXPRESSIONS OF IDENTITIES - A FUNCTIONAL ANALYSIS OF PREHISTORIC NAMIBIAN ROCK ART SITES**

*Lenssen-Erz, Tilman - (University of Cologne) lenssen.ertz@uni-koeln.de*

It is a well-known phenomenon of human identities that they are neither static nor narrowly limited. Even in a relatively homogenous small-scale prehistoric hunter-gatherer society there is not just one single identity which people entertain. This is a field of research that still requires methodological innovation.

There are many parameters under which identities shift, one among them is space. Rock art is perhaps the best source to investigate the different expressions of identities linked to spatial configurations since, as a rule, rock art keeps its original location in a landscape over millennia. This allows examining the relation of cultural markers to the immediate surroundings as it was chosen by the prehistoric artists. From the character of a place and the kind of rock art that was produced there one can draw conclusions concerning the different identities that were advertised in different types of rock art sites. This study also shows that rock art cannot be understood comprehensively without investigation of its spatial context.

ORAL

**16. MEMORY, IDENTITY, POSSIBILITY: A SYMBOLIC DECORATIONAL SYSTEM AS A MEDIUM OF CULTURAL REMEMBRANCE AND SOCIAL SIGNALLING IN THE NEOLITHIC OF THE CARPATHIAN BASIN**

*Sebők, Katalin - (Institute of Archaeological Sciences of the Eötvös Loránd University, Budapest, Hungary) sebokkata@gmail.com*

The presentation surveys the history of a graphic/symbolic system that appears first on clayware in the Middle Neolithic in the eastern half of the Carpathian Basin, and remains in use, evolved into diverse forms and functions, throughout the rest of the neolithic period in the area. The statistical processing of the material of Polgár-Csőszhalom, which is of one of the largest excavated settlements from the Late Neolithic in the Carpathian Basin, raised an opportunity for us to perform a comparative style analysis of a ceramic material with more than 300,000 fragments altogether. The local results were

compared with previously evaluated data sets from several coeval settlements.

The Late Neolithic in the study area is represented by a single cultural complex (Tisza culture), the archaeological material of which is characterized by the overall application of a highly complex graphic system (textile decoration). This system had evolved from a particular, primarily 'ritual' decoration system in the Middle Neolithic as an accompaniment of the extended social and economical changes that have taken place during the formation of the Tisza culture. Therefore, starting with its appearance in the Middle Neolithic Alföld Linear Pottery Culture, our goal in the first part of the presentation is to show the original functions and basic regularities of the graphic system under study.

The northern fringes of the Tisza culture's distribution area are bordered by a large and geographically not really separate interference zone, in the archaeological (especially the ceramic) material of which the amalgamation of the surrounding cultural units' ceramic traditions is a defining factor. The examination of the particulars of this situation relies on materials of two large settlements in the first place: one from the core area of the Tisza culture (Pusztataskony-Ledence 1) and another from the northern interference area (Polgár-Csőszhalom). The questions of the analysis were pointed, beside others, to the structure, reactions and behaviour of the graphic/symbolic system, as well as to the detection of its possible distortions and the changes in use in cultural stress situations. The second part of the presentation focuses on the current results of this work, offering a short survey of our present knowledge about the concepts and layers of social or cultural identity encoded in this system, the embedded possibilities and advantages in different levels of the community from the single individual to supra-regional levels, and finally, on changes in application and use as markers of the system's shifting place in different cultural contexts.

ORAL

## **17. ABOUT SPECIFICS OF ROCK ART OF GOBUSTAN AND SOME INNOVATIVE APPROACHES TO ITS INTERPRETATION.**

*Farajova, Malahat - (Gobustan National Historical Artistic Preserve) malahat@mail.ru*

Petroglyphs of Gobustan represent an important historical source, allowing us to get notion about material and

spiritual culture of the population that inhabited the given region during various historical epochs. From this point of view the study of petroglyphs on Firuz and Firuz 2 sites of Kichikdash Mountain, Gobustan, is of special interest.

In April 2014, a field expedition was organized with the aim of studying petroglyphs on Firuz and Firuz sites. The field material, collected in the process of expeditions became a good base for further studying. With the aim of approach to the study in the context of archaeological complex, archaeological material of Gobustan preserve funds was also involved. Various techniques of taking stamps from petroglyphs, making copy and night photo-fixation were used for the analyses.

For dating petroglyphs we used AMS dating from cultural layers of Firuz and Firuz 2 sites that allowed us to define and understand the sense of petroglyphs of various periods in all their versatility.

Images of boats which were found by the author at the top of the stone, east side, attract attention. We will bring the interesting fact: at the top of the mentioned stone 97 there is a hollow, out of which a straight line is stretching down to the images of boats. We can assume that these images were executed with ritual purposes. It finds its additional argumentation due to numerous hollows with hollowed out channels that were also fixed in the territory of Gobustan preserve. Moreover, it is necessary to take into account that the majority of them are located near petroglyphs.

Images of boats in the upper part of the rock 19, west side, which were also found by the author during the expedition are of special interest.

It should be noted that the petroglyphic art of Caucasian region images of boats are met only in Gobustan.

As a result of archaeological excavations carried out near a burial place in Firuz site, stone with images of boats were found from cultural layer. The archaeological material dated from this layer allowed to confirm the assumption that Gobustan is the earliest center of navigation emergence in this region.

In this case it isn't necessary to exclude cult and semantic sense of images of boats, which were one of the most important vehicles in the economic life of Gobustan hunters.

Findings show that petroglyphs of boats on stone 19

and 97 in Firuz site can be interpreted as ritual.

In its turn, AMS dating of the cultural layer where a stone with the boat images was found, let us assume that the drawing had been executed earlier than the cultural layer was formed and respectively, it is dated back to more ancient period.

No matter what to associate the images of boats with, there is one important fact that these images really testify to the great invention of the past and their wide use in the life of Gobustan people, the first conquerors of the Caspian Sea.

ORAL

### 18. ART OF THE BRONZE AGE STELES OF MONGOLIA

*Magail, Jérôme - (Musée d'Anthropologie préhistorique de Monaco) jm@map-mc.com*

Since 2006, the Monaco – Mongolian joint archaeological mission has been studying the Tsatsyn Ereg necropolis 500 km west from the capital Oulan-Bator. More than 400 graves of Bronze Age are distributed on 30 km<sup>2</sup>. Hundred engraved steles were found near graves and hillocks of deposits of head of horses. Tsatsyn Ereg shows with other sites of the end of the Bronze Age that there was a very powerful civilization before the vast nomad empire of Khunnu (Xiongnu). Indeed, it seems that the tribes, which occupied the territory of current Mongolia, confederated to establish the first empire of steppes. In the third century BC the empire of Khunnu opposes the new empire of China, which is going to strengthen the construction of the Great wall. There are relatively few traces of these illiterate nomads, hunters and warriors whose territory was bigger than the area of present-day Mongolia. In order to understand the origin of their habits better, customs and cosmology, the research carried out by the Monaco – Mongolian joint archaeological mission relates to remains from before this period. The engraved steles known as “deer stone” give a lot of information about weapons and thought of the nomads of the Bronze Age.

These monoliths, some as high as 4 m, have various iconic themes whose style is identical to that from eastern Mongolia to the Altai, from the Gobi to the Transbaikal. From the end of the 2nd millennium to the 5th Century BC, the artists systematically spread out the figures in the same way from the bottom to the top of each stele:

- at the top, two different-sized circles are inscribed showing the sun and the moon;

- under the stars, in the middle part, stags with long rounded antlers are rushing towards the top or the bottom of the stele;

- at the base, there are different weapons, shown schematically (shields, daggers, axes and bows).

Thus, the engraved grouping is? cosmology where each theme corresponds to an area of the Universe: the sun and moon for the sky, the deer occupy an intermediate terrain and the weapons represent the terrestrial space occupied by warrior. A geometric motif, engraved at the bottom of the monument, evokes the separation between the terrestrial and underworld realms. The iconographic themes are often separated by geometric motif to mark clearly the different areas of the Universe.

The presence of small cervids, at the base of the monument, underlines their psychic role; herds of deer plunging into the world of the dead and surging up from the sepulchral space to rejoin the celestial regions. Their bodies have been deliberately elongated to expand their movements between the two cosmological extremes. Their silhouette, marked by the rounded form of their antlers and their legs folded under the stomach, is also found in the mobiliary art of the Steppe. Moulded, sculpted and engraved cervids, from the Caucasus to eastern Mongolia, show very close stylistic particularities.

ORAL

### 19. SOUTH ANDEAN ROCK ART, CULTURAL CONTEXT OF SOCIO-ECONOMIC TRANSITION

*Dudognon, Carole - (University Toulouse Le Mirail 2, UMR 5608, Laboratory TRACES-CREAP, France) carole.dudognon@dbmail.com*

*Sepúlveda, Marcela - (Department of Anthropology, University of Tarapacá, Arica, Chili) msepulveda@uta.cl*

In the Andean foothills from northern Chile, rock art sites are located between 2,800 m and 3,800 m. The paintings were realized inside little rock shelters. Camelids are among the principal animals represented in the Andean rock art and most of them belong to scenes describing the process of domestication which took place 6,000 years ago in the central Andean mountainous regions. An in-depth review of three sites, comprising more than 800 figures and some thirty scenes, indicates that there

is a strong interaction between the anthropomorphic representations and the camelids. Beyond the evocative symbolism, the accuracy of the scenes allows us to identify human practices, when the archeological context is insufficiently documented.

To study these practices, a methodical reading of the scenes (rather than the individual images), allows us to demonstrate the existence of various hunting techniques and objectives, implying various technological investments. To ensure the relevance of our conclusions, we have carried out an analysis of the superpositions and a stylistic study combined with factor analysis. This leads us to a better understanding of the socio-economic situation revealed by the paintings and to the conclusion that various human groups have probably contributed to the production of these paintings.

Thus, we notice a complex socio-economic transition; the change from a hunter-gatherer lifestyle to pastoral activity seems to be a smooth transition. Hunting practices depicted in rock art are oriented towards the capture of alive animals while, at the same time, appears the representation of "structures for the seclusion of camelids". In any case, these representations demonstrate common efforts to optimize the exploitation of the wildlife resources, whereas simultaneously neighboring regions are going through a period of important innovations related to their neolithisation.

In conclusion, our analysis brings new light on the context of socio-economic transition in this Andean area. The study of a rich body of paintings allows a new approach centered on human practices.

**Acknowledgement:** Work financed by Project FOND-ECYT 1130808.

## ORAL

### 20. THE USE AND SCOPE OF AGUADA ICONOGRAPHY IN THE SOUTHERN ANDEAN REGION

*Gordillo, Inés - (Instituto de Arqueología - Facultad de Filosofía y Letras- Universidad de Buenos Aires) ibesalu@gmail.com*

Between the seventh and twelfth century of the Christian Era diverse populations that inhabited the southern valleys of the Argentine Northwest created a particular iconography centered in anthropomorphic- feline and fantastic images. This is the stylistic set known as Aguada

in the archaeology of the area, which is analyzed in this work.

Therefore the proposal is to go further in the analysis of the iconography shared by the different local groups, expressed through various techniques and different types of media, both movable and fixed rock art.

The research implemented for this purpose addresses several levels of design analysis, examining references, icons, composition, visual resources, perceptive effects, etc. Within the iconographic repertoire identified, we will study in particular representations which are more recurrent, those corresponding to the category of complex motifs of figurative - fantastic character as they gather iconic signs which meet imaginative combinations.

During this period -called Period of Regional Integration- various archaeological areas of the region exhibit different stylistic identities which are the result of specific historical trajectories and different situations of each society in the interaction with the others. The main styles, which are clearly identified, differ from the others by the supremacy of some of the technical implementations, the particular management of plastic and compositional resources, the dominance of certain motifs and / or representations of local models, etc. However, there are common rituals and mythical icons that pass transcend the expressive field of that group of societies, in this way showing the active contact between them and the use of a commonly shared symbolic capital. For this reason, some authors have defined this term as.

Similarly, when considering the contexts associated to these representations, we note that they had a privileged place in the sacred spaces of tombs and caves, but also managed in everyday materiality of houses and yards, in scenarios related to domestic life and ordinary experience.

The proposed conceptual approach, although flexible, argues the impossibility of separating the social practice of the material world, recognizing in the latter its capacity of agency. Therefore, to go on with the interpretation of these visual representations, besides its stylistic analysis, we need to contextualize them, considering the actions of people, things and locations that come into play with social practice.

**21. NEW STUDIES AND INTERPRETATIONS OF CAVE ART FIGURES OF THE CUEVA DE EL CASTILLO (CANTABRIA, SPAIN).**

Ripoll, Sergio - (UNED) [sripoll@geo.uned.es](mailto:sripoll@geo.uned.es)  
Bayarri Cayón, Vicente - (Gim-Geomatics) [vicente.bayarri@gim-geomatics.com](mailto:vicente.bayarri@gim-geomatics.com)  
Latova, José - (ASF Imagen) [latova@asfimagen.es](mailto:latova@asfimagen.es)  
Pecci, Hipólito - (LEP) [poliche333@hotmail.com](mailto:poliche333@hotmail.com)  
Ontañón, Roberto - (Museo de Prehistoria de Santander) [ontanon\\_r@cantabria.es](mailto:ontanon_r@cantabria.es)

During the year 1952 Professor E. Ripoll-Perelló and his wife A. L. López were given permission from the Patronato de las Cuevas Prehistóricas de la Provincia de Santander to study the Cueva de Las Monedas in the **Monte de El Castillo**, Puente Viesgo (Cantabria). While they performed these works they had opportunity to visit the cave on several occasions and compare it with the information published by Abbé H. Breuil, assisted by H. Alcalde del Río and L. Sierra in *Les Cavernes de the Region Cantabrique*. Throughout his explorations they could see that many of the published images on the one hand did not correspond with reality and on the other they found numerous unpublished representations. In 1953, my parents decided to carry out the review of the representations described and returned with another permission from the same institution. The work was done in several campaigns and carried out the discovery of almost 300 new figures in the **Cueva de El Castillo**. Eduardo Ripoll have never published the results of their investigations and told me many years later that it was because the change of methodology that was imposed in the 1960s. A few weeks before the death of my father in the year 2006, in Barcelona, in a very solemn manner gave me a great portfolio that kept all the documentation of the Castillo and told me: publish it!

Finally a few months ago I had a clear idea and the work was developed together with a group of researchers, we ask for the mandatory permit to verify suitability of the descriptions of my father, his location in cave and above all make some new photos of certain grounds. The application of emerging technologies in digital image processing has allowed us to expand 280 my father figures to nearly 550 new figures, some of them quite spectacular. And are those present in this Congress. We are aware that over the years have been many researchers who have been studying the great cave, but so far we have not found references to demonstrations that here either does a different reading.

POSTERS

POSTER

**21. ANIMAL WITHIN REACH. THE MANUFACTURING OF STONE ANIMAL STATUETTES DURING THE MAGDALENIAN: TECHNIQUES AND MATERIALS.**

Croidieu, Emma - (UMR 7041 ArScAn - Ethnologie Préhistorique) [emma.croidieu@gmail.com](mailto:emma.croidieu@gmail.com)

This poster outlines one of the magdalenian techniques for manufacturing zoomorphic stone figurines. The production of single figurines, by carving hard material such as stone, is documented by the exemple of nearly 300 fragments of in the round sculptures from the cave of Isturitz (Pyrénées-Atlantiques). Emphasis is placed on the technical possibilities induced by the representation of animals in opposition to anthropomorphic figurines.

The integrated technological study of stone animal sculptures, aims to better comprehend the technical processes involved in the making of these statuettes and to understand the complexity and drive behind this production in the Magdalenian socio-economic system. This analysis allows the reconstruction of the *chaîne opératoire* of statuettes, the study of their breaking as well as the development of functional hypotheses. From archetype to abandonment of the statuette or recycling. Appreciating the techniques related to stone carving in the Magdalenian will translate the technical operations and organization of production in terms of behavior, and to characterize the representational systems in place such that the economic, cultural or social development of these objects can be better understood.

POSTER

**22. VISUAL NARRATIVE ASPECTS OF CLIFF PAINTINGS IN FINLAND**

Niskanen, Karen - (University of Oulu) [karen.niskanen@oulu.fi](mailto:karen.niskanen@oulu.fi)

This paper presents visual narrative perspectives in the study of the late Stone Age and early Bronze Age cliff paintings in Finland, and in particular the distribution and interpretation of the various motifs. Common motifs include anthropomorphs, zoomorphs (mainly cervids), and boats. The research methodology is primarily computer applications and the emphasis on spatial information. The results suggest an important connection

between especially the anthropomorphs and the zoomorphs.

Data consist of the cliff paintings of several sites in Eastern Finland, for example, at Astuvansalmi (80 images) and at Suomussalmi (60 images). GIS analysis is used to measure the visual and spatial aspects of the motifs.

Findings at this point in the research indicate is a rather close relationship between the anthropomorphs and zoomorphs, and there is evidence that there are a set of 'rules' governing their depiction, and that visual narrative analysis provides deeper understanding of the visual elements (including the use of panels, movement, and other spatial aspects) and **how** images reflect narratives. In this study, GIS methodology provides a means of studying physical and spatial aspects of these paintings. On the other hand, visual narrative analysis examines the the rules and relationships evident in the data. Combined, the result is a new perspective on the meaningful components in the paintings in Finland.

'Magoula' is the local term given to manmade mounds on the fertile Thessalian plain, Central Greece, which

are generally associated with Neolithic settlements. These mounds or tell sites are originated by long-term and sometime multi-phase accumulation of debris produced by human occupation. Thessaly is well known for the concentration of these prehistoric sites and contains some remarkable examples. In spite of the great deal of archaeological research focused on these sites since the beginning of the 20<sup>th</sup> century, there is still a gap in the understanding of the factors behind the establishment, distribution and development of these early farmer communities. Even if there has been recently a GIS – satellite remote sensing approach dealing with the landscape distribution of these settlements, much less is known regarding the local extent of them.

This paper shows how the implementation of non-destructive and ground based geophysical techniques can provide key information related to the structural layout of tell sites. Emphasis is given to methodological aspects, the advantages and limitations of the different techniques and survey-related problems. In so doing, we present the preliminary results of the ongoing project IGEAN (Innovative Geophysical Approaches for the Study of Early Agricultural Villages of Neolithic Thessaly, implemented under the

The methods include the extensive and high resolution geophysical surveys to map and characterise in detail the extent of the sites and reveal other buried features of interest. Multi-technique geophysical instrumentation able to survey extensive areas are being used and comprise of a multi-sensor magnetometer system, electromagnetic induction instruments, multi-channel and single channel GPR systems as well as soil analyses.

The new evidence provided so far by this non-invasive approach is uncovering a previously unknown layout of prehistoric occupation which may shed light on archaeological questions related to the origin and long-lasting character of these Neolithic settlements in Thessaly.

ORAL

**2. DEVILISH DETAILS: FINE-TUNING SURVEY TECHNIQUES FOR EPHEMERAL PROTOHISTORIC REMAINS**

*De Neef, Wieke - (University of Groningen, Groningen Institute of Archaeology) w.de.neef@rug.nl*

*Van Leusen, Martijn - (University of Groningen, Groningen Institute of Archaeology) p.m.van.leusen@rug.nl*

This paper will present the Rural Life in Protohistoric Italy project, a multidisciplinary research project investigating

small protohistoric surface scatters in a river basin at the southern end of the Apennine mountain range (Calabria, Italy). Our aim is a better understanding of the detection, preservation, and interpretation of small Bronze/Iron Age sites, both on a landscape and a site-specific scale. Our investigations are predominantly methodological and include high-resolution re-surveys of surface remains, multiple geophysical techniques, test pits, and pedological studies. With the fieldwork stage of our project finished, we can present some preliminary results and propose a method for the study of small-scale protohistoric land use in similar Mediterranean landscapes. Ephemeral protohistoric remains are recorded in most Mediterranean landscape archaeology projects, yet they are rarely investigated beyond the mapping stage. In our research area, the Raganello basin in northern Calabria, the majority of the 250 known archaeological sites consists of small (less than 10m diameter) concentrations of poorly preserved handmade pottery, dating to the Bronze and Iron Ages (2000-800 B.C.). These were mapped during more than 15 years of field walking surveys by the Groningen Institute of Archaeology and occur throughout the landscape, from the foothills surrounding an (uninvestigated) coastal plain to the mountainous hinterland. Although this extensive site corpus offers potential for the study of protohistoric land use and rural settlement dynamics, the legacy survey data lacks the detail needed for solid interpretations.

In this paper, we will demonstrate how detailed studies on a small scale increase our understanding of site-specific function and formation, while at the same time being incorporated in a landscape-scale approach. Our targeted site studies integrate datasets from high-resolution re-surveys of known surface scatters, geophysical detection techniques, detailed re-studies of problematic survey material categories, and minimally invasive ground-truthing through corings and test pits. We can extrapolate these local data to a larger scale by sampling representative examples of different site types. This typology is based on landscape zones and properties of material categories. Furthermore, the landscape level of investigations includes large-scale magnetic prospection in different parts of the research area, combined with geomorphological and pedological studies in order to explain post-depositional processes and site preservation. A LiDAR dataset is used for GIS-based analysis of slope processes.

To illustrate our approach we will present a case study of a dense rural settlement pattern in a particular section of the foothill zone, datable to the Final Bronze Age (1100-950 B.C.). Re-surveys of previously investigated

areas, combined with re-studies of finds categories, have already increased the number of FBA scatters by more than a third. Magnetic gradiometry prospection revealed the presence of rectangular building-sized anomalies dispersed throughout the area, whereas test pits have confirmed the temporal and spatial association between FBA surface remains and these rectangular structures. The implications of these results for regional heritage management, which is still very site-oriented, will be raised.

ORAL

### 3. A NEEDLE IN A HAYSTACK“ WETLAND ARCHAEOLOGICAL RESOURCES AND THE QUEST FOR MORE REPRESENTATIVE ARCHAEOLOGICAL RECORD

*Koivisto, Satu - (University of Helsinki)  
satu.m.koivisto@helsinki.fi*

The majority of archaeological sites situating in wetland environments have been found already when being destroyed, through drainage, dredging or peat cutting. The huge scientific value of these sites is a well-known fact (e.g. Keller 1866; Clark 1954; Coles & Lawson 1987; Coles & Coles 1986; Coles & Coles 1996), but the management of the resource of wetland landscapes is problematic, mostly because of the lack of appropriate mapping and prospection techniques. The saturated sediments covering the deeply-buried archaeology decrease the chances of detection and render several of the most common survey and remote-sensing techniques insufficient. The unusual preservation conditions for organic materials within these sites yield valuable tools for archaeological reasoning and interpretation.

The environmental changes through the Holocene have altered landscape and its ecosystems profoundly. Especially in Finland, situating in the northeast shore of the Baltic Sea, the post-glacial isostatic rebound, local topography and climate history have affected dramatically on the initiation of mires (Ojala et al. 2013; Seppä 2002; Korhola 1995). Based on these factors, Finland is one of the most mire-rich countries in Europe. Surprisingly, wetland archaeological research has been quite scarce in Finland, and these extensive peatland and alluvial landscapes have not been properly understood, explored or documented for archaeological purposes. The aim of my presentation is to move forward from the current inactive state of affairs and I strive to further understanding on the prospection and management strategies in wetland environments. The results

of an ongoing project will be introduced, where three electromagnetic techniques were applied in order to test whether a Stone Age wooden fishing structure (c. 3200 BCE) would produce strong enough signal to be detected with the methods used. To validate the geophysical data and further understanding on the hunter-gatherer fishing methods, the work was followed by trial excavations, documentation, radiocarbon dating and palaeoenvironmental evaluation.

More research, experiences and testing with different methodologies are essential in securing the preservation and research potential of the exceptionally informative but vulnerable archaeological resource. Such approaches are also essential in evaluating the adequacy of archaeological sampling strategies and interpretation, as well as in expanding our knowledge of the human past.

ORAL

#### 4. MORPHOMETRIC ANALYSIS TO EXPLORE THE SURROUNDINGS OF THE MELKA KUNTURE PREHISTORIC SITE

*Maerker, Michael - (Heidelberg Academy of Sciences and Humanities) mmaerker@unifi.it*

*Mussi, Margherita - (University of Rome La Sapienza) margherita.mussi@uniroma1.it*

*Melis, Rita - (University of Cagliari) rtmelis@unica.it*

The area of Melka Kunture (central Ethiopia) is one of the most important clusters of Paleolithic sites in Eastern Africa. The archaeological record spans from ca. 1.7 Ma onwards, with a number of stratified occurrences of Oldowan, Acheulean, Middle Stone Age and Late Stone Age industries, together with faunal remains and human fossils. However, the archaeological sites are affected by present day processes. These processes are mainly triggered by the climatic conditions and specific Paleo-landscape forms and features in the nearer surroundings of Melka Kunture and the upper Awash catchment. Hence, the main aims and objectives of this study are the assessment of the present day geomorphological and hydrological processes as well as the detection of Paleo-landscape pattern.

Based on fieldwork, aerial photo interpretation and a detailed DEM analysis we derived a geomorphological map of the Melka Kunture area. Furthermore, we assessed the major landscape forming process using physically based models and a detailed Terrain Analysis. For this study we utilized the SRTM-X with 25m resolution and ALOS/PRISM DEM with 10m resolution.

The study reveals the spatial distribution of present day landscape forming processes. Especially surface runoff and soil erosion processes were analysed in detail. Moreover, we identified evidences for specific Paleo-landscape pattern in the surroundings of Melka Kunture. In part these features can be explained with tectonic activity, on the other hand they indicate specific pattern of the Paleo-drainage network.

The present development of technology and social immediacy does not allow establishing a unique and complete documentation methodology for every kind of archaeological project, which are very variable in their aims and characteristics. Therefore, the way in which documentation technology is applied to archaeological sites, either for research or for didactics, is a complex issue.

In our project, we employ new documentation technologies and procedures for the research of the settlement patterns in the middle Ebro valley during the Late Pre-

history. We are testing and comparing different methodologies in Bronze Age sites (Los Collados, ca. 1900 cal BC) and Early Iron Age (El Morredón and Cabezo Morrudo, ca. 800-500 cal BC). Each of these sites represents diverse chronologies and social organization structures. Therefore, they have different characteristics (preservation, size, structures, surrounding environment...). Moreover, these sites have been subjected to archaeological excavations with very dissimilar aims and methods. With the new documentation technologies we aim to obtain high quality and homogeneous information from these sites and possibly even to detect new features. Also this information must be the basis for the integration of the already known archaeological data from the different sites in order to be able to interpret them correctly and to create high quality and attractive didactic information and products.

One of the latest steps in the documentation of archaeological environments consists of aerial documentation, by means of an UAV device. This system refers to an Unmanned Aerial Vehicle that can be remotely controlled and its working system can be semi-autonomous or fully autonomous, by using a GNSS (Global Navigation Satellite System).

The use of this technology consists of the creation of a photogrammetric measurement platform that allows the digitalization to obtain the 3D model of each one of the selected archaeological sites from aerial images. This platform must operate autonomously by pre-programming the necessary flight paths. After the takeoff, this UAV system is able to follow a programmed flight path over each site according to the GPS coordinates of the pre-programmed route. The incorporation of a high resolution calibrated RGB and NIR camera models results in the obtaining of high graphic resolution models.

Moreover, the results given correspond to the scientific and informative criteria of the project. Thereby, a series of photographs has been obtained, which by means of photogrammetric and topographic techniques has generated a three-dimensional model of each one of the documented environments (achieving the generation of textured triangulated models and high metric and graphic quality orthophotos). The last chapter in the process of aerial documentation has enabled these results to be utilized also to provide an aerial spherical 360° - a view of each and every one of the environments of the archaeological sites in the middle-valley of the Ebro river.

ORAL

## **6. GEOPHYSICS AND PREVENTIVE ARCHAEOLOGY: COMPARISON WITH TRIAL TRENCHING ON THE CSNE PROJECT (FRANCE)** **DEPAEPE, PASCAL - (INRAP) PASCAL.DEPAEPE@INRAP.FR**

*Hulin, Guillaume - (Inrap) guillaume.hulin@inrap.fr*

*Bayard, Didier - (Ministère de la Culture) didier.bayard@culture.gouv.fr*

*Koehler, Alain - (Inrap) alain.koehler@inrap.fr*

*Prilaux, Gilles - (Inrap) gilles.prilaux@inrap.fr*

*Talon, Marc - (Inrap) marc.talon@inrap.fr*

Many cases are published about benefits of remote sensing techniques in preventive or rescue archaeology. Although these non-invasive techniques offer undeniable advantages such as a rapid coverage for a relatively low cost, important limits occurred. A good knowledge of these limitations is important in order to precisely estimate the reliability of remote sensing techniques. The Canal Seine-Nord Europe (CSNE) project offers a good opportunity to compare geophysics and trial trenching on a preventive archaeological project. This project is located north of France and consists in a 106 km long channel on a surface of 2500 ha. This channel will be used to link the fluvial network of the Seine River to the northern Europe network in order to increase fluvial transportation.

In 2009, about 60 ha of magnetic and electric surveys were done by Geocarta for the developer contractor of this project (Voies Navigables de France). After this first step, trial trenches, regularly spaced on the same area, were realised as the French law requires. These trenches covered 10 % of the whole area and were carried out by Inrap (Institut National de Recherches Archéologiques Préventives).

At the end, thirteen archaeological sites were discovered on this zone. Six of them were detected by trial trenching and not by geophysics. Six were detected by trial trenching and were partially visible on geophysics. Only one was discovered just by geophysics. Comparison between the two approaches shows that only ditches were detected by geophysics. In the case of the different sites discovered on this area, the most important archaeological features were protohistoric and roman graves as well as protohistoric dwellings built on post holes. Four excavations were realised and three of them concerned these archaeological features which were totally undetected by geophysics.

This example clearly shows that geophysics can not be used as a unique technique for archaeological evaluation in this context. The main limiting factors are the size of archaeological remains and the soil itself. This latter is constituted by silts which are particularly common in the northern part of France. Using geophysics on this type of soil has for consequence to totally ignore an important part of archaeological features whereas a lot of them offer a high scientific interest. Although trial trenching give a view on a limited area, in most of the cases, this approach remains the most efficient way to characterise an archaeological landscape and take the best decision concerning future excavations.

### 7. A DEVELOPMENTAL SEQUENCE? HERITAGE MANAGEMENT TO RESEARCH TO HERITAGE TOURISM AT A MIDDLE BRONZE AGE SETTLEMENT IN CYPRUS

*Fogel, Aaron S. (Center for Advanced Spatial Technologies, University of Arkansas, USA) aaronfogel@gmail.com*

*M. Lowe, Kelsey (School of Geography, Planning and Environmental, The University of Queensland, Australia) k.lowe4@uq.edu.au*

Recent road works outside the village of Alampra, Cyprus exposed several archaeological features believed to be associated with the Middle Bronze settlement of Alampra-Mouttes (c1900-1650BCE). Previous investigations of Alampra in the late 1970s and early 1980s by Cornell University included localised excavation of the site and wide scale pedestrian survey of the surrounding landscape. Our study focuses on the salvage of the recently disturbed features exposed during the road works and the management implications for continued development. Additionally, geophysical investigations were implemented to assess the existing interpretations of the site by Cornell University. The geophysical results revealed numerous undocumented subsurface features which were later verified through excavation in our second field season. Thus, what was once a simple salvage operation has developed into a robust archaeological research program. This archaeological initiative has raised the level of interest in local heritage by the community due to perceived economic opportunities that relate to heritage tourism resulting in an evolving conservation ethic.

POSTER SESSION

ORAL

### 8. EXPLORING ARCHAEOLOGICAL LANDSCAPES WITH UAV. LIMITS AND FUTURE PROSPECTS

*Stefan, Dan - (Institute of Archaeology Vasile Pârvan Bucharest) danstefan00@gmail.com*

For the general public, archaeology remains difficult to be perceived outside its main investigation method, the archaeological excavation. Nevertheless, new fields of archaeological exploration have emerged once technology evolved; landscape archaeology, geo-archaeology, geophysics, remote sensing are only several domains allowing the detection and characterisation of archaeological structures located in subsoil, based on non-invasive methods. Representing a special branch of archeometry, these investigations, precede, limit or even replace excavation, being more efficient and less expensive. A special place, with an ever more increased weight factor in the interdisciplinary archaeological research, has been given to aerial archaeology, a research direction opened since the beginning of the 20th century.

Last three-five years' advancement in technology and IT has made possible the emergence of a novel type of flying platform, capable to transport optical sensors (photo and video cameras in the visible domain or multispectral), but also geophysical sensors. High efficiency brushless motors, batteries with high discharge energy, developed in the Lithium-Polymer technology, very resistant and light structural materials based on carbon fibre and, last, but not least, the expansion of microcontrollers and their associated programming technique are some of the main ingredients based on which multirotor flying platforms were built; these machines are capable to execute remote controlled or completely autonomous aerial missions and carry loads of up to 3kg for longer periods. The terminology of this quite new domain is in full evolution. The internationally accepted denomination is that of Unmanned Aerial Vehicles (UAVs), but also that of drones.

For archaeology, the UAV technology offers almost all the advantages of traditional aerial systems (either satellite or aircraft with pilot), at a fraction of their costs, with a remarkably increased flexibility. The capacity to restage, for as many times as necessary, an aerial mission, during the same day or in various seasons, taking advantage of different light conditions, various stages of vegetal growth, presence or absence of melting snow or humidity in soil

(in order to detect contrasts of thermic gradient caused by buried archaeological vestiges), from various altitudes and with different shooting angles, in visible or near infrared spectrum or with magnetic sensors, recommend UAVS as highly adjusted to archaeological applications. Recorded data come directly from sensors and may be processed differentially, with the purpose of detecting archaeological structures or for the creation of 3D digital models of the terrain.

The author will present technical information regarding building UAVs for various archaeological applications, discussing the limits of the method and its further developments, using results from various personal archaeological projects in Romania.c

---

#### POSTER

### 9. GEOPHYSICAL SURVEY ON ?EL MAZO DE LA CASTAÑERA? (CANTABRIA, SPAIN): LOOKING FOR OPEN-AIR DOMESTIC REMAINS

*Carmona Ballester, Eduardo - (Universidad de Burgos) edu-carmonaball@gmail.com*

*Vega maeso, Cristina - (Universidad de Cantabria) cvega-maeso@gmail.com*

*López Jiménez, Oscar - (GIPSIA SL) oscarlj@gipsia.com*

*Martínez calvo, Victoria - (GIPSIA SL) gipsia.sl@gmail.com*

The work is focused on a geophysical survey developed on *El Mazo de la Castañera* (Cantabria, Spain) where there are located 7 caves with archaeological remains from Paleolithic to Early Middle Age. On one of them, *El Abrigo de la Castañera*, it has been conducted a research project directed by one of us (CVM). In fact, this site is the only one that provided a well contextualized data which have proved an intensive occupation during Chalcolithic and Bronze Age. The mentioned research project aimed to explore the potential archaeological record located on the nearby of the *Abrigo de la Castañera*. Especially data about open-air habitat were necessary because there is a notorious absence of this kind of sites on Cantabrian region. The lack of habitats is linked to the low visibility of archaeological remains related to peasant communities from recent Prehistory (post holes, pits, thin deposits, etc.). These kind of remains are difficult to detect with traditional survey because the environment has permanent vegetation coverage. In consequence, a different method should be employed.

In order to achieve this goal a geophysical survey was

requested to GIPSIA SL. To get data the procedure employed was an inductive electromagnetic survey. We worked on a 9 ha area that it was divided on 6 different zones (M1 to 6). The data and its interpretation are presented by georeferenced surface maps. These maps provided images of some anomalies after we have analyzed and processed the data. The aim of this method is to distinguish evidences of abnormal accumulations integrated into non-anthropogenic sedimentary soils. There are two types of maps where results are expressed: Electric conductivity and magnetic susceptibility.

The results show several potential evidences. More precisely, there are traces of anomalies which have some kind of geometrical design or sedimentary filling with archaeological potential. The detection of non-angular structures, with low intensity, is pretty difficult. Therefore, we had to present the results with high contrast in order to observe these traces. The results were different between zones. The most interesting were located in M1, M4 and M6. They show circular anomalies, with several sizes, that are grouped in some specific areas. It was also documented huge sedimentary packages with a high archaeological potential in several cave mouths.

The anomalies detected suggest that it's possible to find archaeological structures related to open-air domestic zones in the future. The research has documented several "hot spots" where we will focus the next phase. This is an important point: the geophysical survey has allowed to detect non-visible evidences to traditional methods and to take decisions to design the next research strategies.

Ojo Guareña is one of the largest cave complex in Spain, consisting of a total of 110 km of 14 interconnected cavities, which has an impressive record of Prehistoric activities from the Middle Paleolithic until the Iron Age. The diversity and variety of the sites include, among others, living areas in cave vestibules, rock art, human bones, grave goods, archaeological objects inside several passages and more than 600 prehistoric human footprints (Ortega et al., 2013). In 1970 this complex was listed as Spanish Cultural Heritage and in 1996 as Castilla y León Natural Heritage.

Exploration Tomography was carried out in Ojo Guareña karstic Complex in order to better identify the morphology of caves entrances and passages containing archaeological remains. This geophysical survey was sought to study Kaite and Palomera Caves, both of which have sheltered human occupation at least since Upper Palaeolithic according to the archaeological prospection data (Ortega and Martín, 1986). Fieldwork consisted in the elaboration of Electrical Resistivity Tomography (ERT) profiles of different lengths and arrays. The data provided by 4 ERT profiles have detected and characterized the cave entrance sedimentary thickness and the so far unknown endokarstic morphologies filled with terrigenous sediments. This work helps us to better understanding the entrances of this large karstic system in relation with the use of caves, and to estimate the presence of new infilling archaeo-sedimentary records.

POSTER

## 10. USING RADAR- AND MULTISPECTRAL REMOTE SENSING TO DELINEATE PALEO-LAKE-LEVELS IN THE LAKE MANYARA BASIN BACHOFER, FELIX - (UNIVERSITY OF TUEBINGEN) FELIX.BACHOFER@UNI-TUEBINGEN.DE

Quénéhervé, Geraldine - (University of Tuebingen) geraldine.queneherve@uni-tuebingen.de

Märker, Michael - (Heidelberg Academy of Sciences and Humanities) michael.maerker@geographie.uni-tuebingen.de

Hochschild, Volker - (University of Tuebingen) volker.hochschild@uni-tuebingen.de

The surroundings of Lake Manyara in northern Tanzania are the focus of several paleo-archeological investigations, since the location is close to Olduvai Gorge, where paleo-anthropological findings can be traced back to *homo habilis*. In the catchment of Lake Manyara two hominin-bearing sites (0.63 and 0.78 Ma), lots of vertebrate fossils and handaxes from different periods were found (Frost et al., Journal of Anthropological Sciences, vol. 90, 2012). Understanding the development and extent of the lake is crucial for understanding the regional paleo-environmental settings of the Quaternary. The oldest lacustrine evidence are the so called lower Manyara Beds (about 1.03 to 0.633 Ma) which are exposed close to the town of Makuyuni (Schwartz et al., Quaternary Geochronology, vol. 7, 2011) and thereby in a distance of more than 27 km to today's shoreline. Casanova and Hillaire-Marcel (Quaternary Research, vol. 38, 1992) documented more recent evidence for paleo-lake highstands. They applied <sup>14</sup>C and Th/U series dating on stromatolites which can be found at paleo-shorelines in a shorter distance to today's Lake Manyara. They identified ages up to 90,000 BP and one uncertain age of 140,000 BP.

To delineate the sediments of the Pleistocene Manyara Beds we used multispectral ASTER scenes (23.08.2006; VNIR & SWIR) to calculate mineral indices with relative band depth techniques. The results were validated with WorldView-2 high resolution satellite data and field reference. For the delineation of the paleo-shorelines we applied radar remote sensing, as well as terrain analysis methods to contribute to a better understanding of the development of the lake. We used the Next ESA SAR Toolbox (NEST) for the processing six TerraSAR-X Stripmap scenes (Level 1B; Polarization: HH and HH/VV). Each scene was terrain corrected and backscatter intensity (sigma nought) was processed. While the paleo-shorelines are hardly noticeable in optical remote sensing im-

ages, their morphological structure is highlighted by an intense backscatter signal. For the successful extraction of the linear paleo-shorelines and terraces a canny filter was implemented in a Python-script. For the resulting lines the corresponding elevations were extracted from a SRTM-X digital elevation model (30 m resolution) data covering nearly the whole Manyara Basin.

The Lower Manyara Beds were successfully delineated with ASTER multispectral data. Several distinct paleo-shorelines were detected with height levels between 10 m and 80 m above today's lake level of Lake Manyara. The results coincide to a high degree with field reference data collected during four field campaigns.

With multispectral band rationing techniques it was possible to extract the maximum visible extent of the Lower Manyara Beds and therewith a preliminary maximum lake level which is located more than 27 km east of today's shoreline. With TerraSAR-X images paleo-shorelines were successfully detected, which could not be delineated in detail by optical remote sensing techniques. The most elevated paleo-shoreline is with an elevation of 80 m above today's lake level on the same elevation as the lowest possible outlet of the endorheic Lake Manyara. Therefore an overflow into the neighboring Lake Engaruka and Natron / Magadi basins seems likely.

---

## POSTER

### **12. THE POTENTIAL OF MAGNETOMETRY TO SURVEY IBERIAN SETTLEMENTS: REVEALING THE HIDDEN URBANISM OF "LOS VILARES" (CAUDETE DE LAS FUENTES, VALENCIA)**

*Cuenca-Garcia, Carmen – (1 Laboratory of Geophysical - Satellite Remote Sensing and Archaeoenvironment (GeoSat ReSeArch), Institute for Mediterranean Studies, Foundation for research and Technology, Hellas (FORTH)) carmen@ims.forth.gr*

*Sarris, Apostolos - (1 Laboratory of Geophysical - Satellite Remote Sensing and Archaeoenvironment (GeoSat ReSeArch), Institute for Mediterranean Studies, Foundation for research and Technology, Hellas (FORTH)) asaris@ret.forthnet.gr*

*Consuelo Mata Parreño (Department of Archaeology, University of Valencia) consuelo.mata@uv.es*

This poster shows the results of a magnetometer survey carried out at 'Los Villares', an Iberian site located in a hill-fort near the municipality of 'Caudete de las Fuentes', in the Utiel-Requena district (Valencia, Spain). The aim of

the survey was to map the extent of buried structures in the area using non-invasive methods. The project is a collaboration between GeoSat Research (Greece) and the department of Archaeology of the University of Valencia (Spain).

The site has been identified as the ancient city of Kelin, where its extensive chronology expands from the beginning of the Iron Age (about 680 B.C.) to iberoroman times (75 B.C.). Kelin became the capital of a large Iberian territory and developed its own coinage (II century B.C.). Some studies have suggested that the site was destroyed as a result of a corrective measure applied by Rome to those Iberian cities that supported the defeated Sertorian side during the civil war. The twenty three excavation campaigns carried out by the University of Valencia between 1956 and 2002 have focused on two main areas at the site containing a number of houses, covering a total of approximately 1000 m<sup>2</sup>. The excavations retrieved a great deal of findings relating to the economy of the community living at Kelin as well as the recording of several phases of the internal structure and architecture of the excavated houses.

A magnetometer survey was undertaken by a team of three people over two days in December 2013, using a single fluxgate gradiometer Bartington 601. Ten survey grids of 20x20m were recorded covering approximately 4.800 m<sup>2</sup>.

The survey revealed a series of both strong magnetic responses and linear negative magnetic anomalies which seem to indicate the location of square and rectangular houses. These structures cover the whole area surveyed and seem to be distributed along a series of perpendicular and longitudinal negative or weakly positive magnetic responses which may show the distribution of roads or perimetral walls. The intensity of the strong magnetic anomalies may be associated with substantial burnt features such as mud-brick walls or other structural materials of the houses. This interpretation would seem to agree with the possible final destruction of the site. Other linear negative magnetic anomalies may be produced by the mud-brick walls that were not affected by the fire or the contrast produced by stone foundations of the houses.

The approach used in this study has proved the great potential of magnetometer survey to map the urban layout of Iberian sites with a final destruction phase in a non-invasive and cost-effective manner. Two days' survey and a small team were enough to get a complete view of the

buried structures at the site and therefore, an approximation of how Kelin looked like before its destruction. Further work intends to implement other geophysical techniques at the site to complement the magnetic results in the non-excavated area. For example, ground-penetrating radar may provide further details on some of the internal structures or information about the depth of burial of the structures.

*Salazar, Diego - (Departamento de Antropología, Universidad de Chile) maaconsultores@gmail.com*

*Troncoso, Andrés - (Departamento de Antropología, Universidad de Chile) atroncoso@gmail.com*

The poster will summarize the methodological process for the detailed documentation of a vast complex of late Prehispanic agrarian elements (fields, irrigation canals) in the Atacama Desert (northern Chile). As opposed to the usual conditions for prospection in temperate regions, where the visibility of archaeological features is usually poor and confusing, here the extreme dryness of the landscape allowed an extraordinary preservation and visibility of fields, canals and other constructions.

The approach was initially based on a combination of visual interpretation of high resolution satellite images (GeoEye 1) and fieldwork for mapping the layout and shape of most of the elements (canals, groups of fields, settlement areas). For the accurate documentation of

smaller or densely built areas, an SFM-based photogrammetry approach was carried out, based on the use of a low cost UAV (Dji Phantom) and a consumer-grade compact digital camera for the acquisition of low altitude aerial images that allowed the generation of 3D models and orthoimages of some areas. Finally, ground based photogrammetry was also used to capture and represent some elements in greater detail.

The main result has been the construction of a highly detailed and accurate map of a complex group of archaeological structures, which has been used since for the analysis and interpretation of the area, and also for the design of new fieldwork seasons.

POSTER

**14. USING AIRBORNE LASER SCANNING AND HISTORICAL AERIAL PHOTOS TO IDENTIFY MODERN AGE FORTIFICATIONS IN THE MINHO VALLEY, NORTHWEST IBERIA**

*Blanco-Rotea, Rebeca - (Technological Research Institute, Santiago de Compostela University, Edificio Monte da Condesa, USC Campus Sur, 15782, Santiago de Compostela, Spain) rebeca.blanco.rotea@gmail.com*

*Fonte, João - (Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), San Roque 2, 15704 Santiago de Compostela, Spain) joaofonte@gmail.com*

*Güimil-Fariña, Alejandro - (Independent researcher) alejandro.guimil.farina@gmail.com*

*Mañana-Borrazás, Patricia - (Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), San Roque 2, 15704 Santiago de Compostela, Spain) patricia.manana-borrazas@incipit.csic.es*

In the Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), we have developed a transdisciplinary research project to study the Modern Age (17<sup>th</sup> century) fortified landscapes in the Galician-Portuguese border. In recent years, different techniques based on geospatial technologies for landscape analysis have allowed us, among other things, to identify and visualize some of these fortifications, to analyse their conservation status and to understand their relationship with other fortified elements. Among these techniques, we include the photogrammetric restitution of historical aerial photos and airborne laser scanning data.

The research of this fortified landscape was based on documentary and bibliographic sources, archaeologi-

cal prospection, architectural survey, photo-interpretation, the formal analysis of archaeological space, where we include the movement and perception analysis, the stratigraphic analysis or the use of a number of representation systems.

Many of these fortifications from the Minho valley present significant conservation problems, since in some cases they are built on earth, wholly or partially destroyed after the war or hidden under dense vegetation. Some of these fortified structures were identified in the documentary sources, but are not visible nowadays or in the field or even on recent aerial photos. In these cases, the archaeological work has been done with the photo-interpretation of historical aerial photos from the 1950s and the use of airborne laser scanning data.

This poster will summarize the workflow and results of the application of these geospatial technologies to the Galician-Portuguese border fortified landscape. For our purposes, the application of airborne laser scanning data has allowed us to identify the archaeological features that were hidden by vegetation. We were then able to document the exact location of some fortifications, to check their condition and, above all, to make them visible, enhancing the visualization of certain structures. Similarly, the use of historical aerial photos, has allowed us to identify some fortifications that are now disappeared, or to check the deterioration that many have suffered from the 1950s to the present.

The landscape is a complex construction in which different meanings, different human actions and various historical layers intersect on a natural space. For its identification, documentation and assessment is necessary to use multidisciplinary approaches and to apply different tools. In this case, conventional archaeological work has been combined with other strategies that have improved our understanding of the Galician-Portuguese border fortified landscape, recovering the memory of some of the fortifications that form part of it and that were apparently lost.

## 2. LA DESTRUCCIÓN DEL PAISAJE EN MURUJUGA (AUSTRALIA OCCIDENTAL)

*González Zarandona, José Antonio - (Universidad de Melbourne) jose.gonzalez@unimelb.edu.au*

Murujuga (Australia Occidental) está considerado como el sitio arqueológico más grande del mundo. Murujuga forma parte del archipiélago Dampier y ha sido objeto de estudio de algunos de los más ilustres arqueólogos en Australia e incluso de Francia. Según algunos de estos expertos, el área contiene más de un millón de grabados. No obstante, desde la década de los años sesenta, este paisaje cultural se ha visto afectado por el establecimiento de diversas compañías, en su mayoría mineras, que han transformado el paisaje y destruido algunos de los grabados únicos que se encuentran al aire libre. Desde entonces la perspectiva común sobre Murujuga ha sido desmantelada por los diversos grupos que reclaman propiedad sobre el área.

Desde hace una década, diversas gestiones del patrimonio se han visto introducidas para poder minimizar el impacto que las compañías le han asestado al paisaje. Algunas de estas gestiones han involucrado a los habitantes de la región, mientras que la gran mayoría de las iniciativas y exploraciones arqueológicas han denigrado y desestimado el valor social que la comunidad indígena tiene sobre el lugar. Los métodos y teorías que se han desarrollado no han sido suficientes para poder explicar y prevenir el daño que las compañías y el neocolonialismo le han inflingido a Murujuga. Por lo tanto, es necesario reseñar los métodos hasta ahora implementados para poder dislumbrar una solución a este conflicto.

Murujuga es al mismo tiempo un sitio arqueológico, un lugar sagrado, un parque nacional y la base de media docena de compañías. En conjunto representa diversos significados a nivel social, cultural y económico. Hasta el momento no existe un solo plan de gestión cultural que se adecúe a las necesidades de todos los involucrados: industria, arqueólogos, población indígena y turismo. No obstante, los estudios hasta ahora realizados han ar-

rojado diversos resultados, los cuales apuntan a la importancia de este sitio arqueológico como el más grande del mundo. Así mismo, la variedad de estilos y técnicas de grabado ponen de manifiesto el valor patrimonial de Murujuga.

Murujuga sólo podrá ser gestionado de manera favorable si se aplican los principios que prevalecen en la Carta de Burra (1999). No obstante, los cuatro valores que definen a un sitio patrimonial (estético, científico, histórico y social) han sido desplazados en favor del valor económico que el área representa para el puñado de compañías que están establecidas en Murujuga. El futuro para este sitio arqueológico sigue siendo incierto y hasta el momento sólo unas cuantas personas están trabajando para que Murujuga sea reconocida a nivel mundial, como uno de los sitios Patrimonio de la Humanidad.

## 3. ATAPUERCA, UN SISTEMA DE GESTIÓN EN RED

*Vicente Domingo, Javier - (ExDirector Gerente del Sistema Atapuerca) javiervicentedomingo@gmail.com*

Los descubrimientos de la Sierra de Atapuerca y el afán divulgador del Equipo Investigador han generado un flujo visitantes.

El modelo de gestión es un modelo en red, cuyo epicentro son los Yacimientos Patrimonio Mundial, complementado en un radio de quince kilómetros por una red de centros.

Esta red se sustenta en la conjunción de la actividad pública y la iniciativa privada: la primera representada por la Junta de Castilla y León, y la segunda por el Equipo Investigador

El Sitio arqueológico:

La Sierra de Atapuerca contiene vestigios fósiles de los primeros seres humanos que se asentaron en Europa y constituye una fuente excepcional de datos sobre el modo de vida de nuestros antepasados. Esta descripción inspira los argumentos del programa de visitantes:

- Agua y cuevas: el karst de Atapuerca
- Hábitat y paisaje de la Sierra
- El azar de los hallazgos
- El proyecto científico
- Atapuerca, enciclopedia de la evolución... 1,3 millones de años de ocupación

Desarrollo didáctico:

- Los argumentos se actualizan con nuevos descubrimientos y como los guías han excavado se expresan

como protagonistas de los hallazgos

- Las visitas son gestionadas por la Fundación Atapuerca

Infraestructuras públicas:

- La Administración regional garantiza la protección del Sitio mediante instalaciones de recepción y vigilancia.
- Dicha Administración y los Municipios más próximos a la Sierra facilitan el flujo de visitantes mediante dos Centros de Recepción y un Parque Arqueológico.
- En la ciudad de Burgos se localizan dos grandes infraestructuras: el CENIEH y el MEH.

Infraestructuras privadas:

- La Fundación Atapuerca tiene su sede operativa en Ibeas de Juarros.

Marco regulador:

Atapuerca dispone de marco normativo propio:

- Figuras de protección patrimonial: los Yacimientos son BIC desde 1991 y su entorno es Espacio Cultural desde 2007.
- La figura de gestión integrada de los centros en red: el Sistema Atapuerca creado en 2009.

El reto de la gestión equilibrada: problemas y soluciones. La gestión de visitas tiene en cuenta las directrices de UNESCO (mantener un equilibrio adecuado entre la conservación, la sostenibilidad y el desarrollo social), pero el equilibrio no es aún perfecto:

- La conservación: No plantea especiales problemas, porque el acceso a las excavaciones está restringido a los investigadores. Las restricciones a la visita son de dos tipos:
  1. Número máximo/día (2.000 visitantes) en determinadas fechas.
  2. La climatología.
- La sostenibilidad: el modelo de centros en red facilita este objetivo por el efecto 'bombeo' de visitantes entre Yacimientos-Parque Arqueológico y el MEH. Los ingresos cubren el 40% de costes.
- El elevado índice de autofinanciación no revierte al sistema.
- El desarrollo: este factor persigue que los bienes del Patrimonio Mundial puedan generar actividades que contribuyan al desarrollo de las comunidades del entorno.
- A este respecto, en el territorio se opina que la gestión de visitantes aporta muy poco al desarrollo económico local.

Conclusión

- La gestión no se circunscribe al Sitio sino que se extiende a todos los centros del sistema, lo que plantea

problemas de coordinación.

- Es positivo que la Administración regional delegue la gestión de visitas en la Fundación Atapuerca, pero lo hace bajo unas pautas rígidas de funcionamiento.
- Para la captación de visitantes es esencial la existencia de un Equipo Investigador que permita mostrar Atapuerca como un campo de trabajo de excelencia científica.
- El mapa de infraestructuras está completado.

#### 5. ARCHAEOLOGICAL RESEARCH AND LAND - ART FOR PUBLIC ARCHAEOLOGY IN A FINAL BRONZE AGE HILLTOP SETTLEMENT OF CASTELO VELHO DA ZIMBREIRA (MAÇÃO-PORTUGAL)

*Delfino, Davide - (Instituto Terra e Memória (ITM Mação); Câmara Municipal de Abrantes; Grupo do Quaternário e Pré-história do Centro de Geociências da UC, CGeo) davdelfino@gmail.com*

*Gheorghiu, Dragos - (Doctoral School, National University of Arts (Bucharest) Instituto Terra e Memória, I.T.M.-Mação) gheorghiu\_dragos@yahoo.com*

Since 2010, the Land and Memory Institute and Museum of Prehistoric Art in Mação has developed a research about the occupation of the territory and the inhabited dynamics in the Final Bronze Age, particularly focused on Castelo Velho da Zimbreira and its relations with the landscape. A prior collaboration in 2009 with the National University of Arts in Bucharest, which resulted in a land art designed to simulate the two wall lines of the settlement, was continued in 2013 within the cooperation in the TimeMaps project ([www.timemaps.net](http://www.timemaps.net)).

The settlement consists of two terracing walls set on a hill with a 360° panorama over a vast territory. The settlement belonged to a series of synchronical hilltop settlements, all set at strategic points along a quartz belt that defined a specific territory. The purpose of the art intervention was 1) to see the visual impact of the walls from the territory, 2) to delimit the area of the settlement, 3) to transmit the in-

formation to the public with the help of the Land Art. This Public Archaeology action to highlight the archaeological structures with a temporary and non invasive performance was followed by the stimulation of the local community which become aware of their heritage. For example, an experiment with fire carried during the nighttime, to observe the intervisibility between the various settlements, offered a new a dimension of the sites and attracted various audience (120 people in one night); old local people are also protagonist, telling various legend site-related. Another strategy will be to bring to life the ancient structures by creating a series of 3D reconstructions as Android applications, so that tourists could view them during visit at the site or when visiting TimeMaps, the European platform.

The involvement of a various public is possible in a direct way (as Master's and doctoral students, the local community members of different age ranges, and local officials), and in an indirect way (as tourists and passing motorists from the nearby highway who have at least noticed the Land Art on the settlement and posted it on various blogs). This as shown that even in areas of apparently no tourist attraction it is possible to keep alive the memory and the function of archaeological monuments by combining the results of archaeological research with art.

Protecting an archaeological monument is not just preventing it from being destroyed. It also means preventing it from being forgotten. The experience of Land Art in 2009 and current TimeMaps experiments show that is possible to bring to life a Bronze Age settlement by to the eyes or the local community, by combining science and art

---

ORAL

**6. CONSERVATION, PRESERVATION AND SITE MANAGEMENT AT THE NEANDERTHAL SITES AT VELDWEZELT-HEZERWATER, BELGIUM**

*Bringmans, Patrick M.M.A. - (The 'Veldwezelt-Hezerwater' Neanderthal Research Centre - Belgium)*  
*Patrick.Bringmans@hotmail.com*  
*Vermeersch, Pierre M. (Catholic University Leuven - Belgium)*

The Hezerwater valley, in the brickyard quarry at Veldwezelt-Hezerwater (Lanaken, Province of Limburg, Belgium), had been an advantageous location for Neanderthal settlement throughout the late Middle and Late Pleistocene. In order to deal with the expected archaeological finds in a structured way, the 'Veldwezelt-Hezerwater Middle Palaeolithic Project' was started by the Laboratory of Prehistory – Catholic University Leuven. During the 1995-2003 period, several stratigraphically separated Ne-

anderthal sites were excavated. Each year an 'open-day' was organized for the general public. In total, more than 10,000 people paid a visit to the Veldwezelt-Hezerwater excavations. The massive response of the general public started the process of making the archaeological sites accessible on a permanent base.

Once the decision had been made to go beyond conserving the Veldwezelt-Hezerwater sites in situ, the choice had to be made as to the nature and extent of the enterprise undertaken. Any disturbance of or alteration to the site would compromise its integrity and would inevitably destroy contextual information. An adequate infrastructure would have to be developed. Properly planned modern walkways could lessen the deleterious effects of increased foot traffic through the site, avoiding climbing, sitting, or standing on remains. Important milestones in the development of the heritage site were: (1) the successful excavations, (2) the opening of 'The Neanderthal-Road' on September 10, 2006, (3) the fact that the site became a listed archaeological monument on December 7, 2007, (4) the presentation of the heritage plan in 2009, (5) the decision by the Flemish Government to grant a major subsidy for the development of the site on August 28, 2013, (6) the start of the project in February 2014 and finally (7) the opening of the heritage site in the summer of 2014.

As the process of discovery is one of the most important aspects of on-site experiences, the visitors of Veldwezelt-Hezerwater do not get an instant overview of the site when they enter. Instead they gradually discover the site by following different routes. The path itself has a continuous clear width and a smooth surface, which has no steep gradients. The insertion of information panels and railings was carefully designed. Given the necessity of bridging great differences in altitude the visitor gradually goes 'back in time'. The story that is told, is that of the Neanderthals. In addition to the main storyline, there are also other themes, including the development of the landscape, climate change and aspects of palaeoanthropology. The preservation of the original quarry walls and surfaces, is realized by means of roof constructions, which are integrated into the surrounding landscape. However, these structures, which give a specific character and identity to the Veldwezelt-Hezerwater site, are visible from the surrounding landscape, and take a 'landmark-function'.

The massive response of the general public to the archaeological excavations at Veldwezelt-Hezerwater resulted in the creation of a heritage site. The preservation of the original quarry walls and surfaces, was realized by

means of roof constructions, which were integrated into the surrounding landscape.

ORAL

## 7. ARCHAEOLOGY BETWEEN RIVERS AND INTEGRATED MANAGEMENT OF TERRITORY - EXTREME SOUTH OF SANTA CATARINA, BRAZIL

*Bitencourt Campos, Juliano - (UNESCO) jbi@unesco.net*

*Zocche, Jairo José - (UNESCO) jjz@unesco.net*

*Pereira Santos, Marcos César - (UNESCO)*

*marcoscesar@unesco.net*

The use and management of natural resources by pre-historic human groups resulted in a range of landscape and material remains that partly reveal their daily life.

This presentation aims to show the results of the studies fulfilled in the research project "Archaeology between rivers: From the Urussanga to the Mampituba", developed by the group Pesquisa Arqueologia e Gestão Integrada do Território of the University of the Extreme South of Santa Catarina. We intend to understand how prehistoric and historic human groups, living and permeating in the region, have interacted with the settled spaces and its social consequences.

The investigated area covers a polygon of 4800 km<sup>2</sup> (80 x 60 km), located in southern Santa Catarina between the mouths of the rivers Urussanga and Mampituba and between the Atlantic Ocean and the mountain formations (Aparados da Serra).

ORAL

## 8. COMMUNICATION STRATEGIES OBSERVED IN PORTUGUESE PRESS TO SAVE ROCK ART OF VILA NOVA DE FOZ CÔA (PORTUGAL)

*Bellmunt, Cinta - (IPHES - Institut Català de Paleoecologia Humana i Evolució Social, Tarragona, Spain) cbellmunt@iphes.cat*

Several unusual factors made possible the conservation of Foz Côa's rock art engraved, currently Human Heritage. In this valley, in 1994, it was building both a hydro-electric power station and a reservoir that could have submerged the archaeological heritage: the ensemble of rock art engraved most important in the world.

Luckily, the capacity of a group of researchers, the archaeologists, managed to mobilize different powers and

to build different international alliances. They strengthened their power of influence against politics.

Furthermore, a great social dynamic occurred. The school of Vila Nova of Foz Côa started a protest movement never seen before in Portugal. The Prehistory became the favourite subject of the children. A lot of activities were organized to save the engravings and they received support from everywhere. The Portuguese society, in general, was mobilized also. The case became a national problem and the head of the state went to Foz Côa. Mário Soares understood the value of the engravings and short time later the constructions were stopped definitely. It was the only time in the history that a reservoir was stopped, even the construction was in progress, to make finally an archaeological park. The action of the Portuguese government was very rare.

The media impact was very important. The journalists were very involved. From the beginning they paid attention to the issue. The archaeologists turned into their principal source of information because they didn't hide the information, contrary to the electricity company, who hidden it. The exceptional value of the engravings was the argument most used and the recognition of international organizations corroborated it.

The media has a function very important but it wasn't the unique reason. In this work we review the different factors involved and the strategies of communication used to save the engravings.

The materials analysed are the contents of 150 news published in the Portuguese press between November 1994 and December 1995, the later was the year of the conflict. This has been complemented with personal interviews to protagonists and experts.

The objective it was to observe in the Portuguese press the strategies of communication utilized to stop the construction: protagonists, arguments, point of view in the news, etc.

POSTER SESSION

POSTER

**9. QUALITY MANAGEMENT OF CULTURAL HERITAGE: PROBLEMS AND GOOD PRACTICES ARE REPLICAS UNDERESTIMATED OR OVER-RATED? THE EXPERIENCE THROUGH ANALYSES OF MAGDALENIAN PORTABLE ART.**

*Avila Filho, Roberto - (Universitat Rovira i Virgili / Muséum national d'histoire naturelle) robertt.avila@gmail.com*

The nineteenth century conceded to the museums much of the assignments we delegate to them today, organizing in the main European capitals collections of old cabinets and new acquisitions, coming from overseas colonies, the Mediterranean coast and the Near East. In which was considered the "golden" century of museums, these institutions were settled as places of scientific interest. The museums of the nineteenth century were recognized as centers of study and taught, getting tagged, not only by numerous and successive achievements regarding to the identification, classification and cataloging of items in their holdings, but also as institutions concerned with its conservation, safety and best presentation to the great public. A tradition got established and still remains; but to what extent?

The present communication arises as parentheses of a master thesis that intend to link two disciplines that should never be kept separate: archeology and museology. From the analysis of Magdalenian portable art collections of the Dordogne, France, some issues have emerged. The profile of these collections presents, in most cases, "moulages"; namely, replicas of pieces of prehistoric art often considered unique. Portable art artifacts require special care of scientific and museological character, according to its most peculiar condition: the pieces bear within themselves the symbolism and significance that the prehistoric man gave to their own objects and world. For obvious reasons of mechanical nature the original artefacts cannot be in several places at the same time and for purposes of conservatory nature, wherever as possible, the transport of the original pieces should be avoided, reasons why the manufacture of replicas is used since the dawn of archeology. Over recent years experts have appropriated computer graphic technology coming from other disciplines to record artifacts with the utmost precision and with the least budget as possible; however, not every ancient methods should be set aside, since the digitalization does not replace the playful action. Therefore, apart from being

part of the science history, casts can be considered one of the recording ways in prehistoric art, issue widely discussed until nowadays, mainly in light of technological advancements.

Thus, through this particular experience of the author and from the comparison between a sample of original pieces and their equivalent copies, this communication aims to expose the examination of the scientific value of the exhaustive analysis of replicas and the educational value from the exhibition of such casts to the public. Following the same thought, many museological/archaeological reflexions emerged on the behalf of numerous problems diagnosticated during the analyses.

The conclusions came, materially, as the enlightening for two questions: could experts use replicas in scientific research itself? Can the casts be used reliably in disclosing knowledge to the public?

POSTER

**THE DOCUMENTATION OF THE PICTOGRAMS IN THE MINE OF KRZEMIONKI OPATOWSKIE.**

*Grzelczyk, Maciej - (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw (master's student)*

*maciej\_100@interia.eu*

*Jakubczak, Michał - (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw (PhD student)*

*michal.jakubczak87@gmail.com*

*Arczynski, Tomasz - (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw (graduate)*

*arczynski.t@gmail.com*

*Jedynak, Artur - (The Archaeological Museum in Krzemionki (curator) artur.archo@krzemionki.info*

*Moko, Klaudia (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw (student)*

The flint mine of Krzemionki Opatowskie is one of the greatest prehistoric mining complex in Europe and one of the most known Polish archeological site. We would like to emphasize the aspect of this site, which until now seemed to be neglected in the scientific discourse, which are the pictograms performed with the use of charcoal.

The poster will be a presentation of the outcome of the project's first phase, which is concerned on charcoal pictograms of the mines walls. Some of them, called "objaniska", are the remains of lighting up torches, others were created with meaningfully. Our main concern is not the interpretation of those images, but the will to display problems which concern both documentation and con-

servation, along with the prospects and threats. A significant amount of the pictograms was destroyed during the construction of the touristic route, and most likely during the excavation of the shafts and corridors.

Currently it was possible for us to document over 60 pictograms. The second phase of the project, which started at the beginning of this year, will center upon creating new, precise plans of the undergrounds, because the only existing plans derive from the 60', and do not include almost half of excavated area of mine. Now we come up against new difficulties, which is the choice of adequate measuring techniques. In spite of using total station, creating plans is still difficult and time consuming procedure, because of the hard conditions occurring in the mine. At the same time high humidity, dusting and low corridors height, render impossible the use of 3d scanning. Our research is also an attempt to find the most preferable way, and a compromise between speed and precision in the documentation.

We hope, that accurate planigraphy and analysis of pictograms in the mine of Krzemionki Opatowskie, will allow a broader interpretation and deriving of the meaning.

# A14 The water as generator of networks

Commission on Theory and method in Landscape archaeology-Archeogeography

## 1. L'IMPORTANCE DES COURS D'EAU DANS L'ORIENTATION, LES DÉPLACEMENTS ET LES COLONISATIONS DES GROUPES DE CHASSEURS CUEILLEURS DU PALÉOLITHIQUE SUPÉRIEUR EUROPÉEN.

*Djindjian, François - (Université de Paris 1 Panthéon Sorbonne & CNRS UMR7041 Arscan) francois.djindjian@wanadoo.fr*

En Europe, les territoires géographiques sont cloisonnés par les massifs montagneux à travers lesquels les cours d'eau ouvrent des corridors ou abaissent des cols qui offrent des itinéraires de circulation aux groupes de chasseurs cueilleurs. Ces itinéraires sont en nombre limité car imposés par la géographie des bassins fluviaux.

Plusieurs exemples caractéristiques de voies de passage suivant des cours d'eau sont décrits ici:

- le passage de la haute-vallée du Danube au Rhin puis au Doubs et à la Saône par la porte de Bourgogne,
- le passage de la Saône à la Loire par la Dheune, la Bourbince et l'étang de Longpendu,
- le passage du bassin de la Saône au bassin de la Seine par la vallée de l'Ouche et l'Armançon,
- la colonisation du massif central par le Nord en remontant la Loire et l'Allier
- la circulation le long de la Saône puis du Rhône jusqu'à la mer et inversement en fonction des variations climatiques qui ferment le passage au niveau de l'extension maximale du glacier alpin du Rhône pendant le dernier maximum glaciaire,
- l'entrée et la sortie du bassin de Pannonie principalement par le Haut-Danube, l'Elbe, la porte de Moravie (Oder), la porte de Poprad, les portes de Fer, la Morava méridionale puis le Vardar, et la Save (col de Postjona),
- les voies de circulation à travers les bassins fluviaux de la Meseta espagnole,
- la colonisation septentrionale au Magdalénien supérieur par les vallées de la Meuse, du Rhin et de l'Elbe.

Les mêmes itinéraires de colonisation ont pu être utilisés dans un sens comme dans l'autre à différentes époques par différents groupes.

Les distances franchies dépendent de la superficie des territoires liés à la mobilité des groupes et à leurs systèmes de gestion des ressources alimentaires dans le cycle annuel. Pour les groupes de l'Aurignacien, du Gravettien et du Magdalénien, leur grande mobilité dans un territoire de plus de 500000 km<sup>2</sup> nécessite une connais-

sance intime de sa géographie et des moyens d'orientation par des amers qui sont des confluences de rivière et des reliefs caractéristiques.

Pour les groupes du Solutréen et plus généralement des industries du maximum glaciaire, leurs circulations estivales vers le Nord nécessitent de longs déplacements marqués par des bivouacs et des grottes ornées.

L'art pariétal en habitats d'abri sous-roche comme en grotte profonde joue un rôle de balisage et de marquage du territoire.

ORAL

## 2. LONG QUIET RIVERS? THE ROLE OF THE CORRIDOR RHINE-SAÔNE-RHÔNE IN THE SETTLEMENT DYNAMICS AT THE END OF THE UPPER PALAEO-LITHIC IN THE JURA ARC REGION.

*Béreiziat, Gérard - (UMR 5199 - PACEA - Université Bordeaux 1, avenue des Facultés, 33405 Talence 1)*

*gerald\_bereiziat\_web.de*

*Floss, Harald - (Eberhard Karls Universität Tübingen, Institut für Ur- und Frühgeschichte und Archäologie des Mittelalters, Abteilung Ältere Urgeschichte und Quartärökologie, Schloss, Burgsteige 11 D-72070 Tübingen ) Harald.Floss@uni-tuebingen.de*

Scene of an intensive occupation at the end of the last glaciation, the Jura Arc region has numerous testimonies of the passage of the last hunter-gatherers. The occupations, mostly in cave or under shelter, are situated in the specific geomorphologic environment between a mountainous context in the East and the natural axis of the Rhine-Saône-Rhône corridor in the West. If this fluvial corridor has been an important field of reflection for the historical periods, its impact is more difficult to argue for the Upper Palaeolithic due to the relatively recent interest in lithic raw material procurement and migration strategies.

Relating natural raw material sources to the archaeological sites, a techno-economical approach to the lithic material opens up to the spatial dimension of the Palaeolithic occupations. Several studies (Béreiziat, 2011, 2012; Floss, 2000, 2014; Hussain and Floss, *in press*, Terberger *et al.*, 2013) have already shown the importance of the fluvial axis for the diffusion of raw materials but a general comparative approach for the whole Jura Arc is still lacking. On the base of the results of the last 10 years of studies in an innovative research field, this communication aims

at showing the connections between the sites and natural raw material sources situated along the rivers Rhine, Saône and Rhône.

New reflections on these procurement strategies will be illustrated by the analysis of exogenous flints in the assemblies of the Jura Arc. The cases of Senonian (Côte chalonaise), Tertiary (Mont-les-Etrelles) and Bohnerzjaspis (Freiburg im Breisgau) flints put new lights on the modalities of this strong communication axis after the last glaciation.

---

ORAL

### 3. LA GESTION DE L'EAU DANS LE CHEMIN DES TROUPEAUX DANS LE SUD DU BRÉSIL

*Herberts, Ana Lucia - (Scientia) scientia.ana@terra.com.br*

Le chemin des troupeaux est une route ouverte au XVIII<sup>e</sup> siècle pour faciliter le transport des du bétail, des chevaux et des mulets de leur lieu d'élevage vers les distributeurs, dans la région sud du Brésil. Cet article vise à analyser la gestion de l'eau dans la formation et l'utilisation de cette route.

Le développement de la recherche a été réalisé à travers l'application de stratégies méthodologiques mises en oeuvre dans l'analyse et l'interprétation du corpus documentaire et des vestiges matériels : recherche documentaire (sources écrites, cartographique et iconographique) dans diverses archives du Brésil et à l'étranger, prospection archéologique systématique d'un échantillon de tronçons du chemin, enregistrement des témoins archéologiques du Chemin et de ses structures routières sur une fiche spécialement élaborée à cette fin, application de la photointerprétation d'images de satellite, développement d'une base de données et structuration d'un Système d'Informations Géographiques (SIG).

La nécessité de trouver les endroits plus appropriés pour la traversée des cours d'eau a influencé le tracé de l'itinéraire de la route. Dans d'autres cas, pour échapper à la traversée des rivières principales, on a privilégié le passage par des petits ou grands affluents des bassins versants, ou des fonds peu profonds. La recherche de l'endroit idéal pour traverser le réseau hydrographique révèle des connaissances empiriques, nécessaires pour trouver les meilleures solutions. Les deux principales contraintes à prendre en considération étaient le relief et les caractéristiques du cours d'eau.

L'articulation entre la route et l'hydrographie locale passe aussi par la nécessité de construire des structures de drainage de type drains et fossés. Les fossés étaient associés à l'évacuation des eaux pluviales, tandis que les drains, aménagés dans les murs de pierres, permettaient le passage de l'eau de pluie. Dans le cas des couloirs formés par des murs de pierres, les structures de drainage ont double fonction : elles permettent l'écoulement des eaux, empêchant l'accumulation de l'eau et la de formation boue. Elles aident à la conservation des murs de pierre, évitant les risques d'altération de leur structure.

Les résultats obtenus ont permis de comprendre comment le Chemin des Troupes et les couloirs délimités par des murs de pierre ont été construits, en indiquant les variables environnementales, la fonction et l'utilisation des couloirs, l'origine de la technique de construction, la disponibilité de matière principale, la main d'oeuvre probablement employée et l'origine des sources de financement.

ORAL

### 4. THE ORGANISATION OF LATER PREHISTORIC SETTLEMENT IN A FLUID LANDSCAPE: FARMERS AND SALT-MAKERS ON THE LINCOLNSHIRE FEN MARGIN.

*Chowne, Peter - (University of Greenwich) p.chowne@mac.com*

The Lincolnshire fen margin between Bourne and Sleaford is a narrow strip (2km) of fluvo-glacial sand and gravel bounded by limestone uplands to the west and fen sediments to the east. In this flat landscape variations in sea level have resulted in marine inundation and localised freshwater flooding as silts deposited in the fenland basin inhibited the natural drainage from limestone uplands. This process of marine silt deposition and freshwater peat growth continued until the drainage schemes of the 17th century and the landscape today provides some of the richest agricultural land in England. Today most of the surface peat has been lost to erosion and buried peats have above the water table are drying out. Formerly buried land surfaces are now exposed to agriculture and hitherto unknown prehistoric activity is entering the archaeological record.

Although this area has been subject to aerial photography, fieldwalking, dyke survey and excavation, particularly in the 1970s and 1980s (Hayes & Lane 1992), it is only with the recent availability of LIDAR data that a more

comprehensive understanding of how communities adapted to the changing landscape has become possible. Current research is focussing on mapping LIDAR and aerial photographic evidence using GIS and relating this to surface artefact collections and the pattern of natural drainage and how these systems were utilised in later prehistory. Several area excavations have been carried out within the study area and date from these investigations informs the mapping (Bell et al 1999; Chowne et al 2001; Lane & Trimble 2010).

The research, which is still in progress, suggests that a series of west-east flowing streams were significant landscape features around which a complex system of fields and settlement enclosures were laid out. Each of these streams are fed by springs some of which retained their significance in medieval and more recent times with one becoming a spa in the 19th century. In the early second millennium BC the point at which the streams enter the fenland became they were the focus for barrow cemeteries. In the early first millennium BC saltmaking begins, and by the late first millennium BC extensive agricultural settlements were laid out.

The fen margin was an environmental interface, a narrow strip of land subject to sea level change and freshwater flooding. Communities adapted the natural watercourses and created their own and within the mapped cropmark complexes we can identify a degree of planning in the layout of enclosures around principle ditches. Whether this relates to the marking of boundaries or properties or drainage/water supply will be discussed in the context of the surface artefacts. These include a metalwork concentration around one of the springs suggestive of a ritual element in the landscape.

---

#### ORAL

### 5. HUMAN ENVIRONMENT CHALCOLITHIC CO-EVOLUTION IN THE FLOODPLAIN AREA OF BALTALALOMIȚEI (SOUTHEASTERN ROMANIA)

*Popovici, Dragomir Nicolae - (National Museum of Romania History) mirel\_d\_n\_p@yahoo.com*

*Haită, Constantin - (National Museum of Romania History) costel\_haita@yahoo.com*

*Bălășescu, Adrian - (National Museum of Romania History) abalasescu2005@yahoo.fr*

*Radu, Valentin - (National Museum of Romania History) valipeste@yahoo.com*

*Florea, Mihai - (National Museum of Romania History) mi-haimfs@yahoo.com*

An important network related to Lower Danube Valley can be established for the Chalcolithic period, including tell type settlements. In the studied area – Baltalalomiței, the most important settlements are: Bordușani-Popină, Hârova tell and Popina Blagodeasca, located on both erosion remnants (“popine”) and edge of the lower terrace.

Two important settlements, Bordușani-Popină and Hârova tell were pluri-disciplinary investigated, from the archaeological, geomorphological, petrographical and archaeozoological point of view. Different zones of occupation were correlated on a topographic base. The study of the natural environment is performed using a percussion corer and sedimentological analysis on grain-size, clay mineralogy and magnetic susceptibility were performed.

The Chalcolithic occupation is represented by succession of houses, both destructed by fire and unburned, and their stratigraphic relationships revealed the organization of space. Most important is the persistence of alignments. All the houses are arranged on the same alignment and almost exactly the same place, the foundation trenches of the later construction have often partial destroyed the walls of earlier buildings.

The area between Danube and Borcea River, show important changes of the natural landscape from Chalcolithic to Iron Age and Middle Ages. The succession of alluvial deposits from the Chalcolithic period to present riches up to 9 m, as reflected by <sup>14</sup>C dating on core sediments, and documents different sedimentary ambiances. On the basis of five percussion corings, located on a transversal transect, a preliminary model of the sedimentological evolution is drawn for this zone. The detailed micromorphological analyses, in thin section, of two sedimentary successions, provide important environmental data and a correlation is drawn with the specific zones of anthropic activities.

The studied sites provided large amounts of fish and mollusc remains along with mammal bones. Concerning the bivalves, gathering detailed studies realized for two tell settlements – Bordușani-Popină and Hârova tell demonstrate a strong correlation between the river level variations and accessibility of such food source. Regarding fishing the most profitable periods are in the spring, coinciding with the reproduction and the flooding but also at the low level of the river water when the ponds dry and concentrate all the fish.

The existence of seasonal and complementary food supply strategies is very likely at Hârova tell and Bordușani-

Popinã: fishing and gathering activities were the most profitable, from spring to early autumn and would have kept small livestock especially for the winter. The study of mammals provided important data on the habitats for wild mammals and feeding areas for domestic animals. The petrography of lithic inventory show strong correlations of the area with Dobrogea zone, source area for most types of raw material.

Integrating all these data, we try to understand the role of water management for the development of these important settlements.

ORAL

## 6. SETTLEMENT IN THE MIDDLE VALLEY OF RIVER JABALÓN DURING II MILLENNIUM B. C.

*Piña Abellán, José Javier - (Universidad de Castilla-La Mancha) j.javier\_aries@hotmail.es*

Recent researchs about settlement during II millennium B. C. in Southern Plateau allows us to testify in this large territory a high percentage of human presence and a great cultural diversity. This article has the purpose to know the kind of settlement identified in the Middle Valley of River Jabalón, an strategic located in the centre of Campo Calatrava (Ciudad Real).

Reflecting history of research and physiografic features of the Valley of Jabalón in Bronze Age, implies a deep and organized methodologic analysis: looking up the archaeological chart, vising thematic cartography, reading and analyzing scientific bibliography, working in archaeological sites... To offer a real information about facts from archaeological charts, we need to visit personally all the sites. After confirming settlements of this period, I made a summary composed by worksheets in which I analysed each settlement, depending on geographical basis (the site name, kind of settlement, location, altitude, extension and municipality) and economical factors (distance between the site and water sources, routes of communication, cultivated soil, pastures, mining resources and relations between different areas). I represented the results fo my research in detailed maps and graphs, indicating the characteristics of the type of settlement.

The archaeological register identified is composed by 69 settlements (25 hilltops, 13 morras, 1 motilla and 30 small sites in plain area) always located near the water resources and lands with an agricultural use, while controlling natural routes to communicate with the valley,

the river banks and the roads which go through them. All of them are essential elements for settlement, control and an stable economical use in the valley of Jabalón. In different areas, we can observe little nuclei of population interested in exploiting certain economical resources. For example, there is an interesting distribution around salty lagoons in Moral de Calatrava.

In conclusion, during the II millennium B. C. the Middle Valley of River Jabalón was highly inhabited by important groups of population. The distribution of the settlement shows symptoms of a planned organization, hierarchical and interconnected around great nuclei or political centres, like hilltops La Encantada, San Cristóbal or Cave of Alguacil. This settlement net increased and strengthens control relations and economical exploitation between settlements and natural landscape. The main economical activity is cattle raising, specifically cattle movements. This territory, whose landscape was intensely modified by human being sand it can be culturally classified in the area of influence of La Mancha Bronze Culture, because they shave the same type of settlement, chronology and material culture.

ORAL

## 7. LE TERRITOIRE DE LA RÉSIDENCE PRINCIFIÈRE DE VIX, UNE APPROCHE GÉOMORPHOLOGIQUE.

*Cruz, Frédéric - (ArtéHis, UMR 6298, 6 bd Gabriel, 21000 Dijon, France) fredericcruz@hotmail.com*

*Petit, Christophe - (ArScAn « Archéologie environnementale », UMR 7041) christophe.petit@univ-paris1.fr*

Les résidences princifières représentent un phénomène social inédit qui s'opère à la fin du premier âge du Fer au nord-ouest des alpes. Ce phénomène est souligné par l'apparition de riches tombes à importations méditerranéennes situées à proximité de sites de hauteurs fortifiés. Ces changements traduisent une complexification sociale inédite, une centralisation des pouvoirs et un saut d'échelle d'intégration spatiale du territoire. Ce dernier est généralement représenté par la méthode des polygones de Thiessen découlant de la théorie des places centrales. Ce modèle théorique nécessitait d'être affiné en prenant en compte les données géomorphologiques des territoires princiers.

Un test a été effectué à partir des données du site de Vix qui représente l'archétype même de la résidence princifière. Dans un premier temps, l'environnement de la partie méridionale du territoire (zone la mieux documentée

archéologiquement) a été analysé pour mettre en évidence les contraintes environnementales de l'occupation de la région. Dans un second temps, l'occupation du Pays châtilonnais par les élites hallstattiennes est observée à l'aide de la méthode des noyaux employée sur les données des sépultures tumulaires du Châtillonnais. Ce travail a permis de montrer la dynamique d'occupation du Châtillonnais par les élites depuis la fin de l'âge du Bronze jusqu'au début de la période laténienne.

La comparaison entre les données environnementales et les données archéologiques indiquent que le réseau hydrographique du Châtillonnais est un élément déterminant dans l'organisation du territoire de la résidence princière de Vix. L'importance de la Seine ne peut être expliquée uniquement par le commerce de l'étain. Ce fleuve représente avant tout une voie reliant le monde méditerranéen à la Manche. Ces travaux ont également permis de développer un modèle géomorphologique originale de ce territoire, validé par les données archéologiques et environnementales des régions voisines. Ce modèle souligne l'importance de dissocier la centralité des résidences princières du point de vue économique, religieux, etc. de leur position géographique qui n'est pas obligatoirement centrale.

ORAL

## 8. GOLD, WATER AND ARCHAEOLOGY (MINAS GERAIS/BRAZIL- EIGHTEENTH CENTURY)

*Guimarães, Carlos Magno - (Universidade Federal de Minas Gerais-Brazil) carlosmagnoguimaraes@yahoo.com.br*  
*Fernandes de Moraes, Camila - (Universidade Federal de Minas Gerais-Brazil) camilet123@gmail.com*  
*Roedel, Luísa - (Universidade Federal de Minas Gerais - Brazil) luisaroedel@gmail.com*

This article approaches the presence of the water as an indispensable element in the colonial mining in central Brazil during the 18<sup>th</sup> century.

Using data from that time period and **archaeological researches**, the approach is developed through a perspective that contemplates, on one hand, the technical nature of the process and, on the other hand, your social configuration.

What becomes evident is the participation of the water in that historical reality as an irreplaceable productive force and also as a problem and a solution.

Understanding how the mining activity was developed inside Brazil in the eighteenth century, as well as the im-

portance of the water in the dynamics of the process requires its contextualization. In this respect, it is essential to consider the context of European colonial expansion developed in the Modern Era.

It is inevitable the association between water and mining activity, because it is crucial for the nuclear activity itself, but also to peripheral and/or subsidiary activities. If their use in numerous circumstances showed positive outcomes in the society of Minas Gerais eighteenth century, water was also an obstacle to the proper conduct of mining activities, by its excess or its shortage. The water was one more element to provoke conflicts in the bustling colonial mining society.

In the context presented above the Hydraulic Archaeology is an important research tool to contributing to approach that historical reality.

ORAL

## 9. LIDAR SURVEYS OF ANCIENT WATER MEADOWS IN THE UPPER RHINE VALLEY

*Sittler, Benoit - (Landespflege Univ. Freiburg) benoit.sittler@landespflege.uni-freiburg.de*  
*Schellberg, Sabine - (KWB Fortbildungsgesellschaft für Gewässerentwicklung Karlsruhe) sabine.schellberg@wbw-fortbildung.de*

Among land use forms that have shaped our landscapes, ancient water meadows have generally received less consideration as compared to remains of medieval ridge and furrow cultivation and enclosures. In parts of the Upper Rhine Valley, the cultural landscape still includes remains of a network of ancient water meadows that featured some large parts of lowlands north of Freiburg (Eichstetten/ Kaiserstuhl) in historical times.

Based on a systematic survey using also LiDAR data available for this region, the design and functioning of this system has been documented in an integrative approach. Besides assessing the layout of this sophisticated network including head mains, ditches and carriers to divert water into pastures, the present study also used historical sources as derived from ancient maps as well as from archives to assess the historic and social context related to this specific type of land use.

The high resolution of the altimetric Lidar surveys with accuracy in the range of a few centimeters, along with

use of GIS and 3-D models proved quite insightful to understand how gravitational gradients were best used to divert water and to fine tune the levels and maintain flows. While no longer in use since the past century, this legacy of a specific type of landuse, with its complex of corresponding earthworks is also a challenging management issue for heritage protection agencies.

---

POSTER

**10. REMOTE SENSING AND ENVIRONMENTAL ARCHAEOLOGY: MAPPING A RIVER SYSTEM AND PREDICTING THE LOCATION OF ARCHAEOLOGICAL SITES IN THE LEITHA-VALLEY (AUSTRIA)**

*Doneus, Michael - (Department of Prehistoric and Historical Archaeology, University of Vienna) michael.doneus@univie.ac.at*

*Fera, Martin - (Vienna Institute for Archaeological Science, University of Vienna) martin.fera@univie.ac.at*

*Zámolyi, András - (OMV, Exploration & Production, Vienna) andras@zamolyi.info*

*Draganits, Erich - (Department of Prehistoric and Historical Archaeology, University of Vienna) erich.draganits.univie.ac.at*

*Fornwagner, Ulrike - (Department of Prehistoric and Historical Archaeology, University of Vienna) ulrike.fornwagner@univie.ac.at*

The Leitha river is an important tributary to the Danube in Eastern Austria. The geometry of palaeo-channels of the Leitha river was investigated in the framework of an archaeological project analysing patterns of prehistoric settlements in this region. For such considerations the present regulated condition of the rivers are not a well suited analogue since they behave in different ways to natural rivers.

Therefore, the 600 km<sup>2</sup> large study area was thoroughly investigated using remote sensing techniques. 36 hours of aerial archaeological reconnaissance flights using RGB and infrared cameras to obtain oblique photography as well as 2.000 vertical aerial photographs were used as the base source of information. Additionally, surveying airborne laser scanning (ALS) data were used to observe traces of old river meanders still preserved in relief. After orthorectification of the relevant photographs, more than 60.000 archaeological and palaeo-environmental features were mapped in a GIS environment. The digitized palaeo-channels were analysed together with additional data such as a digital elevation model, soil maps, Quaternary thickness maps and several lithostratigraphic sections in the alluvial deposits of the palaeo-Leitha

during archaeological excavations in the southern part of the study area.

The analysis revealed more than 300 previously unknown archaeological sites and a dense network of palaeo-meanders belonging to former courses of the Leitha river. Together with the previous available data, the area contains more than 650 archaeological sites, which thus allowed to study the interaction between land use, settlement pattern and the dynamic system of the Leitha river. The constantly changing river channels and related flood hazards in the floodplains have always been an important determining factor for the selection of settlement areas. Archaeological sites, for instance, are mainly located on the rim of the Würmian terraces, at the margin of the sub-recent floodplain. Also, characteristic morphometric parameters of the Leitha river, like stream slope and palaeo-channel shape, were calculated. Fault-slip analysis, seismicity and tilted terraces of the Danube and fault scarps indicate Quaternary activity for at least some of the faults. The effects of this tectonic activity are well preserved in the palaeo-channel geometry and river profiles of the Leitha river. Well-oriented abandoned meander-belts, as an example, reveal possible tectonic tilting towards the Southeast in the Southern Vienna Basin and a palaeo-channel migration towards the same direction.

The study demonstrates that remote sensing techniques are an important source for landscape archaeology. They provide abundant important information for archaeological sites and structures, and – equally important – allow to retrieve palaeo-environmental information over large areas.

ORAL

**11. THE RESILIENCE OF THE OLD COURSE OF THE RIVER SEINE IN THE RIGHT BANK OF PARIS**

*Robert, Sandrine - (EHESS) sandrine.robert@ehess.fr*  
*Noizet, Hélène (Paris I University) Helene.Noizet@univ-paris1.fr*

*Mirlou, Laurent (Paris I University)*

In the "Alpage" Project (diachronic analysis of the Paris urban area: a geomatic approach) a research program supported by the french National Research Agency, historical research based on GIS technology has demonstrated the impact of the old course of the River Seine (in right bank) on the urban fabric of Paris.

Recent archaeological excavations have provided valuable insights into the evolution of the alluvial plain of the river around Paris during the Holocene. The combined use of textual, mapping and archaeological data highlights the historical impact of the ancient course of the river. 910 urban block plans of Vasserot's atlas (preindustrial map) have been georeferenced and vectorised and permitted a morphological study of streets and plots.

The influence and inheritance of past flows on the feudal domains and the sewers has been analyzed. The old course influenced land use in the Middle Ages and in the modern period: in the location of pastoral and agricultural land, or culverts and sewerage systems. From the Antiquity to the present, the Seine has also determined the location of the streets of Paris. The form of the old course is one of the first fringe belt of Paris. During the flood of 1910, the Seine returned to its old bed. Cellars were flooded to the site of old course.

It is now possible to measure the resilience of a former meander on the material and conceptual space layout. The example of the River Seine shows how historical forms linked to water persist over time from prehistory to the present. Forms, structures and functions are changing but geographical convergences persist.

ORAL

**12. TURBID WATERS AND FERTILE FIELDS. THE SACRED GEOGRAPHY OF THE INCA STATE IN THE REGION OF FIAMBALÁ, TINOGASTA, CATAMARCA, ARGENTINA**

*Orgaz Martin, Alfonso - (Escuela de Arqueología. Universidad Nacional de Catamarca) orgazmartin@hotmail.com*  
*Ratto, Norma Rosa - (Museo Etnográfico Juan B. Ambrosetti, Universidad de Buenos Aires, Argentina) nratto@filo.uba.ar*

Archaeologists have always been interested in the study of landscapes throughout the history of the discipline. Initially, research focused on the economic dimension of space where the physical environment supplied shelter, raw materials and different types of resources. In recent years, space began to be considered as a social construction that includes multiple dimensions of people's daily life. However, the concept of the human body and its use as a metaphor for understanding the functioning of social groups was not considered in the organization and structure of landscapes. Currently, the human body is considered as a cosmological symbol where there is no division between the body of man and his environ-

ment. Particularly in the Andean region, the identification of land with the human body and its association with the flow of liquids was described during Inca and colonial times, and continues to this day. In the myths of origin, different elements of nature (hills, rocks, springs, rivers) were represented. These were important in the location and structuring of the sacred geographies.

The human body was a symbolic reference for the political and social life of the Inca state. One example was the process of making *chicha* that was used in all state ceremonies. Technical gestures and artifacts were involved in the different steps of the preparation of *chicha*. Once processed and stored, three levels within the vessel or raki were formed, whose names in Quechua refer to parts of the body which are necessary for procreation: (i) the upper level is the *nawin*, which means eye but also rainwater, male strength and sperm to fertilize the farmland; (ii) the central level is the *aqha*, the *chicha* itself; and finally (iii) the lower level is the *qonchu*, a cloudy sediment representing the woman, female blood, fertility, and a fraction must be saved for the next production of *chicha* in order to accelerate the fermentation process.

We present the association between the Inca sites (Batumgasta and Ranchillos-1) and rivers with red waters of the region Fiambalá (Dept. Tinogasta, Catamarca, Argentina). Our hypothesis is that the optical characteristics (the color red) of the rivers acted as a location factor for the localization and construction of these state sites. Landscape theory is appropriate to discuss and integrate archaeological, historical and landscape evidences in Inca times. Such evidences were articulated metaphorically by the river, which crossed and joined the diverse parts of the whole.

*Fabrega-Alvarez, Pastor - es (INCIPIT-CSIC) pastor.fabrega-alvarez@incipit.csic.*

The Atacama Desert is one of the driest places on earth. In this challenging environment, past and present inhabitants have had to establish an adequate and rational management of the resource most basic to life: water. During the Late Intermediate Period (ca. 950 - 1450 AD), complex social systems developed in the Loa River Basin (Atacama Region, northern Chile), with aggregated populations which depended on a mixed farming and pastoral economy. They established an efficient use of water through the construction of complex irrigation systems and the careful management of soils and crops. Large-scale agriculture in the area served not only as the basis for biological reproduction but for the social reproduction of the community as well.

Sometime during the first half of the 15th Century, the Tawantinsuyu or Inka empire made its dominion over Atacama based on a territorial strategy which implied a highly controlled extraction model. The main attraction for the Inka in Atacama was its mineral wealth, but Inka mining operations had to be provisioned with surplus food produced at agricultural locis.

In this paper we discuss the evidence of preinka and Inka organization of agricultural production on the Loa River Basin, specifically as seen at the sites of Topaín and Panire. We aim to understand and explain the strategies developed by the local communities to manage water and agriculture under two distinct sociopolitical contexts, focusing on the technological, social and political dimensions of production and its changes from a community specialization system to a state-controlled production.

## 1. AS POLÍTICAS PÚBLICAS PARA A GESTÃO DO PATRIMÓNIO ARQUEOLÓGICO ANGOLANO

*Ziva Domingos (Gestor do Património) zivado@hotmail.com*

Depois de 30 anos marcados pela guerra, Angola sendo uma nação jovem está envidando esforços para relançar o seu desenvolvimento a fim de proporcionar uma vida de qualidade ao seu povo. Para atingir este objectivo, o Estado Angolano, desde o fim da guerra em 2002, se lançou como desafio a diversificação da sua economia usando todos os recursos disponíveis nas diversas áreas da vida económica, social e cultural.

É nesta perspectiva que a política cultural pública Angolana aprovada em 2011, reconhece o património cultural e natural, sobretudo o património arqueológico como um dos pilares do desenvolvimento sustentável de Angola com efeitos imediatos sobre a coesão interna das comunidades locais visando a construção de uma nação unida e próspera.

Apesar da existência de um rico e diversificado património arqueológico (sítios de arte rupestre, sítios de arqueologia funerária, acervo museológico, etc.) e tendo em conta as ameaças geridas pelo crescimento económico de Angola, este ideal só pode ser alcançado se de facto as políticas públicas de gestão desses bens patrimoniais forem consolidadas, desde a formação de gestores, o reforço das medidas de protecção, preservação e gestão de sítios, a elaboração das políticas de investigação e de valorização coerentes, o desenvolvimento das estratégias de gestão descentralizada e participativa que envolvem, não só as autarquias locais mas sobretudo as comunidades locais e outros parceiros da sociedade civil.

## PUBLIC POLICIES FOR THE MANAGEMENT OF THE ANGOLAN ARCHEOLOGICAL HERITAGE

*Domingos, Ziva (Heritage Manager) zivado@hotmail.com*

After 30 years marked by war, Angola as a young nation is making efforts to boost its development in order to provide a quality life to its people. To achieve this, the Angolan Government, since the end of the war in 2002, launched the challenge of diversifying its economy by using all available resources in various areas of economic, social and cultural life.

It is in this perspective that the Angolan public cultural policy adopted in 2011, recognizes the cultural and natural heritage, especially the archaeological heritage as one of the pillars of sustainable development of Angola with immediate effects on the internal cohesion of local communities in building a united nation and prosperous.

Despite the existence of a rich and diverse archaeological heritage (rock art sites, burial archeology sites, museum collection, etc.) and taking into account the threats due to the Angola's economic growth, this ideal can only be achieved if in fact the public policies for managing this heritage are consolidated, since the training of managers, the reinforcement of measures for protection, preservation and management of sites, the development of research and promotion consistent policies, the development of decentralized and participative management strategies that involve not only local authorities but especially local communities and other civil society partners.

ORAL

## 2. THE LEGAL PROTECTION OF ARCHAEOLOGICAL HERITAGE IN MOZAMBIQUE (1994-2014).

*Solange Laura Macamo (Eduardo Mondlane University, Department of Archaeology and Anthropology and the National Directorate of Cultural Heritage, Ministry of Culture, Maputo, Mozambique) solangemacamo@gmail.com*

This paper is about the legal status of archaeological heritage in Mozambique, since from 1994, when it was adopted the regulation for the protection of the archaeological heritage. The experiences resulting from its implementation will be here remarked.

Clearly, the legislation itself is not enough to stop damages to the archaeological sites. Some of the problems are related to the abandonment of sites, due to absence of site managers and lack of resources. Another concern relates to development programs, in the context of the protection of the whole cultural heritage.

The materials derive from the archaeological sites across the country, but there are also some examples where the problems of conservation have been identified: the coastal site of Chibuene (1<sup>st</sup> to 2<sup>nd</sup> millennium AD) and the Zimbabwe type site of Manyikeni (XIII-XVII century). The protected Matola site, related to the Early Farming Communities in Southern Mozambique is an example where development programs are taking place. Also, the

Mozambique Island UNESCO World Heritage site has a valuable land and underwater archaeological heritage in need of constant care.

As a methodological approach it will be shown how the regulation is implemented and the context in which the responsible preservation institution deal with the whole heritage. This includes the State role, through its cultural sector and the University.

The role of the archaeologists is considered, in relation to the relevance of their work, not only when it comes to reveal new sites, but mainly for their contribution in presenting solutions for the management of cultural heritage. This leads on the sustainable heritage conservation strategies. There are some questions arising from this reasoning: Firstly, to what extent the archaeological heritage can survive in face of development programs? Secondly, how relevant is the conservation of the archaeological heritage in the society, and how it can be valued?

To answer these, I shall access the existing practice of rescue archaeology and its contribution to archaeological research. However, this legal solution is not always possible and certainly many sites will still remain unprotected. Some experiences resulting from dissemination work are important too, to make archaeology relevant in the country.

The contribution of cultural tourism is perceived for the satisfaction of community needs living near the sites and the necessary care to avoid its negative impact on the heritage. Unfortunately, the use of sites for education and cultural tourism practice is not yet common, in Mozambique, even if there are some isolated initiatives. However, when it is properly planned, cultural tourism can help to solve the majority of heritage conservation problems and enable the implementation of the protective legal tools.

The archaeological heritage is a valuable resource like many others and it should be integrated in the development programs, through management plans.

ORAL

### 3. L'ARCHÉOLOGIE DANS LA NOMENCLATURE DES SCIENCES: APPROCHE STRUCTURELLE ET ORDRE NOUVEAU EN CÔTE D'IVOIRE KOUASSI KOUAKOU, SIMÉON - (DÉPARTMENT D'ARCHEOLOGIE - UNIVERSITÉ FÉLIX HOUPOUET-BOIGNY)

*arqueo@terra.com.br*

Philippe Jockey dans l'Avant-propos de son ouvrage intitulé *L'Archéologie* (1998) écrivait: «L'archéologie est à la mode. Ce constat, établi il y a quelque vingt ans par un archéologue de renom, est aujourd'hui plus qu'hier encore d'actualité. Pourtant, le malentendu autour duquel ce phénomène de civilisation s'est construit perdure. Il existe, de fait, dans notre société moderne, un décalage surprenant entre l'image mythique que le grand public se fait de l'archéologie, l'attrait qu'elle exerce par ce biais, et la réalité quotidienne des pratiques archéologiques.»

La perception de l'archéologie telle que caricaturée ci-dessus, traduit éloquemment l'environnement dans lequel baigne cette discipline surtout en Afrique de l'ouest francophone.

Pour mieux faire saisir ce paradoxe, nous nous attelons à décrire l'évolution de la discipline dans le contexte de la Côte d'Ivoire. L'étude s'appuie sur le dépouillement de résultats d'enquêtes auprès des populations et de textes de lois.

Cette démarche permet de comprendre la spécificité de la gestion du patrimoine archéologique du pays et le rôle que joue l'État dans ce processus.

### 4. GESTION DEL PATRIMONIO ARQUEOLOGICO EN SITIOS DE MEMORIA. CASO CIUDAD VEJA DE CABO VERDE, PATRIMONIO MUNDIAL

*Fernandes, Hamilton - (Curadoria Cidade Velha, Patrimonio Mundial) jairfernandes40@hotmail.com*

*La República de Cabo Verde es un archipiélago de origen volcánico con limitados recursos naturales, formado por diez islas y cinco islotes, situados en el océano Atlántico, a 500 km de la costa africana de Senegal.*

El descubrimiento de Cabo Verde no fue resultado de planes de búsqueda, como el camino marítimo para

la India, ni de misiones de exploración, como las que reconocerían y levantarían planos de los litorales del continente africano.

Ribeira Grande, fue el primer asentamiento humano en el archipiélago de Cabo Verde y la primera ciudad europea del sur del Trópico de Cáncer. Fue creada inmediatamente después del descubrimiento de la isla de Santiago, alrededor de 1460, por el navegante genovés Antonio de Noli. La ciudad tuvo gran importancia estratégico y administrativo, aunque este último carácter se debió más bien al haberse fundado un arzobispado en 1533, por decisión de D. João III.

Ribeira grande ha ayudado a hacer del Atlántico una red de distribución de mercancías, plantas, animales y hombres, cambiando completamente el panorama continental. Con el descubrimiento de las Américas en 1492 y Brasil en 1550, la ciudad gana una importancia y un dinamismo sin precedente.

Cidade Velha tuvo un gran importancia como centro de tráfico de esclavos, sirviendo no solo de plaza frecuentada por comerciantes y empresas involucradas en la trata. Las primeras intervenciones arqueológicas y de restauración arquitectónica.

-Rehabilitación del Patrimonio Arquitectónico o Rehabilitación de convento de San Francisco. En estos trabajos se puso gran cuidado para dejar constancia clara de lo que constituyen restos auténticos conservados del edificio original, frente a la que son nuevos añadidos.  
o Recuperación de itinerarios arqueológicos. Con tareas de limpiezas, excavaciones, consolidaciones, acondicionamientos del camino peatonal, señalización de los restos.

Cidade Velha, ciudad de Ribeira Grande de Santiago tiene un valor universal excepcional para ser inscrita en la lista de Patrimonio Mundial de la UNESCO:

- Por ser la primera capital de las islas de Cabo Verde, producida a partir de 1462, época de inicio de la ocupación de la isla de Santiago, en el contexto del proceso de expansión marítima europea, liderada entre los SS. XV y XVII por Portugal y España y que debido a su posición estratégico, se transformó muy pronto en clave en las rutas entre Europa, África y América.
- Por haber sido la primera ciudad portuaria construida por y para el tráfico trasatlántico de esclavos.
- Por haber sido el lugar donde surgió una nueva cultura, la cultura caboverdiana.
- Por haber albergado una sociedad multiétnica.
- Por haber sido un centro de proyección de poder y

de control del océano y de las rutas de comercio ultramarino albergando, por este motivo, una estructura de funciones fiscales, militares, religiosos, siendo la primera sede de gobierno europeo y de obispado al sur del Sahara.

- Por haber sido un espacio urbano que sintetiza diferentes formas de urbanismo tardo medieval y renacentista y por haber sido en laboratorio para la introducción de productos y formas de explotación agrícolas precedentes de todos los continentes.

## 6. ARCHAEOLOGICAL HERITAGE POLICIES IN BRAZIL: A NECESSARY DISCUSSION ABOUT SCIENTIFIC AND SOCIAL STANDARDS ROBRAHN-GONZALEZ, ERIKA MARION - (DOCUMENTO / UNICAMP) ERIKA@DOCUMENTOCULTURAL.NET

The Brazilian law is very strict regarding the preservation of archaeological heritage, including the different normative bureaucracies intended to create a macro regulation for the procedures of research, preservation and valorization of these heritage.

The internal regulation is also affected by all the international treaties that the country takes part in. The addition of national and international law results in the general research directives used in the country. Even though the legislations are so developed, it is insufficient for the perspective of creating standards of quality for archaeological projects and research.

In this manner, Brazil is today characterized by the huge diversity of criteria for research and for quality of its results. This is brought in perspective by the fact that the country is in an accelerated process of development, creating every month hundreds of new construction projects. In this context what happens in the country is the creation of archaeological teams that do their work in an isolated and independent manner.

The discussion of standards of quality should be of intrinsic value in the country's situation. Patterns of quality should be developed in a way to fit the growing demand for such.

This exposition aims to discuss the critical factor of success for the establishment of standards for the Brazilian archaeology, in the perspective of a practice that not only attends to the specific scientific aspects involved, but also shows itself as a strategic tool for sustainability and social development.

## 7. ARCHAEOLOGICAL HERITAGE MANAGEMENT POLICIES IN INDIA: A CRITIQUE

*Ray, Ranjana - (Calcutta University) prof.ranjana.ray@gmail.com*

The Indian subcontinent was inhabited since c. 2Myrs back. Remains of prehistoric, protohistoric and historic cultural remains are strewn all over the landmass of South Asia. Cultural heritage both tangible and intangible are identified and recorded by Anthropologists and Archaeologists. Ideas and concepts encompassing Socio-political, philosophical and religious thoughts, arts, literature and scientific achievements of ancient and medieval periods form parts of an Indian heritage. Conservation of resources both tangible and intangible as resources, cultural and otherwise and circulation of such knowledge is mandate for heritage management. With the British colonialism developed the legislation for preservation and management of antiquities. Heritage management has attained global perspective with the intervention of UNESCO. Several policies and mandates for preservation of Nationally and ar-

cheologically important monuments and sites have come up in recent years. At the same time public awareness building activities have also come up. The paper will critically discuss and assess the present day legislation, public policies and systems of archaeological heritage management that have come up in India. Archaeological heritage management policies both from the perspectives of anthropology and archaeology will be covered.

## 8. A CONTRIBUTION TO THE UNDERSTANDING OF ARCHAEOLOGICAL HERITAGE POLICIES IN PORTUGAL

*Oosterbeek, Ivo - (GQP-CGC (uID73 FCT); Instituto Terra e Memória; Benefits & Profits Lda) ivoosterbeek@gmail.com*

The care for the preservation of antiques has accompanied the Portuguese political sphere since before the 20th century, but it has especially grown in enactment and public recognition in the last quarter of the 20th century. Since the end of the Portuguese dictatorship (1974), heritage policy making in Portugal has been mainly constricted to the adoption of international recommendations in its legislation, as well as the regulation of professional activity (namely in archaeology).

Though the examination of the legislation would suggest the adoption of public-friendly strategies in heritage management, the ever-shaping structure of the Portuguese governments in the past decades regarding the cultural sector have not allowed for the establishment of stable cultural programs concerning heritage awareness strategies.

As per non-governmental entities: NGO's dedicated to cultural awareness have been diminishing in the last two decades; Higher Education institutions maintain their focus on scientific research rather than social engineering; and private companies in the heritage sector (mainly archaeology and conservation professionals) mostly operate as subcontractors in the construction sector.

In this paper, we aim to review the Portuguese legislation applicable to the archaeological heritage, discuss the concept of 'archaeological heritage' and its uses, and present an analysis of the main contributions of each institution-type (Government bodies, Universities, among others) regarding archaeology research and archaeological heritage.

ORAL

**9 PUBLIC AND PRIVATE GOOD PRACTICES: THE MIAA PROJECT (ABRANTES, PORTUGAL)**

*Delfino, Davide (Abrantes Municipality and Instituto Terra e Memória) davdelfino@gmail.com*

*Oosterbeek, Luiz (Instituto Politécnico de Tomar and Instituto Terra e Memória) loost@ipt.pt*

In 2008 as was initiated a project to create a regional museum of archaeology and art (M.I.A.A.), organized by the Municipality of Abrantes, based on a rich collection including a large archaeological and artistic private collection of archeology and art (Estrada Collection), as well as a public collection of archaeology and two artists donations. Stakeholders of the project and of the future Museum are Estrada Foundation, Fine Arts Faculty of Lisbon University, Polytechnic Institute of Tomar and Land and Memory Institute.

The core component is the private collection, about 4000 artifacts, whose founding owner took charge of the first research, authentication and restoration expenses, all done under public guidance involving several laboratories in Portugal and abroad. The management of this project of research and enhancement of archaeological heritage was paid in a large part by private resources, rendering accessible to the wider public a private archaeological heritage collection, and relying on public structures for guidance and control (higher education and municipality).

The public interest is safeguarded not through full public ownership, but through the management process and a series of regulations to secure full access to research and public accessibility as well. In the process, strong strategies to denounce expose and combat illegal heritage activities are being implemented, including on issues such as sites robbery diggings, forgeries or illegal trading. The paper discusses this experience, its positive results in terms of compatibility between public and private interests and also the difficulties encountered so far.

**10. A BETTER FUTURE TO THE PAST: LARGE SCALE DEVELOPMENT PROJECTS AND THE PROTECTION OF ARCHAEOLOGICAL HERITAGE IN ROMANIA**

*Bors, Corina - (National History Museum of Romania (MNIR), Bucharest) corina.bors73@gmail.com*

*Damian, Paul - (National History Museum of Romania*

*(MNIR), Bucharest) pauldamian60@gmail.com*

About 25 years ago a new reality emerged in Romania: the large-scale rescue/preventive archaeological excavations occasioned by the construction of industrial and infrastructure development projects. The National History Museum of Romania (MNIR) was involved since the very beginning in coordinating such archaeological projects set in given circumstances and took part in all the major preventive archaeological projects related to infrastructure and industrial developments undertaken up to know in Romania. The paper will provide an overview on the most important results obtained throughout such archaeological projects, but also to the lessons learned by this important practical experience. On the same time the paper will refer to the changes in the Romanian legislation and current archaeological practice, but also will point out to the necessary improvements still required for implementing a better archaeological management strategy for protecting the archaeological heritage considering the European standards and guidelines.

ORAL

**11. THE ROLE OF CIVIL SOCIETY IN PRESERVATION OF ARCHAEOLOGICAL HERITAGE IN THE REPUBLIC OF MOLDOVA**

*Musteață, Sergiu (president of the Association of Historians of Moldova) sergiu\_musteata@yahoo.com*

In this paper the author is discussing the role of civil society in preservation of the archaeological heritage in Republic of Moldova. Republic of Moldova signed the European Convention on Archaeological Heritage Preservation (revised version) in 1998, ratified it in 2001 and only starting with November 2002 it entered into force. But, the national law on archaeological preservation was voted by Parliament in September 2010 and entered in force in March 2011. So, after a long period of debates and initiatives Republic of Moldova has its own law on this field. The leading role in this process had the National Association of Young Historians of Moldova. This NGO initiated in 2009 an advocacy project in the field of cultural heritage preservation. As main goal and result was the elaboration a new law on archaeological heritage preservation, based on European an International Convention and actual trends in the field of archaeological heritage preservation.

**Introduction**

The National Association of Young Historians of Moldova – ANTIM, founded in 1997, is a non-political, non-profit association, which has the public benefit as a purpose. By establishing the ANTIM, its founders primarily wanted to meet a social need, by promoting national and international collaboration of young people that stimulates research activities and helps to preserve our cultural national inheritance. ANTIM is an organization that succeeded to affirm itself through multiple projects that cover various area of historical research. It is widely recognized for its scientifically and practical activities, for the initiation and organization of many symposiums, conferences, summer schools and some more ample academic activities. Among ANTIM successful activities was the 2009-2010 project “**The policy of archaeological heritage preservation in the Republic of Moldova: reality and necessity**”, supported by Soros Foundation-Moldova and Swedish Agency for Development and International Cooperation – SIDA. The project included one year advocacy campaign – regional and national meeting, conferences, mass media information activities, publication of leaflets, posters, collection of laws, writing a project of new law on archaeological heritage preservation and its public discussion, including with international experts, etc.

### **From a project idea to a project law**

Republic of Moldova got its Independency in August 1991. Its first Law on cultural heritage preservation was approved in 1993 - the law on monuments' preservation. This law is very general and it was poorly developed in relation to archaeological heritage. The most difficult problem was not just the content of the law, but inefficiency of the state bodies to implement it. For example the National Register approved in 1993 was published only in 2010.

During last two decades Republic of Moldova has signed many international treaties, and from those 10 International and European Conventions on cultural heritage Republic of Moldova signed in 1998 the Granada and Valletta Conventions. But, signing these Conventions did not change the situation of Moldova in the field of cultural heritage preservation. So, after a decade of our Independency a group of scholars from Academy of Sciences of Moldova initiated a new project on cultural heritage preservation, which was not supported by the Government.

In 2005 a group of archaeologists prepared a first law draft project on archaeological heritage preservation, which was discussed for five years in various circles - civil, academic, and even political. In 2009, the National Association of Young Historians of Moldova, as part of Advocacy

project, took the initiative to update and promote the draft law project by involving its initial authors and other domestic and foreign archaeologists, managing to propose to the Ministry of Culture an updated version in line with contemporary requirements. This project received important feedback and support from colleagues in the United States, Germany, Romania and elsewhere.

Project's main purpose was to promote efficient policies for heritage conservation, having the following objectives:

Setting a sustainable partnership with local public administration for the elaboration and implementation of some policies to protect the archaeological heritage.

Development of a coherent long-term national strategy, which would count generally the preservation of cultural and historical heritage and the archaeological heritage, especially among national priorities.

Improvement of national legal framework, by adoption of some laws regarding the protection of archaeological heritage.

Discussions with the decision makers about the opportunity of establishing a viable and accountable structure in the field.

The project was launched on 15<sup>th</sup> of May 2009 at the Round Table “Museum policies in Republic of Moldova”, with the participation of a wide audience, including specialists from museum network of the country. Immediately after the launch of the project, the working group drafted the activities agenda and tasks were distributed among members. Simultaneously, letters were sent to representatives of local public administration of northern districts that were invited at the first seminar of the project. From the beginning were elaborated the leaflet and project's poster, which presented the main information about the project and facilitated the informing of the public about the purposes, objectives and further activities.

During the period May 2009 – May 2010, according to the action plan, were performed a range of activities, structured in three main directions:

**The analysis and evaluation of protection policies of archaeological heritage.** The project has been accomplished in two successive stages: at regional and national level. In first stage, we organised three regional meetings (north, centre and south), attended by approximately 100 representatives of local public administration and

district museums. At these meetings was discussed the real situation of each district and were searched solutions to improve the situation. Also at these meetings were presented the objectives and the activities of the project and were discussed the projects of national strategy and the law for archaeological heritage preservation in Republic of Moldova. The first meeting took place in Bălănești on 16<sup>th</sup> of June 2009, the second in Chisinau on 1<sup>st</sup> of October and the third in Cahul, on 8<sup>th</sup> of October 2010.

#### **Lobby and promotion of cultural policies changes.**

In the second stage were organised working meetings with the representatives of Government and Parliament where was discussed the situation of the archaeological heritage in Republic of Moldova. The project director and a few members of the working group (Gh. Postic, E. Sava, I. Ștefăni) had some meetings in October with Mr. Foca, the then minister of culture and discussed about the problems of cultural heritage situation, especially the archaeological heritage. The Draft Law was presented by the Ministry of Culture and further supported by the Government through a decision submitted in Parliament. On the Round Table, on 9<sup>th</sup> March 2010, were discussed the Law Draft of archaeological heritage preservation with members of parliamentary Committee for Culture, Education and Mass Media. The project working team found a real support from the Parliamentary Committee, being ensured of supporting this project to be included in Parliament agenda. Further, after receiving the opinions about the law draft from the Parliamentary Committee, the working group met again with the representatives of Juridical Committee and Committee for Culture, Education and Mass Media, where were embodied some details. Final conclusion was that most of the opinions of the parliamentary committees were positive and the suggestions are beneficial for the law draft. The final conference, that took place on 20<sup>th</sup> of May 2010 and had 40 representatives from different governmental institutions, including from Ministry of Culture, General Prosecutor, Ministry of Internal Affairs, Hall of Chisinau, universities and others. Representatives from Ministry of Internal Affairs and General Prosecutor showed interest towards the problems that were discussed and stated the availability for further collaboration and exchange of information in the field of cultural heritage preservation of Republic of Moldova.

**Mass media campaigns.** The project was supported by an information campaign to raise the public awareness on the necessity to adopt an efficient protection policy for archaeological heritage. So, we made a series of radio shows, we published a lot of articles in the national written mass media about the problems discussed in the project (copies of the articles are attached). Also, we de-

veloped and distributed leaflets, posters and two compilations of normative acts and international conventions that facilitated the disclosure of the population about the problems approached in the project. On 13<sup>th</sup> of April 2010, was organized a round table with the participation of Mr. Vitalie Josanul, officer in heritage police of Neam county, who presented the experience of Romania in fighting against the violations that leads to damages or destructions of historical heritage. The approached subject attracted the Mass Media interest and was highly mediated.

The Law on Archaeological Heritage Preservation was adopted by a unanimous vote, including the vote of the communist faction which traditionally being in opposition does not support any democrat initiative, by the Parliament of Republic of Moldova on 17<sup>th</sup> September 2010 and enacted by Presidential Decree on 24<sup>th</sup> November 2010. The Law entered into force three months after its publication in the Official Gazette (*Monitorul Oficial*) of 3<sup>rd</sup> December 2010. Therefore, from 3<sup>rd</sup> March 2011, the Republic of Moldova has had a new preservation system for its archaeological heritage.

This Law is the first of its kind in the legislation of Moldova and was elaborated according to own experience, experts' recommendations, Valletta Convention (1992) and ICOMOS Charter (1990). The Law on Archaeological Heritage Preservation of the Republic of Moldova contains 48 articles grouped into 11 chapters. The Law on archaeological heritage preservation opens new perspectives for Moldovan society to improve the situation in the field, and to fight black archaeology and illegal trafficking of antiquities. With this Law the Republic of Moldova aligns itself to other European countries and honours, first of all, its commitments taken with signing the Valletta Convention, and second, other European and International field Conventions.

The preparation, discussion and the lobby process for the project law on preservation of archaeological heritage undertaken by an NGO initiative and supported by the democratic Government a serve as a good practice example of partnership between civil society and state bodies. However, a durable cooperation between these two parts is required in order to improve the situation in the field of archaeological heritage preservation.

**Acknowledgements:** This research is part of the Project "Current trends in archaeological heritage preservation: the national and the international perspectives", supported by CNCS –UEFISCDI, PN-II-ID-PCE-2011-3-0610. Institute of Archaeology of the Romanian Academy, Iasi branch, Romania.

## 1. CONTRÔLE SCIENTIFIQUE ET QUALITÉ DES DONNÉES ARCHÉOLOGIQUES À L'INSTITUT NATIONAL DE RECHERCHES ARCHÉOLOGIQUES PRÉVENTIVES (INRAP) EN FRANCE

*Augereau, Anne - (Inrap) anne.augereau@inrap.fr*

*Koehler, Alain - (Inrap) alain.koehler@inrap.fr*

En France, la réalisation des interventions de diagnostics archéologiques et de fouilles fait l'objet d'un contrôle scientifique et technique par les services du ministère de la Culture qui sont aussi les services prescripteurs des opérations. Les rapports d'opérations sont ensuite évalués en commission scientifique. Mais la qualité des données récoltées sur le terrain est l'affaire de l'opérateur. C'est lui qui définit et contrôle les moyens, les méthodes et les techniques utiles à l'atteinte des objectifs de la prescription ; c'est lui qui est responsable de la qualité des informations archéologiques. La qualité de ces dernières doit s'évaluer à toutes les étapes de l'opération, du terrain à l'analyse scientifique, et toujours au regard des protocoles d'échantillonnage définis qui fondent la représentativité des séries ainsi recueillies.

## 2. PREVENTIVE ARCHAEOLOGY AND SCIENTIFIC RESEARCH: ALLIES OR ENEMIES?

*Demoule Jean-Paul - (Université de Paris I, France) jpdemoule@orange.fr*

While the term heritage normally refers to the transmission of property within a family, the term Cultural or Archaeological heritage refers to a national or ethnic community. Although national identities in the modern sense of the term only appeared in the early 19th century, there have for some time been two different conceptions of the State in the western world. In countries based on Roman law such as France, the State, even if it is disliked, is central to the conception of society. In "common law" Anglophone countries, and especially the USA, the State has never been completely legitimate. This view was further reinforced in the nineteen-eighties through the domination of Milton Friedman's free-market ideology and neo-liberal governments. In their sense, there is no real society any more, only a juxtaposition of consumers, buying or not buying goods and services in a market controlled by an "invisible hand". This situation has direct consequences for scientific researches in the field of

preventive archaeology, sometimes called « developer-led archaeology ». For economic liberal ideology, developers are not economic agents threatening our shared archaeological heritage, who should pay for excavation to conserve it: they become "clients" who chose between different producers, in this case the private companies doing archaeological excavation. This view has had disastrous consequences in terms of research, since many excavations carried out through Cultural Resource Management have never been studied or published. It also has ethical and political consequences for our conception of our common past.

## 4. SCIENTIFIC CONTROL OF STANDARDS OF RESCUE ARCHAEOLOGY IN RUSSIA

*Engovatova, Asya (The Institute of Archaeology of the Russian Academy of Sciences) - engov@mail.ru*

There are approximately 60,000 registered archaeological sites (40% of Cultural Heritage sites). Over 1500 archaeological projects are undertaken annually in Russia.

Rescue archaeology projects undertaken in Russia have risen significantly, now accounting for over 70% of all archaeological research in Russia.

The principle recent trend is a sharp increase in the proportion of rescue archaeology projects undertaken by non-State companies. Since 2006 the number of projects undertaken by private companies has more

then trebled. By 2012-2013 their share of the overall number of projects had risen to around 40%.

The pace of change is largely due to Russia's taxation system. Economic reform has enabled tax-breaks stimulating the growth of non-State business. Yet State organisations (museums, universities, affiliates of the RAS) enjoy none of these tax breaks. The playing field is not level - making it more attractive for both the contractors and the clients of such works to use non-governmental agencies.

This situation raises the serious question of the scientific control of such works.

Background: archaeological research can only be undertaken within Russia with official permits – the "Open List" permit, issued by the Culture Ministry. The first phase of control of archaeological works is the Culture Ministry's consideration of applications – the "Rules For Issuance, Suspension and Termination of Open List Permits" (under Governmental Decree 127, 20<sup>th</sup> Feb 2014).

The next stage of control applies when applications are referred to the Scientific Council for Field Studies of the Russian Academy of Sciences (RAS). RAS verifies applications for compliance with approved procedures in principles of fieldwork, research methodology, and the professional competence of the proposed team. Permits are issued only to specialists with relevant qualifications and fieldwork experience (or involvement in fieldwork, for first applications).

All approved Open List projects must submit a Scientific Report to the Scientific Council For Fieldwork, to demonstrate compliance with scientific practice and fieldwork procedures, and this report must meet specified criteria. Inadequate attention to the Scientific Report constitutes grounds for rejection of the Open List application. Open List applications may also be rejected for applicants who have failed to submit a Scientific Report for previous projects.

Common rules for fieldwork emerged in the previous century, establishing mandatory reporting in established parameters, laid down in the "Procedural Regulations for archaeological fieldwork and compilation of scientific reports". The Institute of Archaeology follows these requirements scrupulously. The regulations apply equally to Rescue Archaeology, and there is no simplified version – to ensure that research standards prevail. Recently attempts were made to pass rules applying to observational researches, but they apply only in cases of

research into damaged archaeological sites.

The result is that the standards of archaeological research are in the hands of the RAS, which passes its findings to the Culture Ministry – as specified by Federal Law N 245-FZ (July 23<sup>rd</sup> 2013).

### **5. TROIS CAS DE PROSPECTIONS RELATIFS À DES DIAGNOSTICS ARCHÉOLOGIQUES EN CÔTE D'IVOIRE (2008-2010): LES ENTREPRISES D'EXTRACTION MINIÈRE LEVIER POUR UN NOUVEL ORDRE ARCHÉOLOGIQUE EN CÔTE D'IVOIRE ?**

*Kouassi Kouakou, Simeon - (Département d'Archéologie Université Félix) [arqueo@terra.com.br](mailto:arqueo@terra.com.br)*

L'archéologie préventive n'est pas encore appliquée mais commence à être pensée en Côte d'Ivoire. En témoigne la réceptivité, croissante, des autorités chargées de la prescription des Etudes d'Impact Environnemental et Social (EIES) de l'Agence Nationale de l'Environnement (ANDE) et du département de l'Environnement, Assainissement et Hydraulique du Bureau National d'Etudes Techniques et de Développement (BNETD). Ces à ces deux structures du pays qu'il revient de faire prendre en compte le volet culturel ou archéologique, selon les directives opérationnelles des bailleurs de fonds dont la Banque Mondiale, lors de l'élaboration des Termes de Références (TDR) des EIES.

En attendant que les archéologues soient associés dans les normes, c'est-à-dire sur la base de la loi et des décrets d'application nécessaires aux travaux, certaines entreprises qui opèrent dans le domaine des mines commencent à accepter des interventions d'archéologues.

Les résultats des prospections, soulignent l'importance des sites et vestiges répertoriés. Ils montrent en outre, l'opportunité qu'offrent de telles initiatives pour la recherche scientifique et l'enrichissement des fonds des musées du pays.

### **6. WHAT DO WE WANT TO SAVE? A CASE STUDY OF RISK ANALYSIS AND QUALITY CONTROL IN THE PORT OF RIO DE JANEIRO, BRAZIL**

*Robrahn-Gonzalez, Erika Marion - (DOCUMENTO / UNICAMP) [erika@documentocultural.net](mailto:erika@documentocultural.net)*

Archeological research done in the port region of Rio de Janeiro has revealed the presence of a complex and well preserved juxtaposing of building structures in the city's underground. Dated from the 17<sup>th</sup> century, when Rio de Janeiro became the center of political occupation for the Portuguese Crown, these remains are representative of colonial and post-colonial Brazilian history.

The port region of Rio de Janeiro is currently undergoing intense urban remodeling with a large volume of ongoing engineering work. In this context, the archeological research we have been developing over the last years in an area equivalent to five million square meters in the heart of the Rio de Janeiro port has two major main challenges, namely:

What do we want to save, considering both scientific and sociopolitical perspectives?

Which methodology and technological tools can help the current and future management of this archaeological underground heritage?

How can we integrate, in real time, the different group of interest and stakeholders involved (including the archaeological heritage management organs and construction entrepreneurs) in light of our need for high dynamics and speed in decision making?

How can we make this knowledge more tangible for society as a whole?

This exposition aims to analyze the development of these researches in the port of Rio de Janeiro and their current results considering these challenges, including aspects of attaining goals, quality control and risk analysis.

## 7. RESEARCH TOOLS FOR REGIONAL QUALITY ASSESSMENT AND PROTECTION

*van Leusen, Martijn - (Groningen Institute of Archaeology)  
p.m.van.leusen@rug.nl*

A *proactive* preventive archaeology, at a regional scale, must rely on the provision of adequate information about the current state of the archaeological resource (taken to include not only the known but also the unknown remains). It must also be adequately informed about the processes that are now operating to damage or destroy that resource.

As a by-product of research recently conducted by my team in the Raganello Basin (northern Calabria,

Italy) we can now report on 'good practice' developed in the detection and assessment of a protohistoric rural landscape that had previously been completely overlooked in both the upland and lowland parts of the study area. It will be argued that the piecemeal destruction of ancient rural landscapes poses a special challenge to heritage managers because of the dispersed nature of the resource and the threats, and that regional quality assessment strategies based on a general classification of landscape types should be put in place so that the limited management resources can be directed where they have the most beneficial effect.

## 1. PEOPLE'S AWARENESS AND SUSTAINABLE DEVELOPMENT: CHALLENGES AND OPPORTUNITIES ON A CONTINUOUS ARCHAEOLOGY IN BRAZIL

*Robrahn-Gonzalez, Erika Marion - (DOCUMENTO / UNICAMP) erika@documentocultural.net*

In Brazil at the environment licencing of new project, actions intending to increase the participation of the affected communities are a constant. There are a wide range of actions possible but those can be exemplified mostly with public hearings aiming the directed impacted communities of the project in this way creating a debate, documentation and awareness of the impacts of the work, control measures and risk analysis.

The participation of society in such processes has caused several movements directed the theme of environmental management and also created a new demand on cultural aspects. This projects involving society brought to surface the people's fight to understand their roles in society as well as their cultural and historical heritage.

As a result, a new area of actions was created for Archaeology where studies must not only reveal aspects connected to the country's past, but must also include historical and cultural aspects of the current communities. In response to this, researches in Brazil have adopted the principle of shared work with the cultural groups that live in the spaces where these researches are conducted.

Therefore the community has become a partner and an integrating part of the research projects whose goals are, among others, the construction of a critical history produced together with the interested parties and with the intention of valuing and promoting their cultural diversity.

This exposition aims to analyze researches developed in Brazil from the perspective of Continuous Archaeology, integrating communities with their past through the concept of Cultural Environment. This exposition will also analyze the results obtained in the sustainable management of cultural heritage in search of an archaeology of the present.

## 2. THE ARCHAEOLOGICAL PROJECT OF BAIXO SABOR: AN OVERVIEW AND FUTURE CULTURAL MANAGEMENT PERSPECTIVES.

*Soares de Figueiredo, Sofia - (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) sofia.csf@gmail.com  
Dordio, Paulo - (ACE- Odebrecht/Bento Pedroso Construções e Lena Construções) paulo.dordio@bsace.pt*

The hydroelectric project of Baixo Sabor is the largest one currently undergoing in Portugal and will submerge an area of around 3,000 hectares in Northeast part of the country, namely in the Trás-os-Montes region. The consequent impacts on the landscape have led to an unprecedented and ambitious archaeological survey- The Plan of Heritage Protection (PSP)- that has attracted major investment and involved both private and public entities.

Although the construction began in 2008, the Plan of Heritage Protection has only been fully established in 2010 and has worked different dynamics in the territory, from Pre-history to the present day. The project main goal, in terms of how it has been designed, is to develop the so-called salvage or the integration of preventive archaeology into wider scientific studies, making it possible for a profound knowledge related with one of the most isolated regions in the country to emerge. Over the past four years, an unexpected cultural heritage has been identified in the Sabor valley; in fact, the area stands as the location of a few unique sites in Europe.

This paper has three main goals. The first is to establish a balance in terms of the implementation, management and outcomes of the Plan of Heritage Protection, characterized as one of the largest archaeological projects ever to be carried out in Portugal, and involving over 200 professionals and 15 specialized companies dealing with heritage. The second is to evaluate the role undertaken by the different entities involved in the process, which are both private and public. Our third aim, and considering that the Plan of Heritage Protection is coming to an end, is to outline a cultural and heritage sustainable development strategy, one that is able to generate social and economic benefits for local population.

ORAL

### 3. STONE - CARVING IN VARANASI (INDIA): PAST & PRESENT PRACTICES

*Jayasawal, Vidula - (Jana-Prava, Centre for cultural studies and research, south of Samneghat, Varanasi) vidula.bhu2@gmail.com*

One of the oldest cities and also a rich cultural centre of India, Varanasi provides good opportunity to study traditional crafts. Stone chiseling in Varanasi had glorious past, and is still practised. Description of ancient text and archaeological findings corroborate the antiquity, while the carving centers of today evince utility of this craft in the modern society.

The two prevalent traditions which stand distinctively apart from each other fulfill quite divergent needs of the society, and are performed by two different set of chiseler. The one with undisrupted continuity and wide practice is confined to making of daily utility articles, like pestle, quern, simple components of architecture (patia), etc. While the other is a specialised chiseling art through which icons and decorative composition are produced. It is this category which forms subject of the present theme. Since, it goes hand in hand with the changing custom, conventions, and economy of the society on one hand and quantum based mastery of craft skill on the other. The field studies carried out by the author, both at the archaeological sites, and the main culture making centres of modern times, in Varanasi region, bring forth various important aspects of the craft.

Starting from the acquisition of raw material, - suitable stone for carving, for instance, is an important factor, - governing both, the execution skills and price of the finished produce. Similarly, the technological knowhow and mastery is another aspect of craftsman ship, which is primarily a family skill transmitted from father to son. However, individual artistic amplitude also plays significant roles in earning reputation of a sculpture workshop. Needless to mention, that the socio-economic status of the craftsman, as well as, the customers adds substantially to the make up of any craft, a lithic chiseling is no exception. The need base growth of craft centres if clubbed together with techno artistic mastery does help a craft earn high reputation which, result in the uplift of the economic status of the craftsman, who in turn can further enrich their skill and imagination.

Policies which could promote need of the craft produce and sustain artistic amplitude of craftsmen with eco-

nomie packages may put a barrier to the erosion of traditional crafts of South and Southeast Asia.

ORAL

### 4. A STUDY OF THE ARCHAEOLOGICAL SITES OF THE BIRBHUM DISTRICT, BENGAL? ITS MANAGEMENT AND SUSTAINABLE DEVELOPMENT

*Basu, Asmita - (Academy for Professional Excellence - APEX) asmita.basu2011@gmail.com*

Extraordinarily rich, vast and diverse cultural heritage in the form of built heritage, archaeological sites and remains since the ancient times are the symbols of both cultural expression and evolution. Ancient temples have been considered as the major sources of various religious faiths, philosophical aspects, cultural and architectural heritages. Birbhum, the land of the red soil" is also referred to as "the land of the brave" in West Bengal and a significant temple town in Eastern India. Several brave kings have dominated Birbhum since the beginning. Remnants of civilizations add profound historical importance to the region. Culturally rich and studded with a number of temples and heritage sites, Birbhum has been an important area of study. Temples of this region combine harmony and symmetry with a high quality of outer embellishments. The lack of interest and comprehension of the past and heritages is turning into a threat for the future generations. Manifestations of Archaeological sites expressed in cultural forms are losing their traditional essence in a rapidly transforming world with modern lifestyles ushering in an era of industrial growth and economic development. In the present scenario sustainable development has become an important challenge to deal with particularly in the age of modernization. It is of utmost importance in this situation to maintain a correlation and cooperation between archaeological heritage management and the new age principles of management.

The present study aims to highlight the growing challenges and possible remedies of sustainable development of archaeological sites through a case study of the temple sites in the Birbhum district of West Bengal, India. The materials have been collected through the field work in this region. Some important temple sites have been selected for the purpose of the study namely- the Temple sites of Supur, Ghurisha and Jaydev -kenduli on the bank of the Ajay river. Different tools of strategic management has been used to analyse the data such as SWOT analysis, competitive advantage analysis etc in

order to achieve sustainable development of the region. As a result we can understand how the application of strategic management principles in the present scenario can help to strike an appropriate match between the internal and external environments which leads to a positive effect on the sustainable growth and development of the region.

In conclusion we may say that the cohesion between the two disciplines namely- archaeology and strategic management will not only lead to the sustainable development of the archaeological sites but also to the economic growth and development of the region. Unprotected monuments and heritages in danger can be revived with the help of building a bridge with the Corporate as well as other Government and Non- Government agencies. Financial support and infrastructure development could be the key support obtained from the corporate world for the sustainability of the sites.

ORAL

## 5. A STUDY OF PREHISTORIC CULTURAL HERITAGE AND MANGAMENT IN ORISSA, INDIA

*Debasis, Kumar Mondal - West Bengal State University)*  
*anth.debasis@gmail.com*

Orissa in India has rich cultural heritage rooted to prehistoric period. There is a continuous habitation of prehistoric people from Lower Paleolithic to Mesolithic, Neolithic and Chalcolithic periods.

An in-depth observation has been made in the prehistoric sites of Shigarh in Angul district and knuar in keonjhar district, in Orissa, India. Shigarh is a site yielding continuous evidence of Paleolithic to Neolithic culture, whereas knuar is a Chalcolithic site. The two sites were studied in view of evaluating the prehistoric culture of the area, the present human activity and causes of destruction due to natural process as well as ignorance. An archaeological site of historic period may be protected but the prehistoric sites are usually neglected in India. The present study is an approach to study the prehistoric culture of Angul and Keonjhar districts in terms of geo-physical setting. The different agents-natural and human activities causing destruction of sites are also examined in the study.

The present study is an approach to make plans and for steps to be taken for protection of these prehistoric sites. the protective measures taken in global context and

their figibility in the area under study is highlighted in the present study.

## 6. HERITAGE OF SKILL IN MAKING CLAY ORNAMENTS IN INDIA

*Chakraborty, Koyel - (Anthropological Survey of India)*  
*kchakraborty88@gmail.com*

*Ray, Ranjana - (Emeritus Professor, Calcutta University) Prof.*  
*ranjana.ray@gmail.com*

Personal adornment is a part of cultural heritage for human being. There is an ample evidence for the use of various kinds of ornaments from the prehistoric to present day. Ornaments made out of clay emerged as early as Neolithic times in India. Indus Valley civilization yielded large number of ornaments made out of clay. A study of clay made ornaments has shown a typological continuity in design and decorations. Clay ornaments, specially the bangle and amulets not only have decorative value but are also connected to a some kind of ritualistic practices. In modern days clay made ornaments have taken a large area in the fashion world. There is a great demand for clay ornaments. Craftsmen have special skill in making the terracotta ornaments. There are ear pieces, neck pieces, pendants and bangle made out of terracotta. It is interesting to note that though in India potters are a caste group who make pots and idols out of clay but the craft of making clay ornaments are now taken up by different caste groups as well. Main reason for this may be the demand. However special skill and knowledge is required for making the clay ornaments. Present study would highlight the aesthetic and ritual values of this unique heritage that is still cherished by Indians and by people from the other countries as well.

ORAL

## 7. INDIGENOUS KNOWLEDGE AND SKILLS OF THE BHOTIYA WOMEN OF UTTARKASHI

*Subhadra, MitraChanna - (Delhi University) channa.subhadra@gmail.com*

The woman of the pastoral sheep herding communities on the upper Himalayan ranges have nurtured skills of wool processing, knitting and carpet weaving from the distant past. they have developed skills passed down the generation for making beautiful items out of raw wool

that is given to them by the men of their community, who herd sheep and go long distance trading as a livelihood. The women, who are tabooed from going to the pasteur, receive the wool in the village and know how to process, spin and dye the wool and then either knit or weave carpets out of them. they have nurtured these skills as household work and are today able to use it for commercial purposes and find a ready market for many of their items. These conditions to market is giving them cash income and is supportive of their social transaction such as, gift giving. The women are able to sustain their traditional role playing and augment in the changing circumstances while keeping alive their traditional craft and skill. Although they sell their product in the market, every item of production is still collected by them from primary sources and is part of their natural environment. This community is one of the several that have traversed the natural geographic barrier of the Himalayan range for centuries, ferrying resources from one region to another, using the natural passes made by the river gorges. These age old practices have continued till almost the present time but are today threatened by climatic change and man made changes in the environment.

This paper will discuss the inter phase of indigenous knowledge, traditional skill and a cash economy in the back drop of a subsistence mode of living and long sustained life was that have evolved in relation to a particular habitat and livelihood pattern. It will also touch up on the transformation brought about by climatic and technological changes.

## 8. MUSICAL HERITAGE OF NORTHEAST INDIA: AN ANTHROPOLOGICAL OVERVIEW

*Choudhury, Manimugdha - (Assistant Professor, Department of Anthropology, Dibrugarh University, Dibrugarh-786004, India) choudhury.imax.manimugdha@gmail.com*

Comprising of seven states, viz, Assam, Arunachal Pradesh, Meghalaya, Nagaland, Mizoram, Manipur and Tripura, the North-East India forms part of the East Himalayan region which extends from Sikkim eastwards and engulfs the Darjeeling Hills of West Bengal. With its long border extending over 4800km, it occupies an extremely strategic position and it is connected with the mainland India by a narrow corridor of foothill land in North Bengal. Such terrestrial location of North East India makes it into an isolated pocket which is one of the important causes for alienation of its population. The location of

this region is important as it shares international borders with Bangladesh, Bhutan, China, Myanmar and Tibet. All the seven sister states of North East India are inhabited by a number of ethnically and linguistically diverse native tribes which have their own distinct traditions of art, culture, dance, music and lifestyles.

Music is an art with unending ramifications and innumerable psychological and cultural affiliation which has always played a crucial role in human society. The general musical form of North East India stamps the characteristics of the whole region. The racial admixture of the various groups of people, settled in this region has tremendously contributed to the folk music of the different groups of population. Each group of the region maintains its own peculiar musical traditions.

The music of North East India constitutes an emotional bond among peoples of different levels of culture. So the folk and other type of music of the North Eastern part of India is the spontaneous musical expression of the masses of this region among different tribes and sub-tribes. Most of the people of this region are agriculturists and reside in the rural areas. The music of the tribal people of this region is always associated with a dance, along with vocal and instrumental music. They cannot even dream of any form of dance without vocal and instrumental music. Folk music of the region is generally performed in chorus accompanied by musical instruments of varied types.

This paper is a humble effort in depicting the diverse musical heritage of the variegated North East India.

ORAL

## 9. SAURA PAINTING : TRIBAL ART OF ORISSA

*Mondal, Munmun - (University of Calcutta, India) moonmoon131413@rediffmail.com*

Orissa is rich with tribal cultural assemblage. Sauras are one of the oldest tribes of India. Saura tribal paintings are mainly 'wall murals' in their houses based on religious and ceremonial themes. Sauras are among the most ancient tribe in India and find mention in the Hindu Epics of *Ramayana* and *Mahabharata*. Aborigines of Saura tribe bear close racial affinity to proto-austroloid tribes that dwell most part of the central and southern India. Saura Art is mainly found in Rayagada, Gajapati and Koraput districts of Orissa. The Saura wall paintings are called *italons* or *ikons* (or *ekons*) and are dedicated to Idital (also *edital*) the main deity of the Sauras. These paintings draw

upon tribal folklore and have ritualistic importance. One of the integral elements of **Saura paintings** are the geometrical shapes that are used to create bold borders for the center-piece that is invariably drawn in fine lines. No features are drawn on the human face but the characters can tell us stories with their 'gestures' even without the facial expressions.

Ikons make extensive use of symbolically pregnant icons that mirror the quotidian chores of the Sauras. People, horses, elephants and the sun and the moon and the tree of life are recurring motifs in these ikons. Ikons were originally painted on the walls of the Saura's adobe huts. The paintings' backdrop is prepared from red or yellow ochre earth which is then painted over using brushes fashioned from tender bamboo shoots. Ekons use natural dyes and chromes derived from ground white stone, hued earth, and vermilion and mixtures of tamarind seed, flower and leaf extracts. Ikons are worshipped during special religious and cultural occasions such as child-birth, harvest, marriage and the construction of a new house.

Saura art is very colorful and is one of the obscuring local traditional craft practiced in Orissa, India. My present paper intends to study the antiquity and characteristics of this local art of Orissa with special reference to its preparation, processing and execution with social content.

ORAL

## 10. CULTURAL RESOURCE MANAGEMENT OF THE VANISHING IVORY CRAFTSMANSHIP OF MURSHIDABAD, WEST BENGAL, INDIA

*Saha, Sudipa - (Ph. D. Student, Calcutta University) sudiparalap@gmail.com*

India is a country of rich cultural heritage both tangible and intangible. This reflects in its countless age old indigenous craft traditions. Among those ivory craft had a long antiquity date back to the time of Indus civilization and continuously practiced still the complete ban of it in 1990. Several centers of ivory carving developed at various places of India. Among them Murshidabad of Bengal was internationally famous for its outstanding craftsmanship. However, the high demand of ivory articles in different parts of the world led to the ruthless killing of the elephants. The cultural use of the natural heritage for a long time became a major threat to each other. When the conflict became severe in nature and caused the depletion of the very existence of the elephant then the

art had to be sacrificed for the sake of the survival of the nature's creature. As such: in 1989 an international ban on ivory trade had completely stopped the practice of the ivory craft in India. There are other heritage crafts of India which are still fighting with the kind of conflict for their existence like conch shell carving, sandal wood carving, rose wood carving and so on. The question is whether the craftsmanship of these kinds of crafts can be saved by a sustainable use of natural raw material/ alternative material or not? If possible then how it can be done? The ivory carving industry of Murshidabad was confined within the hereditary carver family belonging to the *Bhaskar* community. After the ban they tried to survive by applying their skill and knowledge on carving of some alternative materials like, sandal wood but now a days only very few of them are in their hereditary profession. Here in this research work an attempt has been made to find out the probable causes of the disappearance of the craftsmanship and to formulate a fruitful safe guarding policy for revitalisation of the outstanding craftsmanship.

ORAL

## 11. MASK OF CHHAU- A TRIBAL HERITAGE THROUGH THE AGES IN WEST BENGAL: AN ETHNO-ARCHAEOLOGICAL STUDY IN CHARIDA GROUP OF PEOPLE

*Bhattacharyya, Banani - (The Ramkrishna Mission Institute of Culture, Centre for Indological Studies & Research, Kolkata) banani303@yahoo.co.in*

A mask is an important part of theatre craft that is worn normally for performance in dramas or plays, or for amusement. Masks have been used since antiquity for both ceremonial and practical purposes. Masks are believed to embody the spirit of an ancestor, and symbolize a message of wisdom, prosperity, security, and power. It has been worn in cultures throughout the world for thousands of years. These are made of varied materials including paper, cloth, grass, leather, metal, wood etc. They are painted with symbolic designs and vivid colours. Masks and their manifold forms are a very significant mode of cultural expression.

The masks generally made here are of mythological character. The craft of mask making in West Bengal is closely related to the folk dance forms. Purulia district of West Bengal is a place where masks are found in huge variety especially wood masks. Tradition of West Bengal allows the artists to wear masks made of various materi-

als among which wood plays an important role. *Chhau* dance is a mask-dance which represents characteristics of primitive ritualistic dance in its vigour, style and musical accompaniment. Wood masks in West Bengal are the creations of the artisans who with their exclusive use of cuttings and colours give the masks a touch of their originality. The wooden masks of west Bengal have become a popular theatre craft, admired for its simplicity. The wooden mask makers are generally the wood-carvers by caste. The artisans for `Chhau` masks are mostly located in and around Charida and Bagmundi of Purulia district. *Chhau* is a performing art of dance and music which is intimately connected to Chaitra-Parva, the festival of spring celebrated in April every year. This has a special significance to the art through the rituals connected with it. The festival lasts for thirteen days in which the whole community participates. The usage of stylized masks is an important component of Purulia *Chhau* dance. This requires skilled craftsmanship which has also evolved as an art in itself and is being preserved by its community. The craft of mask making along with *Chhau* dance has been a tradition here for well over a century. Charida village in Purulia can be safely attributed the title of "The *Chhau* capital of India". This village has a long tradition of *Chhau* dance even from the days before independence. This fame of the village has not still lost its sheen after 64 years of independence. The paper describes historical background, material used, traditional methods of preparation and cultural significance of masks and also highlights the musicological, psychological and philosophical significance of these masks and focused description of the *Chhau* masks of Charida, West Bengal.

## 12. TRADITIONAL WOOD CRAFTS AMONG THE TRIBES OF ARUNACHAL PRADESH: ISSUES CONCERNING PRESERVATION AND PROMOTION OF CULTURAL RESOURCE

*Chaudhuri, Sarit K. - (Rajiv Gandhi University) saritkchai@rediffmail.com*

Wood craft constitute one of the finest cultural heritages in the context of Arunachal Pradesh - a state sharing its border with China, Burma, Bhutan. This craft tradition is practiced by some of the major tribes of this state who reflect different cultural contours. For instance, wangchos and Noktes of Tirap district can be broadly categorised as animist (in traditional sense), whereas other tribes like Monpa, Sherdukpen of West Kameng and Khampei of Lohit districts represent Buddhist tradition. In all these

tribes, such craft tradition was emerged out of various socio-political as well as religious context. This paper will be a discursive discourse on the history as well as various forms of wood craft tradition of such tribes. An attempt will be made to understand what is happening to such cultural heritage in the context of a market driven one where such tribes are well exposed to wider realities of life. And finally it will examine what role the state and other agencies have initiate to preserve and promote this valuable craft tradition of the tribes of Arunachal Pradesh.

ORAL

## 13. BUILDING AN ETHNOGRAPHY OF LANDSCAPE--AYODHYA HILLS IN PURULIA, WEST BENGAL, INDIA.

*Bishnupriya, Basak - (Calcutta University) basak.bishnupriya@gmail.com*

This paper is part of a wider project on understanding the prehistoric landscape of Ayodhya hills, Purulia. Numerous microlithic occurrences were located in the foothills of Ayodhya range, all sharing the same geological horizon and dated to the late Pleistocene. A detailed study of the site, their location and assemblage show that the major zones of activity were concentrated around prominent natural marker like isolated hills and rock outcrops. Working within the paradigm that landscape is a culturally constructed phenomenon; I wanted to see whether any special significance could be assigned to these artefacts occurrences located close to outstanding natural features. In recent years archaeological approaches in drawing on cultural geographical and cultural anthropological understanding of landscape have shifted from an understanding of archaeological site to places in the landscape. In exploring perceptions prevalent among indigenous communities of the non European world ethnographic research has gone beyond a European construct of the landscape, thus highlighting its contextual nature. Landscape has emerged as dynamic and varied, offering archaeologists with rich insights to work with in unravelling the mysteries of the past.

The focus of this particular paper is on perceptions of landscapes surviving among the indigenous communities living in this region, in the form of ritual, ceremonies, songs, myths and legends, preserved solely in oral tradition. I am using these as critical tool not to establish any unbroken continuity with the past, but to develop an alternative vision of the prehistoric landscape, thus looking beyond artefacts concentrations which are often the only signatures remaining of the archaeological record.

## 1. UNE ACTIVITÉ ÉDUCATIVE INCLUSIVE: L'IMPLICATION D'ENFANTS DANS LES FOUILLES ARCHÉOLOGIQUES RÉELLES SUR LES SITES HIS- TORIQUES

*Ramos Soares, André Luis - alrsoaressan@gmail.com  
(UFSM)*

Ce document présente les activités du Centre pour l'étude du patrimoine et de la mémoire - NEP, l'Université fédérale de Santa Maria, Rio Grande do Sul, au Brésil, dans le développement des activités archéologiques dans lequel les enfants ont participé activement au processus d'excavation dans des conditions réelles. Ce rapport est une activité éducative dans laquelle les élèves de l'école primaire dans la municipalité de São Martinho da Serra, État de Rio Grande do Sul, pourrait participer à des fouilles avec une équipe de l'archéologie. Bien qu'il existe une pratique récurrente d'actions éducatives avec des sites archéologiques simulées, où les enfants peuvent avoir accès au champ de la pratique archéologique, dans la plupart des cas, l'expérience archéologique est associée uniquement à la fouille de sites. Dans d'autres cas, plus fréquents, l'éducation au patrimoine est limitée à des conférences, des brochures, ou autre matériel explicatif.

La méthodologie de travail a laissé les formes traditionnelles de l'éducation au patrimoine dans plusieurs projets existants. Constitue de petite conférence, démonstration de matériel archéologique, son importance pour la reconstruction du passé et du quotidien, ainsi que nous aider à comprendre comment les gens vivaient en d'autres temps et lieux, leurs habitudes de consommation, ce qu'ils pensaient, etc. La différence avec notre travail a consisté à permettre aux enfants intéressés à participer à l'excavation réelle d'une maison du XIXe siècle, l'objet de l'équipe de recherche. La maison, qui a été utilisée comme un espace politique et siège du gouvernement municipal, a été utilisée par d'autres personnes, avec d'autres utilisations jusqu'à son abandon et la ruine. De l'excavation du site de poubelle de la maison, nous pouvons voir les produits déversés et ses comportements économiques, sociaux, culturels, et comme l'hygiène, les soins médicaux, de la nourriture. La participation des enfants à des fouilles archéologiques simulé est une pratique quotidienne au Brésil. Cependant, dans de rares cas, il n'est pas permis aux non-archéologues de participer à des activités sur le terrain, contrairement à d'autres pays comme les États-Unis (Pilles, 1994) ou même en France. En dépit des soins qui

doivent être prises pour la conservation du matériel archéologique, ainsi que leurs caractéristiques telles que l'emplacement, l'intégrité, la spatialité, le contexte, entre autres, sûrement la participation des enfants peut devenir dangereux. Cependant, ce qui a été observé est que, précisément parce qu'ils ont reçu une meilleure préparation et une clarification des activités d'archéologie, nous pouvons affirmer que nous avons obtenu d'excellents résultats dans les campagnes impliquant des étudiants de l'enseignement élémentaire.

Les activités de l'archéologie avec les enfants sont bien connus au Brésil. Participation à des activités de biens archéologie a fourni une grande participation des élèves tout ce que l'expérience éducative durable. Observée dans les évaluations de l'engagement affectif des enfants avec le processus de recherche.

## 2. THE CULTURAL ENVIRONMENT ALONG THE BRAZILIAN AMAZON RIVERS

*Brugnera, Ana Carolina (Universidade Presbiteriana Mackenzie - Faculdade de Arquitetura e Urbanismo) carolina@arqueologiapublica.com*

The objective of this article is to shed a light over how the Cultural Environment composed by several occupation scenarios of cultural landscapes of the Brazilian Amazon river channels was formed. The environment, which is formed by a group of physical and cultural manifestations, reflects the result of intangible assets, such as traditional knowledge and practices of the communities that live or have once lived there, leaving behind edifications, objects, utensils, archeological sites, etc. The culture of native dwellers, as many other societies in the national territory, results from a long-term process of Amazon occupation by a diversity of cultural identities.

However, recent transformations affecting the Brazilian Amazon, due to a globalized and more competitive economy, consider the implantation of major projects that entail social and political contradictions emerging from the relationship between State and society. Facing this scenario, it is imperative that this landscape be analysed in an integrated manner, taking into account the social diversity and not just the existing traditional societies, as well as the organized civil society, the landowners' communitary leaderships, local state governments, companies and their different onlooks regarding the subject, thus enabling and promoting the Territory

Management.

As for the premisses mentioned above, we face a methodological challenge, especially regarding the application of concepts of Territory Management and Resilience to the traditional communities involved, aiming at obtaining results that will leverage sustainable actions, not only from the social and cultural point of view, but also from the economical and political standpoint. In the light of this challenge we will highlight research carried out by Brazilian research programs in the cultural environment of some communities living along the Brazilian Amazon rivers. Mapping of their archaeological, historical and cultural heritage, the sum of testimonies and involvement of local communities, including their way of life and traditional knowledge, technical and specialized analyses that will eventually lead to the interpretation of the cultural landscape – the Applied Science.

As a final goal, there are efforts to promote social inclusion and the strengthening of the native dwellers cultural identity. To achieve these goals we have been developing interaction tools, such as presential activities in the form of Workshops, and the use of social media through channels that promote interaction with research in addition to information democratization and creation of cooperation nets comprising the local community and whoever might take an interest in it.

### 3. SOCIOEDUCATIONAL MODEL FOR HORIZONTAL DISSEMINATION: THE CASE OF THE MIDDLE PALEOLITHIC OF EL SALT (ALCOI, SPAIN)

Jardón, Giner Paula - (Universitat de València) paula.jardon@uv.es

Pérez, Clara - (Darqueo estudio y difusión del Patrimonio SL) claraperez@darqueo.com

Most of scientific knowledge models of dissemination are unidirectionally and unequal strategies. That comes from a perception of the science as a product belonging to the archeologists, but transferred to main population. Some sociologists have pointed that contemporary worries usually are in the basis of many researches subjects. It is not a coincidence that gender approaches or sustainability questions are often focused. Why don't we ask main people about their real interests?. Why don't facilitate that citizens asks prehistorians?. The methodology for this study has been action-investigation and ethnological qualitative approaches. The theoretical frames are

Cultural Studies, Freire pedagogy and Public archaeology.

The preconception about prehistory and neandertals have been registered as a previous stage of an socioeducational intervention on the Batoi barrio of Alcoi placed near of the neanderthal site *El Salt*.

Then, researchers, neighbours, museum technicians and municipality politicians, we defined all together some educational actions. These consisted on:

- 1) interaction between prehistorians and people during the excavation processes.
- 2) work with children and young people in order to produce audiovisuals that they used for communicating to other neighbours and to students from other educational institutions in the city.
- 3) registration of ideas and questions asked from the participants.
- 4) Links between contemporary and prehistoric questions as educational and research object

A model of interaction between prehistorians and local population has been experimented and some lines for the futur have been traced. Some of these can be transferred to other sites contexts.

### 4. THE ANDAKATU PROJECT: AN EXAMPLE OF HERITAGE AND ARCHAEOLOGY KNOWLEDGE SOCIALIZATION

Cura, Pedro - (Museu de Arte Pré-Histórica de Mação) Opedrocura@gmail.com

Oosterbeek, Luiz - (IPT) loost@ipt.pt

Cura, Sara - (Museu de Arte Pré-Histórica de Mação) Osaracura0@gmail.com

Heritage education has assumed an increasing role in current mindsets, regardless of the different realities in terms of geography and socio-cultural frame. The Andakatu Project based in the Museum of Prehistoric Art of Mação (Portugal) is aimed at a wide audience and presents a programme, activities and contents arising from multiple archaeological research programmes conducted at the Museum and its partners (namely universities and research centres. Archaeology, being the starting point, is intertwined with various scientific and artistic aspects in order to encourage questioning, learning and citizenship through a communication based on interactive experimentation.

## 5. THE MANAGEMENT OF CULTURAL HERITAGE IN HYDROPOWER PROJECTS - VALLEY JAMARI, RONDÔNIA STATE

*Schwengber, Valdir Luiz - (UTAD) valdirluiz@gmail.com*

It is known the importance of preventive archeology in Brazil in recent years, considering the volume of work produced by the significant results that has been supplying to the various problems of scientific research and the dissemination of archaeological knowledge in the society. Studies conducted in the installation of power plants in the Valley of Jamari allowed the application of a Heritage Education Program and the production of teaching materials and the creation of a museum of archeology with the Federal Institute of Rondônia - Campus Ariquemes.

A total of 29 archaeological sites were excavated at the project level (PCH Santa Cruz, Jamari PCH and PCH Caanan). Of these, 21 are prehistoric sites associated with groups that produced pottery and polished stone artifacts, such as ax blades, etc.; and 8 are historical sites, which are associated with the rubber boom, the region that stretched from the 1930s until 1970. To date, we estimate that will compose the collection of the Museum of Archaeology of Porto Velho, just over 5000 artifacts, these, 4,800 excavated in prehistoric sites, and other historical sites. Remember that research continues to be done, so it is likely that this number will increase, reaching more than 6000 pieces.

The Archaeological Rescue Program, Monitoring and Heritage Education, associated with application of a term adjustment of conduct for the damage to an archaeological site allowed, besides the execution of a Heritage Education Program with schools in the region, producing a book that has as its object the dissemination of archaeological research in the State of Rondônia, with participation of several researchers who conducted and conducting research in the State of Rondônia. This material is distributed for research and educational institutions in the State of Rondônia and other federal units, as well as libraries, museums and cultural centers. The production of other bibliographical production (in print and on CD-ROM) will be distributed to public schools in the region. Moreover, we highlight the creation of a museum of archeology will be an important instrument for the intensification of archaeological research in this Amazon compartment.

The survey results revealed that pre-historic sites located in the area of ??research that we are conducting

are generally composed of fragments of simple ceramic pots without very elaborate decorations and plastic treatments, like those found on the banks of the River Madeira, for example. On the historical sites these are generally areas where they operated former rubber, which encompassed the area from obtaining raw materials to the family cemetery, which was located close to their houses. Are parts of everyday life that started the "Brazilian" settlement of this region. The archaeological licensing in accordance with the legislation establishing the preservation allows to perform a search in works that represent risks to cultural heritage. The growing participation of society in matters of collective interest stems from greater environmental awareness and equity contribute to minimizing the destruction to cultural heritage.

ORAL

## 6. HERITAGE EDUCATION STATE OF RIO GRANDE DO SUL : PROJECTS, ACTIONS AND POSSIBILITIES .

*Dias, Guilherme - (Colégio Militar de Santa Maria) guilhermediaspoa@bol.com.br*

This article aims to analyze actions in heritage education developed by the Center for Heritage and Memory Studies at the Federal University of Santa Maria developed in the period 2005-2013 and also demonstrate the possibilities of working in this field in the state of Rio Grande do Sul, Brazil.

The projects and actions analyzed in this study cover the development of local, state, national and heritage of Humanity. Are as follows: Building Models Playful as a support for the Teaching of History (2005) Heritage Education in the Municipality of Itaara, RS: War game board Guaranítica Saving equity and inclusion of the subject in the school curriculum (2007), and. (2009). The projects selected for analysis were developed by Core Studies Heritage and Memory under the coordination of Professor Dr. André Luís Ramos Soares team and were selected among others because they are as different ways of working with heritage education.

The actions developed by the projects were mainly the following results: In the project "Building Models as a Playful support for the Teaching of History" (2005) we did: - Enabled the production of models and support materials ( books that explain each part of the model ; Provided to teachers in elementary and secondary shock absorber material for the history lessons; Have you provided the trainees history course a didactic tool for the

discipline of practice teaching. In the project "Heritage Education in the Municipality of Itaara, RS: Redemption of equity and inclusion of the subject in the school curriculum" (2007) we did: Attended a partnership between City Hall and City University, favoring extension actions; Inserted the theme Equity Education in the school curriculum (for a period of 2 years); Held a survey of the heritage of the county; Promoted the involvement of teachers from different disciplines and two municipal schools; Guarani War board game. (2009); We privileged the playful teaching history; Provided support to teachers for teaching history material; Approached the theme of the heritage of history teaching.

After the analysis of the actions, our goal is to evaluate possibilities and demands in the field of heritage education in the state of Rio Grande do Sul showing the heritage education as fruitful for future teaching actions terrain research and extension. To this end we will draw an overview of state reality, with a brief history and state of preservation actions undertaken by municipalities, state and union.

### 7. L'ACTION ÉDUCATIVE EN ARCHÉOLOGIE FRANÇAISE : DEUX EXEMPLES RÉCENTS

*Justome, Elisabeth (INRAP) elisabeth.justome@inrap.fr*  
*Depaepe, Pascal (INRAP - UMR7194)*  
*pascal.depaepe@inrap.fr*

Parmi les missions de l'Inrap, inscrites dans le code du patrimoine, figure la diffusion des résultats de la recherche archéologique auprès des publics. Conférences, expositions, visites de chantiers archéologiques sont régulièrement organisées dans ce but. Les enfants, dans le cadre scolaire, péri ou extra-scolaire, bénéficient quant à eux d'actions spécifiques les mettant en relation directe avec les archéologues, leurs méthodes de travail, et les connaissances les plus récentes dans le domaine. Depuis 2013, les projets se formalisent sous le label EAC, obligatoire pour l'Inrap, établissement public sous tutelle de ministères, avec pour objectif de partager les actions avec plusieurs partenaires, sur un même territoire, sur un temps long et non plus ponctuel. Les différents exemples d'actions réalisées dans le nord de la France montrent que la socialisation de la connaissance archéologique est une réalité; et qu'elle fonctionne d'autant mieux que ces actions sont partagées avec les professionnels de l'enseignement et de la médiation.

### 8. ARCHAEOLOGICAL EXCAVATION, HERITAGE EDUCATION AND CLASS STRUGGLE: THE HOUSE OF DAVID CANABARRO IN SANTANA DO LIVRAMENTO, RIO GRANDE DO SUL, BRAZIL.

*Ramos Soares, André Luis alrsoaressan@gmail.com (UFSC)*  
*Dias, Guilherme*

This paper presents the activities of the Núcleo de Estudos do Patrimônio e Memória - NEP, the Santa Maria Federal University, Rio Grande do Sul, Brazil, in the development of archaeological activities at the home of David Canabarro a "Farroupilha" hero of the Revolution of 1835-1845. The archaeological excavation of this house generated great controversy in the local community. For one part, the representatives of Centers Gaucho Traditions wanted the space became a museum in memory of General "Farroupilha", and by other side, the social movement called "black movement" redeeming the role of this character in "Porongos Massacre", a battle in which the supporters of the revolution slaves were massacred by order of the General. In this article, we explain how the team developed archeology heritage education activities from the dispute of memory and history of the current agents around this character, at the same time to clarify the role of this person in his time and today.

The Methodology of work left alternative forms of heritage education, with teacher training and guided tours on site. It consists of activities with educators, demonstration of archaeological materials, its importance to the reconstruction of the past and daily life as well as help us to understand how people lived in other times and places, their consumption patterns, what they thought, etc. The difference of our work was to present for teachers both views about the "Farroupilha" hero, showing its pivotal role in this revolution, at the same time to demonstrate the legitimacy of the black movement in rescuing the story of betrayal that marked the end of the revolution where the slave question was peripheral issue of revolutionaries. For students of schools, we present the discussion of heroes and villains and how the interpretation of history may change over time. Children sought to make inquiries of the uses of materials in the past.

The perception of history is hardly questioned about social classes vying for the right memory, history and "truth" of the events that happened in the past. When confronted by the historical data both versions on the same character, archeology has questioned the role of research activities and their results to build the current

story. The material culture rescued this project resulted in several research also historical character, pointing out that General David Canabarro, who signed the peace among "farroupilhas" and Brazilian Empire, was also a slave until the end of his days.

Heritage education activities with teachers and students in public schools Santana do Livramento demonstrated that it is possible to perform an archeology and a problem-based education, engaging and full of questions. At the same time, led teachers and students to question their heroes and their historical characters, and the social groups that people base their lives public service.

*ub.edu*

The ways for communication are constantly changing. The immediately consequence is that nowadays, the information flows faster than years ago and it is more easily accesible to scholars.

ArcheoScience is a new Internet platform; a meeting point for researchers and anyone interested in archaeology. The aim of ArcheoScience is to provide all the tools to share and exchange the daily work in archeology. Discussion groups, events, publications, etc. can be shared to promote mutual collaboration among researchers.

One of the most interesting aspects of ArcheoScience is that it allows fostering simultaneous Online Databases (ODB). Databases are critical since they allow a direct comparison between modern samples and those coming from the archaeological record. In recent years, on-

line databases have achieved wide acceptance among researchers, since they allow easy and immediate access and can be continuously updated.

At present ArcheScience is fostering PhytCore. PhytCore is a phytolith database developed in 2010 by GEPEG (Research Groups for Paleoarchaeological and Geoarchaeological Studies) from the University of Barcelona. PhytCore includes digital images of phytoliths from modern plant material, modern soils and paleosoils, as well as archaeological material. PhytCore is structured to facilitate storage and modification of the data and the retrieving of information through one or various simultaneous queries. Phytoliths from modern material incorporate information related to the provenience of the sample as well as different ecological variables (elevation, hydrology, geology, plant cover, etc.). Archaeological phytoliths are linked to the information of the site, chronology, geographical location, level, etc. PhytCore is also open to other scholars or Research Groups who would like to participate. Researchers can share their own data without losing authorship. Sharing the fruits of the research of different teams will allow optimizing the available resources and will guarantee their continuation as well as they will ensure credibility.

ArcheoScience is directed to promote discussion between scientists to improve the quality of the archaeological research and the broadcasting of the information to all the public interested in history and archaeology. You can visit ArcheoScience at: [www.archeoscience.com](http://www.archeoscience.com)

**10. ARCHAEOLOGICAL RESEARCH AND HERITAGE EDUCATION IN PORT UNION / SC: CONTRIBUTIONS TO UNDERSTANDING THE PROCESS OF REGIONAL OCCUPATION.**

*Schwengber, Valdir Luiz - (UTAD) valdirluiz@gmail.com*

*Novasco, Raul - (UNISINOS) raulnovasco@gmail.com*

The Heritage Education is an inherent step archaeological research. In this sense, educational activities related to diagnostic, monitoring and archaeological excavations through which programs are carried out, we seek to establish links between the community and the existing archaeological heritage in the region. To this end, the research conducted at the archaeological excavation stage in the installation of hydroelectric Pardo in the town of Port Union, state of Santa Catarina, we obtained a lot of information about prehistoric and historic occu-

pation of that community that turned into a book, titled "a look at the process of occupation of Port Union: from prehistory to the present day."

First, educational activities were carried out with the aim of sensitizing the community to the local cultural assets. Surveys of immaterial culture, architecture, socio-economic data, and a special way with the archaeological research excavation of two archaeological sites were the main elements for the production of the book. This material was prepared with the purpose of serving as a reference source for teachers, students and anyone interested in knowing a little more about the pre-colonial and historic occupation of the region. The launch of the book "The process of occupation of Port Union: from Prehistory to the present day" held in May 2014 at the School of Basic Education Clementino Brito, Santa Cruz do Timbo, involved students, teachers, local residents, representatives of the hydroelectric plant, the Municipal Department of Education and the Regional Management of Education of Santa Catarina. During the event, plus the launch of the book, also storytelling activities were performed.

Analyzing the results of the survey, it is noted that the importance of archaeological research, be it due to a design of preventive archeology, as a result of environmental requirements, or whether it originated from an academic project, what matters is that this product is attention of the researcher and his commitment to the reality of people living around it, bringing significant issues to your life. Therein lies the value and the ethical principle of research.

## 1. ROCK ART, MUSEUM AND NETWORKING WITH TARGET PEOPLE

*Ray, Ranjana - (Calcutta University) prof.ranjana.ray@gmail.com*

*Chakrabarty, Mita - mita.chakrabarty@gmail.com (Indian Museum)*

Rock art in India goes as far back as Pleistocene period. Prehistoric rock art is widely distributed in hills and rock shelters of the country. There are ethnic communities living in the vicinity who are still practicing wall painting. Prehistoric rock art provides ideas on the contemporary artists, lifestyle, social and ritualistic aspects of prehistoric people and about the flora, fauna and environment of the prehistoric times. Folk art of the area provides with ethno-archaeological tools for reconstruction of prehistoric cultural elements. Most of the rock art sites are in areas away from the access of even of the local people. Excepting the rock art site of Bhimbetka, there is no site museum of prehistoric art in India. Bhimbetka is declared as world heritage site by UNESCO. It is a site museum managed by the Archaeological Survey of India. The surrounding landscape is maintained by the local authority. Major portion of Indian people are denied the opportunity of viewing such splendid art of prehistoric times. In this context the role of museum may be considered for connecting people to the prehistoric art. The target groups are both young and old, local and non-local, but focus is on the younger people starting from the school level. National level museums are situated in metropolitan cities. These museums usually bring prehistoric art to the notice target group. This is usually done with the projection of videos of the rock art and surroundings of the rock art site; by conducting workshops and by engaging local ethnic communities who live in the vicinity of the rock art site and who are still practicing wall art. This is done to enlighten target group on such activities of both the past and the present. Museum authorities use ethno-archaeological methods for such understanding. The present will discuss case of Indira Gandhi National Museum of Man (*Indira Gandhi Rashtrya Manab Sangrahalaya*), located in Bhopal, Central India. The museum is situated on a hill 46 Km away from Bhimbetka in the city of Bhopal. The hill has got a number of rock shelter housing prehistoric art. The museum conducts special exhibitions and workshops. Special attention is given on rock art. Target people are both local and non-local. Participants not only take a look at the replicas of the rock art at the museum but get a chance to visit the rock art sites next door. There are also interactive programmes with

the local artists. The objective is to make people aware of the national treasure in the form of prehistoric art.

---

ORAL

## 2. THE CASAL DE PAZZI MUSEUM: A PLEISTOCENE DEPOSIT IN THE SUBURBS OF THE IMPERIAL CITY

*Patrizia Gioia (Museo Pleistocene - Casal De' Pazzi, Italy) patrizia.gioia@uniroma1.it*

The site of Casal de' Pazzi was discovered in 1981 during the urbanization works at Rebibbia, a district north-east of Rome, now densely inhabited. The finding of a fossil tusk of elephant gave the start to the archaeological investigation in an area of 1200 sq.m. Sands and gravels had filled a stretch of an ancient riverbed dug in the "Tufo Lionato", a volcanic rock dated about 366,000 years ago. In the deposit were discovered more than 2.000 Pleistocene faunal remains. The human presence is testified by a fragment of skull and by over 1.500 lithics. The site, dating to about 200,000 years ago, is the last witness of a series of Pleistocene deposits that punctuated the lower Aniene valley, now destroyed by the spread of the city.

The significance of findings goaded the protection and the promotion of the site, and the partnership among many institutions has made possible the realization of the current museum.

Many actions are followed to carry out a full protection of the site. A structure, specially designed, was built round about the preserved area and the deposit was restored. Museological and museographic actions followed, based on textual, verbal, symbolic and technological communication. Thus, in addition to the traditional forms of exhibition, more direct communication tools were preferred, like those of visual and/or interactive type. The aim was to make the visitor interact with information and also to keep his/her attention alive.

The outside visibility of museum is provided by two large panels with artistic reconstructions of the Pleistocene environment. Then the visitors come into a large outdoor space with a thematic garden exemplifying part of the Pleistocene flora. Here spaces equipped for hands-on labs was also created.

The itinerary includes a view of the deposit, naturally lit, from a footbridge. Then the exhibit hall is transformed in a dark room to project multimedia products that "tell" us the Pleistocene life.

After this emotional “full immersion”, in a covered outdoor space, some panels “tell” the evolution of the landscape and life in the Roman countryside during the last 3.000.000 years.

In the exhibition hall two large windows overlooks the site, and a few showcases show some of the finds, explained also by reconstruction drawings. There is also a “Pleistostation”, by which the visitors can use questionnaires, video games, movies and hypertext.

The narrative approach supported by advanced technologies seems to be particularly meaningful for a museum referred to the ancient prehistory, whose ability to tell its own story is low and where the communication is highly challenging.

The ease of understanding of the complex topics that the Museum offers, has resulted in a significant presence of public, and led to the establishment a network of relationships with the territorial, social and cultural background. Many ongoing activities are designed and planned inside the framework of the close relationships established with the urban study and research centers, mostly the neighboring ones. Thus the museum has set up contacts with the nearby Rebibbia jail, local and city environmental associations, primary school pupils and large groups of university students who carry out their internships there.

The framework program concerning “multimedia technologies for the networking and the valorisation of scientific cultural heritage in the Italian University Museums” is carried out by a network of twelve Italian Universities (Bari, Cagliari, Chieti-Pescara, Ferrara, Firenze, Modena and Reggio Emilia, Parma, Perugia, Roma “La Sapienza”, Salento, Siena, Tuscia), coordinated by the University of Modena. It has been recently approved and financed by the Italian Ministry of Education, University and Research. It aims at activating a network that wishes to contribute to the knowledge, dissemination and valorisation of the scientific cultural heritage by multimedia technologies through the collaboration of UMAC-University Museums and Collections International Committee of ICOM.

The final target will be a bilingual web portal realized in an innovative perspective, considering the experiences of each partner, the peculiar features of the different University Museums collections, their interdisciplinary characterization and the possible uses in a contemporary historical, social and cultural context. The first step is to monitor the cultural heritage of the twelve University Museums, in order to complete the already existing databases and align them to the cataloguing standards released by the Central Institute for Cataloguing and Documentation of the Italian Ministry of the Culture within the General Informative System for Cataloguing SIGECWeb.

Moreover, the Italian University Museums network has identified four common themes that will be on line in order to put in evidence the current or in progress researches regarding the most important university museum collections. The four common themes (Stories, Scientific instruments history, Landscape, Environment) will be developed by interdisciplinary itineraries taking into consideration historical, social and cultural contexts in order to design a new image of the museums and promote national and international synergies.

### 4. PROJECTS, PRESENT ACTIVITIES AND PERSPECTIVES FOR A UNIVERSITY MUSEUM. THE MUSEUM OF PALEONTOLOGY AND PREHISTORY ?PIERO LEONARDI? OF FERRARA.

*Berto, Claudio - (Università di Ferrara, Sistema Museale di Ateneo, Museo di Paleontologia e Preistoria ) claudio.ber-*

*to@unife.it*

*Cangemi, Marina - (Università di Ferrara, Dipartimento di Studi Umanistici) marina.cangemi@unife.it*

*Pancaldi, Roberta - (Università di Ferrara, Sistema Museale di Ateneo, Museo di Paleontologia e Preistoria) roberta.pancaldi@unife.it*

*Sala, Benedetto - (Università di Ferrara, Sistema Museale di Ateneo, Museo di Paleontologia e Preistoria) benedetto.sala@unife.it*

*Thun Hohenstein, Ursula - (Università di Ferrara, Sistema Museale di Ateneo, Museo di Paleontologia e Preistoria) hhu@unife.it*

The Museum of Paleontology and Prehistory "Piero Leonardi" is one of the university museums that belongs to the Sistema Museale di Ateneo, which coordinates and manages all the museum structures and activities at Ferrara University. It was opened in 1967 as a small academic museum available only to University students and professors but, since the late 70's, it was gradually opened to the public and all grade students, even with educational activities and tour guides. Unfortunately, the Museum is closed since 2012, when part of the building has been damaged by the 20th and 29th May earthquakes. The exhibition is divided into four parts: Vertebrate Paleontology, Human Paleontology and Prehistory, Historic Geology and Invertebrate Paleontology. The first two were settled in 1967 and partially renewed during the 80's, the last two were opened in 1997.

In particular, the Human Paleontology and Prehistory section includes, among others, a complete collection of casts of human fossils remains, from first hominids to *Homo sapiens* skulls, that comes from the most important sites of the world, a collection of bones and stone tools coming from several Italian Quaternary sites investigated by the Ferrara University and a collection of bones and tools coming from other museums and universities as a result of exchanges and trades carried out by professors during the last fifty years.

Its "forced" closure is an opportunity to reorganize the Museum and redesign the exhibition. The first step is to catalogue the entire collections following international standards in order to plan the new exposition. The museum is now part of a national network project, which involves 12 Universities with the aim to create a university museum network. This project will allow to complete the cataloguing and to set up a parallel "virtual" and online exhibition, strongly related to both the territory of Ferrara and the national network.

The online exhibition will be focused on three main topics: the first will regard human evolution, the second

Quaternary mammals and the third, strongly related to the territory, will concern the Pleistocene site of Settepolesini di Bondeno (Ferrara, Italy). Videos, 3D reconstructions and interactive applications will be used in order to help the reading and understanding of the contents and to increase the interest on these themes.

Until the museum will be restored, the Sistema Museale di Ateneo is planning to organize some temporary exhibitions opened to the public which will involve part of the collections now hosted in the closed structure. Some of these exhibitions will be implemented with laboratory activities for classes and university students, educational activities and lectures opened to the public. The Museum of Paleontology and Prehistory "Piero Leonardi" is a small, unfortunately closed, university museum, but we strongly wish to renew it through multimedia tools in order to keep it alive.

ORAL

## 5. CULTURE ECONOMICS IN PORTUGAL: WHY MUSEUM NETWORKING MATTERS IN TIMES OF CRISIS

*Marques, Sílvia - Instituto Terra e Memória; Instituto Politécnico de Tomar) sarouelala@gmail.com (*

*Oosterbeek, Ivo - GQP-CGC (UID73 FCT); Instituto Terra e Memória; Benefits & Profits Lda) ivoosterbeek@gmail.com*

The net growth in cultural institutions has been positive since the beginning of the 20th century, though its growth curve may have slowed its pace in the last years. Portuguese Museums have grown in number, and the market supply in the cultural sector has a greater diversity than ever before.

The recent economic crisis has diminished the financial availability for all economic activities, and the cultural sector, being mostly public (as in owned by public institutions), lacks the capacity to adopt certain economic strategies to face the crisis since its capital cannot flow in the stock market.

In this presentation we will analyse national financial initiatives that museums have been using in order to enrich financial availability, discuss the professionalization process of Portuguese museums, and the consequent depreciation of non-professional institutions, and discuss the opportunities brought by the adoption of museum networking.

*Almeida, Nelson José (Universidade de Trás-os-Montes e Alto Douro - FCT PhD scholarship; Grupo de Quaternário e Pré-História do Centro de Geociências; Instituto Terra e Memória) nelsonjalmeida@gmail.com*

Established in 2000, the Rede Portuguesa de Museus (RPM - portuguese museums' network) constitutes a mechanism of quality assurance for Portuguese museums, in compliance with international recommendations. Since 2004, with the enactment of a general law of museums (Lei n.º 47/2004) in Portugal, RPM has been acting on the museums by assessing whether they respond to the national criteria or not in accordance to the general law, and manages a supporting platform for the accredited museums.

The Museu de Arte Pré-Histórica e do Sagrado do Vale do Tejo (MAP - local museum in Mação, Central Portugal) and the Museu Nacional de Arqueologia (MNA - National Museum of Archaeology), both accredited by RPM, have engaged in the network's cooperation program – Pro-Museus.

This was an opportunity not only to present to the public collections from a single region stored in both museums, but the occasion to discuss strategic priorities in times of financial scarcity and to conceive innovative and flexible museographic solutions.

The 'Mudança Global' exhibit resulted from the combined efforts of the staff from the MNA and the MAP, converging not only the human capital of both institutions, but the assemblage of pieces from both museums in the same exhibit, supporting a museologic narrative that could not be achieved with either collection alone.

ORAL

## 7. NETWORKING LOCAL COMMUNITIES THROUGH QUALITY MANAGEMENT AT CULTURAL SITES: THE HERITY NETWORK IN MIDDLE TAGUS AS A TOOL FOR SUSTAINABLE DEVELOPMENT

*Quagliuolo, Maurizio (HERITY International) herity@dri.it*

The HERITY international certification which was concluded in Middle Tagus (Portugal) on the first of November 2013, is a good demonstration of a sentence which was said at the First HERITY Conference from a colleague of ours, Jean Gagnepain -now unfortunately disappeared-, who directed the Museum of Gorges du Verdon at Quinson (F): "we were making quality without knowing it". This is true, but the problem is the recognition of this capacity from an external point of view, and their implementation of regular practices of quality improvement.

The HERITY certification in Middle Tagus made possible to recognize, in addition to some weaknesses, a number of skills and qualities present at museums, archaeological sites, monuments, libraries and archives and other places. Human capital is the main resource there. The challenge presently fronted by these places is to succeed in putting in common these capabilities as an opportunity for developing local identity, cooperation, internationalization issues, services, both to residents and visitors. What these places have in common is the willingness to improve, to ask for help to do it, and the transparency of the management implemented at these sites, clearly demonstrated by the fact that the HERITY international certification was requested and welcomed. The implementation of a practical system starting from this already existent network is presented in the paper as a tool for sustainable development. The 30 sites certified by HERITY in the Medio Tejo region, in middle Portugal, including the rock art sites of Fechadura and Lajeira (Sertã) and the Prehistoric Art museum of Mação can be now the protagonists of a process supporting local pride as well as internationalization instances and economy of scale, possibly under the coordination of a wider body.

ORAL

## 8. OS MUSEUS DE ANGOLA: GESTÃO ACTUAL E PERSPECTIVAS

*Domingos, Ziva - (Direcção de Museus de Angola) zivado@hotmail.com*

Durante estas últimas décadas, as instituições patrimoniais, em particular museus são, de um lado, chamados a satisfazer as necessidades dos usuários (públicos comunidades, locais) que se tornaram cada vez mais exigentes e por outro lado, enfrentar a crise econômica mundial enquanto contribuindo ao desenvolvimento local através da elevação da qualidade de vida das populações.

Para alcançar este ideal, os museus devem desenvolver estratégias novas que lhes permitem oferecer produtos e serviços de qualidade aos seus públicos-clientes respeitando o equilíbrio entre as suas missões de conservação e valorização do património cultural.

Estes desafios de desenvolvimento social tocam também os museus angolanos chamados a melhorar a sua gestão actual e suas prestações para ser capaz de satisfazer as exigências das populações locais. A gestão sustentável destas instituições passa necessariamente pela elaboração de ferramentas estratégicas e operacionais como os projetos científicos e culturais e planos de conservação preventiva completados por mecanismos de avaliação como instrumentos de orientação de projectos de renovação de museus existentes e de criação de novos museus.

ORAL

## 9. LES MUSÉES DE PRÉHISTOIRE ET DE QUATÉNAIRE. DES EXEMPLES ET EXPÉRIENCES DU NORD-EST DE LA HONGRIE

*Ringer, Árpád - (University of Hungary) bolringa@uni-miskolc.hu*

D'où est-ce que nous sommes venus, qui sommes nous et où allons nous ? Pour répondre à ces questions de la philosophie classique, il y a deux sciences, les plus compétentes. Quant à deux premières questions c'est, sans doute, la Préhistoire et à la dernière de celles c'est la Futurologie.

Aujourd'hui la Préhistoire, après beaucoup de changements dans ses paradigmes, est une science bien renouvelée. Elle synthétise les résultats de la recherche du Quaternaire, de l'éthologie humaine, de la microbiologie, de

l'activité cérébrale et de la paléolinguistiques etc. Ainsi elle est devenue d'une science pratique, en jouant un rôle actif de créer de notre vision moderne de l'homme. Si les expositions de Préhistoire et de Quaternaire sont bien organisées, elles peuvent donner des inspirations sur l'émergence admirable de l'homme et sa culture au cours du Pléistocène et Holocène. Elles peuvent s'aviser les visiteurs de la route grandiose, fut mise par l'humanité pendant 2.5 millions d'années, et les s'aviser de leur responsabilité pour garder la culture d'origine préhistorique, et entretenir l'environnement naturel du Quaternaire pour le future.

Dans le Nord-est de la Hongrie la Montagne de Bükk, riches en attractions touristiques, depuis 1911 est un important centre de la recherche préhistorique en Europe. Parmi une centaine des stations préhistoriques il y a trois célèbres grottes, notamment la Szeleta, la Subalyuk et celle d'Istállósk.

Depuis 1999 la Fondation pour la Culture de Szeleta, en collaboration du Musée Herman Ottó de Miskolc, de l'Agence de Développement Urbain de Miskolc et du Parc National de Bükk ont élaboré les plans de quatre musées ou des centres d'accueil liés aux grottes précédentes.

Jusqu'aux nos jours ne sont établis qu'un petit Musée de Subalyuk, au village Cserépfalu, près de la grotte Subalyuk et un Archéoparc privé à la localité Szilvásvár, en relation de la grotte d'Istállósk. Quoique le concours du plan du Centre d'Accueil de Szeleta, près de la ville Miskolc, ait gagné, sans financement il doit attendre à réaliser.

Au lieu de ce dernier l'on a réussi à bâtir un centre d'accueil 'Musée de la Mer Pannon', à côté du Musée Herman Ottó, au centre de Miskolc, dont une partie de l'exposition s'occupe de l'évolution humaine est de ses environnements quaternaire. Cette attraction est bien populaire et donne lieu à l'enseignement pour les lycéens et les étudiants.

Conclusions :

- C'est assez simple à faire accepter le but et le plan de ces établissements par les Bureaux de concours, quoique les attractions de ceux ne soient pas préférées.
- Après avoir gagné du financement, l'on peut distinguer en deux points différents du futur des musées et des centres d'accueil:
- la construction des bâtiments et les expositions sont plus simples;
- que les entretenir.
- L'entretien des musées et des centres d'accueil sont

beaucoup de plus sûr, si ils se rattachent au réseau hon-  
grois des musées, ou si ils sont liés au tourisme. C'est  
l'enseignement qui fait forcer leur attrait.

- Sans doute, l'organisation d'un réseau international de  
ces établissements peut-être le devoir de l'UISPP, où les  
communications et les collaborations pourront aider de  
faire développer même le tourisme archéologique.

At 500 meter above sea level, in the heart of the Carnic  
Pre-Alps lies the beauty and tranquillity of the Pradis pla-  
teau. Hundreds of karstic cavities, wild nature and a spe-  
cial charm, makes this enchantingly place rich in history,  
culture and ancient traditions.

Since Palaeolithic, Neandertals and Sapiens, exploited  
the natural sources of this area. Both our ancestors, we  
demonstrate, were using shelter in these caves carved in  
the rock by the Cosa and Rio Secco streams.

Caves in the Pradis area were important as source of  
knowledge for the Prehistorical man hunting activities:  
like Verdi caves, that were opened as a tourist attraction  
since 1965 or Clusantin caves that hosted small groups of  
Epigravettian marmot hunters. Neandertals occupations  
are recognizable in the Rio Secco cave, an archaeological  
treasure still under excavation, that testifies the transition  
of the last Neandertal cave-bear hunters and the firsts  
anatomically modern human of the Italian North-East.

Thanks to the work of the Cultural Committee and the  
Speleological Group of Pradis the "Museo della Grot-  
ta", that started as permanent collection in 1969, was  
opened to the public in 2001.

Since then, in 2013 a new awareness of the full potential of  
the museal collections, ensued from all the years of expe-  
rience of the Cultural Association of Pradis and the Town  
of Clauzetto administration and from the achievements of  
two archaeological test-pits directed by Dott. Marco Pere-  
sani of the University of Ferrara in 2001 and 2002.

Raised all the funds needed, in June 2005 the first "Ar-  
chaeological research laboratory" started, adopting the  
principles inspired by the newborn "Ecomuseo delle  
Dolomiti Friulane - Lis Aganis", and working in close  
collaboration with the University of Ferrara. The first two  
month laboratory at Grotta del Clusantin recorded the  
attendance of more than 600 participants. The achieve-  
ments granted the setting-up in spring 2007 of a section  
in the local museum displaying the finds recovered in  
this shelter and lead in 2008 to the first popular/scientific  
publication, an introduction to the results obtained.

The presence of a large glade across from the Clusantin  
cave, favoured the launch of the "Prehistory Days", a cul-  
tural and tourism event, targeted to children and fami-  
lies, in order to promote the archaeological specificities  
of the Pradis Valley. These activities, core of the scientific  
communication process, qualified by a correct philologi-  
cal accuracy, related to modern methodologies and dis-  
coveries in the field of archaeological research and evo-  
lution of man and its behaviour.

Archaeological laboratories, that took place from 2005  
until now in the Clusantin and Rio Secco cave, permitted  
to organize, during the opening months, daily guided

tours for the public and schools, with the possibility of participation at the archaeological activities, and several conference sessions part of the project "The last Neandertal in Friuli". Nowadays the museal activities of cultural enhancement of the territory and scientific research represent a key attraction to the Pradis Valley, acting in this scenario as a promotion hub for the whole territory.

## 1. ICE AGE EUROPE – NETWORK OF HERITAGE SITES

*Weniger, Gerd-Christian (Neanderthal Museum) weniger@neanderthal.de*

*Hieke, Katrin - (Projekt 2508) hieke@projekt2508.de*

The Ice Age Europe Network ([www.ice-age-europe.eu](http://www.ice-age-europe.eu)) established in 2013 tells the story of ice age people in Europe and our common heritage in space and time. 18 archaeological sites with important Pleistocene heritage and affiliated museum or visitor center from seven European countries are members. They attract in total nearly two Million visitors per year and are managed by around 300 staff members.

The network was established by the initiative of the partners themselves, who also provide for the basic funding from their own resources to ensure the sustainability of this long-term project. The network's aims are to raise awareness on the conservation of Ice Age heritage and to develop valorisation programs, to exchange best practice for site management and museum display and to encourage collaboration of all kinds, e.g. in the field of science, management, pedagogy, tourism and governance. As a new umbrella brand, the network opens the possibility of reaching well established as well as new target groups across Europe.

First experience from collaboration and from recently started subprojects will be presented.

## 2. MUSEUM OF HUMAN EVOLUTION: TABLETS, SIGNGUIDE, CHILDREN'S GAMES AND VIRTUAL VISITS.

*Alonso Alcalde, Rodrigo (Museo de la Evolución Humana) ralonso@museoevolucionhumana.com*

*Martín Nájera, Aurora (Museo de la Evolución Humana) amartin@museoevolucionhumana.com*

The technology advances produced during the XXI century have caused one transformation in methods and in tools to communicate knowledge. We have carry out a set of actions that we would like to join new technologies and diffusion of the contents of the museum and the site in Atapuerca Range Mountain.

Guide visit whit tablets: individual visitors have the possibility of visiting the museum with a tablet, in which they can access to a large sort of contents and didactic games complementary to the ones that we have at the permanent exhibition at MEH.

Signguides: in collaboration with other institutions that work at the field of elimination banners of communication, signguides have been design, special for people suffering hearing disorder. In this same line we have carried out other actions (tours for people with a reduced mobility, visits with support materials for people vision disorders, etc.) in order to get an accessible museum for everybody.

Children's interactives: Children required special educational attention, which is the reason why there is a special area at MEH where through informatics games and using Kinect technology children and young people get closer the human evolution in an interactive and educational way.

Treasure Map: for families a special map has been produced. Children have to answer to a battery of questions during the marked tour by the MEH. In this way children are the ones that guide their parents and at the same time they take part in the learning process of their children.

Virtual visits: a bank with virtual visits to the temporal exhibitions is being created. In this way we abolish the short-lived feature of these exhibitions and their contents is always accessible through the museum's website.

All this actions are allowing us to complete and update the expository discourse at the museum at the same that boost the establishment of the new technologies at MEH.

ORAL

## 3. HOMÍNIDOS Y HOMÍNIDAS: UNA EXPOSICIÓN SOBRE LA EVOLUCIÓN HUMANA

*Barciela Durán, Patricia (Domus- Museos Científicos Coruñeses) patricia@casaciencias.org*

*Armesto Ramón, Francisco (Domus- Museos Científicos Coruñeses) patricia@casaciencias.org*

*García Visos, Bibiana (Domus- Museos Científicos Coruñeses) bibiana@casaciencias.org*

Dadas las muchas y variadas noticias relacionadas con la evolución humana, la Domus, el museo de A Coruña

dedicado al ser humano, siguiendo en la línea de dar respuesta a los temas de actualidad que suscitan el interés de los ciudadanos, ofrece una exposición sobre nuestros orígenes y la historia evolutiva de las características que nos hacen más humanos, y de las que presumimos.

Desde la antigüedad el ser humano se ha contemplado a sí mismo como el "elegido", creado a imagen y semejanza de los dioses; la aparición de las nuevas ideas evolucionistas no cambió el sentir general de la población, pues la humanidad ha querido seguir considerándose como un objetivo de la evolución, creyendo que si las especies vivas se pudieran ordenar de menos a más, el ser humano ocuparía la cumbre de la perfección. Por eso, como siempre nos hemos creído el ombligo del mundo, el camino de aproximación a esta exposición sobre evolución humana pasa por plantear una ruptura con los prejuicios, falsas creencias y errores que la rodean, pero de forma amable y lúdica, que invite a la curiosidad, pensamiento crítico y al escepticismo informado.

Y de aquí el subtítulo de la exposición, La familia presumida, entendiendo que a la especie humana le gusta resaltar aquellos atributos que considera los más importantes hitos evolutivos de los homínidos.

"Homínidos y Homínidas" es una exposición divulgativa, interactiva e interdisciplinar, dirigida a personas de todas las edades, que combina el rigor de los planteamientos y afirmaciones con el carácter lúdico y popular de las realizaciones museográficas. Se aborda la evolución humana desde una perspectiva que permite incluir las características biológicas más determinantes del desarrollo evolutivo, buscando la motivación, el interés, la sorpresa, la diversión o la reflexión de los visitantes.

Para desarrollar los contenidos se ha recurrido a diferentes soluciones museográficas, experiencias interactivas, mecanismos, módulos informáticos, maquetas o escenografías. Se presentan además réplicas de piezas emblemáticas que sirven para hablar sobre cada una de las cuestiones de la evolución humana que se abordan. Así, cada unidad expositiva está formada por: una pieza emblemática, un módulo interactivo, una cita que ofrece una visión interdisciplinar, y un texto con varios apartados.

Las piezas emblemáticas tienen su espacio destacado dentro de cada unidad expositiva, ya que se trata de reproducciones de importantes hallazgos paleontológicos y arqueológicos. Son, por ejemplo, varias piezas halladas en el yacimiento de la Sierra de Atapuerca (los llamados Elvis la pelvis -pelvis de Homo heidelbergensis -, cráneo

del niño de la Gran Dolina –especie Homo antecessor, descubierta en Atapuerca-, Miguelón -Cráneo 5-, o Excalibur -un hacha de mano-), una reproducción de la pintura rupestre de una mano en negativo de la Cueva El Castillo (Santander) o las huellas de homínidos de Laetoli, Tanzania.

La exposición aborda los siguientes temas: genealogía, la postura erguida, la locomoción bípeda, la pinza de precisión, visión estereoscópica, el volumen cerebral, la adquisición del lenguaje, pensamiento y razonamiento simbólico, la dieta omnívora, el cuidado de las crías, el desarrollo tecnológico, la organización social, y la expansión geográfica.

### 4. EUROPEAN COOPERATION PROJECTS: THE MAÇÃO MUSEUM STRATEGY FOR ACTIVITY AND EXPOSURE ENHANCEMENT

*Oosterbeek, Ivo - (GQP-CGC (uID73 FCT); Instituto Terra e Memória; Benefits & Profits Lda; Museu de Mação) ivoosterbeek@gmail.com*

*Marques, Sílvia - (Instituto Terra e Memória; Instituto Politécnico de Tomar; Museu de Mação) sarouelala@gmail.com*  
*Cura, Sara - (GQP-CGC (uID73 FCT); Instituto Terra e Memória; Instituto Politécnico de Tomar; Museu de Mação) Osaracura0@gmail.com*

*Pereira, Anabela - (GQP-CGC (uID73 FCT); Instituto Terra e Memória; Museu de Mação), belaborralheiro@gmail.com*  
*Cura, Pedro - (GQP-CGC (uID73 FCT) Instituto Terra e Memória; Museu de Mação) Opedrocura@gmail.com*  
*Teixeira, Vitor - (Benefits & Profits, Lda.) benefitsprofits@gmail.com*

*Oosterbeek, Luiz - (Instituto Politécnico de Tomar; GQP-CGC (uID73 FCT); Instituto Terra e Memória) loost@ipt.pt*

Since its reopening to the general public in 2005, the Mação Museum has developed a series of diversified activities in order to promote heritage awareness regarding its collections (mainly archaeological) as well as the archaeological sites in its vicinity (megalithic monuments, proto-historic enclosures and rock art complexes).

Though the scope of the museum's educational program would be constricted by the museum's low budget, this issue was resolved through the establishment of a partnership network, including Higher Education institutions (Instituto Politécnico de Tomar, Universidade de Trás-os-Montes e Alto Douro), non-governmental institutions (CEIPHAR, ITM and ACIAAR), and local enterprises

(Benefits & Profits), allowing the Museum to diminish production costs in its activities.

The success of this networking strategy was then enhanced by the financial and artistic complement of the recurrent candidacy in European cooperation projects regarding the cultural sector. The Culture Programme allowed for the Mação Museum to widen its range of educational and dissemination projects, not only through the co-funding of those projects and enrichment of the already growing network of partners, but also by introducing in the museum a range of artistic experiences, which complement the archaeological nature of the museum's main collection, while being more "public friendly".

In this presentation we will approach the Museum's dissemination strategy through the enrichment of partnerships and the growing range of activities, celebrated via the cooperation solutions provided by European tools. We will stress which educational projects and partnerships were brought about by the different European Projects the museum has applied to (EuroPreArt, ArtRisk, ArtSigns, Transformations, GestArt), and the importance those projects and partnerships have acquired in the Museum's educational program.

#### ORAL

### 5. THE EDUCATION PROGRAM OF MUSEUMS OF LA GOMERA (CANARY ISLANDS, SPAIN): BUILDING HERITAGE IN THE COMMUNITY

*Hernández-Marrero, Juan Carlos - (Museo Arqueológico de La Gomera (Cabildo Insular de La Gomera) museoarqueologico@lagomera.es*

*Cabeza-Marrero, Jaime - (Grupo de Investigación POSASUe. Dpto. Didáctica e Investigación Educativa, Universidad de La Laguna.) jacmarrero@gmail.com*

For a few years and at the same time as the islands' museums opened, a space of convergence of different local agents -such as work teams, projects, neighbours, entrepreneurs, or heritage and education professionals- has been created in La Gomera. All these people have shared working methodologies involving participation processes and networking.

The education program of museums of La Gomera emerges in this context as a practical tool that organises and explains any educational action taken in the islands' museums. It is thus included in this convergence of lo-

cal agents, establishing new links and routes towards achieving island collectivity regarding cultural heritage education and learning.

This plan begins with an analysis of the social, economic, historical and cultural context of the island and it is structured through the educational aims and principles of museums. Then, it establishes some action ambits in which the educational actions are grouped according to the social context where they operate. Thus, every field has an own Educational Program that is addressed to a particular population; educational aims; adapted contents; methodological proposals and critical assessment criteria and procedures for every activity.

These action ambits are:

- 1) IN-Museum: it covers the set of activities about the museum's physical space (contents and the building itself), focusing on exhibitions and addressed to visitors and museum's workers.
- 2) Schools: addressed to formal education (compulsory and non-compulsory). It includes actions in educational institutions and teachers' counselling, such as educational workshops (anually biological anthropology workshops, archaeological excavations, etc...).
- 3) Collectives: this area of action -as vulnerable as important- allows accessing a part of the adult island's population that is organised. The most relevant activity is the museums' forum, an annual event that shows to the citizens what the museums have done during the year.
- 4) Tourism: addressed to tourists as well as to those people that have some relationship with this strategic sector in La Gomera.
- 5) Environment: this field needs to entirely consider the natural and cultural heritage, being the island territory a key concept of action.

The research projects that are carried out in the museums -or those in which they participate- provide information that nourishes the contents of the education program, while -at the same time- the education program supports an increasing rol of the community participating on researches.

Carry out this education program does not involve a higher number of educational actions, but it involves museum networking using any resource available in the island (its scope of work necessarily exceeds the limits of the museum's building); an action agenda; an organisation facilitating the actions' balanced perspective regarding each area of action; and working with and towards all the community, without risk of any kind of discrimination.

---

ORAL

**6. INVESTIGAR PARA TRANSMITIR CONOCIMIENTO: LA EXPERIENCIA DEL ARKEOLOGI MUSEOA DE BIZKAIA EN LA COMUNICACIÓN DEL CONOCIMIENTO DERIVADO DE INVESTIGACIONES ARQUEOLÓGICAS.**

*García Camino, Iñaki (Arkeologi Museoa/ Diputación Foral de Bizkaia) inaki.garcia@bizkaia.net*

Los Museos son por definición instituciones “comunicativas” que ponen en relación los objetos y sus contextos (en nuestro caso arqueológicos) con la sociedad. Por ello la transmisión del conocimiento que proporcionan las colecciones que custodiamos nos parece una labor fundamental y ello se realiza a través de diversos medios.

- la exposición de referencia que muestra la historia de Bizkaia a través de los datos proporcionados por las investigaciones arqueológicas.

- las exposiciones temporales que inciden en determinados aspectos del pasado, especialmente en aquellos que son objeto de las últimas investigaciones y discusiones científicas.

- las publicaciones que pretenden acercar al público interesado, aunque no necesariamente versado, los debates y discusiones que giran en torno a temas de la arqueología actual.

- cursos y conferencias como una oportunidad que favorezca el encuentro entre arqueólogos.

- programas didácticos adecuados al currículo escolar.
- talleres diversos para familias sobre excavaciones, alimentación, vestidos o vivienda a lo largo de la historia.
- visitas guiadas especiales que conecten el Museo y sus colecciones con los yacimientos de donde proceden, resaltando el concepto de Museo Territorio.

Se evaluarán estos resultados y se planteará también la necesidad de vincular estrechamente investigación y comunicación como parte de una misma realidad, lo que no es tan frecuente dado que todavía existe una división de funciones entre los responsables de la investigación (científicos) y de la comunicación (periodistas).

ORAL

**7. THE ATAPUERCA EDUCATIONAL WORKSHOPS: A MODEL ADAPTED TO SCHOOL CURRICULUM**

*Alberto San Martín Zapatero (Sierractiva SL.) alberto@sierractiva.com*

Many schools come to visit Atapuerca. Students are a large audience. That's why our team works to design educational workshops adapted to school. In our workshops children acquire the main educational competences. We want prehistory is transversal to other areas of knowledge.

Many disciplines are practiced at Atapuerca. This is the reason why the didactic team considers it crucial the development of different types of workshops for different types of subjects. Equally important is the adaptation of the workshops to the students' age groups.

In addition to the academic objectives, we also want to promote the conservation of this archeological treasure in the minds of our children.

ORAL

**8. EDUCATIONAL USE FROM A NEANDERTHAL SITE. THE ROCA DELS BOUS AND THE NOGUERA LEARNING SCHOOL.**

*Antoni Bardavio Novi (Campo de Aprendizaje de la Noguera) c5901117@xtec.cat*

*Sònia Mañé Orozco (Campo de Aprendizaje de la Noguera) smane@xtec.cat*

*Paloma González Marcén (Universidad Autónoma de Barcelona) Paloma.Gonzalez@uab.cat*

The Noguera Learning School (<http://www.xtec.cat/cda-noguera/>) is an educational service of the Department of Education of the Regional Government of Catalonia. It is located in the town of Sant Llorenç de Montgai (Lerida). It receives students of different compulsory and post-compulsory educational stages. It also takes part in the initial education of students of the Degree in Prehistory and the Degrees in Child and Primary Education Teacher Training, as well as the Master Degree in Compulsory Secondary Education Teacher Training, all from different universities.

Its main objective is to learn about both prehistoric life, as well as archaeological research. Ever since its foundation in 2005, it works co-ordinately with the team members of the Study Centre for Prehistoric Archaeological Heritage (CEPAP) of the Autonomous University of Barcelona. This team is in charge of the excavations of the Neanderthal site of Roca dels Bous at Sant Llorenç de Montgai, in the area where the Pre-Pyrenees Mountains meet the plains of the region of Segrià in the Ebro Valley. The disciplinary development of archaeology, “thought

archaeology”, has been reflected on the role of archaeology within the school framework leading to different teaching models included in the teaching-learning of history. Therefore, “taught archaeology” responds to this epistemological evolution.

In the case that is hereby described, the site of Roca dels Bous (with its work in progress system, that proposes a permanent visualisation of the current status of the excavations) allows, during the didactic visit of non-university students, the following inductive sequence for the analysis of the objects and structures that have been located during the excavation; descriptive analysis, typological comparative analysis, functional analysis and the formulation of interpretative hypotheses regarding the context of origin.

The school students that take part in patrimonial education proposals, such as the proposal associated to the visit of the Roca del Bous site, in an active and experimental manner (the visit is extended with activities at the Didactic Archaeological Park, with regard to the processes of acquisition of historical knowledge, as well as empathy activities based on the reproduction of typical prehistoric situations which we call Didactic Experimentation in Archaeology), develop a series of values and attitudes that promote critical analysis tools.

The proposal of the Noguera Learning School at the site of the Roca dels Bous intends to develop, based on the knowledge about the organisation of Neanderthal societies that inhabited this location, the capacity to understand a historical and social reality, its evolution, successes and problems, which leads to resorting to the multi-causal and systemic analysis to judge the social and historical problems and facts from the point of view of a critical comprehension of history, permanently compared to our modern society

### 9. EDUCATIONAL STRATEGIES IN ARCHAEOLOGY. SOME APPLICATIONS IN THE PROTOHISTORIC SETTLEMENTS ON THE LOWER REACHES OF THE EBRO

*Genera i Monells, Margarida (Departament de Cultura de la Generalitat de Catalunya  
UNED, Centro Asociado de Terrassa-Barcelona) mgenera@gencat.cat*

Based on the conviction that all archaeological research projects should include not only a specific section devoted to the protection of the remains, but also one for

the social dissemination of the scientific results obtained, in this congress we will explain the general lines along which our work in the Ebro-Siurana river basins has been carried out in recent years.

We will refer in particular to two of the archaeological sites we excavated in 1976: El Puig Roig del Roget in El Masroig (Priorat) and the settlement of Sant Miquel in Vinebre (Ribera d’Ebre), some 70 km from the present-day mouth of one of the largest fluvial arteries on the Iberian Peninsula. Their occupation is related to the mining operations in the Priorat basin and the management and transportation of the area’s geological resources between the 7th and the 1st centuries BC.

Both sites are currently being prepared to be opened to the public and, in the case of El Puig Roig, a classroom is also being installed in the town hall. Likewise, in parallel with the fieldwork, we have prepared various activities for children. This is because we believe that the dissemination of our heritage, presented in a suitable manner, is without doubt the best way of returning to society the investment, in both human and financial resources, in a specific archaeological site and that which will bring the greatest benefits in educational and cultural terms. With this aim, a series of publications has been prepared using the unique objects found during the excavations.

They are to be used as an educational resource with the objectives of transferring to young people the knowledge obtained by scientific means and engendering among them an interest in interdisciplinary study and research. It is hoped that this will also stimulate their ingenuity and artistic creativity, in addition to encouraging the study of the finds made in that area.

One of our main challenges is, therefore, to disseminate the history of the territory itself and to encourage an appreciation of and sensitivity towards its 2 archaeological heritage and natural environment, in order to improve the conservation and protection of the legacy of our ancestors within its own landscape.

### 10. NUMANTIA: AN EDUCATIONAL PROJECT WITH FIVE YEARS OLD CHILDREN FROM SORIA (SPAIN).

*López Torres, Esther - (Universidad de Valladolid) esterlop@sdc.uva.es  
Íñigo Fernandez, Aurora - (Universidad de Valladolid) ainigof@gmail.com*

This paper focuses on the analysis of the design, development and results of a small educational project around "Numantia's Celtiberians" conducted with 24 children from 3rd course of Early Childhood Education at CEIP Fuente del Rey in the city of Soria, over a complete quarter of the year 2012-13. Its main objective was bringing the historical and cultural heritage from their own environment to the schoolchildren to make easier, through experimentation and play, and in particular the visit to Numantia, the understanding of historical time, and hence of all historical references that are outside the classroom such as museums, archaeological sites, symbols, heritage interpretation centres, etc. (Santisteban and Pagès, 2006).

Several studies have shown that difficulties on learning the historical time do not lie in the age of the students but in the selection of contents and its didactic treatment (Egan, 1994; Trepát, 2000; Cooper, 2002; Cuenca and Estepa 2005; Cuenca, 2011).

Learning time assumes experiencing or living that in the context of continuity there has been things or situations that were but no longer are (Trepát, 2011), but, on the other hand, the child is only aware of the passage of time when developing the memory, where the events experienced by him, but also by their parents and by their social group remain (Estepa, 2007).

Using the Project-based learning (PBL) as teaching methodology (work plan with which a group of children and their teacher intend to carry out an action research), the elements that explain what happened in their own environment during the Second Age Iron were introduced, taking advantage of the proximity of the site of Numantia and the resources offered by the Numantia Museum in Soria. The contents relating to that period were adapted to schoolchildren through images, performances, dialogues, narratives... to generate meaningful and playful learning at the same time.

The Celtiberians were very present in children throughout the quarter we worked on them. Through verbalizations the proposed learning was observed to be acquired and, at project completion, after resuming the questions raised at the beginning, we saw that we could answer them all. While we watched the creations of children and the photos taken throughout the process, we recognized what we had learned.

Corroborating what many scholars say, the teaching and learning of history in Early Childhood Education is possible if appropriate strategies that return the leading

role to the students are used. The use of questions that their own historical and cultural environment generates enhances their motivation; and direct contact with the archaeological remains, not only watching but also participating and acting through play, help them to fix and grasp contents that are otherwise too abstract.

ORAL

## 11. DYNAMIZATION MODELS OF ARCHAEOLOGICAL SITES IN SPAIN. TOWARDS A NEW MANAGEMENT MODEL OF ARCHAEOLOGICAL HERITAGE.

*Luque Cortina, Manuel. (Paleorama SL Ctra. Madrid-Irún (N-I), Km 232 (Pol., Gromber), Nave 58. 09195 Burgos) mluque@paleorama.es*

The archaeological heritage is one of the major distinctive strengths of our country, a perception that is not always shared neither by society nor by administrations that devote significant amounts of public money, sometimes without much discretion to raise infrastructures and purchase equipment whose maintenance and subsequent management generate more conflicts that apparently offer solutions. In this article we show the results of assessing and evaluating management models over 40 national archaeological sites and almost 20 years of experience from the private sector in dynamization and auditing archaeological heritage.

Our impression is that the classical model led by administrations is completely outdated "not only of infrastructures lives a location", there is also a need of specialized training, planning, alternative financing, resource control, a good communication plan and a dynamic and a long term attractive design supply. All this costs, and costs every month. The reality is that administrations are overwhelmed by lack of time and resources. It is not possible a management culture without a corporate culture and without the active participation of the society, that ultimately is what gives real meaning to any effort and investment.

We are convinced that the future lies in a mixed model, where the key role of the private sector is assuming the risk of bearing the costs of management and maintenance of public facilities, but with freedom in supply management, always under the watchful eye of the administration and through a transparent plan for the society.

To diagnose the "health" of management and revitalization programs of the analyzed sites several factors were

taken into account: the influence of environment, location, access and signage, structures and general services offered by each location, proximity to places with high load population or areas of population influence, structures monumentality, its distinctive strengths, financing sources, the legal constraints of each space, the ownership of the land, their security measures, conservation status, quality of offering, the team training and the core management leadership, the maturity and effectiveness of its communication model, used learning resources, after-sales strategy, associated research projects, public, private or mixed models implanted, and above all, its corporate management culture.

Apparent discrepancy between corporate or commercial communication (what is said to be offered) and corporate identity (what actually offers), "we are specialized in selling smoke". Excessive dependence on government, both economically and management strategies; the result is a general, ambiguous and low dose of innovation offering. More emphasis on infrastructure is given (architecture continent) than to content, teaching resources and above all, to the real needs of the public. Poor planning in a medium and long term maintenance costs and a lack of faith in the Archaeological Heritage potential as a distinctive strength compared to other sectors with more funding.

A mixed public-private management model in which risks, costs, responsibilities, benefits, and where universities validate the content as a quality certificate, is hereby imposed. A model oriented mainly to a developed sustainable model and to meet the needs in an increasingly demanding public, that should be able to participate more actively in the design and functionality of the spaces. If we want that current efforts and investments make sense, we must begin to educate culturally for the future.

*Cerezer, Jedson (ITM)*  
*Almeida, Nelson (ITM)*  
*Garcês, Sara (ITM)*  
*Marques, Sílvia (ITM)*

The Earth end Memory Institute (ITM) was structured in 2010, joining the efforts of the Municipality of Mação, the Politechnic Institute of Tomar and two Non Governmental Organizations for prehistoric research and cultural heritage. The goal was to make the most of the available resources and to establish with the Museum of Mação and with regional support a competitive and qualified platform to promote internationalization. The ITM launched some structuring projects, such as: the organization, conservation and management of museums (partnership with private enterprises); the artistic and technological education (Andakatu Project) and programs of integrated landscape management.

The program developed by ITM is grounded on the elaboration and application of new educational possibilities in the domains of natural sciences, technology, arts and language. In that sense, ITM cooperates with teachers of elementary and high schools to structure activities in all disciplines, given to schools as a complement to the students learning process. Based in ten years of experience of scientific knowledge socialization about human adaptations in face of climatic, environmental and cultural modifications in prehistory, a support from the European Community was obtained to finance the international project «GESTART- artistic gestures revisit the diversity and convergence of art in Europe». Within this project the art and the cultural heritage are the basic references of different activities involving artists, archaeologists and citizens in domains like ceramics, stone tools knapping, design, literature, photography and cinema. Until the end of November 2014 the project will bring together artists, crafts men and women, archaeologists and art historians bounded towards the consolidation of the cultural landscapes in which citizens of several countries and regions live in.

### 13. EN TORNO A LA HOGUERA: ENSEÑANDO PREHISTORIA A LOS MÁS JÓVENES DE LA TRIBU

*del Pozo Manzano, Elena (IES Manuel de Falla-Madrid) elena.delpozo@madrid.org*

Every student has an Indiana Jones inside. The dissemination of archaeological and paleontological discoveries is important in any Western society, and the transmission of findings from Atapuerca to younger generations is a priority in Spain. As such, it is essential that material on human evolution and Atapuerca is regularly updated by teachers and textbook publishers. Secondary education curricula in Spain offer the first exposure to content related to prehistory, archaeology and human evolution. Students are exposed to this through a range of subjects, including science, social science, philosophy and citizenship. Moreover, visits to the National Archaeological Museum in Madrid, the Museum of Human Evolution in Burgos and sites in the nearby village Ibeas de Juarros make students aware of the need to preserve the human legacy continuously uncovered by science. Students are readily attracted to this subject matter because it provides insights into the mystery of where and who we come from, the way we behave and relate to one another and the links that joins us to species both extinct and living, such as Neanderthals or today's primates. When they learn that people living in Atapuerca thousands of years before had the same needs, feelings, successes and failures as they have, students find the motivation to learn about prehistory. For example, there is a fossil in Atapuerca of an old man who lived for a long period of time without teeth. This means that there was someone in the tribe that chewed food for him and kept him alive. There was also a child who had a terrible infection that affected his brain development and he probably suffered from terrible headaches. Still, the child lived until the age of 5 with the help of the tribe. The way students learn this content has an extraordinary influence on how they value the heritage of Atapuerca on a worldwide scale.

There is a lack of uniformity in the taxonomic classification in secondary textbooks. Most of them ignore the first human species and start with the *Australopithecus Africanus*. *Homo Sapiens Neanderthalensis* is classified in the same evolution line as *Homo Sapiens Sapiens* in some books while others show them as different species. *Homo Antecessor* is a human species that is difficult to locate in the taxonomic classifications that appear in textbooks. Some authors consider it the offshoot species of both *Homo Neanderthalensis* and *Homo Sapiens*,

while others show it as an offshoot of *Sapiens* only. Secondary teachers are aware of the complexity of the hominisation sequence due to the regional variations of human species worldwide. This encourages them to keep updated information to take to their lessons.

This paper discusses the teaching of content related to Atapuerca in prehistory lessons, in textbooks and gives suggestions on how to improve both. "So I am a teacher... sometimes" – Indiana Jones and the Kingdom of the Crystal Skull.

*Maqueda García-Morales, Raúl (Paleorama SL. Ctra. Madrid-Irún (N-I), Km 232 (Pol., Gromber), Nave 58. 09195 Burgos) raulmaqueda@paleorama.es*

*de la Torre Santos, Eduardo (Paleorama SL. Ctra. Madrid-Irún (N-I), Km 232 (Pol., Gromber), Nave 58. 09195 Burgos)*

*Marta Burgos de Olmo (Paleorama SL. Ctra. Madrid-Irún (N-I), Km 232 (Pol., Gromber), Nave 58. 09195 Burgos)*

*María Barahona López (Paleorama SL. Ctra. Madrid-Irún (N-I), Km 232 (Pol., Gromber), Nave 58. 09195 Burgos)*

Most software related to archeology is primarily targeted for the treatment and management of object, structures or the archaeological record. Over the years, the parcels related to our discipline have increased considerably. One of them, the revitalization and management of museums, reception centers and archaeological sites, have had to resort to general programs designed for other environments, or even sometimes nothing to be with the demands of an increasingly dynamic offering to meet the needs of a very concrete and specific segment.

With over 20 years of experience on our backs, in Paleorama we have detected several of these user needs and therefore we have focused our efforts to meet them. For this reason we have developed (still in beta) two programs, Cronotablas and Paleocatálogo 3D. The first is an application to manage in a simple and effectively way, the range of activities of any center or museum. Among its main features are the flow visits control (regardless of the type of activity), logistic and organization, planning and anticipation of associated costs, a powerful alert sys-

tem and two interesting communication and statistics modules. But surely its main strengths is that are working both on local and server mode and its interface is clear, simple and intuitive allowing full control "all at a glance".

It is an ideal application for small businesses and organizations that start their career in the field of the complex Heritage dynamization. The Paleocatálogo is an object-oriented application that allows teachers and students to view, rotate, zoom, download and project the main peninsular and international prehistory objects..

But what is certainly relevant is that both programs may be used free of charge, both individual users and the public or private sector. For a company like Paleorama with a high degree of maturity, the challenge is to give, share, contribute openly to improve and enhance the public's interest in our great heritage, and facilitate other companies the long and thorny road of Heritage business management. Open Innovation is therefore, our next goal.

For the development of our work we have used (in the case of Paleocatálogo) photogrammetric restitution for object scanning, generating high definition models and models with lower polygons to optimize time downloading, facilitating their use in educational environments. In the Cronotablas software, we have used different programming languages such as html5 to support its use and display in the Web and in major mobile and touch devices.

The Cronotablas software has allowed us (1) to eliminate common complex interface problems being able to visualize in an accurate, easy and on one screen view, all the information related to organization and supply management, (2) minimize the disadvantages of working in local mode, allowing remote online access (including mobile devices), enabling transparent management and reducing significantly delocalization problems and finally (3) rigorous monitoring and analysis of the predefined variables through correlation and connection between the different modules. All this translates into control, comfort in users communication with and resources optimization when anticipating and planning the associated costs.

Archaeological heritage is a distinctive strength of our country and has sufficient authority for himself as for developing specific applications to optimize their management, ensuring access and a quality services to the public. The social commitment of Paleorama SL with this educational project is embodied in these two applications as part of a more ambitious and long term open innovation program.

ORAL

## 15. PARCHIPITHECUS: AN EDUCATIONAL ALTERNATIVE TO VISIT MUSEUM OF HUMAN EVOLUTION IN BURGOS USING ICT.

*García Andrés, Joaquín (Universidad de Burgos) jgandres@ubu.es*

*Rodrigo Alonso Alcalde (Museo de la Evolución Humana) ralonso@museoevolucionhumana.com*

Parchipithecus is one educative proposal conceived to make more dynamic visits to the Museum of Human Evolution (MEH) lead to high school students. Because of the nature of this institution and the singularity of its contents, base in human evolution, the set of the activities has been design in order to make the students achieve the basic contents about this process, through the use of some of the most essential premise of it. Using the parallelism between the visit to the museum and the human evolution we aspire to make easy to understand it in a significant way.

In order to get this knowledge, the proposal is based in a didactics methodology and fundamentally active activities, this transfers importance to the student in the bosom of a model of "learning by guide discover". Organize in small teams, the students take over the role of scientist, at the same time that they investigate freely by the facilities of the MEH, they gain the principal contents combine the scientific method and the ludic aspect that reveals the title of this experience.

In fact, the name given to this activity has been given in order to the game that unite all the activities offer, this game has been inspired by other popular game "Parchisi", but with a new point of view focus in the research of information throw thirty-two key questions relatives to four different areas of the museum: Geologic, Evolution, Brain and Prehistoric Culture. Their resolution with more or less success allows players to know their hypothetical level of CC (Key Questions about this four areas), and paying attention on it, their grade of adaptation to the environment.

Distribute in different phases through a large sort of activities, this allows to give space in a integrate way and simultaneous in a different educative levels and, above everything, academic and personals interests with enough flexibility. In this way we expect to create an appropriate context in which develop an attractive visit, alternative to a conventional and significantly in an educational level, in addition we transform the MEH in an alive

institution and a reference of innovation in a formative area, like it is already in a expositive level.

In this sense, the dynamic of the work incorporate a joint of resources link to the CIT, focus in the using of the cellphone, in order to obtain one of the parts of the refer information through of Qr codes, also to communicate between players using Whatsapp, or taking photographs and record videos or record explanations that, eventually, the educators of the MEH provide.

Further than its apparent competitive character, all the didactic activities is subject to the realization of the final common conclusion, of the work realized by each team, this time in the common framework of learning, that it emphasizes that the amount of the contribution makes possible that everybody obtain a complete view and the ensemble of the contents, acquired in a motivated and personal way.

#### ORAL

### 16. LA CUNA DE LA HUMANIDAD: LOS FÓSILES DEL YACIMIENTO A LA EXPOSICIÓN

*M. C. Ortega 1 y 2; E. Baquedano 2 y 3; A. Gidna 2 y 4; A. ZP. Mabula 2,4 y 5 ; F. Diez 2 y 5; M. Dominguez-Rodrigo 2 y 6. 1. Centro Mixto UCM-ISCIll de Evolución y Comportamiento Humanos, Madrid (Spain). 2. Instituto de Evolución de África (IDEA). 3. Museo Arqueológico de Madrid, (Spain). 4. Museo Dar es Salaam, Tanzania (África). 5. University of Dar es Salaam, Tanzania (Africa). 6. Universidad de Valladolid (Spain). 7. Universidad Complutense de Madrid (Spain)*

The fossils presented in the exhibition "The Cradle of Humankind", come from Olduvai Gorge located in the Ngorongoro Conservation Area (Laetoli y Olduvai George) in the Arusha region of northern Tanzania. These sites preserve an impressive archaeological and paleontological record yielding remains of several hominin species such as *Homo habilis*, *Homo ergaster* and *Paranthropus boisei* as well as faunal remains during the last two million years. These derive from the following sites: BK, SHK, MK, FLKN, FLK Zinj, FLK West, PTK, TK, DK y AMK. The fossils often appear fractured, jumbled and encased in hard sedimentary concretions, which complicates their excavation. In addition, the sites are located far from the base camp and field laboratory, which complicates their transport, particularly the very large-sized fossils. This region of Africa does not have paved roadways and transport on the irregular roads can lead to fracturing of the fossils. The path for the fossils from the archaeological sites

to their display in the the exposition is a long and difficult one. All of the hominin and faunal species from diverse time periods are represented. Many of these were recovered by different researchers and excavation teams (the Leakeys during the 1950s and 60s and the current excavation team from 2006 to the present) taking different methodological approaches, both in terms of the excavation as well as the conservation/restoration of the fossils themselves. Specific conservation techniques employed by the current excavation team include in situ consolidation and protection, chemical and/or mechanical cleaning, specimen reconstruction and preservation with the consolidant B-72 at 5% concentration in acetone (CH<sub>3</sub>COCH<sub>3</sub>).

The Leakeys also performed chemical and/or mechanical cleaning, reconstruction with an unknown adhesive (possibly of natural origin), putty-reinforced reconstructions and use of structural supports between large fragments, volumetric reintegration with plaster and surface protection with an unknown natural varnish, possibly shellac. Present-day treatments of the fossils excavated by the Leakeys include stabilizing the moisture exposure through a slow, controlled drying process in a water-tight environment. In addition, a supporting "bed" is often constructed conforming to the contours of the individual fossil. The varnish is removed by applying a 3% concentration gel of dimetilsulfoxide with Klucel, leaving the product on long enough until the varnish is softened and can be removed with dissolvent. This is followed by dripping consolidant on the reconstructed region with Paraloid B-72 acrylic resin at 10% in acetone and subsequently filling in the cavities with a 20% solution of the same. The human fossils which could not be transported to the exhibit were molded directly, in the case of postcranial remains, and surface scanned, in the case of the crania, to produce polychrome resin casts with a similar finish as the originals. The results are entirely satisfactory.

The process was guided by the principle of minimum intervention and reversability, as well as exhaustively documenting the different stages of the process. Extraneous products and dirt adhering to the specimens have been removed without altering the interpretation of the fossil. A non-abrasive and homogenous cleaning has been carried out. The consolidation was done with compatible products and innocuous methods that do not alter the physical/chemical properties of the fossils. The reintegrations were minimal and aimed toward stabilizing the fossil. After analyzing the state of preservation, the moisture and structural stability was made a priority. Previous restorations were respected as long as they did not

institution and a reference of innovation in a formative area, like it is already in a expositive level.

In this sense, the dynamic of the work incorporate a joint of resources link to the CIT, focus in the using of the cellphone, in order to obtain one of the parts of the refer information through of Qr codes, also to communicate between players using Whatsapp, or taking photographs and record videos or record explanations that, eventually, the educators of the MEH provide.

### 17. EDUCATIONAL AND INFORMATION STRATEGIES, DIFFUSION AT MUSEUMS AND PREHISTORIC SITES.

*Martín Nájera, Aurora (Museo de la Evolución Humana)*  
*amartin@museoevolucionhumana.com*  
*Alonso Alcalde, Rodrigo (Museo de la Evolución Humana)*  
*ralonso@museoevolucionhumana.com*

The transmission of scientific knowledge is an actual matter that has acquired a new dimension in the educational and in at museums' world. Information, ways of learning, resources, graphic and interactive possibilities are considered, more often, like fundamental to develop cultural programs, where we can find exhibitions about scientific museums, teaching centre or interpretation of archaeological sites.

Museums bring the public closer to scientific discoveries, they offer exhibitions that keep the scientific method and present in a understandable and entertaining way the importance of Science in our life. Its work is based in the information given by the scientist, in order to update contents, but also how its resources reach the visitors, understanding mediation like a fundamental part of its nature.

But not everything is an exhibition; they also develop an important cultural program that strengthens the knowledge expressed in the collection of the Museum, introducing polemic themes or new points of view that open new perspectives unknown at the moment, searching interactivity and citizen involvement.

Inside the regulate education exist interesting support that goes over the line of just teaching, they take the student into a scientific experience because resources were conceived to increase the creativity of the students bringing to light in a different way a cultural legacy resource, a historic period or a particular research project. But new technologies also suggest different ways of information and an increasing diffusion of the scientific themes: websites have more and more interesting resources to incentive the interest of the society, using audio-visuals carry out strictly based in the scientific

method. Interactive games, interactive games where you have to use different sort of abilities with the new technologies and different levels of knowledge or blogs where you can read about different themes and they get updating in order to bring them closer to society.

Companies working in explaining the cultural legacy are coming out to light and they have begun to invest in new technologies, with the goal of create a net to make themselves known but also to organise their knowledge and the different offers that they have. Mobile applications open new fields of possibilities, and getting closer to different kinds of public until now far to the scientific world.

On the other hand, we can appreciate, day by day, the need of working in a net following the aim of offer a large sort of information about diversity of the museum centres, that has in common one thematic relate to some scientific theme.

Coordinate this actions running by different agents it change into a need to keep a global perspective, join and scientific about everything related with the human evolution area.

---

## POSTER

### 18. SEDUCTION IN THE DISCOURSE OF ARCHAEOLOGICAL DISSEMINATION

*San Martín González, Francisco Javier (Universidad del País Vasco)*  
*activatuneurona@gmail.com*

The resources of oral speech in the spreading of archaeology are as important as the visual. A bad Communicator, like in a radio, can make that the public "turn off" their neuronal receptors and assess their visit to a museum like not positive. The same can happen if you have only the option to recourse to modern technological applications. You cannot know how to use them or simply cannot feel obligated to do so. We propose a series of oral language resources, used in radio journalism, whose use is being studied as part of a doctoral thesis in science journalism, which can be exploited by the archaeological guide in their efforts to attract the attention of the visitor and socialize the knowledge in museums or archaeological sites.

The Garcia-Ureta's (2012: 99-124) studies about the perception of the oral message by the public, referring to radio broadcasters, can very well be applied to the scientists. The author says that "a technically perfect voice can

make it quite indifferent to an audience that connect on the emotional level with a little involved Communicator with the message transmitting or unsure of itself”.

We hypothesize that the increase in use of the oral media resources, as in the radio, will result in the better understanding by the public of the archaeological scientist message. Study the oral and auditory resources that facilitate the understanding of the scientific and archaeological discourse. Check and measure their effectiveness in the communication. According to Armand Balsebre (1996: 23) 4 types of languages are defined in the radio: verbal language, musical language, sound effects... and silence.

We unearth in this poster some characteristics of verbal language, as the ringer, tone, intensity, melody or rhythm, and we will make examples of contents and about resources, that can be connected to the emotional level of the people who attend conferences, seminars, workshops, or visit a museum or archaeological sites.

It has developed an audio-poster, with which we will invite attendees to listen an audio record, in which we apply some auditory resources, in order to measure the perception of the readers/listeners about auditory resources used in the communication.

# A16 Aegean-Mediterranean imports and influences in the graves from continental Europe - Bronze and Iron Ages

Commission on Mortuary Practices in Prehistory and Protohistory

**1. ABOUT THE CONNECTIONS DURING THE BRONZE AGE BETWEEN THE CARPATHO-DANUBIAN AREA AND THE EASTERN MEDITERRANEAN SPACE. POSSIBLE FUNERARY PROVES**

*Schuster, Cristian - ("Vasile Pârvan" Institute of Archaeology - Center of Thracology, Bucharest, Romania) cristianschuster@yahoo.com*

Many archaeologists have spoken of strong connections during the Bronze Age between the Carpatho-Danubian area and the Eastern Mediterranean space. This conclusion was formulated especially concerning the Middle and Late Bronze Age, following the discovery of artifacts that, apparently, came from the south.

Our demarche will try to identify possible relations with the Aegean area in the funerary practice of the communities from the Carpathian area. Singular funerary monuments from Dobrugea, Muntenia, Oltenia, Moldavia and Transylvania will be analyzed. The funerary practices of the following cultural phenomena will be considered: Zimnicea-Batin, Glina, Schneckenberg, Yamnaya, Katakombnaya, stone cist graves, Mures, Wietenberg, Tei, Verbicioara, Monteoru, Noua, Coslogeni, Radovanu, Zimnicea-Plovdiv, Otomani, Suci de Sus etc.

Even a superficial look shows that most of the enumerated cultures had, in the funerary domain, connections with the eastern, North-Pontic areas and western, Middle Danubian ones. Few artifacts, found mainly in Gârla Mare and Zimnicea-Plovdiv graves (cultural manifestations identified on both banks of the Danube, on the territories of Romania, Bulgaria and Serbia) allow the establishment of connections between the Northern Danubian areas and the Mediterranean space. It is obvious that the respective material proofs are the result of exchange between communities and of product imitations (metalwork especially). Weighting the proofs concerning the connection between the areas north of the Danube and the South it becomes evident that there is a quantitative and qualitative difference between the discoveries made in the domestic space and those made in funerary contexts. The funerary monuments, opposed to the settlements and to hoards, prove to be more conservative in showing southern connections.

Even the few anthropological studies reflect that the connections with the South were not that strong. They also show that the intake of population was in some stages from the East (Early Bronze Age – cultures Yam-

naya, Katakombnaya, Noua, Coslogeni), and in others from Central Europe (Middle and Late bronze Age – cultures Otomani, Wietenberg, Gârla Mare).

It can be said that the cultural manifestations of the Bronze Age from the Carpathian area are more connected with what happened in the East (in the Republic of Moldova, Ukraine and Southern Russia) and at the Middle Danube (in Hungary, Slovakia, Eastern Austria). Connections with the south of the Balkan Peninsula existed, including population movements from North to Macedonia, Greece, Anatolia, but they did not have a strong resonance in the funerary practice.

ORAL

**2. ALLOCHTHONOUS VERSUS AUTOCHTHONOUS: AN INTERPRETIVE READING OF THE FUNERARY WORLD OF THE LATE BRONZE AGE IN ALTO RIBATEJO (PORTUGAL)**

*Cruz, Ana - (Instituto Politécnico de Tomar), Ana Graça - anagrace@ipt.pt (Instituto Politécnico de Tomar) anacruz@ipt.pt*

The debate between evolutionist and diffusionist just seems to be endless because we have not been able to find "convergence" between the regionalisms detected in the material culture of excavated sites and relevant influences, whether Mediterranean, Atlantic or Continental, also detected in the archaeological record.

In addition to this discrepancy there is the confirmation - which is also archaeological - of a typological and morphological universe, essentially metal-based, which suggests the circulation of people and long-distance trade. The research developed in Alto Ribatejo takes into account these two fundamental trends of interpretation. However, according to archaeographical data, these trends seem to be "reconcilable." The "reconcilable" concept reflects the approach of two apparently distinct and paradoxical realities. Although Portugal is geographically peripheral to the European continent, it boasts a privileged position in relation to the Mediterranean and the Atlantic. At the micro-level, the Alto Ribatejo also experiences this "centre-periphery" paradigm. Within this univocal relationship, we think there might have been an internal agreement between the communities, which can be justified by very particular localisms and regionalisms, although external influences are obvious in the archaeological record.

The state-of-the-art research on the Bronze Age of the Alto Ribatejo reveals a binary organisation that distin-

guishes one phase comprising the Early Bronze and Middle Bronze (Full Bronze) and another with very different characteristics corresponding to Late Bronze Age (which in turn divides into two phases, Late Bronze I and Late Bronze II), which some authors attribute to the cultural "family" of the Atlantic Bronze.

This apparently paradoxical and dialectical process reveals primarily at funerary level. No burial records have been identified in the excavated settlements. They normally appear on hilltops, either alone or in small groups, and were characterised by us as burial records in the form of tumuli. These burial records are located outside the villages and consist of small circular mounds full of quartz and quartzite pebbles concealing the evidence of urn incineration and are datable to the Late Bronze Age. How and when changes have occurred in the funerary pattern, replacing the megalithic re-use and the burial cist by *tumuli*, and what kind of exogenous scale may have existed in this phase of the Bronze Age are issues that deserve further discussion.

ORAL

### 3. SOUTHERN AND PONTIC AMPHORAE FOUND IN SEVERAL GETAE NECROPOLISES IN THE LOWER DANUBE AREA (5TH - 3TH C. BC)

*Sirbu, Valeriu - (Museum of Brila; Institute of Archaeology Bucharest - Romania) valeriu\_sirbu@yahoo.co.uk*

*Matei, Sebastian - sebastianmatei@yahoo.com (County Museum Buzau - Romania)*

In the 5<sup>th</sup>-3<sup>th</sup> c. BC, the Getae – the north-eastern branch of the Thracians – experienced outstanding progress, as evidenced by impressive residential centres (some of them fortified with brick walls or cut limestone), as well as by impressive tumulus graves (sometimes with sculpted and painted rooms) or by rich treasures of gold and silver.

The Getae settlements and graves yielded numerous and diverse Aegean-Mediterranean or Black Sea imports, with an important place occupied by amphorae, which shows that the Thracian elites were connected to the tastes of the southern civilizations.

Thus, in the Getae graves, particularly those that can be attributed to aristocracy, one has found many amphorae, some southern, from Mediterranean centres (Rhodes, Kos) or Aegean centres (Samos, Chios, Thasos), some from Black Sea (Sinope, Heraclea, Chersoneses).

Our paper will emphasise – in several major necropolises from the Lower Danube area – both the centres that the amphorae are coming from, and their diverse use in graves (as funerary urns or as recipients with wines/food offerings) or at funerary feasts. Based on the spread of the amphorae and of their production centres, we will try to identify the ways by which they entered the area, as well as the possible poleis that mediated the wine and oil trade in the north-Thracian world.

We will also compare the number of amphorae found in settlements with the number that came from graves, in order to underline to what extent these recipients were used in the Getae funerary practices.

The presence of amphorae in some graves, together with other luxury items, shows not only that the dead had significant material resources, but also that their presence are indicators of the social status of the dead and of certain rituals which were performed for them.

ORAL

### 4. GREEK IMPORTS IN THE SOUTHERN GROUP OF TUMULI OF THE EASTERN ROYAL GETIC NECROPOLIS IN THE SBORYANOVO RESERVE (4TH-3RD CENTURY BC)

*Gergova, Diana - (National Institute of Archaeology with Museum-Bulgarian Academy of Science, Institute of Archaeology, University of Rzeszow, Poland) dianagergova@gmail.com*

The excavations of the Hellenistic necropolis of the religious and political capital of the Northern Thracians Dausdava- Helis in the Sboryanovo National reserve throw light not only on the culture, the religious beliefs and the burial "rites of immortalization" that had been practiced by the Getae, but also on historical and political events during the apogee of the development of the Getic kingdom in the last decenia of the 4<sup>th</sup> and the first half of the 3<sup>rd</sup> century BC.

The burial rites, as well as specific features of the Getic Hellenistic tombs show their connection with the earlier traditions of the Early Iron Age Thrace enriched with the contemporary architectural achievements of the Hellenistic world.

The imported pottery and mainly the amphorae from the 11 investigated tumuli of the Southern group,

(4 of them investigated in 1912-1913) originating from Thasos, Knidos, Heraklea Taurica, etc, their contexts, content and chronology through new light to the royal burial practices of the Getae and contribute to the precision of the absolute chronology of the tumuli of the Southern group.

The recent discoveries confirm the hypothesis about their almost simultaneous construction of the tumuli and the connection of the complex with the burial ceremonies of the first known from the written sources Getic king from the pre-Hellenistic and Hellenistic period - Kotela and the probable period of his rule. They contribute also to the historical reconstruction of the role of the Getic kingdom in the political life of the Pontic and Mediterranean world.

#### ORAL

### 5. THE MACEDONIAN FUNERARY MODEL AND ITS IMPLEMENTS IN NORTHERN THRACE - AN OVERVIEW ON THE OCCASION OF NOVEL INVESTIGATIONS IN THE KALLATIAN NECROPOLIS

*Stefan, Maria-Magdalena - (Institute of Archaeology and Art History Cluj-Napoca) madi\_burton@yahoo.com*

*Sîrbu, - Valeriu (Museum of Brila; Institute of Archaeology Vasile Pârvan Bucharest) valeriu\_sirbu@yahoo.co.uk*

*Dan Stefan - (Institute of Archaeology Vasile Pârvan Bucharest) danstefan00@gmail.com*

Monumental tomb architecture was definitely one of the outstanding elements of the royal ideological discourse during Hellenistic times in the Mediterranean basin as well as Asia Minor, attesting the changes in the public representation and reception of rulers, as a social, religious and cultural phenomenon with obvious political symbolism, following the military actions of Alexander the Great. New architectural and ritual developments in the funerary practices (the so called Macedonian tombs) may be clearly linked with the military glory and political growth of Macedonian royals and elites, especially in authority centers around the Thermic Gulf, during the middle of the 4th–3rd cs. BC, as with their adoption of oriental rulers' ideology in terms of individual glorification and deification.

The authors propose to discuss the significance of discoveries of this particular Macedonian funerary category in the lands of their northern neighbors – the Thracians – parts of whom entered under the direct control of Macedonian kings or fought as mercenaries in their

armies, in terms of assessing the degree of exercised or just claimed political control, symbolic challenge of authority, cultural contacts, but also referring to the adoption and circulation of power symbols and ideology on large spaces, in a design specific to a center-periphery system. The analysis is well justified as Thracian tribes had a previous strong tradition of expressing elite status in monumental tomb architecture and developed specific funerary types and associated rituals. Thus, the study aims to explore the impact of Hellenistic type ruler ideology on Thracian chieftains, in the context of emergence of local centralized power structures and continuous competition between families of Alexander's Diadochs for control over parts of his large Empire. In particular, the synthesis on using and adjusting the Macedonian type of funerary architecture in Thrace will benefit from recent studies undertaken in the necropolis of the Greek colony on the western Black Sea coast – Kallatis, studies that have focused on non-invasive investigations of a tumulus covering a masonry tomb exhibiting both Macedonian and Thracian style architectural elements and employment of multiple construction stages. Around Kallatis, other Macedonian style tombs were found in the past, pointing to the specific context in which the Greek city led a great coalition against the Macedonian ruler of Thrace – Lysimachus in 313 BC. Being old and undocumented excavations, their interpretation was often linked with the presence of Scythian authority in the territory of Kallatis. There is, however, a considerable need for data reintegration and reevaluation.

Willing to overcome a, somehow, traditionalist point of view in interpreting material culture, which already placed scholars in a dispute considering the origin of the so called Macedonian Tombs, the proposed study attempts the integration of the Thracian late 4th-beginning of 3rd cs. BC funerary discourse in the larger cultural Hellenistic background of the time, marked by great warrior mobility and military turmoil sweeping over the Balkan Peninsula and Asia Minor.

# Recent Trends and Aspects of Use-wear Analysis A17a and their contributing to the Modernization of Archaeology

## 1. STATISTICAL ANALYSIS OF USE-WEAR MICRO-SCARRING: POTENTIAL AND LIMITS FOR IDENTIFYING TOOL USE.

*Perales, Unai - (Universidad del País Vasco/Euskal Herriko Unibersitatea) perales.unai@gmail.com*

*Ibáñez, Juan José - (IMF-CSIC) ibanezjj@imf.csic.es*

*González Urquijo, Jesús Emilio - (IIIPC-Universidad de Cantabria) jesuse.gonzalez@unican.es*

The development of the methodology of use-wear analysis during the 70's and the 80's of the last century was disrupted by the disputes of the so-called high-power and low-power approach. From the 90's a more pragmatic point of view was adopted by most of the use-wear analysts, stressing that, when possible, all kind of traces should be used to reinforce the reliability of the functional inference. Micro-scarring analysis is a useful source of functional criteria for the study of un-retouched active zones, in contexts where tools have not suffered heavy post-depositional alterations. However, it is still necessary to determine quantitatively the potential and limits of this type of trace, in order to established reliable rules for use identification.

We have quantitatively analyzed micro-scarring in more than 150 experimental tools used for cutting different materials. We have observed that the scar length, the scar density along the edge and the distribution of the scars along the edge (isolated, continuous or overlapped) are the two parameters which can be used for identifying the worked material.

Through the statistical analysis of the data gathered in our experimental collection, we discuss the potential and limits of these two variables, which, beside by the worked materials, are affected by the time of use and the degree of strength applied in the activity. Finally, we establishing the type of inferences which can be achieved resorting to this kind of trace.

## 2. TOO MANY BURINS, TOO FEW GROOVES.

*Domingo Martínez, Rafael - (Universidad de Zaragoza) rdomingo@unizar.es*

The presumed identification of nucleiform endscrapers or burins as cores for bladelets is a commonplace in the

study of the Upper Palaeolithic, but there is a notable lack of functional and technological approaches to this subject. We would like to show how functional analysis could help prehistoric technologists to discern the real balance between tools and cores in lithic assemblages.

This paper focuses on this matter through the study of some examples, from the Gravettian of Arenal de Fonseca (Teruel) to the Magdalenian of Cova Alonsé and Forcas (Huesca), Rascaño and Juyo (Cantabria) and El Cierro (Asturias). There, many endscrapers and burins have been traditionally classified as normative tools after the list of Sonnevile-Bordes. In fact, most of the common lithic cores found in these and other sites provided blades that were too large to be retouched and utilised as projectile elements. There is growing evidence that points to *chutes de burin* as the real blanks for many of the backed bladelets.

In some cases, functional analysis has shown that many of the thick burins and endscrapers (whether classified as nucleiform or not) were mere bladelet cores; in others, they were reused as actual tools, mostly in scraping tasks. Although we cannot establish a formal trend for such a vast region during thousands of years, it is interesting to stress the different solutions achieved by the prehistoric hunters.

ORAL

## 3. NEW EXPERIMENTAL DESIGN AND ITS CONTRIBUTION FOR FUNCTIONAL ANALYSIS: THE GERINGONÇA

*Pereira, Telmo - (ICArEHB, Universidade do Algarve, Portugal) telmojrperreira@gmail.com*

*Rui Martins (ICArEHB, Universidade do Algarve, Portugal)*

*Marreiros, Joao - (ICArEHB, Universidade do Algarve, Portugal) jmmarreiros@ualg.pt*

Functional analysis is characterized by the identification of regular wear marks resulting from the combination of both active tool and passive worked material.

The result of such attrition created between their proprieties is the formation of regular features that can be divided in a way that allow us to infer past human behavior.

For the last almost 100 years, researchers have tried to replicate past human behavior through experimental works, usually replicating present hunter-gatherers technology. Some researchers even use hide, sometimes

made by themselves, trying to reach even closer the spirit of the past hunter-gatherers.

Despite the enormous effort made by these researchers, the exquisite of their tools and the importance of their achievements, many other researchers do not find such results, databases and reference collections reliable. This is because they miss one important thing: absolute control of the variables.

The production of regular features is directly related with each action has several physical variables in use. The change of one variable can have impact in the pattern and mislead the tool interpretation. Consequently, one solution for such problem can be the creation of mechanical devices that control, at least, some of the variables.

Mechanical devices are in the opposite end of the experimental works referred before and can be criticized for being unrealistic since (1) they are not human and (2) humans do not have all variables absolutely controlled when working. However, they allow us to sharp and narrow the limits of the window where each feature and respective intensity occur, meaning that we can fit them into numerical data and then triangulate such information with traditional experimental work or ethnographic data and the archaeological record. With this approach, it is expected that our interpretation of the past will be more accurate and recognize with high accuracy the production of each specific use-wear signature.

In this perspective, we developed a mechanical device that controls several variables: the Geringonça.

Geringonça allow us to control individually with high precision and in real-time the angle, strength, speed, pressure, time of the action, number of movements, type of movement, active and passive materials used.

In this paper we present some of our preliminary results, specifically, cutting *Pinus silvestris* wood perpendicularly to the veins with flakes.

In this experience the only variable that changed was raw material; we used chert and quartzite and our results indicate that each raw material performs differently under the same stress conditions, suggesting that their use might have been related with their suitability and not only due to their availability.

ORAL

#### 4. MONITORING AND INTERPRETING THE USE-WEAR FORMATION ON EXPERIMENTAL QUARTZITE STONE TOOLS

*Pedergnana, Antonella - (IPHES-URV)*

*apedergnana@iphes.cat*

*Ollé, Andreu - (IPHES-URV) aolle@iphes.cat*

Use-wear analysis has been largely applied to determine stone tools functionality, but not so many efforts have been done to extend this methodology to non-flint raw materials. Although functional analysis on quartzite implements is normally performed, practically no experimentation focusing on this kind of rock has ever been undertaken on a systematic basis. We assume that, within the framework of use-wear analysis, sometimes a reduced number of experiments on quartzite implements has been performed. Nevertheless, the resulting implications were hardly ever investigated. Indeed, we noticed that as a prevailing attitude to deal with these methodological weaknesses (when analyzing use-wear on non-flint raw materials), analysts applied the same methodology developed for flint artifacts.

Knowing that quartzite mechanical behavior differs from that of flint (because of structural differences), we recognize the need to sort a set of functional parameters specifically related to this kind of rock, relying on a comprehensive experimental collection. Therefore, a large-scale experimental program focused on the formation, identification and possible interpretation of use-wear traits on quartzite was initiated. The experiments included different quartzite varieties, presenting slightly different characteristics (in order to highlight analogies and divergences related to their mechanical behavior when a force is applied) and were conducted on different worked materials.

Sequential experiments have been set up with the purpose of monitoring use-wear formation processes, that means that we casted the fresh edges and then we observed them (after having been used) microscopically throughout the various steps of utilization. For data recording, we resorted to imaging through both optical and electron microscopes (OLM and SEM), stressing the importance of the employment of an integrated approach.

Experimental residues of the worked materials were scanned as well with microscopic facilities with the aim to understand their role as interfacial medium affecting

use-wear formation. EDS (elemental x-ray spectroscopy) has been used to document the presence of rock particles detached from the tools edges and then embedded in the residues of the worked materials. Those particles are considered to be crucial for the formation of use-wear on stone tools.

Results obtained on experimental flakes allowed us to infer more closely the mechanical behavior of quartzite and specific use-wear features have been carefully described. Then, the potential of different microscopic techniques has been evaluated and it emerged that the most reliable and elaborate results are obtained when the two approaches are combined: in an integrated approach the disadvantages of one technique are compensated by the advantages of the other one.

ORAL

## 5. MICROWEAR ON EXPERIMENTAL GRANITE TOOLS

*Agarwal, Neetu - (Universitat Rovira i Virgili, Tarragona, Spain) neetu1501@gmail.com*

*Ollé, Andreu - (Universitat Rovira i Virgili, Tarragona, Spain) aolle@iphes.cat*

Most usewear research has been undertaken with either European flint or other siliceous material with similar physical and microwear properties or obsidian. Very few studies have been made using coarse-grained rocks like basalt, quartzite, quartz, volcanic tuff and rhyolite.

Granite has been utilized for making stone tools in quite a few Lower Paleolithic industries in Africa and India, namely, Isimila, Tanzania in Africa, Lalitpur, and Hunsgi-Baichbal basin, India. However, to our knowledge, no study has been conducted to study usewear traces on granite, and so we fail to have any functional information for these tools.

Therefore this study was undertaken to see the feasibility of identifying use-wear traces on experimental granite flakes and to determine the effects of different use-actions and contact materials on the tool edges.

Detailed, sequential analysis of microwear development was undertaken. For this purpose, we utilized a short range of contact materials varying in hardness, namely, meat, wood, hide and bone and only two use-actions, namely longitudinal unidirectional or bidirectional and transverse unidirectional actions. The edges of the

used tools were examined under a Scanning Electron Microscope (SEM) at magnifications ranging from 25x to 1000x.

The short experimental programme showed that the use of granite tools leaves recognizable wear features on the tool edges and edge aspects, and this wear is characteristically different for tools used on different contact materials and use-actions.

ORAL

## 6. DOCUMENTING AND ANALYZING HAFTING-TRACES USING GIGapixel IMAGES. A CASE-STUDY FROM THE LATE UPPER PALAEOLITHIC SITE OF LA CATIVA (TARRAGONE, SPAIN)

*Vergès Bosch, Josep María - jmverges@iphes.cat (IPHES-URV)*

*Morales Hidalgo, Juan Ignacio - jignacio.morales@gmail.com (IPHES-URV)*

Hafting-traces could be evident at different scales, from millimetric chipping to micrometric polished surfaces. The isolated observation single evidences could be enough in order to identify the presence of hafted tools. But anyway the spatial and topographical relationship between the whole set of traces needs to be established to construct an identikit picture of the kind of haft and the hafting techniques employed.

Traditional photographic documentation, whether it is done by optical or electron microscopes, presents some continuity limitations in order to relate wears at different scales or distant between them. In these cases we dispose of different images from different tool areas, and at different magnification, that must be interrelated descriptively. This fact became evident when use-wear needs to be interpreted using the photography as a raw data, or when we select some examples to illustrate reports and publications.

The construction of gigapixel mosaic images allows displaying in a single composition the whole surface of an interest point independently of its size. It allows observing the selected area at different scales, with the only boundary of the magnification and resolution of the acquirement conditions of the individual images. Using this procedure is possible to reconstruct the microscope observation conditions in both study time and publication. Additionally it is not necessary to choose a single point to show as an example, allowing

observing any place of the represented area at different magnifications.

The gigapixel images performed in the study of the endscrapers from the level B of la Cativera allows to present and discuss the didactic and scientific possibilities of this kind of documentation.

---

ORAL

## **7. A PROPOSAL FOR THE MORPHOLOGICAL AND CHEMICAL CHARACTERIZATIONS OF EXPERIMENTAL MICRO-RESIDUES ON STONE TOOLS BASED ON AN INTEGRATED APPROACH INCLUDING SEM AND LIGHT MICROSCOPY**

*Pederagnana, Antonella - (IPHES-URV) apederagnana@iphes.cat*

*Ollé, Andreu - (IPHES-URV) aolle@iphes.cat*

*Asryan, Lena - (IPHES) lasryan@iphes.cat*

Residue analysis has been used with improving frequencies within the lithic studies to obtain more information about the function of ancient stone tools. Very often this kind of analysis has been applied in combination with use-wear analysis to improve the accuracy of the functional interpretation.

In spite of the great progress accumulated in the study of residues, a number of methodological problems has been put out by analysts, especially related to the identification of residue types. Over many decades Optical Light microscopy has been the dominant methodology in the study of residues, that means that residue identification is normally based on differential morphological features and colours. However, besides from general difficulties in finding and recognising archaeological residues, there were always other factors conditioning this recognition, such as post-depositional processes, which inevitably modify the original morphology of micro-residues.

The main aim of this research is to provide some methodological improvements to residue analysis by means of the creation of a catalogue composed by microscopic images including experimental residues obtained from plant and animal sources. A special concern has been raised to find an approach for correctly identify residues on archaeological stone tools, trying to avoid the possibility to misinterpret them because of overlapping morphologies. With this purpose, Light Microscopy has been employed as well as Variable-Pressure Scanning Electron Microscopy and

advantages and disadvantages of both techniques have been highlighted. By comparing micrographs taken with both techniques, we can obtain a more complete morphological characterization of the various residue types. We have also applied energy-dispersive x-ray spectroscopy (EDS) for elemental analysis of residues, which has showed its great potential in reducing the possibility of an erroneous interpretation.

In addition, modern contamination has been considered as a possible source of misinterpretation and a special care in the cleaning procedures has been claimed. In our opinion, analysts should not underestimate the presence of modern contaminants when scanning lithic archaeological surfaces and might learn how to discriminate background noise due to handling.

The results of this study have shown that only the use of different microscopic techniques (OLM, SEM) and the application of additional chemical analyses permit to properly interpret the organic residues found on the surfaces of the archaeological stone tools.

By providing chemical and morphological composition of experimentally produced residues and by stressing the importance of detecting modern contaminants we believe that we improved, to some extent, the accuracy and effectiveness of lithic micro-residue analysis.

---

ORAL

## **8. APPROACHING BEHAVIORAL STRATEGIES IN A FUNCTIONAL PERSPECTIVE**

*Longo, Laura - (Musei Civici Fiorentini) longoflint@gmail.com*

*Skakun, Natalia - (Institute for the History of Material Culture - RAS) skakunnatalia@yandex.ru*

The exploitation of specific resources in order to produce food brought the scientific community to investigate two main questions. First, what were the driving factors and changes that caused human adaption towards tool production and tool use? This brings up the second question: how can we properly investigate tool production and utilization? The heuristic approach of functional analysis/traceology is complex. It includes use-wear analysis, raw material characterization and procurement, and experimental reconstruction of the operational sequences in terms of tool production, tool use and abandonment. This approach demonstrates the methodological model that enables archaeologists to

investigate the evolutionary phenomenon of artefact production and utilization as a process through which the technological, cultural, and adaptive paths of human groups can be reconstructed.

Functional analysis demonstrates its interpretative potential in a comprehensive mixing of all the behavioural attributes with functional, technological, stylistic, cultural or even ecological perspectives. The adoption of the new strategies of tool production and subsequent utilization would have predicted responses in embracing reliable strategies; particularly those involving logistical mobility, since tools represent *Homo* articulation with the environment. Tool production and utilization provide a mechanism to manipulate a given environment and obviate risk as well as to allow for conscious changes in mobility strategies. In addition, tool assemblages are the extra-somatic adaptive response of humans who colonized different niches, representing an innovative adaption perfect for foraging necessities.

We are presenting the results of research carried out on stone tools involved in plant processing through microscopic analysis of both micro-wear analysis of the working areas associated to residues, identified and characterized as starch granules. The analytic techniques are described. A synthetic approach was applied to identify and describe use-wear traces by means of LPA, Leika MZ6 (10 to 40 X) and HPA through the combined potential of the SEM and Digital Microscope (Hirox KH-7700) applied to wear-traces analysis.

The aforementioned analytical techniques allow us to investigate complex and standardized technology that developed in Europe about 30,000 years ago, which transforms plants in to highly nutritional food. It also allows for the investigation of how it affected modern human capacity to cope with the harsh climatic condition of MIS 2.

The new data obtained improves the consistency in the existing data on the systematic utilization of vegetables in AMHs diet and the development of technological strategies in order to transform raw material (rhizomes and starch) and to produce elaborated output (flour and even cooked rice) that can either be transported or stored. The behavioural consequences of the developed and diversified substance strategies – such as demographic changes and greater independence from environmental and seasonal fluctuations – might have been part of the evolutionary success demonstrated by AMHs compared to the strategies of the late Neanderthals.

Traceology, as intended in its broader approach, including both use-wear and residues analysis, can contribute by bring pieces of evidence about vegetable food processing. Additionally, new technologies and analytical improvements are helpful in adding data to the interpretation of tool processing.

ORAL

## 9. EXPLORING THE RELATIONSHIP OF USE DURATION AND SURFACE ROUGHNESS FOR LITHIC MICROWEAR

*Evans, Adrian A. (University of Bradford, UK) A.A.Evans@bradford.ac.u*

*Macdonald, Danielle A. (CEPAM-CNRS, Université de Nice Sophia Antipolis) danielle.macdonald@cepam.cnrs.fr macdonald.danielle@gmail.com*

Previous experimental research has shown that laser scanning confocal microscopy (LSCM) is a useful quantitative tool for the study of prehistoric stone tool function. This research has demonstrated that basic roughness parameters can characterize microwear on lithic surfaces, distinguishing between different contact materials. However, further exploration is needed to understand the effect of use duration on worn lithic surfaces. Preliminary experiments suggest that surface roughness measurements plateau once polish develops on the surface of the tool, but the intervals of duration were not fine-grained enough to capture the point of stabilisation (Evans *et al.*, in press).

This presentation will focus on a current program of experimental research that addresses how the length of use affects the surface characteristics of lithic tools. In this study, tools were used on several contact materials at increasing time intervals. Surface roughness characteristics were measured at each interval using a laser scanning confocal microscope. These experiments allow for the comparison of surface parameters over time on the same tool, tracing changes in wear on the tool surface. The results of this study are presented and avenues of future research that can contribute to the development of applied method in quantitative lithic microwear analysis are highlighted.

ORAL

### 10. USE-WEAR POLISH QUANTIFICATION THROUGH CONFOCAL MICROSCOPY: DISCRIMINATING BETWEEN DIFFERENT HARVESTING POLISH

*Ibáñez Estévez, Juan José - (IMF-CSIC) ibanezjj@imf.csic.es*  
*González Urquijo, Jesús Emilio - (IIIPC-UC) jesuse.gonzalez@unican.es*

*Gibaja Bao, Juan Francisco - (IMF-CSIC) jfgibaja@imf.csic.es*  
*Anderson, Patricia - (CEPAM-CNRS) peachypie616@hotmail.com*

During the last decade, confocal microscopy has proved to be an accurate and easy to use technique for use-wear quantification.

We have used this technique to discriminate between different use-wear polishes resulting from harvesting wild cereals in natural stands, cultivated wild cereals and domestic cereals. Some experimental tools of reed and wild grass cutting were also analyzed (22 tools in total).

Several variables measuring surface texture were found relevant for discriminating between the different types of microwear polish. The degree of polish development appears as a relevant factor affecting surface texture. Lacking an effective method to control this variable, we have isolated it choosing highly developed areas of microwear polish. Our experimental results show that, when using fine grained flint varieties, the type of flint is not a relevant variable affecting the results of polish quantification.

Finally, we have used the discriminant function resulting from the analysis of the experimental tools to classify 75 archaeological tools from the Early Natufian to the Late PPNB, showing an evolution in the characteristics of cereal being harvested which are coherent with the archaeobotanical data.

The study of macrolithic tools in the Mesolithic site of Font del Ros (Southeastern Pyrenees, Spain) has been allowed to identify a group of pitted stones. The tencnofuncional attribution of these elements, discussed in Roda Gilabert et al. (2012) states that the origin of these use-wear is related to the bipolar knapping. In this presentation we propose to document the plastic deformations linked to bipolar technique and record the modification of the active surfaces on both anvil and hammer stones.

Sequential monitoring of bipolar size by laser scanning confocal microscope (LSCM) allows quantitative data and characterizes the formation of pits. The analysis of variables as slope and roughness express the topographical variability and synthesize the characterization of active surfaces.

The micro scans show plastic deformation and allow the quantification of the use-wear patterns. Similarly, the comparison of these data with artifacts from archaeological traces reveals significant differences between the different types of use-wear.

Surface metrology indicates that pitted stones are related to thrusting percussion on hard materials. These tools are key in identification identify bipolar knapping. The Scanning Laser Confocal Microscope (SLCM) is a reliable technique for the quantitative analysis of use-wear on macrolithic tools.

*Benito Calvo, Alfonso - (Centro Nacional de Investigación sobre la Evolución Humana (CENIEH). Paseo Sierra de Atapuerca s/n. 09002 Burgos. Spain) alfonso.benito@cenieh.es*

*Mora Torcal, Rafael - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistòria (CEPAP). Facultat de Filosofia i Lletres. Universitat Autònoma de Barcelona. 08193 Bellaterra. Spain.) rafael.mora@uab.cat*

Macro lithic tools gestures and kinematic allow distinguishing two main roles: active elements (hammer stones) and passive elements (anvils). Usually these two categories have been differentiated from physical attributes as measures or weight. It has also been proposed that the types of stigmas distinguish between hammers and anvils. However, these considerations are mainly based on descriptive criteria.

We propose GIS image analysis together with metrological data to distinguish between these two categories. To test the validity of this method has been selected a sample of artifacts developed for a pilot program and a number of pieces from the Mesolithic site of Font del Ros (Southeastern Pyrenees, Spain). Spatial analysis with ArcGIS, was produced by geo-referenced photographs of objects. The digitization and mapping of the outline and use-wear visible on the photos allow positioning attributes and tags on each instrument. The collected data is used to calculate spatial pattern indices.

From a technofunctional point of view use-wear on active and passive percussion tools tend to be positioned in different areas of the objects, especially in the freehand hammer stones used in tangential percussion and anvils involved in processing activities (axial percussion). However, the bipolar technique or indirect percussion on anvil makes difficult to differentiate between the two categories.

The marks identified show a certain degree of variability, and pose a problem of equifinality in the precise determination of the functional context these tools. This hinders the quantitative differentiation between active and passive element and determines the ambivalent nature of these tools.

ORAL

### 13. ADVANCES IN MICROSCOPY: NEW TOOLS FOR USE-WEAR ANALYSIS

*Borel, Antony - (Département de Préhistoire, UMR7194-CNRS, Muséum National d'Histoire Naturelle - Institut de Paléontologie Humaine, 1 rue René Panhard, 75013 Paris, France) borel@mnhn.fr*

Two of the main issues for use-wear analysts are 1) to provide clear and appropriate documentation to support their observations and 2) to provide quantified analyses and interpretations. Several attempts to solve these issues have yielded promising results with, for example, the gigapixel image concept on one hand and the application of profilometry and laser confocal microscopy in the other hand. However, they have not, as of yet, been widely applied and use-wear analyses are still mainly performed using either Scanning Electron Microscopy (SEM) or Optical Light Microscopy (OLM). We propose here to explore, test and compare new type of microscopy which could be relevant to improve our understanding and interpretation of use traces.

Four types of raw materials (flint, obsidian, quartz and quartzite) with different physical properties are selected in order to evaluate the applicability of each microscope on different raw materials. Two artefacts by type of raw material are used on two different materials (wood and bone) in a scrapping activity. A cast of the edge of interest is made from each artefact before use and each artefact is then used during 1 hour.

Six microscopes (an optical light microscope, a scanning electron microscope, two digital microscopes, a white light interferometry confocal microscope and a laser scanning confocal microscope) are used to take the same point of interest on the cast and on the stone after use at magnification 50x, 100x, 200x, 500x, 1000x and 2000x.

The properties of each microscope will be presented and the systematic comparison of the micrographs from each of them will enable to discuss their advantages and disadvantages regarding to their use for use-wear analysis.

The study is not completed yet (but may be ready for the conference) and thus no final conclusion can be given. However, we will be able to demonstrate how technological enhancements can improve the observations of use traces and how the use of new

microscopy techniques can help establish more objective and standardize methodological procedures. Some of these new techniques are also promising for the observation of artefacts made of raw materials usually difficult to observe through common microscopy techniques.

## 1. EXPERIMENTAL ARCHAEOLOGY AND RESEARCH OF FUNCTIONS OF ANCIENT TOOLS.

*Skakun, Natalia - (Institute of the history of material culture, RAS) skakunnatalia@yandex.ru*

*Terehina, Vera - (Institute of the history of material culture, RAS) terehinavera@mail.ru*

Scientific experiment is empirical research method. Such obligatory rules are applied to experiments to make their results reliable research source: clear formulation of aims; presence of previous theoretical works serving as basis for hypotheses; serial and repeated character; careful fixation of results. Experiments put forward following aims: to confirm or cancel current hypotheses; to help in correct interpretation of results of visual studies of research object, to build up the system of argumentation.

Attempts to use various experimental methods in archaeology have old tradition. Experimental archaeology received new powerful impulse in 1950-s in the USSR thank to works of the great Russian scientist S.A. Semenov. He and his followers treat experimental and traceological research as firmly connected methods of investigation of prehistoric technology. Undoubtedly experimentation plays leading role in analysis of technology of the manufacture of tools, but its role in investigation of tool functions can hardly be diminished. Practice of use-wear analysis shows that experiment is not only a source of new information concerning verification and establishing exact function of tools, but also serves as a basis for research of their productivity, gives basic data for reconstruction of production methods and economic complexes.

Results of research of materials of an unique aeneolithic site – flintworking workshop Bodaki (Ukraine) can serve as an example of employment of experimental-traceological method. Places of primary flintworking, open working area and a blade production workshop were singled out among excavated settlement structures basing on functional composition of flint finds. A series of flintknapping experiments made possible reproduction of technology of blade removing with various pressure techniques. Research of toolkit in living structures of the site showed that it was composed of various instruments used in agriculture, processing of wood, bone, hides, weaving, mineral paint and ceramic production. Experiments were conducted for research of use of these tools and their effectiveness. Flakes and blades made from local Volyn flint were used for these experiments. Oper-

ation were reconstructed on the basis of traceological research, archaeological and ethnological data. These experiments made possible to clarify difference in use-wear between tools used for cutting plants: cereals, grass and reeds. They showed that use-wear traces of sickle inserts independently of their placement in the slot of a handle and duration of use differ from tools used for cutting grass and soft reeds. Besides these, experiments in working wood, bone, antler, and hides were conducted. Experiments in ceramic production were especially important.

Employment of experimental-traceological analysis of inventory made possible not only to reconstruct technology of flintknapping, single out tools used in various branches of economy, but also get new data on organization of aeneolithic economy. Our results show that at that epoch settlements specializing at flintwork emerge near flint sources, and all production branches, needed for normal life of their inhabitants were functioning in their economy.

## 2. THE ROLE OF USE-WEAR ANALYSIS IN THE IDENTIFICATION OF TOOL USES AND HOUSEHOLD ACTIVITIES ON THE LATE NEOLITHIC SETTLEMENT OF POLGÁR- CS/ SZHALOM, HUNGARY

*Tóth, Zsuzsanna - (Eötvös Loránd Science University) zsu-  
zsanna.toth11@gmail.com*

Polgár- Cs/ szhalom is an important site in the Hungarian Late Neolithic. It is situated on the Great Hungarian plain and consist of a tell and a flat settlement. The study of the large worked bone and antler assemblage originating from the site combines tipological investigation with raw material preferences and traceological study, too.

Use-wear analysis was carried out on a sample material containing mainly bevels made on different raw materials (animal bone and red deer antler). Our primary interest was, if we can differentiate between tool uses, which can refine our knowledge about household activities carried out on the site. The method for the study was optical use-wear analysis with high magnification combined with experimentation and ethnographichal comparison for the identification of the wears found on the tools.

As result we may say, that use-wear analysis performed

with high magnification optical light microscopy is a time consuming, but efficient tool for the exact identification of different tool functions tipologically very similar. Archaeological experimentation is crucial for the identification of the observed wears, which can be efficiently completed with ethnographical informations mainly on the level of gestures. The data gained like that can help in the identification of different household activities, the differences between the individual households and their distribution on the site.

### 3. FLINT STORIES FROM IRISH EARLY NEOLITHIC HOUSES: SOME TRENDS AND ISSUES FROM A USE-WEAR PERSPECTIVE

*Mallia-Guest, Sol (University College Dublin) - Sol.Mallia-Guest@ucdconnect.ie*

This paper presents some preliminary technological and functional trends observed on the flint assemblages from eight Early Neolithic rectangular timber houses in southeast Ireland (c. 3750 cal BC). Despite the limitations of the sample under study, this research suggests a link between specific depositional practices and particular artefacts' life histories including certain activity associations.

The methodology applied follows a well-established integrated approach that combines a basic technological and attribute analysis, with observations at low and high magnifications based on optical microscopy and contextual information to reconstruct an artefact's life. While the flint assemblages were studied in full from a technological point of view, a selection of formal and informal artefacts with potential for use-wear analysis was carried out by means of a stereomicroscope (up to 100x) and later subject to standard "high-power" microwear approach (100x-400x) with the aid of a reflected-light microscope. Functional inferences on use motion and contact material – supported by a small experimental reference collection - are derived based on the set of conventional variables, and possible activities in which these artefacts were involved are put forward. The functional, technological and contextual dimensions are ultimately interpreted as a whole to explore the role flint artefacts played amongst these early farmer groups.

At first glance, there is little variation amongst these houses regarding overall assemblage composition and artefact type/materials worked. On one hand, evidence of hide-working activities is well attested while unam-

biguous traces interpreted as resulting from cutting siliceous plant are elusive. More obvious differences appear in technological terms when comparing knapping by-products, formal artefacts and blanks – particularly blade and blade-like finds – in their specific depositional contexts. However, more definite activity associations are yet to be made for these artefacts that are seemingly selected as foundation/closing deposits. Overall, convex end and end-side scrapers, offer a richer picture regarding modes of use at play through their lives, demanding, as well, further experimental work.

Lithic house assemblages and use-wear studies aiming at reconstructing activities within a domestic context are not easy to reconcile. This is partly related to the character of the assemblages, as they are the result of secondary deposition, usually poorly preserved (i.e. high frequency of heat-affected finds), and, as in the Irish case, only comprising a small number of finds.

This study highlights a number of trends identified amongst flint assemblages from Irish Early Neolithic timber houses that are not fully associated with bias introduced by these issues. Instead, when considered through a biographical approach, it becomes apparent that certain items associated with particular activities were being selected for special deposition, pointing to the role of flint in reinforcing aspects of these groups identity through everyday practices.

The Morgado Superior cave is a karst cave located in the municipality of Tomar (Santarém, Portugal).

As other caves of the same area it has provided stratigraphical data and votive deposits falling within the Holocene, more precisely in a diachronic time range that extends from the Calcolithic till the early Bronze Age. These are representative of the first attempts of domestication of the landscape and its consolidation, revealing this new way of life: the agro-pastoralism.

In the Morgado Superior cave there are multiple burials with a lot of votive objects like jars, many bones and lithic tools (blades, arrowheads etc.), beads, pendants and other decorative items in association with more than 2.000 human bones.

The number of the grave goods elements is low in relation with the number of the human individuals buried in the cave. Within the use wear study we analysed the grave goods in order to understand both their meaning in this funerary context and their function in the economy of this prehistoric society. We have focused our attention on the most representative elements of the grave goods: arrowheads, parure elements and bone artefacts.

For this study we made an experimental collection for comparing the use wear and the manufacture traces present on the archaeological finds with the ones on the experimental collection to see if these artefacts were made only for the burial rituals or were usual objects. The other question concerns the production system of the tiny parure elements made in stone and bone. For our analysis we use a combination with high power approach and low power approach preferring the use of the low power approach for studying the manufacture traces of the parure elements.

This study allowed us to understand that the majority of the grave goods were usual objects but with a strong symbolic value. Since in the Morgado Cave there are a lot of grave goods showing prior breaks, the symbolic value of these objects doesn't seem to get lost even if the objects were broken. The strong symbolic value of the arrowheads is shown also by useless arrowheads made in cortex of the silex.

The use wear analysis of the grave goods from the Morgado Cave allowed to identify the strong symbolic val-

ue of the elements of the grave goods for that human community but at the same time to hypothesize a funerary practice which did not provide a special respect for the body and the grave goods of the previous dead. For these reasons we hypothesize a progressive spoliation of the previous grave goods.

ORAL

## 5. FINDING EVIDENCE FOR BEHAVIOURAL AND TECHNOLOGICAL ADVANCEMENT IN THE PALAEO-LITHIC THROUGH MICROSCOPIC USE-WEAR AND RESIDUE ANALYSIS

*Pawlik, Alfred - (University of the Philippines, Archaeological Studies Program) afpawlik@gmail.com*

The emergence of anatomically modern Homo sapiens is associated with traits of 'modern behaviour' as seen in the more or less sudden appearance of 'packages' as part of their cultural assemblage. Examples are the beginning of art, blade technology, tools made of organic materials like bone and antler, hafting and composite tool design.

Indications for modern behaviour, tool complexity and a high level of constructive planning and memory could be detected already at Middle Palaeolithic sites of the German Lower Rhine Valley, including the type locality of homo neanderthalensis, as early as 120kya. On the other hand, lithic assemblages without any formality usually associated with expedient technology and characteristic for the Southeast Asian Palaeolithic and Epipalaeolithic can as well include implements used for complex multi-component tools.

This paper presents case studies on the Middle Palaeolithic sites of Inden-Aldorf and Neandertal in western Germany (Pawlik & Thissen 2011; Pawlik & Schmitz, in prep.) where evidence for complex behaviour and advanced technology of pre-modern hominins were detected, as well as Ille Cave on Palawan Island, Philippines (Pawlik 2012).

Microwear analysis can significantly contribute to the discussion on the development and expansion of modern behaviour and enhance the limitations of traditional technological and morphological analysis of lithic assemblages.

ORAL

**6. TECHNICAL CHOICE AND BEHAVIOUR AT MESOLITHIC HUNTERS-GATHERERS OF EASTERN SICILY**

*Iovino, Maria Rosa - (Leiden University, NL) miarosa@tin.it*

Technical choice and behaviour at Mesolithic hunters-gatherers of eastern Sicily

Previous discussions on the Mesolithic research in Sicily have generally taken place within a typological framework.

Mesolithic style-life, basically determined by lithic industry and fauna remains, is generally associated with hunting-gathering activities.

In this paper I will discuss, through use wear analysis on knapped lithic tools, Mesolithic contexts of eastern Sicily and the reconstructed human behaviour for tool making, using and discarding.

ORAL

**7. FLINT TOOLS PROCESSING AND USE IN NORTH-EASTERN BULGARIA AT THE END OF LATE NEO-LITHIC**

*Mateva, Boryana - (Historical museum-Isperih, Bulgaria) boryanamteva@yahoo.com*

Late Neolithic settlement, chronologically related to the culture Boian-Bolintineanu, of which arises the considerable collection was found in 2003 during excavations of a Thracian fortress of IV-III BC in archaeological reserve Sboryanovo, northeastern Bulgaria.

The total number of flint objects discovered to date is 1490. Over 90% of the raw flint is yellowish-grayish spotted flint with many inclusions, cracks and defects, apparently originating from small nodules collected on the surface and in the riverbeds. The rest of it is typical Ludogorian (Dobrogean) honey-colored flint with excellent quality characteristics. Overall proportion debris- tools are typical for the Neolithic and Chalcolithic settlements in the area. The type of tools, use-wear traces, methods of treatment and the raw material used are specific to the Neolithic period only.

The analysis of the raw material used and the method of processing tagged trends in production, resulting in the subsequent bloom of flint industry in the Chalcolithic of the Balkan-Danubian region.

ORAL

**8. SICKLE TOOLS FROM MICROWEAR PERSPECTIVE. A CASE STUDY OF PREDYNASTIC AND EARLY DYNASTIC SITE TELL EL FARKHA (EASTERN NILE DELTA)**

*Winiarska-Kabacińska, Małgorzata - (Poznań Archaeological Museum) mwinkab@interia.pl*

*Kabaciński, Jacek - (Institute of Archaeology and Ethnology, Polish Academy of Sciences) jacek.kabacinski@interia.pl*

That paper presents results of microwear studies of limited set of flint specimens (17 objects) from Early Dynastic beds of site Tell el Farkha. The assemblage was extracted from a small trench W01/98 located at the edge of Western Kom and excavated in 1998 by Polish Archaeological Mission to Eastern Delta. Even if limited in number it reflects basic tool types recorded in that time at Tell el Farkha site. Analyzed set of flint tools shows large variability as typology and function it concerns. From that perspective the most important seem to be results of observations of inserts with denticulated lateral edges. Traces of use recorded during a micro-wear study confirm a complexity and diversity of economic activities performed by the inhabitants of the settlement during the Early Dynastic Period. It points first of all to extensive farming related to wheat production as well as production of items for everyday use, like baskets, mates or plant containers and food preparation. That is not a surprise considering very intensive and varified nature of the settlement at Tell el Farkha during that times.

ORAL

**9. EXPERIMENTS AND ETHNOGRAPHIC OBSERVATIONS WITH THE THRESHING SLEDGE: A HISTORY**

*Anderson, Patricia C. - (CNRS, CEPAM, Nice) patriciacanderson@hotmail.fr*

Microwear analysis of blades and flakes from ethnographic threshing sledges created the first corpus for interpreting archaeological blades with traces like those used in a threshing sledge. Segmented Canaanian blades were interpreted as probable inserts in a form of threshing sledge from the early Bronze Age of Iraq, and Skakun first interpreted contemporaneous blades from the Chalcolithic in the Balkans as used in a threshing sledge. However, the Canaanian blades differed in morphology from ethnographic inserts known at the time, and could

not have fit into grooves found in present-day threshing sledge boards. Cuneiform texts of the time described a different kind of instrument, more like a raft made of lashed staves, with blades inserted using bitumen or tar.

We reconstructed this instrument several times and used it over 15 years in various areas of southern France in order to check its functioning principles, structure, affect on the straw and ears, and microwear traces developing on the blades, as well as the nature of the alteration of the flint surface due to this use. Experiments were enriched and adjustments made to the form of our experimental Bronze Age sledge by cooperation with engineers measuring the work of this instrument, and by observations of present-day threshing sledges still working in Syria and Tunisia. In particular, the Bronze Age reconstruction, having relatively few inserts and of a rather small size, resembled the Tunisian threshing sledge, used with flint blades until the 1960s, when metal blades replaced them. Working with a Tunisian sledge maker, we inserted flint blades in the Tunisian sledge and compared observations of the users. These observations lead us to readjust certain details in the form of the threshing sledge we were using in our experiments, and to change the speed at which it was pulled. The flint inserts were preferred over the metal ones. And at the time when it was used, flint sledge inserts in Tunisia, like during the Bronze Age, were mined and prepared far from their area of use. The experimental and ethnographic study also included phytolith analysis of the plant material after it was threshed using the sledge, revealing these were cut in a characteristic way.

After a number of years, the very slow forming traces on the experimental threshing sledge blades, allowed comparison with archaeological tools, and phytolith analysis of storage structures and chaff tempered mudbrick provide a second proxy for the use of this tool in archaeological sites dating from the late Neolithic in Syria, showing this instrument was part of the Neolithic package spreading from the near East to Western Europe, and found in Spanish colonies in the New World. The instrument could have functioned further north, according to our experiments in England. Ongoing research involves new morphologies of threshing sledge blades and straw storage structures from the Neolithic to the Bronze Age of northern Syria.

ORAL

## 10. AUSTRALIAN ABORIGINAL GRINDING STONES, GRINDING PATCHES AND GRINDING GROUNDS

*Fullagar, Richard - (University of Wollongong) richard\_fullagar@uow.edu.au*

*Hayes, Elspeth - (University of Wollongong) ehh998@uowmail.edu.au*

Australian grinding stones and grinding patches are sometimes found in concentrations that suggest extensive grinding grounds, where numerous grinding activities were undertaken. It is often argued, if not assumed, that grinding stones are linked with food processing. In this paper, I report recent experiments and new data that suggest grinding grounds may also be linked with fibre processing for craft production of string, nets and other craft objects. The age of grinding patches and rates of visitation at these open sites are very difficult to assess but likely to be older (perhaps Pleistocene) in northern Australia and younger (probably late Holocene) in the south of the continent.

The function of grinding stones and bedrock grinding patches at several sites in the Pilbara of northwestern Australia were sampled in situ by taking PVS peels (to record wear) and water extractions (to recover residues). The PVS peels were examined under reflected light to document wear traces. The water extractions were mounted on glass slides and examined under transmitted light to document visible residues. Based on existing comparative reference collections of wear and residues, the initial analyses suggested the processing of plants including seeds for food. Subsequent experiments, not previously undertaken, replicated ethnographic description of processing spinifex grass clumps to prepare fibres for nets and baskets. The initial interpretations of wear suggesting seed processing were re-evaluated.

The residues (phytoliths and starch grains) and wear (polish with fine striations) on archaeological specimens indicate processing of plant tissue including tubers and grasses. Where the wear is most developed, the polish on some grinding stones is markedly undulating on both high and low zones of the microtopography. On experimental stones, abundant short, narrow striations aligned in patches appear typical of processing spinifex. It is possible that a thin film of resin on the stone surface contributes to the visual effect. Re-evaluation of images of the micro-polish on some of the archaeological specimens suggests that spinifex processing was also among the likely tasks performed in the past.

The identification of plant processing on archaeological grinding stones might not be an indicator of food preparation alone. At least some artefacts may have been used for softening plant fibres to be utilised for manufacture of craft items such as baskets and nets. Plants may have been ground for other purposes, such as medicines or poisons. We should not assume that starchy plant processing is necessarily linked with food preparation. Further research is required to test alternative hypotheses.

ORAL

### 11. A POISONED CHALICE: INVESTIGATING THE PRESENCE OF POISONS ON PALEOLITHIC ARROWS

*Valentina, Borgia - (University of Cambridge, UK) vb330@cam.ac.uk*

*Carlin, Michelle G. - (Northumbria University, Newcastle, UK) m.carlin@northumbria.ac.uk*

*Crezzini, Jacopo - (Università di Siena, Italy) crezzini@unisi.it*

Ethnographic documentation tells us that very often hunters poison their weapons with toxic substances. The ease with which poisons can be obtained from plants and animals, and the benefits arising from their application on throwing weapons (a safe distance from the hunter's prey, killing large size prey relatively quickly) suggests that this practice could be widespread among prehistoric hunters. In particular, the poisonous substances can incapacitate the animal, irrespective of whether the weapon causing a mortal wound: this is crucial for the recovery of meat and furs in good conditions.

In this paper we present the development of a method for the detection of toxic substances on European Upper Paleolithic stone and bone points. This research is part of a wider project on the analysis of residues on the prehistoric projectile points in collaboration with the Dept. of Chemical and Forensic Sciences of the Northumbria University, Newcastle.

The investigation makes use of mass spectrometric analysis to establish the presence/absence of potentially toxic substances even after thousands of years.

The plants of the Ranunculaceae family, particularly monkshood, as well as other common toxic plants such as hemlock or *andstrychnos toxiferia* (curare) are those on which we have more historical information and form the basis of this work.

Using a completely non-invasive method, samples were taken from the ethnographic materials preserved in the Museum of Archaeology and Anthropology of Cambridge (UK), and samplings are scheduled at the Pitt Rivers Museum of Oxford (UK) and Museo Etnografico Pigorini of Roma (Italy).

The method preview the research of the toxic molecules starting from the present plants and working backwards through the study of the historical and ethnographic weapons.

ORAL

### 12. MICRO AND MACROSCOPIC ANALYSIS OF UPPER PALAEOOLITHIC BACKED KNIVES FROM JAPAN

*Sano, Katsuhiko - (The University Museum, The University of Tokyo) sano@um.u-tokyo.ac.jp*

The large blade industry emerged in the middle Upper Palaeolithic in the north-eastern region of the Japanese main island. This industry comprises numerous backed knives, endscrapers, and retouched blades. Although the "backed knives" from the large blade industry are classified to one typological category, the morphological variability suggests their multiple functions. The excavations of the Takakurayama site provided a number of blade tools, including tanged points, backed points, leaf-shaped points, and backed blades, which have traditionally been classified to "backed knife". A usewear analysis of the "backed knives" from the Takakurayama site was conducted in order to better understand the functions of the morphologically diverse tool type.

A total of 43 "backed knives" was micro- and macroscopically studied. For analysis of micro-traces, the KEYENCE VHX-1000 digital microscope was employed at a magnification ranging from 100x to 1000x. Macro-fractures were observed by the naked eye and were photographed using the Canon EOS 7D SLR digital camera attached to the EF 100mm f/2.8L Macro IS USM lens.

The study on micro- and macro-traces indicates that while there are "backed knives" which were indeed functioned as a knife for processing multiple materials, great numbers of the "backed knives" were used as hunting weaponry. As the large number of hunting traces was observed on the "backed knives", the delivery methods of these hunting weapons are also discussed based on the results of projectile experiments which have been performed for reconstructing the prehistoric projectile

systems. Although it is still difficult to accurately reconstruct prehistoric projectile methods, the patterns of the impact fractures on the backed pieces from the Takakurayama site implies that several specimens were mechanically delivered projectile armatures.

The usewear analysis of the “backed knives” from the Takakurayama site suggests that the morphologically diverse tools were used as knife as well as hunting weaponry. There are some correlations between the function and the morphology, such as leaf-shaped form with hunting weaponry and un-pointed form with knife, whereas the other morphological sub-types show multiple traces resulted from hunting and the processing of osseous materials and hide. The large number of fractured pieces due to impact which may include mechanically delivered armatures illustrates that hunting was closely related to the occupation at the Takakurayama site and the existence of the processing tools designates that the subsequent processing activity of faunal remains were also undertaken.

### 13. EXPLORING PALAEO-LITHIC WEAPON DELIVERY SYSTEMS USING A CONTROLLED AND REALISTIC EXPERIMENTAL SET-UP: PRELIMINARY RESULTS

*Schlösser, Nina-Maria - (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) schloesser@rgzm.de*

*Iovita, Radu - (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) iovita@rgzm.de*

In the last decades many researchers in the field of lithic use wear studies made an effort in developing solid methods to identify stone artefacts that were used as tips of penetrative hunting weapons (lances, javelins, darts, and arrows). This study focuses on the approach proposed by Karl Hutchings [1], which relies on secondary fracture characteristics (namely, Wallner lines [WL] and fracture wings [FW]). These features occur on crack fronts of brittle solids, like glass, obsidian and finer-grained chert, and are used to infer the precursory loading rate of the impact that caused the fracture and, consequently, the type of launching mechanism used in the delivery of the weapon.

New experiments were conducted to evaluate the reliability of this method. Since in a previous controlled experiment from Iovita et al. [2] only impact velocities were simulated, whereas other similar experiments only

reported launch velocities, we aimed to check velocity curves from launch to impact. Using soda-lime glass points and synthetic targets in the same experiment, we wanted to produce a comparative, yet well controlled dataset with a more ‘realistic’ set-up, using animal targets and a naturally-occurring raw material. We measured the velocities and acceleration of three delivery systems (lance, javelin, and spearthrower dart) to 1) evaluate the magnitude of the distinction between impact velocities (at target entry as well as inside the target) and 2) determine if the pattern observed can be related to a particular delivery system as claimed in the literature.

In total 75 identical glass copies of a Levallois point [2] and 75 knapped obsidian points of the same size were hafted on the spears/darts and thrust/thrown on a complete wild boar carcass by experienced experts (25 each per delivery system). The acceleration curve for each shot was measured, including during the actual impact, using an accelerometer mounted to the weapon itself. Projectile velocities were recorded using a video camera. The broken points were analysed under a microscope and WL and FW photographed and fracture speeds calculated.

Preliminary results suggest that the relation between precursory loading rate and the pattern observed is weak and dependent on factors that are difficult to reconstruct archaeologically, such as species hunted and point-type used. The influence of parameters like hide and flesh, which slow down a travelling projectile, play a more important role than previously assumed during impact until moment of crack initiation. Consequently they should not be underestimated when reconstructing weapon launching mechanisms from artefacts of archaeological origin.

ORAL

### 14. AMBIGUITY IN TERMINOLOGIES USED TO DOCUMENT IMPACT WEAR ON PROJECTILE POINTS: TOWARDS AN IMPROVED DESCRIPTIVE FRAMEWORK

*Coppe, Justin - (Université de Liège), Veerle Rots - veerle.rots@ulg.ac.be (Université de Liège) justin.coppe@ulg.ac.be*

Recently, lithic projectile points have become a key element in discussions about the complexity of Palaeolithic human behavior. The appearance of different projection systems has certainly played an important role in technological changes that occurred during the Palaeolithic. Unfortunately, only the lithic components of these projection systems are generally recovered, and over the

years, several studies have focused on finding macroscopic and microscopic evidence that would allow the identification of potential lithic projectile points in the archaeological record.

Initial studies used a more typological approach to describe the morphology of the damage observed, while subsequent studies used a terminology based on the description of fracture initiations and terminations. At present, there is quite some variation in the descriptions of the wear features and fractures observed, both in their detail as in the elements that are considered as being diagnostic of projectile use. While discussion may reign about the latter, it is clear that the descriptive framework that is currently used lacks some homogeneity and if one wants to be able to evaluate the degree to which evidence may or may not be diagnostic of projectile use, it is important that we share a common vocabulary and that we agree on the fracture and wear characteristics that ought to be described. Some attributes are only mentioned infrequently, such as the size of certain removals as well as the association between different fracture types or damage features on a single piece. Independent of their potential importance, it often makes it difficult to compare the wear features observed between different researchers as well as to make robust statements about the diagnostic value of certain traces or fractures.

We present a synthesis of the variation in terminology that was identified in projectile studies and we attempt to document what researchers have referred to with specific descriptions. Above all, we would like to open discussion in view of the creation of a shared and systematic descriptive framework for wear features or fractures that may potentially result from projectile use.

## **15. EXPERIMENTAL MANUFACTURE AND USE OF LATE EPIGRAVETTIAN PROJECTILE IMPLEMENTS: NEW EVIDENCE FOR INTERPRETING USE-WEAR PATTERN ON LITHIC WEAPONS**

*Duches, Rossella - (MuSe - Museo delle Scienze di Trento)  
rossella.duches@muse.it*

*Peresani, Marco - (Dipartimento di Studi Umanistici, Sezione di Scienze Preistoriche e Antropologiche, Università degli Studi di Ferrara) marco.peresani@unife.it*

*Kompatscher, Klaus - (MuSe - Museo delle Scienze di Trento)  
klaus@azzolini-kompatscher.it*

The use-wear based criteria for recognizing ancient lithic weapons are nowadays strongly debated (Lazuèn, 2014; Rots and Plisson, in press). The difficulty in identifying projectiles implements is related to the great variability of extrinsic and intrinsic techno-functional parameters that influence wear patterns. If an integrated macro- and microscopical approach is required, it is also crucial considering all the wear features present on an armature and interpreting them on the basis of strong experimental references. A new contribution to this issue comes from an experimental program carried out by the authors and focused on Late Epigravettian projectile implements.

The experiment in fact addressed the production and use of lithic armatures from the Late Epigravettian layers of Dalmeri rock shelter (North-eastern Italy). Among lithic armatures, backed points and backed (bi)truncated bladelets are the most common artifact types and their production represents a mental template well rooted in the bladelets operational project (Duches and Peresani, submitted; Montoya 2008a; 2008b). The main goals of the experiment were to explore the performance of these types of projectile implements in penetrating medium-size ungulates, to prove their functional suitability within the bow-arrow delivery system and to create a reliable experimental reference of impact damages essential for the archaeological interpretation. The experimental protocol was thus devised to reflect the efficiency and the operating conditions of this kind of projectile during the Late Epigravettian. Some variables were kept fixed (choice of the projecting mode, animal target, shooting distance, setting) while some others were modified (armatures typology and numbers of them, hafting, bow poundage, shooting angle).

The results let to define the pattern of use wears meaningful in recognizing Epigravettian armatures and to evaluate the role of different mechanical stress in creating that pattern. First of all, the projectiles demonstrated the efficiency of this kind of lithic implements. About the fractures, the experimental evidences could be summarized as follow: a) a tip breakage is strictly connected to the fact of hitting a bones (as the edge crushing); b) the point of fracture on the tips matches in 80% of the cases with the end of the hafting; c) the combined action of bending and compressive stress in hafting area causes rarely a simple bending fracture but more frequently different and multiple breakages; d) the compressive stress contributes to the wear pattern in creating specific features on the tip and also on the cutting elements; e) hafting and armatures arrangement influence both the penetrating capability and the durability of this kind of projectiles. In conclusion, this study adds new clues

in methodological debate about criteria for recognizing ancient lithic weapon and raise the requirement of a revision of the data collected in macro-fracture analyses considering the forces involved in projectile impacts and the variability of their combination.

ORAL

## 16. IMPACT TRACES ON ROCK CRYSTAL ARTEFACTS

*Fernández Marchena, Juan Luis - (IPHES, Institut Català de Paleoecologia Humana i Evolució Social, Zona educacional 4 (Edifici W3) Campus Sescelades URV, 43007 Tarragona, Spain / Àrea de Prehistòria, Universitat Rovira i Virgili, Fac. de Lletres, Av. Catalunya 35, 43002 Tarragona, Spain) juanl.ferna@gmail.com*

*Rabuñal Gayo, José Ramón - (GEPN - Grupo de Estudios para a Prehistoria do Noroeste, dpto. Historia I, Universidade de Santiago de Compostela, Fac. Xeografía e Historia, Pz. da Universidade, nº1, 15782 Santiago de Compostela) jr.rabunal@gmail.com*

*García-Argudo Ripoll, Gala - (Estudiante del Grado en Arqueología en la Universitat de Barcelona (UB) gala.garcia.argudo@gmail.com*

In archaeological sites in NW Iberia there are frequently found lithic assemblages with a great presence of rock crystal elements. These sites are chronologically ascribed to the final moments of the Upper Paleolithic and the first moments of the Holocene. Despite their frequency, these elements have only been studied from technological and/or typological perspectives. Due to the appearance of a great lithic assemblage in rock crystal in the cave site of Cova Eirós (Triacastela, Lugo, Galicia), we decided to develop an experimental and

functional analysis about this raw material. Some of the conditioning factors that affect to this raw material are the small size of the pieces and the scarce number of configured elements. For this reason, a wider experimental programme about use wear traces was prepared taking into account these factors, in order to document the different types of traces derived from each activity. After a first analysis of the archaeological industries, some macro and microscopic stigmas might correspond more to their use as projectile armatures than to their use in daily works (fleshing, wood cutting, etc.).

Due to the appearance of these stigmas, we decided to enlarge the experimental programme with an experiment focused on rock crystal projectiles. A series of experimental tools, both configured and not-configured, were used hafted in arrow shafts using different hafting

systems. After shooting them to the target using a bow, all the tools were analyzed macro and microscopically with diverse optical means, mainly an OLM with Nomarski prism and a portable microscope (PCE-MM200) to document macroscopic fractures. Macro and microscopical analysis allowed us to document a hole series of typical stigmas of the reaction of rock crystal to impacts and pressure. Furthermore we documented microscopic fractures and traces considered diagnostic of projectile elements in other raw materials.

With this experimental programme we were able to confirm some of the tools from Cova Eirós that were provisionally considered as projectiles. This confirmation and all the new data obtained allow us to extend the reference collection of images for the analysis of other assemblages. Finally, we can state the great versatility of the industries in this raw material, either configured or not. The effectiveness and resistance demonstrated by rock crystal in its use in daily works and as projectiles can explain its great presence in certain contexts like Cova Eirós.

## 17. AN EXPERIMENTAL STUDY ON POST-DEPOSITIONAL FACTORS AND ITS IMPACT ON LITHIC MATERIALS

*Pyżewicz, Katarzyna (Institute of Prehistory, Adam Mickiewicz University in Poznań) kpyzewicz@gmail.com Gruzdz, Witold (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw) wittold@gmail.com*

The aim of following communication is to examine post-depositional perturbations occurring on the sites with flint materials. We wanted to investigate the macro and microscopic changes on lithics which resulted from natural and anthropogenic factors.

The applied research methodology was a combination of the experimental method and use-wear analysis.

The studied lithic materials come from our experiments and few Polish Paleolithic and Mesolithic sites (i.a. Podgrodzie, Suchodółka, Łuãwka).

As a result of our experiments we gained detailed information about lithic pseudo-artefacts, pseudo-microscopic traces of using and hafting, and post-depositional effects on use-wear traces.

We put special emphasis on macro and micro damages

resulting from selected factors. Nowadays, the majority of sites in Poland are found during field surveys in the farming area. The effects of ploughing disturb the spatial distribution of lithics and affect the appearance of artefacts in the macro- and microscopic scale. This was one of the reasons for including experiments that could verify such perturbations in our research. Additionally, we made trampling experiments and investigated their effects on micro-wear level scale.

Our studies were later compared to the experiments made by other researchers and ethnographic information. Additionally, we made a case study based on the materials from few Paleolithic and Mesolithic sites to compare our results with the archaeological data.

Our research proved that ploughing and trampling have a strong impact on deformations of the lithics. Some of these factors may be also responsible for creating tools and disturbing the proper interpretation of flint materials. Simultaneously the created post-depositional traces were also dependent on other factors (i. a. type of the flint raw material or sediment in which lithics were placed), which confirms the complexity and problematic interpretation of artefacts.

## 18. EXPERIMENTAL REPLICATION OF AUSTRALIAN GRINDING STONE IMPLEMENTS

*Hayes, Elspeth - (University of Wollongong) ehh998@uow-mail.edu.au*

*Cnuts, Dries - (University of Liege) dries.cnuts@ulg.ac.be*

*Fullagar, Richard - (University of Wollongong) richard\_fullagar@uow.edu.au*

*Pardoe, Colin - (Bioarchaeology & Anthropology), Chris Clarkson - c.clarkson@uq.edu.au (University of Queensland) colin.pardoe@ozemail.com.au*

*Stephenson, Birgitta - (In the Groove Analysis) itg.analysis@gmail.com*

Until recently in Australia, lithic tool-use experiments were dominated by flaked stone with relatively few studies of ground-stone. This paper reports on a workshop, during which tool-use experiments were designed to document the wear traces associated with grinding various materials, different processing techniques and sandstones of different hardness. The specific variables were selected to build a use-wear and residue reference library applicable to archaeological grinding implements

proposed for detailed functional analysis.

Experimental sandstone grinding implements were used primarily to process organic and inorganic materials, documented ethnographically. Other materials were processed to investigate characteristics of seeds that were unavailable locally. Upper and lower stones were used together to grind seeds and bone; and abrading stones were used to file bone, stone and wood, and to grate haematite. The experimental stones came from five geographic regions in Australia, each associated with the archaeological assemblages proposed for study. Use-wear was sampled with polyvinyl siloxane peels, which were examined under a stereomicroscope and a metallographic microscope. Residues were extracted with two solvents (water and a tri-mixture of acetonitrile, ethanol and water), and subsequently mounted on slides and examined under transmitted light microscopy. The slide preparations were stained to highlight constituent plant and animal tissues.

The hardness/softness of the sandstone and the degree of grain cementation have a strong influence on the development and appearance of use-wear. On the hard sandstone, the processing time affected polish formation. Use-wear patterns were distinctive of the broad categories of processed material (seed, bone, stone, haematite and wood). Key use-wear features relating to activity and processed material are reflected in the degree of grain rounding and grain levelling, the presence of macroscopic surface striations and the occurrence of micro-fractures, polish and striations observed at high magnification.

Residues included collagen and cellulose fibres, starch granules, phytoliths, resins, bone fragments and pigment crystals. As for use-wear, the residues were also distinctive of the broad categories of processed material. Staining was particularly useful to distinguish plant and animal tissues.

The experiments provided insights into the wear formation on sandstones of different hardness and degree of cementation. Stained cellular structures provide a reliable basis for distinguishing the investigated plant and animal tissue subjected to mechanical damage, resulting from grinding and pounding. Studies are underway to further test the viability of residue identification on ethnographic specimens of varying ages, and experimental grinding stones greater than 30 years

The residue and usewear experiments build on previous studies and help form the basis of a systematic and

collaborative use-wear and residue reference library for ground-stone tools in Australia. Future experiments will focus on the wider range of plant taxa processed by grinding and documented ethnographically.

**20. PREHISTORIC DRILLING AND BEAD PRODUCTION: EXPERIMENTAL CASE STUDY FROM THE BALKANS**

*Gurova, Maria - (National Institute of Archaeology with Museum, Bulgarian Academy of Sciences) gurovam@yahoo.fr*  
*Bonsall, Clive - (School of History, Classics and Archaeology, University of Edinburgh) c.bonsall@ed.ac.uk*

This paper focuses on a series of experiments in drilling minerals and biominerals using both mechanical and pump drill techniques and subsequent operations of bead fashioning.

Replicas of micro-borers from Early Neolithic sites were made using high quality cherts from Bulgaria, southern Romania and southern England. Samples of various

rocks, minerals and biominerals that would have been available to Neolithic peoples in Southeast Europe were selected for experimental bead production. On Mohs scale of mineral hardness the materials ranged from 3 to 6.5. Actual bead production was approached by manufacturing 16 delicate beads of 5 different materials using fine sand and water abrasion. Though not conclusive, the experimental work was instructive in many of the parameters, procedures and technical details of prehistoric drilling.

One of the most challenging results of the experiments consisted in the use-wear and technological traces observed on the drill bits and the bead holes and surfaces. The use-wear database on perforators used in the experiments could serve as comparative reference when considering archaeological collections of similar items. The detailed photo documentation and micro observation has provided useful insights into various aspects of prehistoric drilling.

**21. HUNTER-GATHERERS OF SOUTHERN PATAGONIA AND TIERRA DEL FUEGO (XVI ? XX CENTURY): THE INCORPORATION OF NEW RAW MATERIALS**

*De Angelis, Hernan - (Centro Austral de Investigaciones Científicas. CADIC-CONICET) hernandeangelis@yahoo.com.ar*

*Bautista Belardi, Juan - (Universidad Nacional de la Patagonia Austral. CONICET) juanbautistabelardi@gmail.com*

*Carballo Marina, Flavia - (Universidad Nacional de la Patagonia Austral) flaviacarballomarina@gmail.com*

One of the most outstanding aspects during the contact between the European population and the hunter-gatherer of southern Patagonia and Tierra del Fuego (16th to 20th century) was the incorporation of raw materials such as glass and ceramic stoneware, used to manufacture endscrapers and glass arrowhead. This situation was documented by both the ethnographic and the archaeological records.

There is a very important documentary record corresponding to the Selk'nam population that occupied almost the entire territory of Isla Grande de Tierra del Fuego. One of the first studies regarding this subject belongs to F. Outes (1906), whose description of the scrapers are coincident with those of other contemporary

and subsequent authors such as C. Gallardo (1910) or M. Gusinde (1982). Regarding the glass arrowheads, the best descriptions were published by M. Gusinde (1982), who described the manufacture of arrows and specifically shafts. Finally, to continental Patagonia, G. Muster (1871) refers to the use of glass artifacts for the treatment of sun-dried hides.

The analysis of artifacts - manufactured with these raw materials - from archaeological sites in the South of the continent and Tierra del Fuego with known contextual information allows us to discuss the incidence of this incorporation into the technological repertoire.

For that purpose, the presence of glass and ceramic stoneware artifacts must be overviewed in several sites and a techno-functional experimentation program with a microscopic base on glass and ceramic stoneware must be presented. Later, their performance on different materials is evaluated and a reference framework is established with the purpose of being compared with the artifacts found in several other archaeological sites located in these spaces. The experimental study is based on the replication of these instruments using both raw materials and their use on different materials such as wood, hide and bone. Thus, we identify the modifications produced on the edges in this way, to be able to compare them with the archaeological materials.

The results obtained show the use of scrapers solely for the work on hide, with a kinematic transversal at the edge. Besides, they put in evidence -for historical moments- the preeminence of this artifactual type in continental Patagonia and in some sites in Tierra del Fuego.

ORAL

## **22. FUNCTIONAL ANALYSIS OF EXPERIMENTAL POLISHED STONE AXES AND ADZES: TECHNOLOGICAL, WOODWORKING AND HIDE PROCESSING WEAR.**

*Masclans Latorre, Alba - (Universitat de Girona)  
alba.masc@gmail.com*

*Palomo Pérez, Antoni - (Universitat Autònoma de Barcelona)  
antonipalomo@gmail.com*

*Gibaja Bao, Juan Francisco - (IMF-CSIC)  
jfgibaja@gmail.com*

Our main aim lies in provide a better understanding of which role did stone axes and adzes played among the

communities living in the NE of the Iberian Peninsula around the middle of the 5th and the 4th millennium cal BC, either as an object of work, tool, medium of exchange and/or symbolic item. In order to conclude in which production processes these tools were involved and what was their function, we required a large and systematic experimental framework.

We have designed an experimental program headed to replicate some of the activities in which this kind of artifact may have been involved according to ethnographic data. In the present communication we will expose the results of our research with hide processing and different kind of woodworking, using eclogite and hornfel rock as a support. This reference collection enables us to identify and interpret wear patterns and develop an accurate methodology applicable to the archaeological data. We include both low and high magnification approaches (10X to 400X) in order to be able to perform a complete characterization of macro and micro wear patterns taking into account edge damage, micropolish features, residue disposition, rounding and lineal traces, both in matrix and in crystal surfaces.

In this communication we will expose our results related to the establishment of use wear identification patterns originated in the course of tool production (technological wear) and during its use in the course of tree felling, woodworking activities involving carpentry and handi-craft, and hide processing, both fresh and dry.

We are in the right path to establish criteria that allow us to distinguish technological wear from different kind of woodworking and hide processing wear. Up to now our results have been positive not only in the process of discriminating the worked material, but also in the moment of carrying out the kinematics and the hafting orientation identification.

## **23. FLINT TOOLS FOR PRODUCTION OF BONE AND ANTLER ADZES AT EARLY MESOLITHIC SITE KRZYŻ WIELKOPOLSKI 7 (WESTERN POLAND)**

*Winiarska-Kabacińska, Małgorzata - (Poznań Archaeological Museum) mwinkab@interia.pl*

In 2003 a rich early Mesolithic peat-bog site was discovered by a town of Krzyż, at the northern edge of the

Notec River. During excavations in the years 2005-2013 large inventory of flint, bone, antler and wood artefacts was collected placed within a developed stratigraphy of the beach zone. A series of 49 AMS dates allow to place the settlement within the frames of second half of Pre-boreal and Boreal periods preceded by a short episode of the Younger Dryas.

The faunal assemblage reflects the typical game species of Mesolithic forest hunters, including, auroch, horse, red deer, elk, roe deer and brown bear accompanied by birds and turtle. That is accompanied by a strong evidence of specialized fishing and hazel nuts processing.

A large set of tools made of bone and antler is accompanied by organic rests with traces confirming their local production. Traseological analysis of stone tools delivered information on tool kit used for production of bone and antler adzes and on diversified ways they were used during that process.

ORAL

#### **24. HIDE POLISH OF WORKED BONE OBJECTS FROM DIFFERENT EAST EUROPEAN UPPER PALEOLITHIC SITES OF BUKI (RUSSIA)**

*Akchmetgaleeva, Natalia - (Kurchatov' state museum of Local Lore) achmetga@mail.ru*

The paper represents an analysis of use-wear traces on bone objects from the East European Upper Paleolithic sites Byki-1, Byki-7 (Layer I), Byki-7 (layer Ia).

The used methods for micro- and macro analysis studies of worked bone objects are based on methodology developed by the Saint-Petersburg Use-Wear Lab (Institute of history of material culture, Russian academy of sciences)

We have defined a limited complex of tools with use-traces of hide polish. Absent polishers. Knives for cutting and knives for softening or kneading skin are rare. Among the most tools with hide polish are needles, awls and points. The polish to them varies depending on the quality of hides and kinematics.

Number of represented types of tools and their percentage in the total number of worked bone objects at these

sites vary. Analysis of the tools with hide polish helped us to clarify the functional purpose of ancient settlements.

ORAL

#### **25. THE BISEAUX ON LARGE UNGULATES RIBS DURING THE BRONZE AGE IN NORTH-EASTERN ITALY: FUNCTIONAL AND EXPERIMENTAL ANALYSES.**

*Bertolini, Marco - (Università di Ferrara) marco.bertolini@unife.it*

*Thun Hohenstein, Ursula - (Università di Ferrara) ursula.thun@unife.it*

Functional analyses and experimental works on animal hard tissues artifacts have been sparsely applied in the Italian territory, above all in Bronze Age contexts. Recent researches, carried out on several sets of artifacts coming from sites dated between the Middle and Late Bronze Age in North-Eastern Italy, have highlighted a good amount of biseaux made on large ungulate ribs.

This paper aims at identifying the function of these objects through an experimental work, in order to reproduce the same category of artifacts that have been utilized on different materials and in different ways.

The analyses of the archaeological remains and the experimental artefacts were performed at low magnification using a stereomicroscope Leica EC3 S6D with integrated digital camera. Then, the surfaces analysis at high magnification was carried out by using a metallographic microscope in reflected and transmitted light (Optika Met: 50x-500x). For larger objects, silicone replicas of the active borders were made (Provil® Novo) and when necessary, Scanning Electron Microscopy was used (Teknehub of the University of Ferrara).

The experiments were carried out using the experimental tools on various hard materials, such as wood (fresh and dry) and antler (dry and wet) and elastic ones (fresh and dry skin). During the testing phase the time of use, the state of the material processed, the gestures employed (direction and quantity) were monitored and recorded.

All the archaeological artefacts bear quite similar use-wear. Some of them have fractures and micro-chipped areas on the distal margin that indicate the contact with a hard and durable material. The remaining artifacts, however, present edges slightly smoothed and less evident anomalies. On the upper face use-wear stops after

about 5 mm from the distal edge, while on the lower face it seems to be slightly larger, about 1 cm from the edge. At the microscope very dense striations, longitudinally oriented, are visible on the distal edge, while proceeding in the mesial portion of the artefact, they become more rare and often oblique. At high magnification the analyzed surfaces are fairly uniform near the edge and more irregular distancing from it.

The experimental work has allowed us to hypothesize that some of these artefacts were used for the removal of the fresh and dry bark. Infact, experimental use-wear presents macro-and micro-morphologies compatible with the ones detected on the archaeological remains.

ORAL

## 26. SPATULAS AND ABRASED ASTRAGALUS: TWO TYPES OF TOOLS USED TO PROCESS CERAMICS? EXAMPLES FROM THE ROMANIAN ENEOLITHIC

*Margarit, Monica - (Valahia University of Targoviste, Romania) monicamargarit@yahoo.com*

In most of the Eneolithic assemblages, all over Romania, constantly appear two types of artifacts: spatulas made on longitudinal bipartitioned rib and abraded astragalus.

The autochthonous literature considered them tools used in different stages during the operative chain of ceramics production. Starting from this functional hypothesis, we developed an experimental program in order to establish its reality. Thus, after the tools were processed, the spatulas were used in the action of modeling the ceramics' form, in order to eliminate the excess of raw material and to homogenize the surface. The astragalus, abraded previously to their utilization, were used for the ceramics finishing, in order to create a mechanic polish of the surface.

The experimental program proved the fact that, indeed, we can accept the fact that this functional hypothesis may be one of the utilization variants for the two types of artifacts.

ORAL

## 27. PEEPING THROUGH A POT-HOLE

*Vidal, Aixa - (UCM) aixavidal@gmail.com*  
*Mallía-Guest, Sol - (UCD School of Archaeology) Sol.mallia-guest@ucdconnect.ie*

This paper presents a preliminary experimental attempt, informed by ethnohistorical accounts, to understand the technical gestures and the material correlate deployed during the process of repairing pottery vessels by boring/drilling patching holes, through a microscopic use-wear approach to the lithic tools employed.

An experimental programme was carried out including flint borers and drillers used by a traditional master potter as well as an inexperienced individual. The technique comprises boring, involving hand-held tools, and mechanical drilling, reproducing the toolkit identified in historical sources. Also, a variant to boring, that combines this rotational motion with tapping, is included as observed in traditional practices. To replicate prehistoric manufacturing and firing conditions, two sets of pottery, one with quartz, mica and schist inclusions and another, with organic temper, were subject to a standard firing temperature below 900° C. In addition, abrasive agents such as sand and water were incorporated to observe their role during the boring/drilling process. The macroscopic analysis of the damage seen on the borers/drill tips was complemented by a standard high-power approach based on optical microscopy observations (100x-400x).

On one hand, use-wear patterns observed are presented and discussed in terms of the user's experience, the mode and variant of the technique employed for the activity, the ceramic fabric, and the role of abrasive agents. Overall, variations in the character and extent of the microscopic wear amongst these tools are not substantial and correlate with the intensity of the damage. Secondly, task efficiency is also explored in terms of user/time and failed attempts, including the fragmentation of both tool and sherds during the task with skill and sherd-thickness playing a significant role.

Assessing skill and more specifically wear patterns resulting from pottery manufacture are known to be problematic issues in use-wear research. Experimental programmes have frequently focused on working unbaked clays. On the other hand, pottery, since fired, imposes new challenges due to its hardness and brittleness and, in particular, because the actions taken are irreversible

with the risk of damaging the piece completely. Since the reasons behind repairing containers can be economic and functional as much as symbolic, this experience also triggers questions on the role of the agents carrying out this activity in past societies inasmuch as the context of use and deposition. We highlight the potential contribution of historical techniques, manifested in a traditional trade that was in existence less than a hundred years ago, in understanding a very specific skill-set, and the overall feasibility and material constraints of this activity for which the ethnoarchaeological record is limited.

POSTER

**1. VERS UNE TRACÉOLOGIE À FORT GROSSISSEMENT DE LA PRÉHISTOIRE DU NORD-EST AMÉRICAIN: CRÉATION ET UTILISATION DE RÉFÉRENTIELS EXPÉRIMENTAUX ADAPTÉS**

*Chabot, Jacques - (Université Laval) jacques.chabot@hst.ulaval.ca*

*Dionne, Marie-Michelle - (Université Laval) marie-michelle.dionne.1@ulaval.ca*

Dans plusieurs laboratoires de tracéologie à travers le monde existent des référentiels expérimentaux pour aider à comprendre les microtraces des outils en silex. En Amérique du nord, de tels référentiels sur les matières premières utilisées par les préhistoriques sont rarissimes. Depuis 2 ans, avec deux subventions spéciales, nous avons commencé à concevoir des référentiels sur huit variétés de cherts que l'on retrouve de l'état de New-York à l'est du Québec (Gaspésie) et deux variétés de quartzites provenant du nord du Québec (quartzite de Ramah et de Mistassini). Non seulement ces référentiels sont très utiles pour comprendre les dynamiques d'usure, mais dans ces deux premières phases, nous avons aussi travaillé à comprendre un type d'outil universel dont il est très difficile de saisir la fonction: les outils ad hoc (expedient tools). La base de données obtenue laisse entrevoir l'étendue des possibilités quant à l'interprétation de la fonction des outils. Entre autres, elle atteste clairement de l'existence de processus d'usure variables suivant: 1. les propriétés intrinsèques des matières premières lithiques utilisées; 2. les modes d'utilisation; 3. les propriétés intrinsèques de la matière travaillée. La compréhension de ces processus permet de mettre en évidence la valeur interprétative et le potentiel de la donnée tracéologique pour l'archéologie de la préhistoire du Nord-Est de l'Amérique. L'exposé

portera donc sur ce projet et l'importance de concevoir des référentiels adaptés aux matières premières découvertes archéologiquement ainsi qu'aux contextes culturels à l'étude.

**2. EXPERIMENTAL AND USE-WEAR RESEARCH OF PRODUCTION INVENTORY OF AENEOLITHIC SITES IN BULGARIA.**

*Skakun, Natalia - (Institute of the history of material culture, RAS) skakunnatalia@yandex.ru*

Complex investigation of inventory of Aeneolithic sites in Bulgaria included technical and morphological analyses, use-wear studies, experimental works and ethnographic observations.

An opinion existed that flint industry of Aeneolithic cultures of Bulgaria was an archaic element, and high level of development of cultures was based only on discovery of treatment of the first metal – copper. Not diminishing the significance of this discovery it should be noted that flintworking of Aeneolithic epoch achieved outstanding results which made possible obtaining a blank with optimal technical qualities – the long blade. Experimental works proved that it was possible only with definite technology of flintworking and cracking it with a lever. Emergence of blanks from fragments of these standard superregular blades stimulated emergence of new instruments which were singled out with the help of use-wear studies. Because these tools were met for the first time, identification of their functions was impossible without experimental works which included replication of the technique of flintworking, and tools identical to ancient ones; use of the latter, finding out their productivity, and experimental reconstruction of the whole productive cycles of main economic branches.

Among new tools made from large blade fragments inserts for planes-scrapers, inserts for leather working lathe used for hides; inserts for planes-whittling knives, planes-scrapers used for wood should be mentioned. The character of macro and microwear made possible reconstruction of these instruments. Use-wear traces on experimental replicas were absolutely the same as on archaeological instruments. Construction of these tools and modes of their use find direct ethnographic analogies in many regions of Eurasia.

Besides these instruments inserts of a thrashing sledge were singled out for the first time in Bulgarian materials. The character of their use is similar to the use-wear on sickle inserts only at the first glance. Differences are in intensive blunting, macro deformation of the working edge, character of linear traces and polishing. A number of experiments was carried out near one Aeneolithic settlement of the Black Sea zone of Ukraine. A special area was prepared for an experiment participants of which were local peasants in accordance with ethnographic data. Oxen from local peasant households were used to drive sledge. The work was carried out during a week. Macro and microwear traces on inserts which experienced hard working pressure after 4 hours of work were identical to use-wear traces on archaeological tools. Thrashing sledges with flint, stone and basalt inserts were discovered in a number of burials in Caucasus and Southern Russia. Ethnographic parallels to this agricultural device are well known in many regions of Eurasia.

Thus complex research of production inventory from Aeneolithic sites in Bulgaria evidently show that tight connection of use-wear analysis and experiment bring substantial contribution not only to solving the problem of determination of tool functions, level of supply of ancient productions with specialized instruments, but serves as one of important sources for paleoeconomic reconstructions.

ORAL

### 3. EXPERIMENTAL RESEARCH OF THE USE-WEAR ON WORKING PARTS OF SICKLES AND KNIVES FOR HARVESTING GRASS AND REEDS

*Terekhina, Vera (The Institute for the Material Culture History of Russia, Academy of Sciences, St. Petersburg, Russia)*

*López-Rodríguez, M<sup>a</sup> Cristina (Department of Prehistory and Archaeology of University of Granada, Spain) mcris-tinalopezrodriguez88@gmail.com*

*Skakun, Natalia - (Institute of the history of material culture, RAS) skakunnatalia@yandex.ru*

*Jurado-Cortés, Andrés (Department of Prehistory and Archaeology of University of Granada, Spain)*

Analyses of tools connected with treatment of plant materials occupies one of leading places. Studies of various types of sickles, thrashing sledge inserts and grindstones are most numerous. Diagnostic signs for these tools: macrowear, linear traces and polishing are well studied

now.

Information about instruments used for harvesting grass and reeds is much more scarce. Characteristic of difference in use-wear of working parts of these tools and sickles used for harvesting wild and domestic cereals is nowadays insufficiently studied.

A series of experiments carried out by the international crew basing on the Eneolithic expedition of the IMCH RAS in Bodaki village in Ukraine was devoted to these questions. Outcrops of high quality Volhynian flint used as raw material for experimental tools are located in this area. Experimental blanks were used as inserts for sickles with straight or curved wooden or antler handle, tools of crescent shape; knives for grass and reeds with a handle or without it. During experiments the square of worked area, productivity of work of each tool, working time and use-wear were documented each 15 minutes (macrowear, linear traces, polishes; topography of these signs was also documented).

Harvest was carried out in fields occupied by modern mild wheat. Experimentators with different experience worked in two ways: a) cutting plants near the ground, and b) harvesting only ears. Experiments in cutting grass were conducted at areas with different grass vegetation which produced different use-wear on working edges.

As a result of these experiments a reference collection of flint tools used for harvesting main kinds of plant materials which were widely used in economy and everyday life of prehistoric societies was obtained.

POSTER

### 4. EXPLOITATION OF THE PLANT ENVIRONMENT DURING THE PRECERAMIC NEOLITHIC OF DJA'DE-EL-MUGHARA: PRELIMINARY RESULTS OF THE FUNCTIONAL STUDY OF THE GLOSSY BLADES.

*Pichon, Fiona - (Paris-Sorbonne, UMR8167 east and the mediterranean sea) fiona.pichon@paris-sorbonne.fr*

Around 10 000 B.C. in the near east a long-term process began which would change humanity's way of life from that of hunter-gatherers to that of farmer-breeders. These changes can be observed in particular on the dja'de-el-mughara site (syria, excavated by eric coqueugniot) which yielded a continuous stratigraphy from the final PPNA to the beginning of the former PPNB.

Functional analysis of its lithic material, glossy blades especially, represents an essential field of research to increase our knowledge of the local cultural traditions and better our understanding of these human groups entering a process of neolithisation. Functional analyses of contemporary glossy blades have already demonstrated their importance to comprehend how neolithic groups used the vegetation during the process of plant domestication.

This study was conducted as part of my doctoral research prepared under the joint supervision of Pr. Monchambert (Paris-Sorbonne University, UMR 8167 east and the Mediterranean Sea) and Dr. Coqueugniot (UMR 5133 Archéorient).

I am currently studying a sample of about fifty flint polished blades. The analysis of use-wear traces combines observations with a low power optical microscope (x40) and with a high-power digital one (x400). A comparative basis for observations is constituted by a set of experimental tools used with plants both present and absent at Djâde.

The technological study of the glossy blades revealed the homogeneity of the selected blanks: thin, often with a rectilinear profile with sharp edges. The raw material usually is a very fine-grained, high quality flint. Various types of glossy blades were defined: unilateral or bilateral denticulate blades, denticulate with back and with truncation and denticulate on ogival base obtained by direct or alternate retouch.

The on-going use-wear study shows traces of polish characteristic of harvesting siliceous plants. Because those microscopic traces are particularly well developed and preserved, one of the objectives of my research is to characterise types of microwear polish depending on the kind of plant harvested, while correlating this information to the type of used blanks and the type of retouch affecting the used edge.

The delineation of the gloss and sometimes the preservation of the adhesive bear witness to the hafting arrangement. Most of the time, the gloss follows a rectilinear delineation, which attests parallel hafting in a straight or curved haft. Some elements present a sharpened base spared by the gloss: the retouch then seems to have facilitated the hafting.

The remarkable preservation of the Djâde lithic assemblage gives hope for promising results in the understanding of the exploitation of the vegetation in Djâde. The confrontation of the technological, typological and

functional data will eventually allow highlighting the technical choices made by the gatherers on the site.

POSTER

## 5. TO EACH CEREAL ITS OWN USE WEAR, PRELIMINARY DATA

*D'Errico, Davide - (Leiden University) archeodavidederrico@gmail.com*

The study presented here concerns the acquisition and processing of experimental data regarding the wear traces from cereals on flint tools. In the long debate (Anderson-Gerfaud 1988, Gassen 1993, Jensen 1994, Gibaja 1998, Ibanez et alii 2008, Van Gijn 2010) about the possibility of recognise several species of cereals through the traceological approach, the opportunity to recognise the morphological characteristics typical of the various species through an experimental phase aimed at the reconstruction of the various steps regarding the development of the traces on the tools surface has been little exploited.

As already discussed in a previous study (D'Errico 2012 in press) it is useful to divide the surface of the object used in three different areas: Edge area (outermost area more in contact with the worked material), Inner edge area (intermediate area, strictly close to the edge) and Inner surface area (innermost area of the surface).

This project, of which here I present the preliminary results, is finalised to the understanding and the definition of the different traces generated by the harvesting of *Triticum monococcum*, *Triticum dicoccum*, *Hordeum vulgare* and *Triticum spelta*.

In addition to the classical methodology that uses the low and high magnification, the experimental data will be processed with ImageJ in order to have a 3D graphic restitution of the surface of the objects with the purpose to study, in a general way, the changes that have occurred during the development of the trace and the differences detectable between the various types of cereals and, more specifically, how the different areas respond to the modifications caused by prolonged use for harvesting activities.

The aim is to define the principal features of each trace through the analysis of the objects during their use (60 minutes, 90 minutes, 120 minutes and 180 minutes) and in addition, from a more closely descriptive/comparative point of view, to recognise the similarities and the possible differences between the different types of trace.

POSTER

**6. MESOLITHIC BONE ARROWHEADS FROM IVANOVSKOYE 7: TECHNOLOGY OF THE MANUFACTURE AND USE-WEAR TRACES.**

*Zhilin, Mikhail - (Institute of Archaeology Russian Academy of Sciences, Moscow) mizhilin@yandex.ru*

A multilayer peat bog site Ivanovskoye 7 is situated in Central Russia, 120 km to the north from Moscow. D.A. Krainov in 1972-1974 and M.G. Zhilin in 1992-1997 excavated there early, middle and late Mesolithic cultural layers with rich bone industry.

Various arrowheads were discovered in Mesolithic layers. Most of them were made from elk long bones. All arrowheads including fragments, preforms and blanks were studied with the help of a stereomicroscope with magnifications from 6 to 70 times. Experiments in making replicas of these arrowheads from elk bones with replicas of flint tools from these layers were carried out by the author. These bone arrowheads were shafted and shot from an exact replica of a Mesolithic bow in a target made from peat and covered with a fresh wild boar skin. After it experimental arrowheads were studied under a stereomicroscope, and traces of manufacture and use-wear were compared with Mesolithic artifacts. All stages of experiments were carefully documented.

The following chain of operations was established in the manufacture of bone arrowheads from Mesolithic layers of Ivanovskoye 7 site. Elk long bones were soaked in water for softening, after it long narrow splinters were removed with the use of the "groove and splinter" technique. Sometimes direct percussion with a hammerstone was used to reduce the width of a splinter. Then splinters were turned into preforms with the help of crude scraping or whittling. Fine whittling and scraping was used for shaping the preform into arrowhead. At this stage various details such as barbs, grooves, slots for inserts were made with the help of grooving, sawing, planing and scraping. Some arrowheads were decorated with engraved ornamentation. Final treatment included grinding with fine grained abrasive slabs and bright polishing with hide. Slots of composite arrowheads were filled with glue made from coniferous pitch mixed with bee wax and charcoal powder, and heated. When the glue became soft inserts were put inside these slots. Of special interest is final treatment of one long needle shaped arrowhead with the help of the turning lathe, which left typical dense spiral traces. Use-wear traces in-

clude rounding or smashing of the tip of the point and polishing running from the point gradually disappearing. Inside the polished area thin short or longer clearly cut scratches running from the tip along the axis of the arrowhead or at acute angles to it were observed, indicating hitting rather soft slightly dirty material. Linear traces in the shape of grooves running from the point, resembling traces on soil digging tools indicate hitting the ground when the arrow missed the target.

Described research showed good skill of Mesolithic inhabitants of Ivanovskoye 7 site in the manufacture of bone arrowheads, which they used for hunting various animals. Numerous bones of the latter from Mesolithic layers confirm this.

POSTER

**7. PECKED AND POLISHED MATERIALS FROM SOUTHERN PATAGONIA: AN EXPERIMENTAL TECHNO-FUNCTIONAL APPROACH**

*Alvarez Soncini, María Celina - (CADIC-ANPCyT) mcalvarezson@gmail.com*

*Mansur, María Estela - (CADIC-CONICET) estelamansur@gmail.com*

Utilization of polishing and pecking techniques has often been associated with the emergence of Neolithic contexts. However, it is now well known that these techniques were also applied by hunter-gatherer societies, sometimes for the manufacture of stone artifacts, such as clubs, weights or balls, others to make artifacts in different raw materials, such as wood, shell or bone (beads, knives, retouchoirs, harpoons, awls, etc.). In South America, pecking and polishing techniques appear in hunter-gatherers contexts since about 10000 years BP.

Identification of materials made by pecking and polishing techniques is not always easy, particularly in the case of those which do not have defined morphologies, where it can be difficult to distinguish taphonomic and technological traces. The approach to these materials has usually been performed descriptively, due to the lack of a techno-morphological and functional analytic framework. Consequently, it is also difficult to evaluate the role that these materials had within the technologi-

cal strategies implemented by hunter-gatherer societies.

The aim of this paper is to present some results of a research about polished and pecked materials in hunter-gatherers contexts of southern Patagonia. We will focus especially on the analysis of manufacturing and utilization techniques.

Our approach is based on an experimental program about tool manufacture, use and analysis, which is still in progress. This program included as a first step the identification of raw materials used for the archaeological pecked and polished materials of the area, followed by evaluation of the geological contexts and field work to recover raw materials.

Then, they were formatted to be used in experiments that include different technological and functional processes: treatment of faces by pecking or polishing techniques and utilization on different materials as wood, bone and hides.

Macro and micro wear analysis were carried out by means of binocular stereo microscope (40X) and reflected light metallographic microscope (200 and 400X), recording aspect of surfaces before and after modification and use.

The raw materials used for manufacture of the archaeological collection are principally volcanic rocks. In the first part of the experimental program, we worked and used clasts of these volcanic materials. Considering the lack of an analytic framework to study them, the results obtained up to now should be considered as preliminary. Anyway, they already show that there are differences between intentionally polished surfaces and those modified by natural phenomena (rolling, glacial erosion, etc.) and that use wear polishes are also identifiable on polished surfaces.

As we previously said, the main purpose of this investigation is to generate a comprehensive model for interpreting macro and microtraces formation processes on archaeological materials made by pecking and polishing techniques. The results obtained up to now on the diverse volcanic rocks indicate that it is possible to undertake this type of analysis.

As a second step, we will start the intensive study of the archaeological collection. Although we still need to enlarge our experimental series, we believe that progress of this study will allow microscopic identification of surfaces that are modified by anthropic actions.

POSTER

## 8. ELEMENTS OF EXPERIMENTAL ARCHAEOLOGY APPLIED TO PECKED EGYPTIAN PREDYNASTIC ROCK ART

*Caruso, Stefano - (La Sapienza Roma) stef.caruso@google-mail.com*

The creation of experimental replicas of Egyptian Predynastic petroglyphs is the focus of this study. Many experimental archaeologists and rock art specialists have replicated various types of pictograms or petroglyphs but never relative to Egyptian Predynastic rock art. Moreover a standardized experimental protocol has yet to be created or implemented, even though the creation of such a protocol would be useful for the understanding of rock art technology. Several research questions are addressed in this work: (1) what tools and raw materials were used to create these petroglyphs? (2) What were the creation methods and the kinds of tools made to create these figures? (3) Is it possible to create an experimental protocol that can be used and replicated to analyse any other pecked or incised rock art typology? If so, what are the most important criteria to take in consideration for such a protocol?

The present study was carried out with technical traces analysis and experimental archaeology methodologies. The first step was to undertake an in-depth historical, cultural, geographical and geological study of Predynastic Egypt and its rock art. I analysed the specific morphological features of the pecking marks that form the petroglyphs in order to hypothesise the tool typology implemented to create the rock art. The experimental part of the research consisted in the replication of these petroglyphs in a laboratory environment. The tools were created with materials (flint, quartz, bone, copper and horn) and methodologies (hafting) pertinent to the considered period. I then proceeded to the creation of pecking marks on sandstone surfaces (without creating a specific artistic figure) documenting and analysing the tool pertinence and manuality involved in these actions.

The results of this study are manifold, regarding archaeological and anthropological aspects of prehistoric research. I focused mainly on technological traces, testing the adequacy of the different implemented tools and the morphology of the pecking marks they created. Furthermore, the experimental part of this project was extremely useful to evidence the importance of manuality and how it helps to understand the creation methodol-

ogy of rock art figures.

In conclusion this project has allowed to hypothesise a set of raw materials and tool typologies implemented in rock art creation, a possible sequence of gestures and technical knowhow that helped in this production and to create an experimental protocol that will be useful for further research in rock art technology and prehistoric stone-working.

POSTER

**9. PREHISTORIC FLINT SCRAPERS OR THE GUN-LOCK FLINTS? EXPERIMENTAL AND USE-WEAR CRITERIA (ACCORDING TO ARCHAEOLOGY OF KAZAN, TATARSTAN)**

*Galimova, Madina Sh. - (Institute of Archaeology, Tatarstan Academy of Science) mgalimova@yandex.ru*

*Sitdikov, Ayrat G. - (Institute of Archaeology, Tatarstan Academy of Science) sitdikov\_a@mail.ru*

Flint artefacts are frequent type of finds at Kazan because of the city geographical position. Kazan Kremlin – the medieval hill-fort is situated on the mouth of Kazanka River – left tributary of Volga. Some prehistoric sites were probably located here but its cultural layers were destroyed later during the activity of medieval and historical town. The problem of distinction between prehistoric scrapers and the gun-lock flints arose in 1995-2005 during the intensive excavations aimed at historical substantiation of the 1000-year Anniversary of Kazan.

Flint scrapers from the excavation trenches at the Kremlin and near Kazan State University amount to 54 artefacts (Sitdikov, 2006). An experimental study has been organized by the authors to solve the problem mentioned above. The replicas of gun-lock flints as well as fire stones (flints) were produced and used in order to define use-wear features. Experimental shooting has been provided of Vladislav Khabarov (National Museum of Tatarstan Republic). The shots were fired using the replica of Russian musket of 1806, which was successfully used before during the historical-military reconstructions. The medieval fire steel (an occasional find) was used in our experiments in order to reveal traceological features of the fire flint replicas. Use-wear peculiarities of flint scrapers (rounding of working edge and specific form of striations on it) are well known for researchers (Vaughan, 1985; Korobkova, Shchelinsky, 1996; Poplevko, 2007). Microscopic analysis experimental replicas of gun (musket) - flints and the fire ones allow us to determine

its use-wear features.

First we have observed the remains of powder on the flint surface, especially on the hafted part. Main traceological feature has defined as damage of striking edge, the last one become discontinuous. The margins and hafting edge demonstrate analogous but less intensive use-deformations. Initial shots make the flint striking edge more sharp. Also there are notched micro-scars here, which appear on one face at the beginning of shooting and further – on both faces. After making 25-30 shots the striking edge become more rounded therefore a gun-flint lost its firing properties and must be turned or replaced. Also “ring-shaped” micro-fractures have been observed sometimes on the striking edge. Use-wear peculiarities of the fire flint replicas seem to be similar with additional long striations on the faces. Massive shape of the fire flints is regarded as its supplementary feature however some gun-flints found in Kazan occurred to be massive also. As a result of our experimental and use-wear study the most of the “scrapers” found in Kazan have been identified as gun-flints. Only four of them were used as fire-stones. However some gun-flints demonstrate use-wear features of real scrapers to be remaining on the local parts of striking edge. Such a reutilization of prehistoric scrapers is supposed to be caused by shortage of high quality flint among the population of Kazan during the 17 - first half of the 19 centuries. Extreme utilization of the gun-flints made of qualitative raw in the assemblages under study serve as evidence of our conclusion.

## 1. DÉTERMINATION DE L'EMMANCHEMENT DES ÉLÉMENTS DE PROJECTILE LITHIQUES PAR LEURS TRACES D'USURE

Jardón Giner, Paula - (Universitat de València) paula.jardon@uv.es

Gilbert Pion - gilbertpion@wanadoo.fr

Hortelano, Laura - (Universitat de València) lauhorpi@alumni.uv.es

Tout au long du Paléolithique Supérieur et le Néolithique on constate l'existence de projectiles composites qui se généralise à partir de l'utilisation de l'arc et la conservation exceptionnelle de quelques flèches préhistoriques entières en est la preuve. Mais ce n'est pas le cas pour la plupart des éléments lithiques qu'on interprète comme des pointes ou barbelures de flèches.

La position des éléments des projectiles préhistoriques dans leurs fûts a été évoquée et approchée dans des études fonctionnelles. L'analyse de la position et l'orientation des fractures d'impacte ou parasites est un indice d'habitude employé dans les hypothèses de reconstitution des emmanchements.

Nous présentons ici une expérimentation qui vise à répertorier les fractures issues des situations d'emmanchement et d'impacte lors de lancement des flèches.

L'observation à la loupe binoculaire (OPTTECH LFZ, zoom de 0,7 à 4,5 et oculaires de 10x) et au microscope Olympus BH2-UMA, objectif de 5x, 10x, 20x et 50x, el oculaires de 10x) des éléments de 500 projectiles provenant des sites de La Fru et Gerbaix (fin du paléolithique Supérieur des Alpes du Nord français) donne comme résultat une large typologie de fractures d'impacte. Nous avons émis des hypothèses d'emmanchement de différents types d'éléments de projectile.

Une expérimentation est menée à terme pour essayer d'identifier des positions dans les fûts des flèches par la typologie et position des fractures. Le lancement de flèches dont la morphologie et l'emmanchement reproduisait cette hypothèse et l'étude des fractures résultantes s'avère révélatrice des possibilités de détermination de modèles des flèches par l'étude des fractures.

ORAL

## 2. AND WHEN THERE IS NO HANDLE? DESCRIPTION AND PROBLEM OF DISTINCTION BETWEEN BONE TOOL PREHENSION AND WRAPPING.

Mayca, Justine - (Aix-Marseille Université, LAMPEA (UMR7269)) justine.mayca@gmail.com

Technic and functional wear on bone tools is now well known thanks to the numerous studies done in the last decades about them. This is not the case of prehensile wear, which has been seldom tackled about bone industry. A punctual interest about hafting of bone tools can be seen, following mostly the discovery of tools with preserved handles, or else with focalized studies about some specific themes such as hafting of assegai points. However, two particular technics, direct prehension and wrapping, have been largely forgotten. Thus, our aim is to know which traces are left by these technics, and what the problems resulting from their identification are.

Nevertheless, before answering these issues, we focused on problems of terminology related to the ambiguous nature of these technics. The terms "direct prehension" are quite clear because they simply correspond to the hand-holding of a tool, without any intermediary elements. Having said that, how to qualify the prehensile zone that could be intentionally shaped to make the prehension easier, or, on the contrary, that could not be shaped? Concerning the wrapping, it seems to be a male hafting with a soft handle. Can this definition be really applied when we envisage a punctual wrapping held only by hand? Does this arrangement have the same function as a hard handle that extends the hand?

With these considerations in mind, we have conducted several experimentations whose main modality is the tool prehensile mode in its use: direct prehension (or hand-held use), direct wrapping with hide, and hide wrapping inserted in a handle. Many other parameters have been taken into account: time of use, worked material, action mode, mode of force application, movement... Then, experimental objects have been observed at low and high magnification and compared to some archeological pieces.

Polishes that resulted present strong similarities, they are all characteristic of hide work. Microscopic analysis shows a general polish characterized by a hard aspect, filled weaving and a homogeneous distribution on a heterogeneous topography with rounded and smooth tops. However, location, extension, degree of polish de-

velopment, orientation and density of striation reveal some variations that could allow us to distinguish, at least partially, the prehensile mode.

These types of prehensile wear also seem to be found on archeological pieces, as the analysis of some bone tools from the final Neolithic of the south-east of France shows. Hand-held tools even seem to be particularly frequent, although a more comprehensive study of archeological series would be necessary if we want to confirm it. However, these results lead us towards a new way of thinking about the importance of hafting at this period and thus about technical investment in the bone industry.

ORAL

### 3. HAFTING AND PROPULSION TECHNIQUES OF SOLUTREAN SHOULDERED POINTS WITH ABRUPT RETOUCH

*Muñoz Ibáñez, Francisco Javier - (Universidad Nacional de Educación a Distancia) fmunoz@geo.uned.es*

*Márquez Mora, Belén - (Museo Arqueológico Regional) bel-en.marquez@madrid.org*

*Martín Lerma, Ignacio - (Universidad de Murcia) ignacio.martin@um.es*

*Marín de Espinosa Sánchez, Juan Antonio - (Sílex. Arqueología y Difusión del Patrimonio) info@tallarsilex.com*

The shouldered points with abrupt retouch are one of the most characteristic tools of the extracantabric region Upper Evolved Solutrean hunting repertory. The change towards barbed and tanged arrowheads into shouldered ones may have been related with the propulsion systems. Moreover, their morphological and volumetric variability can be due to the different ways of hafting. This type of arrowpoint, characteristic of Cueva Ambrosio (Almería-Spain), was first described by Breuil in 1912 and has never been studied until now from both a ballistic and traceological point of view.

Thus, we have knapped 45 flint replicas of shouldered points to be mounted in 8 different ways on 30 shafts. These tips have been fixed with birch resin and in some cases reinforced with gut into shafts of different length and diameters, thus creating arrows with one tip, two or three armatures. The different ways of hafting have been based on archaeological samples and on those coming from the modern archery. The arrows have been shot with three bows of different poundage i.e. a reproduction of the Holmegaard flat elm bow of 40 lb and 2 laminated flatbow of 40 and 50 lb respectively, into 2 fallow

deers, previously shot in culling procedures. The most natural conditions for the shots have been observed.

Their ballistic and penetration capabilities have been evaluated as well as their viability to be shot with the bow, being scarce the probability of a correct flight and impact with a spear-thrower due to their low weight. A use-wear study has been performed on those arrow points that have been recovered in order to be compared with the archaeological record.

The results also have allowed to establish four basic types of hafting for the shouldered points, with slight variations for each. Moreover we have confirmed its hunting efficacy and its perfect ballistic performance to be mounted in arrow shafts. Finally, we have observed a direct relation between the way of hafting and conservation and fracture of the arrowpoints. This experimental work, still in progress, will increase the amount of experimental data to be compared with the archaeological samples.

### 4. UTILISATION AND HAFTING OF UPPER PALAEO-LITHIC BACKED BLADELETS- A CASE STUDY FROM CUEVA MORÍN, CANTABRIA

*Bradtmöller, Marcel - (University of the Basque Country) marcel.bradtmoeller@ehu.es*

*Perales, Unai - (University of the Basque Country) perales.unai@gmail.com*

*Sarmiento, Alfredo - (University of the Basque Country) alfredo.sarmiento@ehu.es*

*Zuluaga, María Cruz - (University of the Basque Country) mcruz.zuluaga@ehu.es*

The aim of this paper is to summarise the recently conducted investigation of utilisation and hafting arrangements of backed blades and bladelets from the Gravettian levels of Cueva Morín (Excavation 1966-69 by Echeagaray & Freeman).

A macroscopic study of artefact morphology as well as a detailed use-wear analysis of selected pieces was conducted, in order to get an idea of how and for what these tools were used. While dealing with assemblages from a 40 year old excavation, the record of, so far unmentioned, residues on the surface of some of these artefacts was unexpected. Due to Raman and SEM-EDX scans of these remains, done by the SGIker of the University of the Basque Country, further important information about the variability of position and composition of these residues

could be added to the main research question.

The results provides us with an improved picture concerning projectile technology of hunter gatherer communities during this timeframe, in throwing a detailed light on the design and utilization patterns of these artefacts. Finally, we emphasize the benefit of using new methods of analysing, especially when working with old excavated assemblages.

### 5. EXPEDIENT VS. FORMAL HAFTED TOOLS IN THE PROTOAURIGNACIAN (EUP)

*Pasquini, Amaranta - (LAMPEA (Laboratoire Méditerranéen de Préhistoire Europe Afrique) - UMR 7269, France) amerasi@gmail.com*

Between 40 and 30 ka BP, major changes characterize the Middle-Upper Palaeolithic "transition" in the Western Europe: the appearance of Sapiens (AMH) and disappearance of Neanderthal fossils; the generalization of blade stone tool technology (replacing the Mousterian technology), as well as the bladelet production; the spreading of osseous tool technology.

Chronologically dated to the beginning of the Upper Palaeolithic on coastal Mediterranean areas, the Protoaurignacian is considered one of the first techno-complexes linked to AMH.

The Protoaurignacian complex is characterized by a lithic tool-kit composed by a small amount of typological/formal implements (backed bladelets, end-scrapers and retouched blades above all).

The majority of utilised items from some of the French Protoaurignacian sites analyzed (Observatoire, Esquicho Grapaou, Laouza, Cottés) is made up by "unretouched blanks" and, among these pieces, a specific technological category (thick-end elongated items from the débitage technical process) systematically shows recurrent hafting traces.

This implies that already since the Early Upper Palaeolithic the items considered only as "technical debris" (or issued from a secondary blank production) represent in fact a significant group of utilised tools, as do the retouched ones.

During the Protoaurignacian, tools are made by morpho-technical characters of the blank instead of retouch modification (on the blanks). This latter is rather linked to

the hafting arrangement than to the active part of the tool, which is often unmodified. When present, the retouch hardly changes the general form of the active part of the tool (e.g. end-scrapers on flat blades).

All these aspects highlight how difficult our perception of actively used prehistoric "implements" (instrumentum = tool as a whole) among the lithic assemblages can be, without carrying out use-wear analysis and in absence of organic handle evidence.

Furthermore, the attention paid to hafting traces would allow to establish indirect evidence of hafting arrangements, rarely preserved, on particular worked material (e.g. ivory).

### 6. HAFTING TRACES ON MICROBLADES FROM THE LGM MICROBLADE ASSEMBLAGES IN HOKKAIDO, NORTHERN JAPAN

*Iwase, Akira - Archaeology Laboratory, Faculty of Social Sciences and Humanities, Tokyo Metropolitan University) yiu51057@nifty.com (Nakazawa, Yuichi - Division of Human Evolution Studies, Graduate School of Medicine, Hokkaido University) nkzw2011@live.jp*

During the Last Glacial Maximum (LGM, 25-16ka), climatic conditions were extremely harsh, and floral and faunal populations declined in Siberia. There are two hot topics currently debated in the northeast Asian prehistory; the LGM human depopulation and the origin and spread of microblade technology. Graf (2006, 2009), for example, placed the maritime eastern Asia including Japan not only as the LGM refugia for humans from higher latitudes, but also as the potential homeland of microblade technology. These studies suggest that the investigation of Japanese archaeological evidence around the LGM will contribute to the study of technological adaptations in northeastern Asia. This study presents the results of use-wear analysis on the LGM microblade assemblages recovered from Hokkaido, northern Japan, and discusses the tool-use behavior and hafting technology of the earliest microblade assemblages in northeastern Asia.

The LGM lithic assemblages of Hokkaido are composed of three groups: Flake, Blade, and Microblade assemblages (Izuho 2013). Among them, the LGM microblade assemblage is characterized by the "Rankoshi type microblade cores" which set platforms at the end of elongated wedge-shaped preforms and detach microblades along the longer axis. The assemblage consists of highly standardized stone tools including microblades, burins, endscrapers and perforators.

Present study examines LGM microblade assemblages recovered from the two sites; Kashiwadai 1 and Obarubetsu 2 in the central and southwestern Hokkaido, respectively. Microblades, endscrapers, burins, burin spalls, perforators, blades, and flakes from two sites were sampled for the analysis. The raw materials consist mainly of the high-quality "hard-shale" and small amount of obsidian. The use-wear analysis was conducted by the high-power and low-power approaches. To observe microscopic traces, an incident light microscope (Olympus BXFM-S) was used.

Results of use-wear analysis are as follows; (1) bright spots on the dorsal ridges of microblades imply that they were slotted into hard hafts (osseous implements), (2) burin-like and spin-off fractures suggest that microblades were used as lateral edges of hunting weapons, (3) use-wear polishes on burinated edges indicate that the burins were used primarily for antler, bone, and ivory (ABI) workings, (4) use-wear polishes formed by dry hide boring were remained on the bit of perforator, and (5) dry hide polishes with perpendicular striations suggest that distal ends of endscrapers were used for dry hide scraping.

The preliminary traceological analysis on the LGM microblade assemblages implies that standardized stone tools were functionally specialized for different tasks. Furthermore, hafting traces and ABI polishes suggest that burins were used for shaping the osseous points, along which microblades were slotted. The LGM hunter-gatherers with the earliest microblades developed the complex hunting weapons. The tool specialization and tool complexity will illuminate the hunter-gatherers' technological adaptation to the landscape where resource patches were dispersed under the rigorous climate of the LGM.

### 7. THE RED-STAINED FLINT CRESCENT FROM GESH- ER: AN INSIGHT INTO PPNA HAFTING TECHNOLOGY

*Shaham, Dana - (Institute of Archaeology, The Hebrew University of Jerusalem) dana.shaham@mail.huji.ac.il*

*Grosman, Leore - (Institute of Archaeology, The Hebrew University of Jerusalem) lgrosman@mssc.huji.ac.il*

The Pre-Pottery Neolithic A (PPNA) period in the Levant is marked by major changes in human culture and socio-economic behavior, as attested by the beginning of cultivation, sedentary lifestyle and emerging social complexity. We wish to present an additional aspect of in-

novation, namely a new adhesive technique for hafting.

The study pertains to a red-stained flint crescent found in the PPNA site of Gesher, Israel. By its actual distribution, the red staining could be associated with hafting the crescent in a shaft. Several lines of evidence enabled a reconstruction of an innovative adhesive technology and the materials.

In order to reveal the chemical and mineralogical composition of the red staining these analyses were carried out:

1) The morphology and chemical composition of the samples were analyzed with Environmental Scanning Electron Microscope (ESEM) equipped with energy dispersive X-Ray Spectroscopy (EDS).

2) Analyses of the mineralogical composition were carried out by X-Ray Powder Diffractometer (XRD).

3) Characterization of the attributes observed by the above methods was carried out by Infra Red Spectrometry (FTIR) analysis.

Interpretation of the results was based on information derived from comparative ethnographic data and relevant studies of the archaeological record.

The SEM image and the chemical analyses revealed that the residue is comprised of two layers: the paste and the vegetal matrix above it. The mineralogical composition of the paste comprises calcite (CaCO<sub>3</sub>), quartz (SiO<sub>2</sub>), and clays. The red color of the paste derives from iron oxides; and the presence of hematite was recognized. While the paste was not burned, heating would have been the only way in which a homogenous red stain could have been created.

Accordingly, the adhesive includes a silty-clayey mud and ochre minerals as a paste with loaders like quartz and vegetal material atop of it. The 'ochre' paste served as the main adhesive component, yet technologically it should be defined as mud plaster.

The results provide us with an opportunity to reconstruct the complex technological chaîne opératoire employed in the hafting of the crescent. The study contributes insights into hafting technology that was used during the Early Neolithic period. Similar mud plaster technologies were used for the manufacture of numerous artifacts at Gesher (e.g. architecture, beads etc.). It seems that technological innovations went hand in hand with the socio-

economic and cultural transformations of the PPNA.

ORAL

## 8. NEW DATA ON THE HAFTING MODES OF THE NEOLITHIC SICKLES IN THE WESTERN MEDITERRANEAN

*Gibaja Bao, Juan Francisco - (IMF-CSIC) jfgibaja@imf.csic.es*  
*Ibáñez, Juan José - (IMF-CSIC) ibanezjj@imf.csic.es*  
*Mazzucco, Niccolo - (CSIC) nicco.mazzucco@gmail.com*  
*Gassin, Bernard - (CNRS) bgassin@libertysurf.fr*

The first studies on the hafting modes of the Neolithic sickles, began almost ten years ago with the analysis of a series of sites from the NE of the Iberian Peninsula. During the last years we have been gradually publishing our results, demonstrating the existence of different typologies of harvesting tools since the early phases of European Neolithic.

Through a functional approach to lithic industries, we have tried to relate such differences in the morphology and functionality of the sickles, to the development of different agriculture techniques, as well to specific cultural and technological traits.

Moreover, sickle tools can help us in the understanding of the Neolithization process itself. With the aid of other disciplines (e.g. faunal, archaeobotanical and chronological data), it is indeed possible to relate the existence of different types of sickles with the existence of a variety of 'migratory routes' followed by the first agro-pastoral communities during their diffusion across the Mediterranean, from ca the VII millennium calBC.

After analyzing a great number of contexts of the Iberian Peninsula (Spain and Portugal), Southern France and Morocco, we actually extended our research to Northern and Southern Italy. In this work we present the last results of our research.

ORAL

## 9. HAFTING TECHNOLOGY IN WOODEN TOOLS. CASES FROM THE NEOLITHIC WATERLOGGED SITE OF LA DRAGA (NORTH-EASTERN IBERIA)

*López, Oriol (UAB)*  
*Rageot, Maxime (CNRS-CEPAM)*

The excellent preservation of organic materials in the waterlogged site of La Draga (Banyoles, north-eastern of Iberia) allows the analysis of tools, utensils and goods elaborated on wood. In this site, two different early Neolithic occupations have been documented, both placed within the ending of the Cardial Ware Neolithic culture. Phase I (5,324-5,000 cal BC) is characterized by the collapse of wooden structures (presumably dwelling structures), which have been preserved in an anaerobic environment. The layers corresponding to Phase II (5,210-4,980 cal BC) are not covered by the water table, that's why wooden artefacts are not preserved.

The types of wood products represented in La Draga are diverse and according to functional hypotheses they can be related to different uses. Among them we would like to emphasize some of the agricultural instruments (sickles) as well as tools used for woodworking (adzes). We will characterize here the hafting technology of these tools according to the study of the production process of their hafts, reviewing how the raw material was obtained, which were the techniques used to cut and chip logs and how the final production of tools was carried out. In some cases (sickles), this study will be complemented with use-wear analyses describing microwear produced by the haft or related to the use of a hafted tool. Recently, we have started a new research line on adhesive substances elaborated from plant resins whose results are preliminary so far.

ORAL

## 10. THE USE OF THE EGOLZWILL III SICKLES (SWITZERLAND): FIRST RESULTS

*Nielsen, Ebbe - (Kantonsarchäologie Luzern) ebbe.nielsen@lu.ch*  
*Kienholz, Anna - (Arbeitsgruppe für Experimentelle Archäologie in der Schweiz (AEAS) anna.kienholz@gmx.ch*  
*van Willigen, Samuel - (Landesmuseum Zürich) Samuel.vanWilligen@snm.admin.ch*  
*Ibáñez, Juan José - (IMF-CSIC) ibanezjj@imf.csic.es*  
*Gibaja Bao, Juan Francisco - (IMF-CSIC) jfgibaja@imf.csic.es*

Some of the sickles recovered in the waterlogged site of Egolzwill III (Switzerland), dated in 5440-5420 BP (4280-4250 cal BC), are exceptionally preserved, showing a single flint blade obliquely inserted into a straight wood shaft which is composed of a extremity used for handling the tool and an opposed pointed extremity of unknown use. The reconstruction of the use of the Neolithic sickles in most of the archaeological sites has to be based exclusively on the analysis of the flint elements.

In this case, the preservation of the flint elements and the wood shaft allows us to have access to a more detailed analysis of how the Egolzwill III sickles were used. The preliminary microwear study of 10 complete sickles and 7 flint blades shows, in some of the sickle elements, some abrasive traces, indicating that the cereal stems could be cut near the ground, probably in order to get a long cereal stem, while in other cases the typical harvesting gloss indicates a higher cutting of the stem. Some transversal abrasions in the cutting edge in some blades could indicate an uprooting movement. In some cases, the pointed extremity of the wood shaft is polished by friction against an abrasive material, probably the ground. In fact, in some of the sickles, the pointed extremity was treated by heating, most probably to harden the point, making it more resistant against abrasion. This polishing of the point could indicate that this zone entered in contact with the ground when the harvesting motion was being carried out

Taking account of the use-wear traces in the flint blade and in the wood shaft, several hypotheses on the harvesting gesture are put forward, which have to be tested experimentally. Finally, the characteristics of the Egolzwill sickles are discussed in the context of the Neolithic sickles in Europe and the Near East, showing the enormous diversity in the harvesting techniques among the first farming communities.

### 11. MACRO- AND MICRO-TRACES OF HAFTING ON THE QUARTZ TOOLS OF THE PLEISTOCENE SITES OF THE SIERRA CAPIVARA IN PIAUÍ (BRAZIL).

*Clemente-Conte, Ignacio - (AGREST Y Arqueología de las Dinámicas Sociales, Departamento de Arqueología y Antropología, IMF-CSIC, Barcelona) ignacio@imf.csic.es*

*Boeda, Eric - (Professeur Université Paris X – Nanterre, Membre de l'Institut Universitaire de France. CNRS – UMR 7041 ArScAn, Anthropologie des Techniques, des Espaces et des Territoires au Pliocène et Pléistocène (AnTET). Maison de l'Archéologie et de l'Ethnologie) boeda.eric@gmail.com*

*Farias-Gluchy, Maria - (Professeur en Arqueologia de la Universidade Federal do Rio Grande do Sud (FURG) mgluchy@gmail.com*

Analyzing the 'controversial' quartz tools of the Pleistocene sites of the Sierra de Capivara (PiauÍ, Brasil), we recognized the presence of various macro-wears which show a regular pattern in their distribution and morphology. Such traces consist of a series of 'notches' that were performed on the edges in order to adapt the tools morphology for the hafting, probably through the application of some kind of vegetal fiber as 'rope clamp'. In the interior of such notches, quartz surfaces show the presence of microscopic wears, mainly bright polishes, with a flat topography and a compact texture characterized by large and fine strias. All of these wears are attributed to the contact with vegetal matter. In the site of Vale da Pedra Fourada, with a radiocarbon date of ca. 25.000 yrs. BP, a tool associated to the work of soft vegetal fibers has been identified, showing traces very similar to the ones produced by hafting. Both types of traces have been reproduced experimentally.

Though the debate continues regarding whether the organic material on ancient lithic artefacts can survive and be microscopically identified, the study of residues is in fact already one of the key components of functional analysis. Indeed, the study of different kind of organic residues (e.g. bone, wood, plants, blood cells, starch granules etc.) on the archaeological lithic artefacts is currently being carried out by many authors.

Here we focus on a particular type of residue, the "black spots" observed in some archaeological lithic artefacts from different sites (e.g. Umm El Tel and Hummal in Syria, Campitello in Italy, les Vachons in France, Königsau and Inden-Altdorf in Germany, Diepkloof Rock Shelter in south Africa, some sites in the Yukon Territory, Canada, etc.) and interpreted most commonly by researchers as being residues of bitumen, tar or bark birch pitch, pine or other plants resin, used for hafting the lithic artefacts. The most commonly employed methods for identification of these residues have been through use of optical and scanning electron microscopy to determine morphological features, and energy dispersive spectrometry (EDX) and the chromatography-mass spectrometry (GC-MS) for identification of chemical composition.

Here we present a reference collection including different substances which, alone or mixed with other products, can be used as hafting adhesives: tars and pitches, bitumen, beeswax, conifer resins, pistacia resin, etc. A selection of these substances is analysed using a combination of techniques including optical microscopy, scanning electron microscopy with energy dispersive spectrometry (SEM-EDX), Raman spectroscopy, and gas chromatography-mass spectrometry (GC-MS).

The combined use of these techniques provides a detailed morphological and chemical characterisation of these substances, which is strong enough to identify

preserved archaeological residues.

As archaeological case studies, we present here some examples of very different Palaeolithic sites showing such "black spots" apparently related to projectile hafting: Azokh Cave, in Nagorno Karabagh, Gilvaran and Kaldar, in Iran, and Cova Eirós, in Spain. Although the reference collection is still in construction, the combination of techniques demonstrated the feasibility of differentiating and identifying some of the analysed residues, while also excluding the identification of some of the spots as hafting residues.

## POSTER

### PRELIMINARY RESULTS FROM A SPECTROSCOPIC ANALYSIS OF RESIDUES ON GRAVETTIAN LITHIC ARTEFACTS

*Zuluaga, María Cruz - (University of the Basque Country) mcruz.zuluaga@ehu.es*  
*Bradtmöller, Marcel - (University of the Basque Country) marcel.bradtmoeller@ehu.es*  
*Sarmiento, Alfredo - (University of the Basque Country) alfredo.sarmiento@ehu.es*

The paper presents preliminary results from a non-destructive analysis of lithic artefacts using Scanning Electron Microscopy and Raman spectroscopic analysis to establish the identification of preserved (hafting) residues on Gravettian tools from Cueva Morín, Cantabria. In so doing SEM-EDX has been used to obtain information about the morphology and chemical composition in these extremely tiny samples.

The characterization of the residues was performed using a CARL ZEISS EVO 40 scanning electron microscope (SEM) operating with an Oxford Xmax X-ray microanalysis system (EDX). Secondary electron images and elemental distribution maps were taken in high vacuum mode (without coating the samples in order to avoid sample modifications). Raman spectra were recorded with a Renishaw InVia Raman spectrometer coupled to a Leica DMLM microscope having a spatial resolution for the 50x objectives of 1-2  $\mu\text{m}$ . In this work a laser of 514 nm with a holographic net of 1800 lines/mm was used. This laser has a nominal power at the source of 50 mW, being the maximum power at the sample of 20 mW.

EDX spectra recorded at different positions of the residue surface allowed to conclude about the composition, although the distribution of the chemical elements differs

from one area to another. And also the chemical analyses differ between different samples. The EDX analysis of remains on a fragmented projectile point indicated further the presence of carbon, calcium and phosphorous in the residue area and oxygen and silicon in the flint area, whereas Na, Mg, S, Cl, Fe, Al, K were present as minor elements. However phosphorous is absent in other residues and Al, K, Fe and Ti appears with C and Ca.

A particular problem for Raman analysis of these artefacts was found in the application of resin or organic compounds to the flint substrata has resulted in large fluorescent backgrounds. Nevertheless, useful information has been obtained which assists in the interpretation of the uses of some of the artefacts. The Raman spectra of hafting residues consist mainly of charcoal in different crystallisation states with broad bands at  $\approx 1300$   $\text{cm}^{-1}$  and  $\approx 1600$   $\text{cm}^{-1}$ . A preliminary Infrared analysis of one backed bladelet residue was performed using a Jasco 4200 FTIR spectrometer for determining spectra in medium infrared (400-4000  $\text{cm}^{-1}$ ) using the potassium bromide pellet technique. In spite of the small amount of the sample the spectrum's quality is good enough to identify the presence of phosphate in the residue. Both Raman and FTIR spectra show spectral features related to C-H bonds, although the nature of this organic compound has not been already determined. Analytic results confirm the organic nature of the residues at the flint substrata. Organic residue of one backed bladelet contains P whereas is absent in most of the other samples.

While this poster is dealing with preliminary results only, the conducted methods are providing interesting data for a further understanding of the utilisation of these lithic artifacts.

## 1. GLOBAL REVIEW OF THE ROCK-ART SHELTERS OF EL ARRASTRADERO? (ALBARRACÍN, TERUEL, SPAIN)

*Bea, Manuel - (3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza) manubea@unizar.es*

*Angás, Jorge - (3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza) j.angas@3dscanner.es*

In 2014 we have carried out the global study and documentation of the eight rock-art shelters known in the "Arrastradero" area, in the mountain range of Albarracín (Teruel, Spain). New technologies in documentation were used in the study: geometric documentation, photogrammetry and digital tracing. But the most important aim of the project was to carry out an exhaustive review of this large number of rock-art shelters distributed in a very reduced territory.

It was absolutely necessary to review one of the most important rock-art nuclei in Aragon, given that the latest global study was carried out almost 25 years ago, bearing in mind that the results never have been published with a high level of detail.

Among these rock-art sites we could document two of the most surprising and high quality Levantine rock-art shelters in Aragon, with some of the better naturalistic motifs, forming real hunting and symbolic scenes or with some singular characteristic as the use of the roof to paint a large scene or the use of white colour pigments, or the large dimension of the motifs (some of which exceed 70 cm in length).

Some of the other sites, with schematic or subnaturalistic motifs, present pure symbolic scenes or with economic functions, some of them interpreted as domestic scenes.

One of the most important aspects is the spatial coincidence of very different rock-art styles. In this way, it is possible to observe one of the most naturalistic Levantine examples, but also some other sites with the more classical schematic style, while there are others which are

very difficult to classify in any of the two greater groups mentioned, and that we could define as a subnaturalistic style.

The analysis of these sites points out the definition of this territory as a genuine "hinge territory" through the evolution of prehistoric periods. We can find good parallels for themes and motifs in many different areas, both inside the mountain range of Albarracín and outside: in Cuenca or the basin of the rivers Martín and Guadalope.

The study of these sites may shed light on the evolution of different rock-art styles, especially the Levantine, in a territory that is so far from its classic area of development.

ORAL

## 2. A NEW POSTPALAEOLITHIC ROCK-ART NUCLEUS IN TORMÓN (TERUEL, SPAIN)

*Bea, Manuel - (3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza) manubea@unizar.es*

*Angás, Jorge - (3D Scanner Patrimonio e Industria, Spin-off University of Zaragoza. Group "Primeros Pobladores del Valle del Ebro" Area of Prehistory, Dpt. Sciences of Antiquity. University of Zaragoza) j.angas@3dscanner.es*

*Royo, José Ignacio - (General Direction of Cultural Heritage. Government of Aragon) jiroyo@aragon.es*

In the municipality of Tormón (Teruel), in the mountain range of Albarracín, there are four rock art shelters included in the World Heritage List. Two of them were studied by H. Breuil and H. Obermaier. In 1981 the rock art shelter of Cabras Blancas was discovered, and 13 years later La Paridera. The discovery of those sites, always coincidental, were carried out individually and staggered in time. Nevertheless, since 2008, 16 new rock art sites in Tormón have been discovered, so this territory has become in one of the area with a larger number of rock art shelters in Aragón.

The rock art motifs on these shelters, all of which are located in the same distribution area in just 100 ha of surface, can be classified as one of the two main post-Palaeolithic rock art styles: Levantine or schematic.

The schematic representations are documented just in three of the sites, with classical motifs of this style, as vertical bars, zig-zags or anthropomorphic figures, as well as

other elements that could be defined as abstract.

Some of the Levantine rock art sites have certain characteristics, both thematic as technique or spatial location. These aspects make them to appear as some of the most relevant and singular elements of all the rock art in Aragon and even in the Iberian Peninsula.

Among those characteristics, it is worth highlighting those motifs depicted in white (despite there being motifs in red and black), a great fight scene between two groups of archers, large representations of male deer in a naturalistic style, large bovid figures, another motif of a bovid with the representation of the ribs. Along with these particularities of theme and colour, we have to emphasize the importance of the rock art shelter of Hoya de Navarejos III. In this site, there are two panels inside a narrow and short natural gallery that is associated to an outdoor space limited by slabs buried in the ground.

We present a preliminary study of this new rock art nucleus, carrying out a methodology by using new technologies, that appears as an area with a singular entity, despite it being possible to observe some common characteristics with those in the mountain range of Albarracín, but also with a series of distinctive features that make it one of the most important post-Palaeolithic rock art areas of the Iberian Peninsula.

### 3. CONTRIBUCION AL CONOCIMIENTO DE LA FASE DE LOS JINETES: EL CASO DEL JEBEL RAT, ALTO ATLANTE, MARRUECOS

*Bravin, Alessandra - (Doctorado en curso Université Aix-Marseille) cercid@cobratours-maroc.com*

El arte rupestre de la fase de los jinetes es una manifestación cultural difundida en un área muy extendida del Magreb y del Sahara, tan como grabados que como pinturas.

En Marruecos este arte se encuentra en todo el Sur, donde destaca el sitio de Foug Chenna en la región pre sahariana del valle del Draa. El segundo sitio más importante de Marruecos es el Jebel Rat, en una meseta a 2400 metros. Las pinturas de esta fase son raras.

Los jinetes del Rat se distinguen de los demás jinetes de Marruecos por ciertas particularidades que hacen de ello

un sitio único, y para comprender en que el Rat es diferente, hay que presentar las características típicas de esta fase.

La figura más típica es un personaje a caballo, el jinete, empuñando una lanza y un escudo. La segunda figura típica es el infante, también armado. El jinete se encuentra aislado o en escenas de duelos, de batallas y de caza a gacelas y muflones. Las figuras de esta fase se reconocen inmediatamente por el estilo esquemático y simplificado y por las dimensiones reducidas de no más de 30 cm. La lanza es una simple línea sin detalles de la punta y el escudo es un disco con piqueteado invasivo. La técnica empleada es el piqueteado, siendo el pulimentado muy raro. Todos estos elementos ofrecen escasos elementos informativos sobre el armamento, el arnés y el ropaje de los personajes.

El interés de un grupo de jinetes del Jebel Rat viene del hecho que, diferentemente de lo demás, estas figuras muestran ciertos detalles sobre la lanza y el escudo. En este grupo el tamaño de las lanzas es muy grande, con grandes puntas con nervadura axial, pareciendo la miniaturización de las grandes puntas de la fase antecedente, atribuida al Bronce final. Los escudos de este grupo, realizados en contorno, presentan "decoraciones" en la superficie interna, y parecen continuar la tradición de las decoraciones de los grandes escudos, ellos también pertenecientes al Bronce final.

Todos estos detalles, encontrados solamente en el Jebel Rat, nos parecen elementos de continuidad entre la fase del Bronce final y la fase de los jinetes, representando una forma de transmisión del saber cuánto a la producción de armas. La idea que el Rat fue abandonado al final del Bronce, según la hipótesis de unos autores, no parece estar avalorada y este grupo podría ser el más antiguo de la fase de los jinetes de Marruecos.

### 4. NUEVAS MANIFESTACIONES RUPESTRES EN EL NORTE DE URUGUAY.

*Cabrera Pérez, Leonel - (Departamento de Arqueología Facultad de Humanidades y Ciencias de la Educación.) leonel-cabreraperez@gmail.com*

En los últimos quince años en el norte del territorio de Uruguay se han descubierto una extensa área con Arte Rupestre, totalmente desconocido hasta entonces. Los

trabajos desarrollados han puesto de manifiesto, más de ciento cincuenta nuevos sitios arqueológicos con miles de petroglifos, los que pueden aparecer agrupados en un número mayor a los 100 por sitio, o aislados, con bajo número de representaciones. Los diseños son mayoritariamente de tipo geométrico abstractos, elaborados por técnicas de picoteado y/o abrasión (raspado y aun pulido). Desde el punto de vista morfológico, encontramos diseños que muestran motivos simples o con cierta complejidad, efectuados con trazos, en los que frecuentemente, todas las líneas o superficies se vinculan en una sola entidad. Igualmente existen motivos compuestos sencillos, resultados de la reiteración de figuras simples o diseños complicados, de tipo "meandriiformes" o grillados, muchas veces sin rigor geométrico, así como motivos indeterminados o sobrepuestos.

Tales petroglifos, podrían ser incluidos, de acuerdo a los modelos formulados para un amplio territorio del continente americano -República Argentina y Brasil-, dentro del denominado "Estilo de Pisadas" o "Tradición Meridional", definido a mediados del siglo XX. Dicho estilo fue formulado a partir de la región Patagónica, donde aparecen grabados cuyos diseños muestran supuestas huellas de animales (puma, guanaco y ñandú) y pisadas humanas, a las que se le suman elementos geométricos o signos en abundancia tales como círculos, zigzag, espirales, tridígitos, etc, con una cronología inicial de unos 4.000 años A. P. Dicho estilo con origen en los Andes Centrales y que esencialmente hace uso de la técnica del grabado, se habría expandido por una extensa región del continente americano, cubriendo áreas de Argentina, Bolivia, Brasil y Paraguay, áreas en las que se muestran discrepancias cronológicas notorias.

En nuestra región de estudio, Norte del territorio de Uruguay, si bien alguno de los indicadores señalados está presente, faltan aquellos considerados como de mayor valor diagnóstico, como las denominadas "pisadas". Nos proponemos profundizar en el análisis regional de la manifestación, mediante la contextualización de las manifestaciones y las variantes regionales implícitas. El proyecto en curso desde el año 2009, tiene además un carácter de salvataje, ya que en el área se explota la roca soporte, mediante canteras de extracción de lajas para la confección de pisos, por los moradores de la región. Tal hecho ha motivado que además de la investigación, se desarrollen paralelamente actividades de extensión, tendientes a la valoración y preservación de dicho patrimonio cultural.

## 5. THE REPRESENTATIONS OF EYED IDOLS IN THE SCHEMATIC ROCK ART OF EXTREMADURA

*Collado Giraldo, Hipólito - (Instituto De Estudios Prehistoricos GI Quaternario-Pre-Historia G.I. CUPARQ) hipolitocolado@gmail.com*

In Schematic Rock Art, the Eyed idols representations are considered one of the most important typologies of this style. They have very clear parallels with stones and ceramic objects that have been found in settlement contexts, megalithic chambered tombs. In cases they have been found adorning ceramics

These objects have a widely diffused across the Iberian Peninsula, especially within the south, and date from the Final Neolithic and across the duration of the Copper Age. This chronological spread allows us to adjust the chronology of the final stage of the Schematic rock art tradition.

Within this paper, we wish to catalogue and discuss these figure types in Extremadura region of Spain, paying particular attention to their characteristics, distribution and chronology, as well as discussing the following:

- To analyze and discuss the Schematic rock art eyed idols depictions and their distribution, in particular those designs that are indigenous to the Extremadura region. We argue that geography played an important role in how these figures were circulated, suggesting that a specific cultural tradition existed within the region.
- To make a comparative study with the remaining eyed idols depictions that are known from the Iberian Peninsula and with these to identify particular clusters and the various cultural exchanges strategies that may have influenced such a distinctive repertoire of figures.

Oosterbeek, Luiz - (Instituto Politécnico de Tomar, Estrada da Serra 2300 Tomar; Instituto Terra e Memória (ITM, Mação); Grupo Quaternário e Pré-História do Centro de Geociências (u. ID73 - FCT) [loost@ipt.pt](mailto:loost@ipt.pt)

Nash, George - (Instituto Terra e Memória (ITM, Mação); Grupo Quaternário e Pré-História do Centro de Geociências (u. ID73 - FCT) [georgenash@btinternet.com](mailto:georgenash@btinternet.com)

Over the past five years, the RUPTEJO project has attempted to bridge one of the largest gaps in archaeological research in central Portugal, that of the lack of a comprehensive rock art corpus. Starting from the comprehensive literature review, this project aims to dramatically increase the corpus of rock art not only in quantity but also in quality thus deepening and contextualizing the way we approach rock art. Our approach may also allow the construction of a new interpretative model for this area of the Iberian Peninsula.

So far, the project has achieved a number of goals which include a detailed inventory of all sites, a comprehensive direct tracing database of all available engraved latex molds, a comprehensive documentation programme, along with an accompanying photographic record. The result is a detailed and useable corpus of material that is unique and the surviving legacy of a rich archaeological landscape that was destroyed in advance the Fratel Dam project in 1974.

This paper will present the results of detailed work so far of the Tagus Valley rock art (latex) molds; a material that has allowed scholars an invaluable insight to the extent and complexity of one of the largest rock art complexes in Western Europe.

## 7. REGARDING COMPOSITION AND SCENOGRAPHY PROBLEMS IN SCHEMATIC CAVE PAINTINGS OF THE IBERIAN PENINSULA

García Arranz, José Julio - (Universidad de Extremadura) [jj-turko@gmail.com](mailto:jj-turko@gmail.com)

It has traditionally been believed that schematic cave paintings of the Iberian Peninsula were based on a system of consistent representation in groupings or juxtapositions of distinct figures that are typically based on formal defined models that may be more or less geographically extended. These formal models or motifs, except for figures representing humans, animals and other tools, weapons or idols—rarely show any sort of visual connection with elements from their everyday reality or physical surroundings. The blending of features, with a lack of ethnic details in the human figures, a static nature and a lack of interaction between figures, also adds to the difficulties encountered when taking on a descriptive or narrative approach. Therefore, from a current perspective, it is difficult to find compositions that describe any sort of concrete scene or event. This particularly conceptual and distanced view of reality makes it possible to interpret these paintings as a pictographic language based on a determined combination or association of painted signs that are typically synthetic or abstract. However, on some occasions, those paintings that combine different human or animal motifs (or a combination of both), seem to potentially reconstruct economic activity “scenes”—mainly of hunts or grazing-, fighting or dancing. On the other hand, upon close observation of the juxtapositions— or overlaps—of the motifs, it is possible to detect certain repeated associations within the pictograms, including branch-shaped figures, zoomorphism, wake patterns and anthropomorphisms, resulting in certain compositional constants whose meaning or functionality is scarcely evident

To date, partial approaches have been taken to address scenographic groupings and composition problems in schematic cave paintings of the peninsula—making reference to a season, a group of seasons, or a specific geographic area—, and at times, establishing certain parallels with other sets of similar features. We feel that there is the need to review this issue, taking a global look at the most significant “scenes” found in Iberian schematic art, in order to draw conclusions based on the greatest amount of available evidence. This methodology should be based on the idea that the potential “scenes” or events narrated in cave paintings do not refer to specific or localized events, but rather, to generic or timeless concepts, and that they have an essentially informative purpose that tends to refer to the local availability or control of resources or means of survival.

## 8. PRIMITIVE ENGRAVINGS IN THE MEGALITHIC COMPLEX OF MEZORA (ARCILA, MOROCCO)

Gozalbes García, Helena - (Universidad de Granada) [helen-](mailto:helen-)

*agoga@hotmail.com*

*Gozalbes Cravioto, Enrique - (Universidad de Castilla-La Mancha) Enrique.Gozalbes@uclm.es*

In 1829, during his visit to the megalithic monument of Mezora, the British traveller Sir Arthur de Capell Brooke identified several engravings which, due to its characteristics, he considered as parts of a gateway in the circle. Nearly half a Century later, Ch Tissot failed to identify the motifs, although he managed to recognize the hypothetical gate. Since then these aspects are lost in the historical-archaeological researches, which mostly pointed out that they had not found the engravings.

Mezora, megaliths. Study of the surface of megaliths, detecting antique engravings.

During the course of an investigation conducted in 2013 we have identified several of the antique prints, the ones which coincide with those mentioned by Capell Brooke, and we have also located the area of the mentioned door, which had to be modified by the moving of the some of monoliths (probably during the diggings developed in 1932-1936)

Presence of engravings in certain megaliths of the Mezora Circle

## **9. PECKING THE CRYSTALS: AN AMAZING EXAMPLE OF SCHEMATIC ROCK ART IN SARDINIA**

*Gradoli, Maria Giuseppina - (Geologist, PhD researcher, Dept. of Archaeology, University of Leicester (UK) ggradoli@yahoo.it*

*Anardu, Venerio Giuseppe (Geologist, PhD, freelance) - anardu.geol@yahoo.it*

The present work aims to report, for the first time in Sardinia, the presence of an open-air site rich in channels and cup marks pecked on a layer of perfectly formed calcite crystals. The prehistoric people using or visiting the site must have been attracted by the mineralogical nature, consistency and colour of the substrate on which the rock art was engraved, leaving an extraordinary testimony of their symbolic and spiritual world.

The site was noted during a surface survey for human occupation of caves and rock-shelters in the central part

of Sardinia, and it is now under study to better assert the different patterns of engravings in view of their presentation during the conference.

The site is located on the upper part of a limestone plateau, near a rock shelter overlooking a wide and long valley. More than one hundred cup marks and other schematic signs of no easy interpretation are present, even though the striking feature is represented by a one centimetre deep central pool with irregular channels departing from it and ending with cup marks of different size. This pattern of channels and cup marks was obtained pecking a slightly oblique surface made of different calcite crystals, mainly white and transparent or pink-brownish in colour, having a total thickness ranging from 30 to 60 centimetres. The pecking action was intentionally performed in order to remove the first few levels of clear crystals, leaving the pink-brownish one as background for the figure.

Such an extraordinary example of open-air rock art is a tangible proof of the existence in Sardinia, as all over the world, of this typology of rock art considered since this moment not present in the Island. The intentional engraving of the crystalline surface - unique to Sardinia - by prehistoric people encourages prospection and research for other similar phenomena in the whole of Sardinia.

## **10. ENGRAVING VS PAINTING: THE SEVERAL GROUPS OF SCHEMATIC ROCK ART IN THE EXTREME OCCIDENT OF IBERIAN PENINSULA**

*Martins, Andrea - (Associação dos Arqueólogos Portugueses) andrea.arte@gmail.com*

The post Paleolithic schematic art is distributed in all Portuguese territory and can be divided in two major groups defined by technical differences: the schematic engraving and the schematic painting. The difference doesn't result from a cultural choice, but instead of the adaptation to the geologic and geomorphologic characteristics of the different landscapes which are anthropized through the engravings or paintings. The iconography is mainly identical, being adapted to the context, resulting in different morphological details of the execution techniques. We can mention a crono-cultural iconographic uniformity during recent prehistory with different transmissions according with the localization in the landscape. Within each community territory there is a

choice specific locations for the execution of the repertoire according to the diverse social and symbolic parameters. The different types of rock shelters, panels or cavities presenting schematic art take part of a conceptual programme in which each local should be understood as a stage where the communities, or some members of it, actively participate in the creation of symbolic and ritual narratives.

We will present some examples of this symbolic diversity in Portuguese territory contextualized in the schematic art universe.

ORAL

### 11. THE ROCK PAINTINGS FROM EBO (KWANZA SUL, ANGOLA)? RECORDING, PIGMENTS ANALYSES AND CHRONOLOGICAL ELEMENTS

*Pombares Martins, Cristina - (UTAD - Trás-os-Montes and Alto Douro University, Portugal/ FCT- Fundação Para a Ciência e Tecnologia, Portugal) crisaugst@gmail.com*

The archaeological research in Angola was developed in several phases, from its beginning in the nineteenth century, but never obeyed to a constant program. Today this reality starts to change.

Angola has many archaeological contexts of unparalleled richness. The region of Ebo, in Kwanza Sul Province, is a unique cultural landscape, possessing several shelters with rock paintings, peculiar funerary monuments, myths and legends, ancestral knowledge and practices, linguistic richness.

The first systematic study which is taking place now about the rock art of this region will be present here.

The recording of Ebo's rock art was done through non-invasive methods, followed by laboratory work, using software tools essential for the digital processing of the images of rock paintings.

The documentation includes also the analysis of context of the shelters with rock art - localization, planimetry, excavation, materials and pigments analyses.

The tracings made digitally allowed us to identify several phases in the rock paintings of this almost unknown region.

Alongside the work of recording of rock art, the results obtained from Micro-Raman spectroscopy, based on the

pigments samples collected from one of Ebo's shelters, allowed the identification of the main compounds used in the production of pigments.

To the elements which enable to establish a relative dating for the Ebo's rock art, it has been added a direct radiocarbon dating, until now.

The set of all these data contributes to the knowledge and understanding of Ebo's rock art and it adds new elements to what is known about the rock art from Angola.

ORAL

### 12. L'ART DES DOMUS DE JANAS. MÉTHODES, TECHNIQUES, RÉSULTATS

*Tanda, Giuseppa - gtanda@unica.it (Università di Cagliari)*

En 2011, avec le projet "Cultura visuale preistorica: le domus de janas decorate", nous avons repris l'examen des questions paléontologiques abordées jusqu'ici également à des projets interdisciplinaires, pour une analyse de toutes les données matérielles et monumentales, dans une perspective qui aurait comme référence les cadres culturels de la Méditerranée centrale, à l'aide des technologies innovantes aussi expérimentales.

La stratégie de base du projet couvre quatre domaines:

A. Les Domus de Janas dans les aspects structuraux, fonctionnels, d'architecture, de l'environnement, décorative- culturel, des matériaux archéologiques;

B. Le paysage anthropique entourant les Domus de Janas et les monuments de la même époque, en particulier les habitats;

C. La reconstruction des sociétés du millénaire IV - III . C. diversement articulée en termes de modes de vie et d'économie, dans les quelles le modèle funéraire de la domus de janas est presque généralisé;

D La « sémiotique » de la production d'art des hypogés:

L'argument que nous avons l'intention d'explorer dans ce congrès couvre les gravures observées dans 52 Domus de Janas .

Je vais me concentrer uniquement sur certains aspects du relief et de la classification des motifs figuratifs, qui, à notre avis, sont d'une grande importance . Très souvent, en effet, l'analyse des figures gravées sur les parois des

monuments ou sur les rochers à l'extérieur est fait pour des motifs définis uniquement sur la typologie et donc parfois classés selon des paramètres purement subjectifs.

Il vient souvent aux descriptions et interprétations de type subjectif.

L'utilisation d'une méthode de classification de nature technique viendrait peut-être à des interprétations objectives.

Nous voyons un résumé de la méthode et des problèmes

Pour la classification technologique des motifs figuratifs "à martellina" a été utilisé une méthode spécifiquement conçus et testés dans la nécropole de Sos Furrighesos - Anela: méthode rigoureuse qui répond à la nécessité de «considérer les gravures que les données archéologiques dans le plein sens du terme, comme des objets réels, des éléments par conséquent, qui ont caractères concrets et précis, définissables avec précision et sécurité dans ses traits particuliers et spécifiques" (Tanda 1984, I, 15-21).

Cette méthode est divisée en 5 parties qui, à son tour, se divisent en divers aspects secondaires, incluant d'autres éléments, dans un système hiérarchique

Avec cette méthode, il y aurait aussi la possibilité de reconstruire les phases opérationnelles des décorations des tombeaux: le traitement des surfaces des parois des hypogées, l'identification des instruments utilisés, les méthodes de réalisation, le choix d'utiliser l'espace pour valoriser et faire ressortir certains motifs, la réutilisation partielle des représentations, la réalisations modèles en superposition

La classification typologique est inspirée par les plus grands systèmes européennes de classification (la Valcamonica, le Mont Bego, la Péninsule ibérique, la Scandinavie) et d'Afrique (le Maghreb), dont nous avons pris les éléments et les mots appropriées aux caractéristiques des gravures de la Sardaigne, s'imposer ainsi, avec une grande spécificité.

Il est divisé en 7 classes: I. Les animaux; II. Les figures humaines; III. Les armes et les outils; IV. Les véhicules; V. Les figures géométriques; VI. Les coupules; VII. Figures variés.

Dans la méthode illustrée, la typologie suit la classification.

Soutien fondamental de la classification est le relief,

graphique et photographique.

À cet égard, il convient de noter que un des objectifs de la recherche est également l'expérimentation de techniques innovantes. Ils étaient des expériences du scanner laser et du photographie en 3D, précis, rapide, peu coûteux et objectif.

*Santos da Rosa, Neemias - (PhD Candidate in Cuaternario y Prehistoria, Universitat Rovira i Virgili (URV), Tarragona, Spain) neemias\_of@hotmail.com*

The project "Investigación cronoestratigráfica de los soportes y recubrimientos de las pinturas rupestres de la Serra de la Pietat, Ulldecona (Montsià, Tarragona)", led by the Institut de Paleoecologia Humana i Evolució Social (IPHES) and with the collaboration of several institutions, as Universidad de Barcelona (UB), Universidad de Castilla La Mancha (UCLM) and Texas A & M University, has been developing a study focused on the analysis of micro samples of rocky supports and crusts related to Levantine and Schematic paintings of the Ermites rock art assemblage, in Serra de la Pietat (Ulldecona, Tarragona). The main objective of this project is to obtain indirect dating of the paintings, using to achieve such goal, the AMS 14C method, whereby calcium oxalate content in the microsamples are analyzed to define the chronological and cultural framework of this rock art group.

The methodology has been supplemented by petrographic and stratigraphic analysis of several micro samples through X-Ray Micro-Diffraction and Raman Micro-Spectroscopy on thin sections, reaching a very detailed knowledge about the stratigraphy of calcium oxalate and sulfate crystals on which we have attempted to perform a dating. However, the study revealed many technical issues that must be considered for this type of research.

Microsamples not always have enough calcium oxalate to obtain the amount of carbon required for a successful or reliable radiocarbon dating. Moreover, the results do not yield a direct dating of rock art paintings. However, some of the results are very significant suggesting two chronostratigraphic horizons before the Neolithic period for Levantine tradition and other more recent dates for the Schematic tradition in Serra de la Pietat (Ulldecona, Tarragona).

If we want to yield more accurate results on the minimum and maximum ages for such rock art panels, will be necessary to extract samples of pigment remains to determine the relative stratigraphic position of the painting event in relation to overlying and underlying calcium oxalate accretionary crusts.

## 1. LATE PREHISTORIC INCISED ROCK ART IN SOUTHERN EUROPE: A CONTRIBUTION FOR ITS TYPOLOGY

*Coimbra, Fernando - (Instituto Terra e Memória) coimbra.rockart@yahoo.com*

Late prehistoric incised rock art occurs in several countries from Southern Europe with a large range of motives. It's possible to observe anthropomorphic figures, zoomorphic figures (horses, dogs and deer), weapons (halberds, axes, spears, swords, daggers, arrow heads), many diverse geometric motives and several symbols, among other figures.

In this paper the author presents a contribute for a typology of this kind of rock art, joining not only common themes to countries such as Portugal, Spain, France and Italy, but also some examples that are typical from only some regions of the same countries and from others like Kosovo and Greece.

ORAL

## 2. FILIFORM ROCK ART IN MOUNT BEGO (TENDE, MARITIME ALPS, FRANCE)

*Bianchi, Nicoletta - (Scholarship holder soprintendenza per i beni archeologici del piemonte) nicoletta.bianchi@gmail.com*

Rock carvings, pecked and filiform, of mount bego region are situated in the high valleys of the mercantour national park, at altitudes of over 2000 metres and located within 1,400 hectares subdivided into eight main sectors, of which marvels and fontanalba are the most remarkable because of the great number of engravings. Pecked carvings can be date to late prehistory essentially because of the presence of different kinds of engraved weapons (daggers, halberds and axes). Furthermore, the human occupation of the site during prehistory is confirmed by archaeological digs in *gias* del ciari as well as in other rock shelters, highlighting human presence on the site from early neolithic.

The typo-chronological study of carved weapons, based on the typological comparison between engraved and real weapons found in archaeological context, provided

a chronological interval starting about 3700 B.C. and lasting until the end of the bronze age. Nevertheless, the discovery of archaeological material prior to this interval compels to admit the possibility that other motives were made in early neolithic.

Previously, carlo conti and giuseppe isetti claimed that the most ancient mount bego engravings were filiform motives and they based their hypothesis on the superimposition between pecked and filiforms engravings. Recent works on superimpositions have shown that in some cases pecked carvings really overlap filiforms and that, consequently, some filiforms pre-date pecked engravings.

Just on the base of superimposition relations it is difficult to quantify the anteriority of filiform motives; though it is undeniable that common points exist between filiform patterns - tree like motives, pectiniforms, scalariforms, zig-zags, net-patterns - and motives dating from neolithic, from other sites and in particular from iberian peninsula.

Moreover the use of incision during late prehistory is attested by the presence on the rocks of engravings realized half-and-half by pecking and incision: they can be lines «of construction» of the figure and lines «of detail» executed by a fine and superficial incision, or made by an incision in V section, which could be qualified of «polissoir».

Filiform carvings seem acquire more importance at the end of the early bronze age, when the number of the pecked carvings - especially weapons - is considerably reduced compared to the previous periods. In time, filiform motives complete pecked compositions and are combined with them. The big mixed compositions, pecked and filiform, seem to translate the expression of a transition period, corresponding to the end of the bronze age, during which pecked tradition definitively gives up her place to a tradition exclusively filiform.

The study of filiform engravings complete the chronological setting established for the carving activity in mount bego. The finding of filiform motives covered by some pecked engravings denies the hypothesis that in mount bego region only pecked carvings date from the late prehistory; besides, the repetitive association of pecked engravings and filiform patterns suggests an important interaction of the two carvings tradition.

It is possible to consider the coexistence of the two techniques, incised and pecked, and succesively a progres-

sive disuse of pecked tradition, in favour of an increasingly present schematism.

ORAL

### 3. FILIFORM FIGURES IN THE ROCK ART OF VALCAMONICA FROM PREHISTORY TO THE ROMAN AGE

*Sansoni, Prof Umberto. - (CCSP - Dip. Valcamonica Lombardia) dip.ccs@gmail.com*

*Cinzia Bettineschi Dott. (CCSP - Dip. Valcamonica Lombardia)*

*Silvana Gavaldo Dott. (CCSP - Dip. Valcamonica Lombardia)*

The report examines the engravings made with the "filiform" (scratched) or polissoir technique in Valcamonica, dated to the pre- or proto-historic age. In Valcamonica, most of the figures are pecked, but the filiforms, although fewer in percentage, in certain sites and areas show some original and meaningful features.

The whole *corpus* of filiforms of Valcamonica has been analysed; a specific typology has been drawn up, linked to the typology used for the pecked engravings. Under and overlaps with dated pecked figures have been analysed in order to provide a dating for the filiform phases. Scenes and complex associations have been studied, and reveal that many panels have a symbolic and ritual value and some correspondences to some recently discovered paintings.

The associations and especially the overlaps between the filiform and the pecked engravings have made possible to define the chronological *excursus* of the filiforms themselves, from the late Neolithic up to the Roman era (and with a later phase from the late Middle Ages to the twentieth century). The pre- and proto-historic filiform phenomenon is concentrated mainly in the Iron Age, especially since the sixth century BC until the Romanisation in the early centuries of the Christian era. If we exclude the thousands of short, often confused signs that surround the pecked images or the traces of the preparatory sketches, three particular categories of filiforms can be defined: the completion of pecked figures, usually in their finer details; geometric shapes such as circles, pentagrams, *trias* or more structured geometric shapes; complex images as anthropomorphic, zoomorphic, buildings, handicrafts, symbols and inscriptions. The analysis of the overlaps between and among filiform and pecked figures reveals that in the middle Iron Age on some surfaces (Foppe di Nadro r. 24 and r. 27, Pià

d'Ort r. 24) the two techniques coexist, alternate, complement each other; in the late Iron Age, on other panels (in Piancogno and again Foppe di Nadro, r. 24, r. 43) the filiform technique is used exclusively or predominantly.

The geometric shapes and the complex images, typologically near to the similar pecked engravings, feature a certain stylistic naivety and often their own logic and symbolic structure. Their relationship with the contemporary pecked images is strong, as well as the thematic parallels with painted figures. The themes represented have a strong symbolic or ritual meaning, thus giving filiforms a significant role in the context of pre- and proto-historic engravings.

### 4. THE FILIFORM ROCK ART FROM KOSOVO

*Krasniqi, Shemsi - (University of Pristina) shemsi.krasniqi@gmail.com*

The study of rock art in Kosovo has started a few years ago. Until now eight sites were discovered, and most of them represent the filiform rock art. The most important site is Zatriq, where in the place called Sharenice, hundreds of symbols since prehistoric period are engraved on the rock surface, and a rite of passage occurs there even today. All the other sites of the filiform rock art, except Krileve, are at the megaliths complexes (Papaz, Llaushe, Aqareve, and Vitak). The motives of filiform rock art from Kosovo are very similar with motives found in other Mediterranean and European areas (asterisk, tree like motives, pentagram, vulva, net pattern, circle, square, lines). Some associations of symbols are very frequent, and what is more important, some of them correlate very well with the meaning of today's ritual. This paper presents some comparative analysis, interpretations, and a typology of filiform rock art in Kosovo.

## 6. LES GRAVURES RUPESTRES FILIFORMES DE LA PARETE MANZI DE MONTELAPIANO (CHIETI, ITALIE)

*Di Fraia, Tomaso - (Université de Pisa (Italie) tom.difraia@libero.it*

En 2010, le prof. Aurelio Manzi a découvert une série de gravures rupestres sur l'arête rocheuse qui sépare les villes de Montelapiano et Villa Santa Maria (province de Chieti), sur le côté gauche du Sangro, aujourd'hui à environ 35 km de la mer.

Les gravures sont situées sur une paroi rocheuse (*Parete Manzi*) presque verticale et exposée à W, pour une surface d'environ 100 cm de hauteur (à partir de 90 cm au-dessus du sol) et 300 cm de largeur. Il y a seulement une figure peinte, tandis que les autres sont gravées.

Cette étude fournit une première documentation et essaie de proposer quelque interprétation.

L'information suivante a été obtenue par la vision directe pendant trois explorations, par une première documentation photographique et par un dessin au décalque.

Les gravures montrent principalement des sillons minces ou très minces et seulement quelques signes, cependant aniconiques, ont été réalisés avec une rainure plus large et concave. Un élément de cohérence stylistique est la taille relativement petite des figures (une des figures plus complexes, le nœud de Salomon, mesure moins de 4 cm), ce qui suggère une forte homogénéité culturelle et une probable continuité chronologique.

Ce site a des caractéristiques particulières:

1) le site est dans une position difficile à atteindre par la très forte pente et la présence de pierres très instables; en effet jusqu'à 2010 on ignorait ces représentations, même si elles sont situées à une courte distance d'une zone urbaine et ne sont pas couvertes par la végétation; 2) l'utilisation presque totale de la technique de gravure par de fines rainures (la Parete Manzi est le seul d'une

douzaine de sites d'art rupestre dans la province de Chieti avec cette prédominance); la seule figure peinte (en noir) semble plus ancienne, si on observe entre autres la détérioration de la roche de support;

3) la typologie des figures s'éloigne du répertoire connu dans les autres sites d'art rupestre de la province. Parmi les représentations réalistes on trouve plusieurs variétés de poissons et des figures interprétables comme des harpons. Les signes géométriques/abstraites comprennent des étoiles à cinq pointes, motifs à peigne, escaliers, losanges, «papillons», carrés, faisceaux ou enchevêtrements de lignes et un nœud de Salomon.

La question se pose des liens possibles, idéologiques et symboliques, avec un site des Pouilles (Cavone di Spinazzola, Bari) surtout pour les raisons suivantes: 1) l'utilisation exclusive (Cavone) ou presque totale (Parete Manzi) de la technique de la gravure; 2) la ressemblance de nombreux sujets; 3) la superposition ou juxtaposition de figures dans de différents moments, mais toujours dans le même panneau de roche. Il est possible que de petits groupes de personnes se déplaçant sur de longues distances aient exprimé leur imagination dans des endroits très lointains. Dans ce cas, on peut penser à la transhumance comme un vecteur pour la diffusion des idées.

## 7. THE ROCK ART FROM FIGUEIREDO (SERTÃO, PORTUGAL): TYPOLOGY, CHRONOLOGY AND INTERPRETATION

*Coimbra, Fernando - (Instituto terra e memoria) coimbra.rockart@yahoo.com*

*Garcês, Sara - (Universidade de Trás-os-Montes e Alto Douro) saragarcês.rockart@gmail.com*

The rock art from Figueiredo is constituted by three carved rocks with incised motives, some done with a medium/thick groove and others with filiform groove. Two of them were discovered after an intensive forest fire. Since these rocks are flat to the ground, they were covered by earth during a long time, being the engravings from these two examples very well preserved.

All the three rocks were traced by the authors in two different fieldworks and, between them, rock 1 was covered by plastic and industrial sand during eight months in order to remove, in a natural way, the lichen that were over several filiform figures. After that, some experiments with a 3D laser scanner were also done.

This paper presents the results of all the research done regarding these three rocks, which is a contribute for the typology, chronology and interpretation of the incised rock art in Portugal.

It was found that the diversity of motives on Rock 1 from Figueiredo allows considering it one of the most important regarding incised rock art in southern Europe. Furthermore, some figures of this rock are extremely rare in this kind of art, appearing some of them only done in pecking technique. Other motives can be associated with cross cultural contacts in southern Europe during late Bronze Age/Early Iron Age.

### **8. LOS GRAFITIS FILIFORMES DE ÉPOCA HISTÓRICA EN LA ROCA Y EN LOS ENFOCADOS DE IGLESIAS Y EDIFICIOS CIVILES. ALGUNAS COMPARACIONES Y PROPUESTAS DE INTERPRETACIÓN**

*Troletti, Federico Dott - (CCSP) federico.troletti@lett.unitn.it*

La comunicación examina el vasto repertorio de grabados/petroglifos filiformes del yacimiento de Campanine di Cimbergo (Valcamonica) datables en plena época cristiana (del siglo XV al XIX).

La comparación entre los grabados filiformes de la roca y los de las paredes de las iglesias se comenzó ya hace diez años, por lo que, se proponen también algunas consideraciones para la metodología del estudio de este "arte incisorio".

El estudio ha demostrado la presencia de imágenes cultas y representaciones populares. Hay además muchas escenas con hombres armados y fortificaciones militares. Otros signos muestran llaves, animales, dados, horcas para el linchamiento, águilas heráldicas, nudo de Salomón, escritos en latín e italiano. Para la interpretación y la datación también han sido analizados los grabados filiformes descubiertos en las paredes de algunas iglesias de Valcamonica.

El estudio ha demostrado que tales grabados están presentes en el enfoscado de edificios civiles y religiosos, y están extendidos por casi toda Italia, pero también en varias zonas de Europa; de este modo, ha sido posible analizar las imágenes y comparar los petroglifos filiformes de las paredes de las iglesias con los de las rocas y se han encontrado muchas semejanzas.

### 1. VARIABLES BIFACIALES

Otte, Marcel - (Université de Liège, Belgium) [Marcel.Otte@ulg.ac.be](mailto:Marcel.Otte@ulg.ac.be)

La pratique des enlèvements bifaciaux se retrouve à tous les moments et en tous lieux de l'histoire humaine. Cependant, d'innombrables variables permettent d'y distinguer des facteurs régionaux (Keil Messer Gruppe), chronologiques (Acheuléen) et traditionnels (Chine). De telle sorte que globaliser l'ensemble de ces variantes, pour cette seule raison technique, ne suffit pas à y comprendre la signification.

ORAL

### 2. BIFACE OR CORE ? AN INTRIGUISH ARTIFACT IN THE MIDDLE PALAEOOLITHIC ASSEMBLAGE OF FOZ DO ENXARRIQUE (RÓDÃO, PORTUGAL)

Raposo, Luis (Museu Nacional de Arqueologia, Lisboa, Portugal) [luisraposo@mnaarqueologia.dgpc.pt](mailto:luisraposo@mnaarqueologia.dgpc.pt)

Among the vast Middle Palaeolithic lithic assemblage Foz do Enxarrique, site dated to c. 30 kyr, located at the Tagus valley, near the Spanish border, it is worthy to be noted a singular artifact of bifacial elongated conception. Having not in mind the entire assemblage and a few technological details, it would easily be assimilated to a bifacial tool, maybe a kind of backed biface (*biface à dos*).

This strictly typological classification will be discussed. True Middle Palaeolithic bifaces from the same region will be presented. And comparisons will be made with Acheulian bifaces. In all, the impression given by current data, maybe because of its incompleteness, is much more one of discontinuities, technological, typological and "culturally" speaking, than the contrary. Which models would better fit this data? Is it possible to use in this context evolutionary concepts such as the ones of "flux and go" or "bottle neck"? Or are the traditional migrationists / diffusionists explanations still acceptable? The fact is maybe that all of these approaches are deleterious to some extent, due to the inherent nature and the circumstantial insufficiencies of the available empiric data.

ORAL

### 3. COEXISTENCE OF DÉBITAGE/SHAPING AND VARIABILITY OF RAW MATERIALS BETWEEN MIS 8/7 AND MIS 5: THE EXAMPLES OF SAINTE ANNE 1 AND PAYRE.

Santagata, Carmen - (UMR 5199 PACEA Université de Bordeaux 1) [salvacim@libero.it](mailto:salvacim@libero.it)

Moncel, Marie-Helene (UMR 7194, CNRS e Department of Prehistory, National Museum of Natural History, Paris, France) [moncel@mnhn.fr](mailto:moncel@mnhn.fr)

In the context of the work of PCR *Regions Auvergne and Rhône-Alpes*, the study of series of Sainte Anne 1 and Payre allowed us to define the coexistence between débitage reduction process and shaping, correlated with the variability of raw materials, although with different proportions and associations.

The cave of Sainte-Anne 1 was visited during MIS 6/5e: tools were produced mainly by volcanic rocks, followed by quartz and flint (represented by twenty-six genetic types). The lithotype most represented is the flint of the Puy basin, although regional and external resources are present too. Fauna, highly fragmented as result of periglacial action, reflects the existence of severe weather conditions. The site Payre, located along the Rhone valley, has a sequence that goes from MIS 8-7 at the end of MIS 6/5 (Moncel, 2008). Fourteen human remains were discovered. The local and semi local flint is the dominant raw material. Basalt, quartz, quartzite and limestone are available on the banks of the Rhone River and the Payre. The fauna is composed of elephant, horse, rhinoceroses, cervids, large bovines, tahr, chamois, bears, cave lion, dhole, wildcat, lynx, red fox and beaver.

At Sainte Anne 1, any differential resource management was observed in the débitage reduction process (Levallois, discoid, opportunist) except blank selection (Santagata, 2012). The materials rarely used (quartz and volcanic rocks) play the main role, while the quality is not always fits. Although few in number, handaxes are varied by raw material, technical, functional and morphometric features. Series of Payre, in contrast, show specialized uses of lithotype in relation to technical and/or functional features of products: if flint and limestone have the predominant role in the débitage reduction process, the shaping has applied to volcanic rocks, although their quality is not always high. Rare handaxes are very simple tools, characterized by the variability of typo-technological characters.

Although numerous hypotheses are being put in place to clarify the terms of chronological coexistence, geographical or techno - functional débitage/shaping reduction process, technical variability of observed characteristics, the variability of technological characters, the different use of raw materials, the coexistence of local and exogenous lithotype, the absence of certain production phases show the high degree of technical flexibility and strategic complexity implementation. The question under analysis is the role of handaxes in these technical systems, considering that the nature of the raw material used in these cases has certainly contributed to the idea of a set extremely related to the particularities of territory and needs (functional or cultural) specifics.

ORAL

#### 4. LATE MIDDLE PALAEOOLITHIC BIFACIAL TOOLS IN WESTERN EUROPE: TAXONOMIC COMPLEXITIES AND REGIONAL TENDENCIES

*Ruebens, Karen - (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, Schloss Monrepos, 56567 Neuwied, Germany) karen.ruebens@eva.mpg.de*

During the late Middle Palaeolithic (MIS 5d-3, ca. 115,000–35,000 BP) bifacially worked tools, including handaxes, form a substantial part of the Neanderthal tool kit. Across this time period, they occur in many regions of Western Europe, often in dominant proportions and are characterised by a large degree of morphometric variability. Two main biface-rich entities are commonly distinguished in Western Europe:

1) *the Mousterian of Acheulean Tradition (MTA)* defined by the French record and typified by cordiform and triangular handaxes 2) *the recent Micoquian or Keilmessergruppen (KMG)* occurring in Central Europe, characterised by backed (Keilmesser) and leaf-shaped bifacial tools

Additionally, a plethora of smaller, often poorly defined, bifacial tool entities have been proposed for assemblages which do not conform to either the MTA or KMG definition. Together with the existence of a dense cloud of different terms and types, often with different meanings in different languages, a rather disjointed view currently exists on this late Middle Palaeolithic bifacial phenomenon. Therefore, the research presented here aims to provide a new, integrative, perspective on the techno-typological and region-specific characteristics of these Late Middle Palaeolithic bifacial tools by:

- Unravelling this epistemological confusion and creating a simplified comparative framework that incorporates all the existing local terms and types

- Taking a macro-regional approach, incorporating data from across Western Europe, and for the first time including the regions of Belgium, The Netherlands, Britain, northern, western and eastern France

1,303 bifacial tools from 14 case study assemblages were analysed through a detailed attribute analysis and compared with additional data from 61 comparison sites. At a micro-scale, results indicate high levels of variability between individual bifacial tools and assemblages, which can be linked to differing local conditions, such as raw material, site use, tool function and resharpening. At a macro-scale, a threefold regional distinction can be made between the MTA, KMG, and 'the Mousterian with Bifacial Tools (MBT)': At this level, an additional sphere of interpretation is required to explain the observed large-scale differences. It is therefore suggested that the MTA and KMG can be interpreted as two different cultural traditions, reflecting different lines of socially-transmitted information. Further work is needed in relation to the MBT, which is located at the crossroads of MTA and KMG influences, to better understand its causal factors and behavioural implications. Overall, this research demonstrates the advantages of a wider-scale approach to the archaeological record and the presence of regional behaviour among late Neanderthals.

ORAL

#### 5. ANALYSIS OF BIFACIAL ELEMENTS FROM THE GROTTES DE LA VERPILLIÈRE I & II AT GERMOLLES IN SOUTHERN BURGUNDY, FRANCE

*Frick, Jens Axel - (Universität Tübingen) jens-axel.frick@ifu.uni-tuebingen.de*

*Floss, Harald - (Universität Tübingen) harald.floss@uni-tuebingen.de*

Lithic bifacial elements are quite common in Late Middle Paleolithic assemblages in eastern France. Lately, there were discussions about the formation of space time units in the late Middle Paleolithic in Western Europe and the bifacially backed knives with para-burin blows (*Keilmesser mit Schneidenschlag*) from the *Grotte de la Verpillière I* (formerly also known as *Grotte de Germolles*) were part of these discussions concerning the formation of clusters in space and time like the *Keilmessergruppen* (Jöris), the *Moustérien mit Micoque-Option* (Richter), the

*Industrie charentiennes à influences micoquiennes* (Farizy), the *Micoquien* (Gouédo, Deloze, Depaepe), the *Moustérien de tradition acheuléenne* (Desbrosse), *Micoquien* and *Moustérien de tradition acheuléenne* (Floss, Frick) or the recently established Mousterian with bifacial tools (Ruebens). In this frame, we present production, techno-functional and morphological analyses of all known bifacial elements from the *Grotte de la Verpillière I* (VP I, from old excavations and the excavated backdirt of these) and from a new cave with intact Middle Paleolithic layers, the *Grotte de la Verpillière II* (VP II), which is 50 m south of the well-known *Verpillière I*.

The bifacially backed knives from the VP I (first presented in the 1970s by Desbrosse and others) and all other bifacial elements from every condition (old excavations, excavation of back dirt areas and excavations in intact layers) from both caves were now (re-)analyzed in the course of running research projects to the paleolithic occupation of southern Burgundy (DFG FL 244/5-1, SFB 1070 B01 and PCR UMR 6298 ARTeHIS) at the University of Tübingen and Dijon, led by H. Floss. Beside the production analysis and morphological shape comparisons, we demonstrate the separation into techno-functional units (TFU) and techno-types (TT) of these now way more than 60 bifacial elements.

In a technological production view all of these pieces are quite similar made. The analysis demonstrate that both surfaces of the bifacial elements are produced in a plano-convex way independent from its top view shape (symmetrical or not, back or not). In most cases the edges are also shaped in a plano-convex way. Reuse and recycling processes (reshaping and remould) are also visible. The morphological shape analysis of the top view show the broad range and the heterogeneity. With the aid of the production and shape analyses we are able to form TFUs on these pieces and can sort the bifacial elements into different TTs. The intact lithic assemblages from both caves also demonstrate that these bifacial elements are accompanied by a Levallois production of unifacial stone artifacts and not as formerly suggested with a Quina production.

The formation, classification and distinction of assemblages belonging to the Middle Paleolithic of Western Europe are integrated into enduring discussions. Both caves yield a heterogenous bifacial component and a homogenous unifacial Levallois production. Our analysis may help to get an idea of the bifacial diversity in the southern part Burgundy and may support the finding of criteria to group lithic components and assemblages.

ORAL

## 6. BIFACIALLY BACKED KNIVES (KEILMESSER) IN THE CENTRAL EUROPEAN LATE MIDDLE PALAEO-LITHIC.

Olaf Jöris - (*MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution Schloss Monrepos, 56567 Neuwied, Germany*) [joeris@rgzm.de](mailto:joeris@rgzm.de)

An overview of sites, production strategies and raw material morphology, and their implications for the understanding of Late Middle Palaeolithic regional entities. A large number of Late Middle Palaeolithic assemblages from Central Europe contain, or are even characterized by, bifacially backed knives (*Keilmesser*) – asymmetric bifaces with a single active edge. Indeed, in some assemblages, morphologically different forms of *Keilmesser* represent the most dominant tool type. In contrast to their often highly standardized *châines opératoires*, flaking strategies at these sites appear much more variable. Given the different raw materials used for *Keilmesser* manufacture and the varying morphological properties of these materials, it is noteworthy that entirely different strategies were applied to produce virtually identical tools. Raw material morphology or size played only minor roles in the production of these tools, while the production process itself best documents the *Keilmesser* tool concept. This observation adds raises the question about the degree to which certain tool forms have to be regarded as desired products, and to what extent should these be evaluated in terms of cultural markers.

ORAL

## 7. BIFACIAL KNIVES IN THE MICOQUIAN SITES IN THE NORTH-WESTERN CAUCASUS AND NEIGHBORING REGIONS: TYPOLOGY, TECHNOLOGY, AND REDUCTION

Golovanova, Liubov - (*Laboratory of Prehistory*) [labprehistory@yandex.ru](mailto:labprehistory@yandex.ru)

Today in the Northern Caucasus there are known 9 Middle Paleolithic sites containing 29 layers with Micoquian industries. They are dated from late MIS 5 through late MIS 3. Similar industries were earlier defined as East-European Micoquian (Bosinski, 1967; Gabori, 1976) or East-European Mousterian (Praslov, 1984).

Presence of bifacial tools of certain types is the main feature that characterizes the Micoquian industries of

Northern-Western Caucasus and distinguishes them from other Mousterian industries in the Caucasus. These bifacial tools include small broad triangular handaxes (Breit dreieckige Faustkeilblätter), laurel leaf-like projectile points, and various bifacial and partly bifacial convergent tools and side-scrapers or knives (closed to Bocksteinmesser, Prondnikmesser, Wolgogradmesser types) (Bosinski, 1967).

The Micoquian assemblages are wide spread in the Eastern Europe, from the Volga River in the east to the Northern Ural Mountains in the north, and the Prut River in the west. Within this area, Crimean Peninsula is the region, where the largest number of Micoquian assemblages is known. The most striking feature of these industries is the common presence of a numerous and diverse group of bifacial scrapers and knives. Since works of Kolosov (1986), researchers pointed to a close proximity of these tools to Central European types, such as Bocksteinmesser, Prondnikmesser and Klausenische, although they always stressed that typical tools of these types are individual in the Crimean Micoquian. The Crimean researchers classified bifacial knives based on their forms, distinguishing triangular, trapezoidal, segment-like and other types (Chabay, 2004; Chabay et al., 2008).

In most regions, where the Micoquian industries are known, including Western, Central (Burdukiewicz, 2000), and Eastern Europe, and North-Western Caucasus, it is noted a high level of variability among bifacial knives. Researchers often suggest that each bifacial tool concept is correlated with various methods of production, resulting in large degrees of morphological variation (Ruebens, 2013). The application of a morphologic-technological analysis for the study of variability in bifacial scrapers-knives in the Northwest Caucasian industries suggests that the variability of the tool's forms and details of their design may be resulted from several factors, including situational application of specific technological methods and selective reduction. On the contrary, the similarity of many types of bifacial knives within the entire distribution area of Micoquian industries, noted above, suggests that not single, but close technologies of Micoquian bifacial scrapers-knives were used.

One of the most significant artefacts of the Middle Palaeolithic toolkit is the bifacial backed knife. Its wide morphological variability allows us to distinguish a lot of subtypes that are, in specific cases, related to the both regional and chronological groups (Bockstein, Klausenische, Wylotne, Ciemna etc.). These groups are defined mostly within the geographic area of Germany and Poland, where bifacial backed knives are relatively abundant and their stylistic pattern is well preserved.

A different situation prevails in Moravia or Slovakia. Many collections contain pieces that fulfil the definition of such a type – a tool shape formed by reduction of both surfaces, deliberately formed knife tip, use of natural or artificial backing that is situated in front of the working (cutting) edge, which is primarily formed in a bifacial manner. There are also important differences. Preserved pieces are often small, sometimes microlithic, the Prondnik para-burin scar is often missing and the working edge is rejuvenated using unifacial retouch. A typical feature of both Moravian and Slovakian bifacial backed knives is their high metrical and morphological variability and it is for this reason that we are not able to connect them to any group mentioned above.

The study is based on the both techno-typological and raw material analyses of several Middle Palaeolithic sites in Moravia (K?lna Cave, Moravský Krumlov IV, and Šipka Cave) and Slovakia (Bojnice I and Bojnice III). These new analysed assemblages are compared with sites in Poland, Hungary or Germany where Neanderthals should adapt to different conditions. Interpretive problems concerning the classification of bifacial backed knives will be discussed in this presentation by focusing on the reduction sequence in relation to the stylistic pattern (mental template) of such tools.

The author will propose the theory that both types of backed knife – the well preserved pieces from Germany and Poland and the very reduced items from Moravia and Slovakia – belong to the same techno-complex (called Micoquian, Prondikian, or *Keilmessergruppe*) which is divisible only in distinct regions. It is also argued that the variability of artefacts reflects the availability of different raw materials (quality of raw material and distance to the outcrops) and/or different levels of reduction (taphonomy of individual pieces).

## 8. BIFACIAL BACKED KNIVES IN THE MIDDLE PALAEOLITHIC - INTERPRETIVE PROBLEMS OF VARIABILITY

Neruda, Petr - (Moravské zemské muzeum) pneruda@mzm.cz

ORAL

## 9. THE BÁBONYIAN AND ITS POSSIBLE RELATION TO INDUSTRIE OF LAYER 7C

Ringer, Árpád - (University of Miskolc) [bolringa@uni-miskolc.hu](mailto:bolringa@uni-miskolc.hu)

The Bábonyian industry was discussed by the present author on the basis of the finds from five open sites in north-eastern Hungary in a study published in 1983. These sites are located on the eastern slopes of the Bükk Mountains, near the towns of Sajóbáony and Miskolc, and near the settlement of Mályi. The techno-typological features of the Micoquian-like leaf-shaped tools dated to the Eemian interglacial show many similarities with bifacial backed knives (*Keilmessergruppen*).

The paper is made up of two parts:

- The first offers an overview of earlier research on the Bábonyian, of the new studies on its chronology and of the raw materials used by this industry, as well as of the industry's technological and typological traits.

-The second part is devoted to a comparison between the lithic artefacts from the Miskolc–Kánás-tető site and the analogous artefacts from Layer 7a of the Kulna Cave in Moravia.

We are in opinion that the Bábonyian is a Middle Paleolithic special industry, characterised by leaf shaped tools and Keilmessers. The chronological relation between the tool kit of Kánás-tető and the lithic artefacts from Layer 7a of the Kulna Cave is possible, around 60-70 Kyr BP.

ORAL

## 10. A TECHNO-TYOLOGICAL VARIABILITY OF BIFACIAL LEAF POINTS IN THE MIDDLE PALAEO-LITHIC ASSEMBLAGES IN THE EASTERN EUROPE AND CAUCASUS

Doronichev, Vladimir - (Laboratory of Prehistory) [labprehistory@yandex.ru](mailto:labprehistory@yandex.ru)

In the territory from the Carpathian to the Caucasus, there are known numerous finds of bifacial leaf points. They are often found in reworked contexts or in surface locations, sometimes yielding large lithic assemblages and sometimes containing finds of Late Acheulean handaxes, and differently defined by researchers as Late

Acheulean or early Middle Palaeolithic. A few late Middle Pleistocene stratified sites, which are dated to MIS 7 and MIS 6 and yield in situ assemblages comprising true leaf points or foliates with double-convex bifacial finishing, document that the appearance of this technology marks the transition from the Lower to Middle Paleolithic in this vast region. In the region, the earliest in situ finds of leaf points are documented in assemblages from layers Vb, Va, and V at Korolevo 1, dated by TL date of  $220 \pm 35$  ka, and paleomagnetic and pollen data to MIS 7.

These assemblages contain elongated and narrow bifaces (or fragments of such bifaces) with double-convex cross-sections, identified as leaf point pre-forms, and elongated leaf points with pointed or narrow oval-shaped bases and double-convex bifacial retouch, often supplementing with tools (scrapers and points) with plane-convex bifacial retouch. These tool sets are associated with non-laminar technique, indicating by the presence of cores with recurrent flaking (identified as proto-prismatic or Levallois), and insignificant percents of laminar (Ilam=4-9) and Levallois blanks (IL=2-7, up to 15 in Korolevo 1/5b).

Although in Eastern Europe, the leaf point assemblages that present the early Middle Paleolithic in the region are not yet associated with hominin fossils, an early leaf point industry from Ehringsdorf (Germany), which has a U/Th date of  $243 \pm 6$  ka and is dated to MIS 7, is associated with the Ehringsdorf skull presenting the earliest unquestionable fossil of typical *H. neanderthalensis* in Europe. In the Caucasus, the only hominin fossils associated with this industry type are two incisors from layers 6 and 5b in Matuzka Cave, both having a shovel-like shape typical for Neanderthals.

In the Northwestern Caucasus and Eastern Europe, the technology of bifacial foliates with double-convex cross-sections continues to exist, although ceases to be the dominant with the distribution of later Middle Paleolithic industries, which are characterized mostly by leaf-shaped points, scrapers and asymmetrical knives with plane-convex bifacial retouch, and which most of researchers define as Eastern Micoquian. These assemblages are associated with numerous fossils of classic European Neanderthals. In the region, the Eastern Micoquian assemblages are first documented during early MIS 5, and they continue to exist until the end of Middle Palaeolithic at about 40 ka ago. As a consequence of such temporal trend in the leaf point technology one can suggest that the Eastern Micoquian presents an industry type that developed during early MIS 5 (apparently, synchronously with the Keilmesser group in Central Europe)

from the early Middle Palaeolithic assemblages with double-convex bifacial retouched leaf points. The available hominin fossils indicate that the leaf point industry appears to represent the initial stage of early Middle Palaeolithic Neanderthal occupation of the Eastern Europe and Caucasus.

ORAL

### 11. BIFACES AND LEAF-POINTS OF EASTERN FRANCE : WICH PART AND ROLE OF THE RAW MATERIAL ?

Lamotte, Agnès – (Université Lille 1) [agnes.lamotte@univ-lille1.fr](mailto:agnes.lamotte@univ-lille1.fr)

Galtier, Frédéric (Ass.Sauv.Patrim.Haute-Saone)

Willemann, Georges (Ass.Sauv.Patrim.Haute-Saone)

In Haute-Saône departure, the study of surface collections and of few rare preserved stratigraphy sites show that the bifacial phenomena takes part of the middle palaeolithic until his passage to the upper palaeolithic. In this region, the raw material is very attractive by his diversity and disponibility. In this part of the region of 125 km by 75 km, we can find many geological formations from metamorphic, volcanic to sedimentary rocks rich in silicious formations (Trias, Jurassique, Cretace, Oligocène) but also non-silicious blank (terraces context, fluvio-glacial context). Rich of this large choice, men were strolling and working a relationship between the realization of tool depending on the raw material. Five great sedimentary complexes gave them around 16 kinds of flint, chert, quartz, quartzites, sandstone knapped since the beginning of Palaeolithic. Then, seven of them have been choosen and affectionnated for bifaces shaping, and for two of them only, leaf-point shaping. So even if knappers are strong of adaptation toward rognon morphology, in the case of leaf-points, a clear selection has been made in direction of flint plaque, ovalair and biconvex rognons and flake blanks.

ORAL

### 12. MIS-3 ASSEMBLAGES WITH ASYMMETRICAL KNIVES FROM POLAND: AN EXAMPLE OF LATE MICOQUIAN/KEILMESSERGRUPPE TRADITION.

Urbanowski, Mikołaj - (Szczecin University, Institute of History, Archaeological Department) [m.urbanowski@univ.szczecin.pl](mailto:m.urbanowski@univ.szczecin.pl)

Several cave sites were excavated during the last decades in the northern part of Polish Jura. The caves were excavated during the careful and slow field works, supported by multidisciplinary studies focused on palaeoenvironmental reconstruction and extensive absolute dating. The results of such work changed the existing vision of the ending part of the Middle Paleolithic in this part of Europe.

The Stajnia Cave (N 50° 36'58,28", E 19° 29'04,24"), where the excavation conducted by the author started in 2006 yielded a very rich assemblage of flint artefacts from the stratigraphic complex D, dated stratigraphically, palaeontologically and absolutely to the early and middle part of the MIS-3 period. The end of deposition of the youngest D1 unit is located about 45 ka BP. The assemblage from D1 unit represent a typically Middle Palaeolithic technology containing the discoidal and Levallois methods of debitage, as well as clear traces of extensive production of cutting tools which may be classified as the asymmetrical knives or scrapers, as only a part of them is fully bifacial. About 7000 thousands of the flint pieces, coming from a relatively small excavation area were analysed technologically and metrically. Selected part of the artefacts was also subjected to use-wear analysis. Among the artefacts, numerous animal bones were found, many of them cutmarked. The Middle Palaeolithic character of the site may be also attested by the human teeth discovered in the rear part of the cave, which were attributed to Homo neanderthalensis.

The result of the analysis, combined with the other archaeological finds from D1 unit, as like the traces of sophisticated boneworking and structuring of the space enriches the picture of the very late Neanderthal communities from Central Europe. From the techno – stylistic point of view, the flint industry present in stratigraphic complex D of Stajnia Cave may be connected with a very late part of the Micoquian (Keilmessergruppe) tradition, however some similarities to other LMP traditions as Quina and Bohunician may be observed. Interestingly, no traces of the elements typical for the "transitional" Central European industries as leaf points or Upper Palaeolithic elements were traced. Such pattern is repeated in the other sites of Polish Jura, including Biżnik Cave and Komarowa Cave, which suggests that very late Middle Palaeolithic industries in this region may be more diverse than we expected.

ORAL

**13. THE BIFACIAL REDUCTION STRATEGY DURING THE EARLY PHASE OF EUP IN THE MORAVIA (CZECH REPUBLIC).**

*Nerudová, Zdeňka - (Anthropos Institute, Moravian Museum Brno) znerudova@mzm.cz*

Upon the refittings of bifacial artefacts comes from Szeletian workshop site we can describe a specific mode of bifacial reduction (Nerudová 2009; Neruda – Nerudová 2005; Nerudová 2011). This method corresponds to the procedure reminiscent of the Micoquian technique of lithic reduction: using the technique of flaking, a back is formed on the artefact (or a natural back is used), from which thinning blows are delivered to both faces as if from a core platform. This procedure enables the reduction of the artefact's thickness without any significant loss in length. To the purpose massive first blanks, natural pebble fragments, or flat blocks were used. The incomplete pre-forms of such prepared bifacial artefacts are morphologically and technologically identical to Micoquian backed knives. The final artefact – a thin and elaborate leaf point – does not emerge until the above-mentioned back is reduced.

The same mode of bifacial reduction have been detected on the numerous Szeletian sites. On the other hand we can observe high morphological variability of different bifacial tools. The technological similarity of bifacial tools production and their variability have been resolved by statistical and GIS studies.

The seemingly (?) high morphological variability of points is given by several factors: by the raw material used, by the tool's practical purpose, by the settlement's purpose and by distance from the raw material sources. Only four out of more than hundred known Moravian Szeletian sites have so far been examined *in situ* (Vedrovice V; Valoch et al. 1993 and Moravský Krumlov IV; Neruda, Nerudová 2010) which, on the basis of radiometric dates, are being connected with Lower Szeletian. In these assemblages we can observe an evident morphological and technological similarity between Szeletian and Micoquian (Neruda - Nerudová 2005; Nerudová 2009). The similarity may be given not only by similar strategy of utilising raw materials or by a similar natural environment; identical technology in assemblages which can be considered parallel, basing on radiometric dates (Micoquian and Lower Szeletian; Neruda - Nerudová 2013), may suggest a common maker.

The possibility of cultural determination based on morphological analysis of bifacial tools in the Moravian Szeletian is considerably complicated by their high morphological variability, even though morphological analysis has shown that it is mainly the A-shapes (willow leaf-shaped), B-shapes (partly leaf-shaped) and E-shapes (almost leaf-shaped) which are dominant. It has come to light that morphological variability increases at settlement localities where it is associated with the real purpose of tools used for various activities, such as cutting, scraping or drilling.

GIS-analysis has proved that points, which were found at longer distances from the raw material deposit, diminish in size (Nerudová et al. 2011). Larger points are recorded in those Szeletian assemblages, which are considered to be younger.

While Late Middle Palaeolithic industries are characterised by a well-documented diversity of stone tool types and blank production methods (Quina, Discoid, Levallois, Clactonian, etc.), the latter of which can at times be exclusively represented in certain assemblages, the bifacial tool component sometimes portrays clear similarities in use and manufacture method. Beyond sharing both comparable volumetric structures and arrangement of active and or prehensile area, the recurrence in several assemblages of specific groups of bifacial tools used for either wood-working or butchery is particularly striking. Here we address several techno-economic and cognitive aspects of biface production and use combined with a consideration of their context. Is the same degree of variability in function and manufacture method equally vis-

ible in the retouched tool component? What scales of mobility or technical use-lives do these different bifacial tools portray? Do certain highly elaborate flake tools also reflect equally complex behaviours? How to interpret the presence of carefully manufactured pieces in exotic raw materials alongside others made in local varieties that are hardly reduced but nevertheless equally functional? Finally, which components may have carried a symbolic value or shed light on technical abilities or functional objectives evident in the conception, elaboration, use, and ultimate fate of these bifacial pieces.

Several recently analysed assemblages with a relatively significant bifacial component from the Dordogne and Atlantic Pyrenees show certain similarities or important differences. In characterising the coexistence of flake production and bifacial shaping, whether accompanied by the ramification of associated reduction sequences or not, we attempt to reveal to what extent and in which ways certain bifacial tools stand out. When combined with technological and cognitive considerations. This approach provides new insights on an important behavioural facet of Neanderthal groups who occupied the Aquitaine Basin after the Last Interglacial.

ORAL

### 15. BIFACIALLY BACKED KNIVES (KEILMESSER): TOWARDS A QUALITATIVE UNDERSTANDING OF MIDDLE PALAEOLITHIC TOOL CONCEPTS.

*Olaf Jöris - (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution Schloss Monrepos, 56567 Neuwied, Germany) joeris@rgzm.de*

Bifacially backed knives (*Keilmesser*) are a tool type that occurs occasionally in both the late Lower and early Middle Palaeolithic contexts. However, during the Late Middle Palaeolithic of Central Europe they appear far more frequently. Despite their variability in shape and size, Late Middle Palaeolithic *Keilmesser* appear standardized at a very high level. This standardisation is, however, only poorly described by classic analytical methods with major reference to purely metrical proxies that relate to shape and size. As an alternative to these methods, qualitative approaches such as refits and flake-scar analyses can be systematically applied. Both methods provide valuable data to be analysed allowing for a detailed reconstruction of the life-histories of the artefacts studied. It is the reconstructed artefact life-histories that allow for a more profound evaluation of the degree of tool variability in terms of morphological variation. Thus, quali-

tative data on tool variability allows for discrimination between variation due to individual artefact life-histories on the one hand and overarching tool concepts, deeply implemented within hominin groups on the other.

ORAL

### 16. NEW MICOQUIAN WORKSHOP FROM OPEN-AIR SITE IN SW POLAND

*Wiśniewski, Andrzej - (University of Wrocław, Institute of Archaeology) andrzej.wisniewski@uni.wroc.pl*

Bifacial tools of the Micoquian culture vary regionally and chronologically. According to S.W. Krukowski (1939-1948) who was a pioneer in the field of research on Micoquian tools in Central Europe: "Within the range of the main attributes distinguished in industries the Prdniks (knife) are very polymorphic". This diversity results from imposed mental patterns, access to raw material as well as range and type of activities and mobility systems of humans.

It is well known that determination of the origin of techno-typological diversity requires data on the entire life-cycle of the tools ranging from the selection of raw materials to the shaping and reworking of tools. However, most bifacial finds, are represented by highly reduced tools due to their intensive use. In these cases a technological analysis is constrained. It is not surprising that the more reliable data on sequence of technological operations provide places where manufacture of bifacial tools took place and where by-products and failed forms of tools have been abandoned.

Lately a site with large number of artifacts related to the production of bifaces has been recognized at the open-air site Pietraszyn 49a located in the foreland of the Moravian Gate in Upper Silesia (Poland). This area has long been known for Micoquian finds but until recently only small collections (>100 spec.) or single implements have been recorded in this region. This paper presents preliminary results of technological analysis of data obtained from the excavation at the site Pietraszyn 49a in 2012 and 2013.

The site is situated in the valley of Troja river in the Głubczyce Upland. The age of site remains an open question. According to the preliminary geological study, the chronology of the site Pietraszyn 49a corresponds to a lower or middle part of Weichselian, however, its older age cannot be excluded.

The site Pietraszyn 49a provided over three thousand of stone artefacts. The density of artefacts is very high (above 360 specimens per 1m<sup>2</sup>).

It seems that the production of bifacial tools, within which knives and hand axes dominates, was based on selected chunks or nodules or even flakes made of erratic flints. Most of the specimens are virtually represented by abandoned pieces due to knapping mistakes or fractures of raw material. It is worth mentioning that technological study of bifacial tools shows a kind of compromise between the shape of raw material and "Micoquian patterns". It seems that single bifacial tools with traces of strong reduction were brought from outside the site. Presence of single expedient tools like unifacial side-scrapers was also confirmed.

Summarizing, the new data from Pietraszyn 49a bring a light to the recognition of the first steps in the production of Micoquian bifacial tools, which are generally unavailable to us and poorly recognized. New observations allow determining methods and techniques used during bifacial production.

ORAL

### 17. SPATIO-TEMPORAL VARIATION IN LATE MIDDLE PALAEO-LITHIC NEANDERTHAL BEHAVIOUR: BOUT COUPÉ HANDAXES AS A CASE STUDY

*Ruebens, Karen - (MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, Schloss Monrepos, 56567 Neuwied, Germany) karen.ruebens@eva.mpg.de*

*Wragg Sykes, Rebecca M - (PACEA, UMR 5199, Université Bordeaux 1, Bâtiment B18, Avenue des Facultés, Talence CEDEX 33405, France) rebecca.wraggsykes@u-bordeaux1.fr*

Recent broad-scale comparative studies of Neanderthal lithic assemblages have contrasted previous views of the Middle Palaeolithic as a period of stasis. Throughout the Middle Palaeolithic, ca. 300,000-35,000 years ago, distinct changes can now be observed in the Neanderthal behavioural repertoire; this includes trends that are spatially and temporally patterned. Such material culture diversity is especially apparent in the late Middle Palaeolithic (MIS 5d-3; ca. 115,000 to 35,000 BP) and is most obviously expressed in the archaeological record through differing bifacial tool types.

This paper examines one aspect of this late Middle Palaeolithic bifacial diversity by providing a much needed, up-

to-date consideration of the *bout coupé* or flat-butted cordate handaxes, widely regarded as generally restricted to MIS-3 Britain. First, their relationship to the general reoccurrence of handaxes in late Middle Palaeolithic Western Europe is discussed, including comparisons with the Mousterian of Acheulean Tradition (MTA). Primary data focusing on metrics, technology and typology was collected and analysed for 1,122 late Middle Palaeolithic handaxes from sites in Britain, southwestern, western and northern France, Belgium and the Netherlands. Secondly this *bout coupé* phenomenon is presented as a case study to explore behavioural implications of such spatio-temporal variation in lithic material culture. Different explanatory factors, such as raw material, site function, tool function, reduction/resharpening and social learning are explored, alongside potential links to Neanderthal population dynamics.

It is concluded that the *bout coupé* form is not merely a point within a continuum of bifacial variability, but its form is distinct and sometimes maintained throughout the functional life of these handaxes. It illustrates regionalised socio-cultural behaviour implying specific lines of social transmission had developed among late Neanderthals.

## 1. THE INFLUENCE OF LANDSCAPE ON NEANDERTHAL RANGE VIEWED FROM THE LEVANT

Henry, Donald - (University of Tulsa) [donald-henry@utulsa.edu](mailto:donald-henry@utulsa.edu)

Belmaker, Miriam - (University of Tulsa) [miriam-belmaker@utulsa.edu](mailto:miriam-belmaker@utulsa.edu)

Bergin, Sean - (Arizona State University) [sean.bergin@asu.edu](mailto:sean.bergin@asu.edu)

The geographic distribution of Neanderthals across Eurasia has largely been understood relative to: (a) their adaptation to cold conditions in their western European core area, (b) their response to the on-set of harsh climatic conditions during OIS 4, and (c) their replacement and retreat in front of an advancing wave of Modern Humans during OIS 3. This research has largely centered on the morphology and distribution of the Classic Neanderthals dating to OIS 5-4.

From an adaptive perspective, researchers have focused on geoclimatic and biotic evidence with little attention given to the influence of terrain on Neanderthal land-use strategies. Recently it has been suggested that the Neanderthals were morphological more adapted to rugged terrain than Upper Paleolithic AMH groups that preferred more open landscapes.

We review these factors and explore the effects of Neanderthal preferences of habitat and landscape. We use digital spatial analyses to define site catchments energetically and to calculate Ruggedness Indices for each site. Ruggedness Indices are based upon least cost analysis of the area surrounding sites and utilize slope, direction and distance as factors when calculating walking time to each location within a site catchment. These data-sets, in turn, are compared for sites associated with Neanderthal occupations (defined by fossils and archaeological proxies), early Upper Paleolithic occupations (defined mainly by archaeological proxies), and random terrain points across the region with predictions of the minimum cost of transport (for AMH and Neanderthals) for the average walking distance, or time taken for the acquisition of stable food resources for several time intervals.

This study sheds light on the degree to which terrain may have played a role in shaping Neanderthal and AMH land-use strategies.

## 2. SPATIAL DISTRIBUTION OF ARTEFACTS IN THE MIDDLE PALAEOOLITHIC LAYERS OF KŮLNA CAVE (CZECH REPUBLIC)

Neruda, Petr - (Moravské zemské muzeum) [pneruda@mzm.cz](mailto:pneruda@mzm.cz)

The main goal of archaeological work is reconstructing the behaviour of primeval populations. Unfortunately, the static character of archaeological finds affects the quality of information we can use for *quasi*-historical synthesis. Artefacts were abandoned in particular phases of their modification (reduction) meaning they reflect only specific points in time of human presence on a site. It is therefore difficult to interpret the life of artefacts over a longer period of time on the basis of techno-typological analyses alone. To solve this problem it is necessary to use contextual data related to the archaeological finds because this will, in particular cases, reflect dynamic aspects of human behaviour.

One approach is the study of spatial distribution of finds on a site to investigate the organisation of living space. Typically, however, only modern archaeological excavations fulfil all the necessary requirements for using the more powerful tools of GIS oriented programs. The most important information is the position of finds in any coordinate system. But, it is evident that most large Palaeolithic sites in Europe were excavated at times when measurements of all three co-ordinates (x,y,z) were not recorded, meaning we cannot simply visualise finds from these sites within 3-D space. This problem is introduced and discussed during the first part of this paper: Are we able to transform the period system of documentation into any data that are possible to analyse using e.g. ArcGIS programs?

The potential for older excavations to be studied using spatial distribution analyses was tested at Kůlna Cave (Czech Republic) on Middle Palaeolithic layers 11, 7c, 7a and 6a, excavated in the 1960s-1970s by Karel Valoch. Using a specific algorithm for the shifting and geo-referencing finds, it has been possible to create density rasters (Spatial Analyst Extension of the ArcGIS) and define the position and composition of accumulations of finds. Maps of find distributions show the behaviour of Neanderthals within the cave space changed over time (between technocomplexes). It is also evident that the spatial distribution in the layer 7a is very complex, with places oriented to specialised tasks.

Such results are very important for the comparison of behaviour of both Neanderthals and Anatomically Modern Humans within Kůlna Cave, which is the second main topic addressed by this analysis: implied results concern both depositional and post-depositional processes, and relate ultimately to the question of repetitive visits to Kůlna Cave by anatomically modern humans and Neanderthals.

ORAL

### 3. NEANDERTHALS OF CRIMEA - CREATIVE GENERALISTS OF THE LATE MIDDLE PALAEOOLITHIC

*Bataille, Guido - (University of Cologne, Institute for Prehistoric Archaeology) gbataill@uni-koeln.de*

In the Crimean mountainous region a high number of Middle Palaeolithic sites, 30 of them multi-layered, could be documented covering a temporal range between the end of the Last Interglacial (OIS 5d) and the Denekamp/Arcy Interstadial (OIS 3) (Chabai & Uthmeier 2006, 298). According to techno-typological peculiarities the Crimean Middle Palaeolithic is subdivided into two techno-complexes: the Micoquian and the Mousterian (Chabai 1998, 11 f.). Assemblages of the Crimean Micoquian (CM) are characterized by plano-convex bifacial technology and non-Levallois flake production. Assemblages of the Levallois-Mousterian variant Western Crimean Mousterian (WCM) are dominated by lineal and recurrent Levallois strategies for flake and blade production and usually lack bifacial elements.

Selected stone assemblages of Kabazi II (CM and WCM) form the empirical base of that study. Activities connected with raw material procurement, lithic production and faunal exploitation are reconstructed and set into the broader context of the Crimean Middle Palaeolithic. By comparing the spatial distribution of lithic and faunal elements of *in situ* surfaces a higher resolution of on-site activities, such as single occupational events, could be achieved (Bataille 2006, 2010, 2012).

It can be concluded that activities connected with recurrent occupations were causative for the formation of the investigated layers. A complex land use system with only ephemeral activities in connection with Micoquian stations in contrast to the more intensely used camp sites of the same industry can be seen (Bataille 2012, 204 f.). Contrary to that, the short-term Mousterian stations seem to generally function as spots for resource acquisition with only sporadic traces of consumption (Bataille 2010, 69 ff.). Cycles of specialisation on steppe species

and a more generalistic exploitation of a variety of different species can be observed, resulting from the adaptation to seasonal variation.

Concluding from that, a complementary settlement and migratory system can be reconstructed: while investigated Micoquian stations can be correlated with a low regional mobility, the investigated Mousterian inventories exhibit a high regional mobility both during warm and cold seasons.

### 4. LATE NEANDERTHALS IN PALAEOENVIRONMENTAL CONTEXT: A STAJNIA CAVE (POLAND) CASE STUDY

*Urbanowski, Mikołaj - (Szczecin University, Institute of History, Archaeological Department) m.urbanowski@univ.szczecin.pl*

Stajnia Cave is a small, 25m long karstic cavity located in the northern part of Jurassic upland of Wy-yna Czstochowska in southern Poland (N 50° 36'58,28", E 19° 29'04,24"). It has been researched since 2006 by a multidisciplinary team of scientists from Szczecin University and partner institutions conducted by the author. Complex stratigraphy of the site represents a timespan from the pre - Weichselian till Holocene times. The most thick and archaeologically rich sediments were deposited in early and middle MIS-3 period (layers D1, D2 and D3 forming stratigraphic complex D). They contain a rich flint assemblage of late Micoquian (Keilmessergruppe) tradition. The end of deposition for the complex D is marked by its uppermost unit D1 and dated geologically, paleontologically and absolutely (14C) to about 45 ka BP. The Neanderthal presence at the site is additionally attested by the human teeth found there, which were attributed to this species. The rich (over 50 000 bones and bone fragments analysed so far) non-analogous faunal assemblage, dominated by the remains of reindeers, cave bears and wild horses complete the picture of the site intensively visited by humans.

Except the typical archaeological, geological and paleontological studies many other analysis were done, including microscopic studies of the sediments, as well as spectroscopic studies of the organic residues found inside the D1 unit (with FTIR and DTMS methods). Plant remains, including charcoals were studied mostly on macroscopic level, although microscopic studies of the pollens and phytoliths were also done. The isotopic

studies on bones added some valuable information for the reconstruction of the climatic shift between deposition of D2 and D1 units, which fully correspond with results of extensive studies on microfauna. The studies on the seasonality of thanatocenosis revealed some interesting the Neanderthal hunting habits.

All the information gathered from different analysis allowed to reconstruct a picture of late Neanderthal life-way with a precision not available before for this region of Central Europe. The precision of the picture concerns not only a detailed environmental reconstruction, but also a reconstruction of some unexpected dietary habits. The results combined together allowed us to understand, that despite former visions, the Neanderthal living north of Carpathians after MIS-4 climatic deterioration were not the seasonal immigrants in a hostile environment, but formed a stable settlement, based on subsistence strategies perfectly fit into local conditions.

*Nigst, Philip R (Division of Archaeology, University of Cambridge, UK, and Department of Human Evolution, MPI EVA, Leipzig, Germany) nigst@eva.mpg.de*

The Middle Dniestr valley in the Ukraine is well-known for its rich record of Middle and Upper Palaeolithic sites (Chernysh, 1973; Klein, 1973, Kulakovska,2003). These include the long sequences of Molodova I, Molodova V

and Korman 4 with Middle Palaeolithic archaeological horizons characterized as Mousterian of Levallois Tradition. Together with some other sites in the northwest of the Middle Dniestr valley, they have been grouped in the so-called Prut-Dniestr-Group of Levallois Mousterian (Meignen et al., 2006, Usik,2006).

Here, we present new data from the site Neporotovo 7 in the Middle Dniestr valley. The site was discovered in 2012 by the current team. In 2013 test pits were excavated and first sections studied. For the first time in the Middle Dniestr valley, we were able to document the Last Interglacial – Early Glacial pedo-complex. Our current studies include field and laboratory work combining archaeology (lithic technology, zooarchaeology), geology and dating. A large part of our studies is devoted to a good understanding of taphonomy and site formation processes. We are applying a chronostratigraphic approach (Haesaerts et al., 2003; 2010) to the Last Interglacial – Early Glacial pedo-sequence of the Middle Dniestr valley.

At Neporotovo 7 five archaeological horizons were documented, located above and below the Eemian soil. In this presentation we focus on the two MP levels that are post-Eemian and most probably located in Early Glacial and Early Pleniglacial sediments. We discuss the new lithic technological data from Neporotovo 7 in its chronostratigraphic and environmental context.

Further, we compare the new Neporotovo 7 dataset with the existing data on the Mousterian, including the Mousterian horizons of Molodova V. It has been suggested that the Mousterian horizons of Molodova V date to MIS 3 (Haesaerts et al., 2003). This will be discussed against the new data from Neporotovo 7. Regionally, the Middle Dniestr Levallois Mousterian shows technological similarities to the Levallois Mousterian of Crimea (e.g., Kabazi II, Level 8), which is also argued to date to MIS 3. It exhibits differences in technology to the Mousterian of Transcarpathia (south of the Carpathian Mountains; e.g., Korolevo I, Level IIb). The goal of this presentation is to discuss the Middle Dniestr Levallois Mousterian technocomplex in its local and regional context.

**6. LATE PLEISTOCENE NEANDERTHAL OCCUPATION IN THE MEUSE RIVER BASIN IN BELGIUM: WANDERING HUNTER-GATHERERS OR STOCKY CAVE-DWELLERS?**

*Bringmans, Patrick M.M.A. - (The 'Veldwezelt-Hezerwater' Neanderthal Research Centre - Belgium) Patrick.Bringmans@hotmail.com*

Although *Homo troglodytes* Linnaeus 1758 has long been proven to be an invalid taxon, many archaeologists were convinced that Palaeolithic humans, like the Neanderthals, were predominantly cave-dwellers. By the 1970s, scientists began to realize that this was an incorrect assumption. Caves turned out to be unrepresentative samples of where and when Neanderthals were present and what they did.

The richness of the Middle-Palaeolithic record in Belgium is quite overwhelming. For instance, in 1829, the first Neanderthal skull ever was discovered in Engis. In 1886, two nearly perfect skeletons were found at Spy with numerous Mousterian-type implements. In 1993, the 'Child of Sclayn' was unearthed in Scladina Cave. Although we have much to learn regarding these cave sites, a 'Landscape Archaeology' of the Middle-Palaeolithic is increasingly possible. The most important open-air Neanderthal site in Belgium is Veldwezelt-Hezerwater. There, seven well-preserved, *in-situ* open-air settlements were discovered in a loess-soil sequence. Veldwezelt-Hezerwater was excavated in the context of a broader landscape project.

Neanderthal occupation of Late Pleistocene Belgium appears to fall mainly within Marine Isotope Stage [MIS] 5 en MIS 3. There is no evidence for Neanderthal presence during the 'Eemian' (MIS 5e). However, Neanderthals were present at Veldwezelt-Hezerwater just prior to the Late Saalian/Eemian transition, probably during the Zeifen Interstadial (MIS 6.01). There are no convincing indications of human activity during the MIS 5d-c period. However, there is clear evidence for Neanderthal presence correlated with MIS 5b/a. The second half of MIS 4 seems to have been abandoned by Neanderthals. During MIS 3, it would appear that Neanderthal occupation was restricted to very brief pulses occurring mainly between 60 and 35 ky BP, coinciding with the milder phases of MIS 3. There appears to exist a strange dichotomy between open-air and cave sites in the Meuse River Basin in Belgium. The last known open-air sites were occupied until

50 ky BP. The cave sites were inhabited by Neanderthals only between 50 and 35 ky BP. This shift from open-air sites to cave sites could signal an extremely small Neanderthal population size from 50 ky BP onwards.

Based on the Middle-Palaeolithic record from the Meuse River Basin, Neanderthals were way more spatially ambitious than the cavemen we once had thought them to be. It actually turned out that caves were probably the last refuges of the Neanderthals in the valley of the Meuse River. As a result of the dramatic climate swings and the retreat of the 'mammoth-steppe' in the second half of MIS 3, they would have to survive in ever-smaller groups, becoming largely confined to the caves. Survival stresses would have been particularly acute in winter. While potentially desirable residences for Neanderthals, most caves often had very unwelcoming, sitting tenants. These caves were usually used as 'dens' by cave bears, cave hyenas and cave lions. It would appear that hunkering down in a cave would be the choice of 'last resort' for Neanderthals.

ORAL

**7. SPATIAL CHARACTERIZATION AND PREDICTION OF NEANDERTHAL SITES BASED ON ENVIRONMENTAL INFORMATION AND STOCHASTIC MODELLING: A MODEL COMPARISON**

*Märker, Michael - (Heidelberg Academy of Sciences and Humanities, Research Centre "The Role of Culture in Early Expansions of Humans" at the University of Tübingen) michael.maerker@geographie.uni-tuebingen.de*

*Bolus, Michael - (Heidelberg Academy of Sciences and Humanities, Research Centre "The Role of Culture in Early Expansions of Humans" at the University of Tübingen) michael.bolus@uni-tuebingen.de*

We present a unique spatial dataset of Neanderthal fossil sites in Europe that was used to train a set of stochastic models to reveal the correlations between the site locations and environmental indices. For this, all Neanderthal fossils had been classified into Pre-Neanderthals, Early Neanderthals, and Classic Neanderthals.

In order to assess the relations between the Neanderthal sites and environmental variables as described above we applied a boosted regression tree approach (TREENET) and a statistical mechanics approach (MAXENT). The stochastic models employ a learning algorithm to identify a model that best fits the relationship between the attribute set (environmental variables) and the classi-

fied response variable, which is in this case the classes of Neanderthal sites. A quantitative evaluation of model performance was done by determining the suitability of the model for the geo-archaeological applications and by helping to identify those aspects of the methodology that need improvements. The models' predictive performances were assessed by constructing the Receiver Operating Characteristics (ROC) curves for each Neanderthal class, both for training and test data. In a ROC curve, the Sensitivity is plotted over the False Positive Rate (1-Specificity) for all possible cut-off points. The quality of a ROC curve is quantified by the measure of the parameter area under the ROC curve.

The dependent variable or target variable in this study are the locations of Neanderthal sites described by latitude and longitude. The information on the site location was collected from literature and own research. Since the spatial characterization of Neanderthal sites is essentially depending on the site accuracy, we spend large effort in correcting the data by a twofold approach: i) we checked and transformed the coordinates to the same projection. In this case we use a Universal Transverse Mercator (UTM) WGS84 projection; ii) all sites were checked for site accuracy using high-resolution maps and Google Earth.

The study illustrates that the models show a distinct ranking in model performance with TREENET outperforming the other approaches. Moreover, Pre-Neanderthals, Early Neanderthals and Classic Neanderthals show specific spatial distributions only in part reproduced by the different models. However, all models show a wide correspondence in the selection of the most important predictor variables generally showing less climatic influence in site selection criteria from Pre-Neanderthals to Classic Neanderthals. In a next step, we will compare our results for sites with Neanderthal fossils with results obtained when including also Middle Paleolithic sites without Neanderthal fossils.

Zooarchaeology and stable isotopes of bulk collagen led to the suggestion that Neanderthals obtained most of their dietary protein from large herbivores in open landscapes. However, recent findings based on plant remains in the tooth calculus and archaeological remains of small games and marine animals have moderately refined this picture. Moreover, the consumption of plants by hunter-gatherers is expected to have no significant impact on the isotopic signature of the bulk collagen, since many plants have a dramatic lower content in protein than animal meat. In this paper, we aim at quantitatively evaluating their consumption of plants and animal prey by Neanderthals using nitrogen isotope analysis of individual amino acids. Indeed, this approach has recently been proposed as a useful tool especially for the estimation of animal trophic position in terrestrial ecosystems meaning that it should be more sensitive to the contribution of plant resources.

We analyzed bone collagen samples that were already extracted from skeletal remains used in previous studies of bulk collagen stable isotopes. In addition to human and animal collagen materials from Spy Cave, we also analyzed faunal remains from the nearby cave of Scladina (Sclayn, Belgium).

Based on the isotopic analysis of amino acids, the Spy Neanderthal individuals relied strongly on terrestrial resources, ii) they relied not only on herbivores but also plants presumably consisting 17-27% of whole dietary protein, iii) there was an inter-individual variation in prey preference. It was also suggested that the Neanderthals occupied an ecological niche being quite different from those of spotted hyena but rather similar to that of wolf.

The Spy Neanderthals analyzed in this study showed fairly similar trophic positions in the terrestrial ecosystem despite that they lived in different chronological time. They not only relied strongly on herbivorous mammals but also certainly included plants as a protein source. Interestingly, a large inter-individual variation in prey preference were newly found that were not discernible on bulk collagen isotopes. In agreement with recent find-

ings, our results suggest that Neanderthal subsistence strategies were not involving merely hunting and scavenging but were more diversified. Although only a few individuals were analyzed in this study, we have shown that our approach would be promising for the study of Neanderthal subsistence.

POSTER

## 9. RECONSTRUCTING OCCUPATIONAL MODELS: BONE REFITS IN LEVEL I OF ABRIC ROMANI

*Modolo, Marta - (URV-IPHES-UNIV. FERRARA) marta.modolo@gmail.com*

*Rosell, Jordi - (URV-IPHES) jordi.rosell@urv.cat*

The archaeological record is the result of different long-acting processes. The study and the application of bone refits, technique adopted in archaeology since the 70's, is based on the reconstruction of broken and fractured elements to determine formation processes, to solve questions about vertical movements of remains, to evaluate post-depositional processes and to recognize the activity areas. In this way we can reconstruct some of the natural and cultural processes involved in this record. The accumulations formed by anthropogenic processes have a register located mainly around archaeological structures such as hearths and agglomerates of travertine. The aim of this paper is to present the application of this methodology and the results obtained in the Level I of Abric Romani (Capellades, Spain), which chronology was determined around 46 Kyrs by means of U/Th ages. This mousterian site is located in a tufa-draped cliff in the northeastern Iberian Peninsula and various evidence of natural and human activity has been identified in. The site is composed by a sequence of travertine platforms, which are more than 20 m high. The human occupations are located between these platforms, which are isolated from each other and this fact allows analyzing more accurately all the accumulations. Starting from the characterization of faunistic assemblages, throughout anatomic, taxonomic and taphonomic study, it is possible to define exploitation of the animals. Bone refits are made in this way: remains analysis for each squares (differentiation of anatomical elements depending on taxon and size), by closest square and in overview, by analysing all the squares of the area (considering greatest accumulation). Once the refits are carried out, all the data has been analysed and processed to obtain the spatial patterns of the investigated level. The main aim is to explore the anthropogenic use of the site, in particular during the occupation of Level I, and to value the degree of synchronicity between the different identified struc-

tures, such as hearths and the activity areas. This kind of analysis can be used in order to evaluate the differences between occupational patterns, subsistence activities, domestic areas, level of group's sophistication and duration of employment of the sites. This fact shows the importance of these studies to understand the diversity of occupational patterns and ways of life of the human communities of the European Middle Palaeolithic.

POSTER

## 10. LE MOUSTÉRIEN DES BALZI ROSSI (VINTIMILLE, LIGURIE, ITALIE) MIS EN VALEUR PAR L'ÉTUDE DES COLLECTIONS ANCIENNES

*Rossoni-Notter, Elena - elenarosso@hotmail.fr (Musée d'Anthropologie préhistorique de Monaco)*

*Notter, Olivier - notterolivier@hotmail.com (UMR 7194, Muséum National d'Histoire Naturelle)*

*Simon, Patrick (Musée d'Anthropologie préhistorique de Monaco)*

Le complexe de sites des Balzi Rossi (Vintimille, Ligurie, Italie) a livré très tôt des dépôts témoignant d'occupations moustériennes multiples et successives. Dès 1895, et jusqu'en 1914, des fouilles ont été entreprises dans les grottes du Prince, du Cavillon, des Enfants et à l'abri Lorenzi par le chanoine Léonce de Villeneuve, à la demande du Prince Albert 1<sup>er</sup> de Monaco.

Compte tenu de l'ancienneté des fouilles, des travaux historiographiques (consultation d'archives, référencement/récolement des collections) ont consolidé la base de ces travaux. Le contexte des vestiges reconsidéré, une étude pétroarchéologique et technotypologique du matériel a été réalisée.

L'identification des lithotypes, qui enrichit la lithothèque référentielle pour la zone liguro-provençale, révèle une exploitation majeure des ressources littorales périphériques (silex, calcaires) et semi-locales ligures (micro-quartzites) par les groupes moustériens. Les chaînes opératoires de production attenantes à ces matières, longues et ramifiées, se sont le plus souvent déroulées *in situ*. En revanche, les pièces en matériaux allochtones (silex de l'arc de Castellane, de la région nord varoise, d'Apt-Forcalquier, rhyolite du massif de l'Estérel, radiolarite de Ligurie orientale) sont isolées et illustrent des aires d'approvisionnements pouvant aller de 35 km jusqu'à 150 km à l'ouest et à l'est des sites. Le plus souvent retrouvés, ces artefacts ont pu être rapportés sous une forme achevée. En outre, les galets calcaires et quartzites

apparaissent contingentés aux débitages laminaires, les autres matériaux homogènes aux débitages Levallois.

L'analyse technotypologique et morphofonctionnelle a permis de caractériser puis rapprocher certains assemblages. Ainsi, les industries des Foyers I-II-III du Cavillon et A-B-C-D-E du Prince ont en commun l'emploi de percuteurs durs, des méthodes Levallois à pointes et à lames et des méthodes laminaires unipolaires, associé à de nombreux racloirs, encoches et pointes retouchées. Néanmoins, les industries inférieures du Prince se différencient par la présence de grands éclats calcaires, galet aménagé, limaces et des retouches plus souvent écailleuses. D'autres assemblages sont spécifiques tels que les quelques artefacts appartenant au foyer moustérien le plus récent du Cavillon (Foyer Inférieur de Rivière), constitués de lames massives et allongées issues des méthodes Levallois et laminaires. L'abri Lorenzi livre un petit corpus essentiellement composé de nucléus (SSDA, laminaires et Levallois) et de quelques éclats bruts et retouchés (racloirs, encoches, pointe moustérienne). Les industries de la Barma Grande s'inscrivent plutôt dans des faciès faiblement Levallois. Enfin, les données récentes, recueillies sur certaines séries de la grotte des Enfants et de Costantini, ont parfait cette première étude comparative.

Ces résultats, confrontés à ceux provenant de fouilles récentes (abri Mochi, abri Bombrini, Ex-Birreria, Ex-Casino), ont permis de proposer un panorama technologique du gisement des Balzi Rossi durant le Paléolithique moyen. Encadrée par les données chronostratigraphiques, biochronologiques et paléoenvironnementales, le Moustérien s'étend des stades isotopiques 5 à 3 et admet une certaine hétérogénéité diachronique et synchronique, inhérente à la fonction des occupations.

This poster presents the middle Paleolithic site of San Quirce (Palencia, Spain). San Quirce is a Neanderthals camp, currently has only intervened in a small portion. This site is located in the extreme north of the Duero Basin on a fluvial terrace +22- 23 m (T9). It is located in a strategic contact area, between the Cantabrian Mountains and the Northern Plateau.

We have obtained a sequence of OSL dating between  $74 \pm 16$  ky in sandy deposits overflow (profile E side quarry variation level III) and  $154 \pm 18$  ky in the excavated area level III.

This site is unique in the Northern Plateau by the extraordinary conservation of lithic Middle Paleolithic record, enabling technical, space, and use studies. San Quirce presents a rich and varied record allowing us to identify how has been managed the space occupied, mainly, with meat consumption and work on plant resources.

From a technological point of view, the instrumental repertoire San Quirce presents significant variability with respect to the main Middle Paleolithic situations. The lithic assemblage lacks great complexity, is highly specialized in light denticulate, with little punch, characterized by a very rapid production; and poor cutting ability. Likewise, the pronounced bifaces or cleaver morphotypes are not documented; neither, Levallois or Quina methods. It has not been identified Acheulean tradition nor Mode 3*sensu stricto*. San Quirce cannot be included in the Mode 1 and Mode 2 developed models, but must be framed in a Mode 3, determined by the precise settings of this group.

Paleoanthropological research in Greece has been sparse, despite the significance of the country's geographic position for human evolution in Europe. PaGE ("Paleoanthropology at the Gates of Europe: human evolution in the southern Balkans") is a five-year interdisciplinary project that conducts intensive, geoarchaeologically informed and target oriented Paleolithic fieldwork in Greece. One of the main goals of the project is to illuminate important aspects of Neanderthal behavior and investigate the possible late survival of Neanderthals in refugia of the Greek Peninsula. The region of Mani (Southern Greece) includes important excavated Neanderthal sites and yet it has not been investigated systematically. Here we report the findings of the 2012 PaGE survey in Mani, as well as the preliminary results of the test excavation at a cave, launched in 2013.

Forty-six caves, rockshelters and open-air sites in lowland settings were systematically surveyed and recorded. Documentation included the collection of 'off-site' data, such as geomorphological indicators of former sea-levels, which will potentially provide inferences on how geomorphological processes affected the preservation of sites and hence overall site distribution patterns.

In the surface assemblages, retouched tools are mainly represented by side scrapers, end scrapers, piercers, denticulates and notches, along with Levallois blanks and cores. In the excavated assemblages, both the Levallois and discoidal flaking techniques can be identified. Excavated specimens manufactured on a non-local rock indicate potential raw material transfers greater than 50 km and suggest links among the different regions of Mani, related to mobility patterns.

Since 2012, the PaGE research in Mani has nearly doubled the number of known Middle Paleolithic sites from the region. It has confirmed that the peninsula has the strongest 'Neanderthal signal' identified to date in Greece, suggesting a dense hominin presence during the Middle Paleolithic. Nearly all sites identified in our survey are located at coastal areas. Despite the dramatic influence of Pleistocene landscape dynamics, this distribution emerges as a persistent pattern, perhaps indi-

cating a preference for coastal locations. Unraveling the Neanderthal occupation of Mani is expected to illuminate important aspects of Middle Paleolithic adaptations in one of the southernmost coastal extremes of Europe.

### 13. EVOLUTION OF NEANDERTAL SUBSISTENCE STRATEGIES AND MOBILITY PATTERN IN SOUTHWESTERN FRANCE

*Rendu, William - (CNRS) williamrendu@hotmail.fr*

Recent works on the late Middle Paleolithic from Southwestern France have identified the existence of diverse populations characterized by distinct cultural features, attesting that several Mousterian societies succeeded one another through time. These societies evolved under different paleoclimatic contexts, adopting original strategies to exploit their biotope. However, the majority of the zooarchaeological approaches focusing on the spatial distribution of the activities within the territory has considered the Neanderthal populations as a unique entity and few studies have really discuss the diversity of the subsistence strategies developed by the Mousterian societies in Southwestern Europe.

We propose here to tackle this issue through a synthesis of the zooarchaeological data available for three distinct groups from this region: the Quina Mousterian, the Mousterian of Acheulean Tradition and the Discoidal denticulate Mousterian. For this study, 40 stratigraphic levels from 16 sites have been retained, based on their chronocultural attributions, the preservation of their archaeological records and the origin of the faunal assemblages.

By taking into account several zooarchaeological criteria: faunal spectra, game selection, selective transport, hunting seasonality etc... the study suggests that different subsistence pattern and strategies might have been developed.

Quina Mousterian diet was characterized by the nearly exclusive exploitation of reindeer and the lack of diversity in its diet. Reindeer migration would have directly conditioned the settlement pattern of the Quina populations and thus their mobility.

On the contrary, denticulate hunting would have been more diversified and seasonally completed by Bison specialized hunts. The exploitation of diversified prey would have counterbalance the seasonal fluctuation of the bison concentration within the environment.

Finally MTA Mousterian exploited a large range of preys with no evidence of temporal segmentation of the hunting activities. At least for the moment, no recurrent use of hunting specific location is established. It seems that the exploitation of different prey with different behavior has conducted to minimize the influence of the hunting strategies on the distribution of the activities within the territory.

This paper demonstrates that the development of different subsistence strategies in the late Middle Paleolithic in Southwestern France had a direct impact on the organization of the activities within the territory and, thus, on the mobility of these populations. The whole society organization seems to have been directly influenced by the hunting strategies. To conclude, this paper underlined the necessity to better characterize the behavioral diversity of the late Neandertal populations

Collagen is the predominant protein in bone and directly reflects the isotopic signature of the dietary com-

ponents as well as environmental aspects of the habitat. The unique chemical preservation of Late Pleistocene Neandertals and contemporaneous faunal bone collagen provides direct insights not only into Neandertal ecological and cultural behavior. Different aspects such as prey choice and hunting strategies can be evaluated using the stable isotopic composition of different elements. Moreover ecological aspects such as niche partitioning of herbivorous and carnivorous mammals (including the Neandertals), trophic ecology and habitat characteristics can also be exposed by the isotopic approach as well as different landscape use pattern of this hominid.

We propose to evaluate the potential and limitations of the isotopic approach through a comparison and completion of its results with those of other fields such as zooarchaeology, tooth wear and dental calculus analysis for a broader approach. This study will focus on NW-Europe during the Late Pleistocene till the last Neandertal fossils are documented (ca. 36,000 years ago). We will pay particular attention to the Belgian sites of Scladina, Spy and Goyet, the last two having yielded late Neandertals. Several newly discovered Neandertals and coeval herbivorous and carnivorous mammal remains from the "Troisième caverne" of Goyet will be integrated in the context of previous research to get a deeper understanding of the Late Pleistocene mammoth steppe ecosystems to which Neandertals belonged. Here we present the carbon, nitrogen and sulfur composition of the collagen from herbivores, carnivores and humans, which reflect an average fractionated isotopic composition of the diet of the last years of an adult mammal. Calculating dietary contributions was made using SIAR (a specific package for stable isotopic analysis using the software R).

Carbon and nitrogen isotopic analyses allowed us to establish prey-predator relationships in Goyet, Scladina and Spy caves. The Neandertals from Goyet were very similar to those of Spy, suggesting high contribution of mammoth in the diet. The sulfur isotopic composition of collagen being linked to the characteristics of the bedrock, we could figure out significant differences within and through the sites, which indicate different foraging areas for several mammal species as well as for the Neandertals for Spy and Goyet.

So far the unique addition of sulfur isotopic analysis to that of the carbon and nitrogen provided important information about foraging areas of Neandertals within one site and between sites. All studied Neandertals individuals had a similar diet, probably rich in mammoth

meat, while all Neanderthals from each site, Goyet or Spy, had similar foraging areas but these areas were different between Neanderthals from Spy and Goyet.

Field-analytical study of the remarkable hearths at Abric Romani (Spain) has revealed the repeated occurrence of polymer-rich carbonaceous polymorphs. Their spatial pattern and properties have allowed to recognize exploitation by Neanderthal groups of subsurface volatile-rich hydrocarbon deposits. Their high socio-economic value was suggested based on evidence for controlled heating of the highly calorific combustible and advanced technology for preparation of secondary products used for lightning, surface cover, and colouring materials. Modern analogues have allowed to establish that deposition of the carbonaceous materials is particular to aerosol fall episodes following cosmic events. These recent situations have provided diagnostic signatures to characterize the raw sources and identify transformation products. In the continuity of the Abric Romani record, we intend to further investigate the carbonaceous materials technology from diverse Neanderthal contexts.

The data reported here have been obtained from stratified Neanderthal sequences that range from the Middle to the late Pleistocene (OIS 9-4): Bolomor Cave (Valencia, Spain), Bau de l'Aubésier shelter (Vaucluse, France),

Cave XV of Vaufray (Dordogne, France), Bison Cave at Arcy-sur-Cure (France) and Maras shelter at Saint-Martin d'Ardèche (France). We have refined our field/multi-analytical protocol to achieve the finest situ characterization of the carbonaceous materials within their host matrix from the field down to the submicroscopic level. For all the Neanderthal sites studied, in situ concentrations of carbonaceous materials which are similar to the ones found at Abric Romani are identified in distinctive strata. Based on the comparison of these assemblages to the ones encountered in recent natural contexts, coloured polymer filaments and brittle grains of vitreous glassy carbon filled with alumino-silicate cement of marine origin help to recognize intentional introduction of fresh raw sources that were collected short time (months to years) after their fall. The greater abundance of thermally resistant polymers, lime and refractory minerals and the close association of the carbonaceous polymorphs to firing microdebris, particularly pine charcoal, allow to establish the use of the carbonaceous materials as combustible, together with fresh wood, even in the absence of obvious hearths. Metal-rich carbonaceous microresidues on smooth, highly fired bone microfragments trace the use of the carbonaceous materials as a polishing paste made of a plastic aliphatic matrix with hard micron-sized metal inclusions. Polished stone and shell fragments with similar surface treatment are observed. The close association of polymers and concentrations of weakly consolidated clay aggregates allows to recognize residues of prepared carbon-rich clay materials with coloured surfaces.

The data presented show a long established link between recurrent Neanderthal occupation in well maintained habitation contexts and exploitation of freshly deposited hydrocarbon-rich materials that periodically accumulated in deeply incised valleys. The similitude in meticulous processing of the exceptional materials and its use for fabrication of resembling finely worked objects across distant regions reinforce the hypothesis of a strongly maintained community of technical practices with mature cognitive and social capacities. The close association of the carbonaceous materials with pine wood suggests favorable accumulation of the raw sources in pine forest ecosystems which were diversely exploited by Neanderthals.

*Martínez Moreno, Jorge - (Centre d'Estudis del Patrimoni Arqueològic de la Prehistoria. UAB) jorge.martinez@uab.cat*

Some models have depicted the Ebro valley as a relevant bio-geographic feature to explain the possible survival of Neanderthals in Iberia at the end of MIS3. However, several chronometric and contextual problems have hindered a detailed description of the archaeological evidence provided by this region.

This paper presents the results of our research onto the Neanderthal occupation of the border areas between the Ebro valley and the Southern Pyrenees. Middle Paleolithic sites from the Pre-Pyrenees of Lleida detected in this area are Roca dels Bous, Trago, Cova Gran de Santa Linya and the recently discovered sequences of Abric Vidal and Abric Pizarro.

This group of sites is yielding a key dataset to the study of Upper Pleistocene Neanderthals. If these sites may support the possible endurance of Neanderthals in the area <40,000 BP, deserves to be analyzed.

Technical attributes derived from the analysis of knapping methods and in the configuration of retouched tools, yield evidence of the emergence of a regional Mousterian techno-complex. The configuration of this stable cultural tradition could be conformed around the MIS 5e, surviving until the late MIS3. This tradition disappears suddenly, being replaced by Upper Paleolithic techno-complexes.

The review of the available data allows modeling Neanderthal settlement patterns in the area and to provide new insights on the biogeography of Neanderthal populations, a key argument for the understanding of the MP/UP transition.

We discuss the meaning and the implications derived by the notion of *technical stasis* detected in the Mousterian lithic assemblages from the Pre-Pyrenees.

Finally, the reliability of some of the commonly used proxies for assessing the Neanderthal presence is discussed, with special attention to the use of radiometric data.

## 17. DIACHRONIC VARIATION IN THE MIDDLE PALEOLITHIC SETTLEMENT OF ABRIGO DE LA QUEBRADA: A VIEW OF NEANDERTHAL TERRITORIAL MOBILITY

*Eixea, Aleix - (Departament de Prehistòria i Arqueologia. Universitat de València) alejo.eixea@uv.es*

*Villaverde, Valentín - (Departament de Prehistòria i Arqueologia. Universitat de València) valentin.villaverde@uv.es*

*Zilhão, João - (Departament de Prehistòria, Història Antiga i Arqueologia. Universitat de Barcelona) joao.zilhao@ub.edu*

There is an abundant literature on the difficulties generated by the assessment of space use in Middle Paleolithic archaeological levels as a result of the fact that, in a large proportion of cases, these levels correspond, following the terminology proposed by Bailey (2007), to cumulative palimpsests. In the Mediterranean area of Iberia, recent studies have focused on the finer dissection of the diachronic components of the different units of occupation subsumed in such palimpsests, based on the analysis of spatial distributions of raw material units (Machado *et al.*, 2011), hearths and the vertical projection of finds (Sañudo and Fernández-Peris, 2007; Marrero *et al.*, 2011), with little progress in the joint assessment of these aspects, as well as on stone and bone refits (Vaquero *et al.*, 2012). Our purpose is to establish the use of space within the site, focusing on the differences observed when comparing the upper levels (I-V) with the lower ones (VII-VIII). The results obtained are compared with other sites from the Valencian area and allow us to highlight some features characterizing the occupation of the territory by Neanderthal groups in the central region of the Iberian Mediterranean.

Abrigo de la Quebrada is a rockshelter situated near Valencia. The excavations, still in progress, have revealed 8 archaeological levels. The human occupation evidence is found in levels II-V, VII and VIII, while most intensive occupations are those in levels III, IV and V (Eixea *et al.*, 2012). Level III has a date around 40,500 BP, and level Level IV around 43,930 (Eixea *et al.*, 2012; Villaverde *et al.*, 2008). The lower levels (VII-VIII) probably date back to MIS5. In the stratigraphy different rates of sedimentation and therefore different possibilities for spatial analysis can be observed.

Level IV is a cumulative palimpsest with a high density of finds and where isolating the different phases of occupation is very difficult. Processing of animal remains and knapping activities are structured by hearths that occupy the central part of the excavated surface. In contrast, occupations are better defined in Level VII, as shown by the study of hearths and refits. These contrasts reflect not only differences in the rate of deposition but also differences in mode of human use. Bearing in mind the time factor, the taphonomic analysis and spatial distributions of finds bring up significant differences in knapping systems, breakage patterns, abundance of carnivores, raw material procurement and blank selection. These data suggest differences in both function and duration, with the Level VII occupations being shorter and seemingly characterized by less intensive processing of the faunal remains.

ORAL

**18. DID STONES SPEAK ABOUT PEOPLE? FLINT CATCHMENT AND NEANDERTHAL BEHAVIOUR FROM AREA 3 (CAÑAVERAL, MADRID-SPAIN).**

*Ortiz Nieto-Márquez, Irene - (Universidad Autónoma de Madrid) irene.ortiz@uam.es*

*Baena Preysler, Javier - (Universidad Autónoma de Madrid.) javier.baena@uam.es*

Middle Paleolithic catchment patterns have been exhaustively studied in the past. However, it is essential to clearly define Neanderthal technical and strategic abilities in relation to raw materials self provide, from a temporal perspective.

Here we present a study of quarrying activities in open air sites occupied during Mousterian period in Madrid (Spain), with different patterns of lithic catchment. For that, we have used technological studies, spatial analysis and refits information.

At El Cañaveral archaeological complex, several sites has been identified, in relation with natural flint outcrops. Those examples have provided information about flint supplying patterns, both in primary and secondary deposits. In addition, different "operative chains" and diverse systems of ramification and recycling process were employed depending on the final objectives.

It could be possible to appreciate the addition actions by analyzing the diacritic superposition of knapping series in blanks, cores and supports of different qualities.

Changes into categories, dimensions and raw material qualities, allows a first identification of lithic actions along the time as a proxy of standardize or random human behavior when catchment actions took place.

POSTER SESSION 2

POSTER

**19. RAW MATERIAL ECONOMY ON THE MIDDLE PALAEOOLITHIC SITES OF THE CSERHÁT REGION, NORTHERN HUNGARY**

*Markó, András - (Hungarian National Museum) markoa@hnm.hu*

In the Cserhát region, northern Hungary a large number of Middle Palaeolithic sites have been discovered during the intensive field works since 2000. The assemblages yielded bifacially worked and leaf shaped implements together with numerous Middle Palaeolithic side-scrapers and very few Upper Palaeolithic tool types. A common characteristic trait of the collections is elevated ratio of etralocal felsitic porphyry (imported from at least 95 km) among the raw material and in some cases the obsidian variants with the sources lying 160-190 km from the archaeological sites were used also.

In the presentation two different industries will be discussed. The sites of the Bábony-type industry (local variant of the Micoquian or Keilmessergruppe) are known mainly after surface collections, while a quite original assemblage was excavated near Vanyarc after the field trips around this village.

Our filed observations showed that the lithic artefacts were found in a hard, decalcified clay, close to the present-day surface, but the archaeological level was only slightly disturbed and clear spatial patterning of the artefacts were observed.

The ratio of the felsitic porphyry in the excvataed assemblage from Vanyarc reached 33% of the inventory, which means 650 pieces of this long distance raw material. Moreover, the refits in one of the find concentrations show that the tools were retouched on the site and even primary flaking of felsitic porphyry could have been proved.

These results may shed light to the raw material economy of the assemblages, known after filed surveys until today.

Our result from the study of both the surface collected and excavated assemblages of at least two different Late Middle Palaeolithic industry show, that the open-air sites in this region are traces of short term occupation of mobile groups of humans. On the other hand, both the archaeological connections and the raw material types suggest strong eastern connections of the assemblages with linear raw-material procurement system, reaching at least for 100 km as the crow flies.

The archaeopaleontological sites of Pinilla del Valle (Madrid, Central Spain) have provided a set of important items: i.e. Neanderthal teeth, lithic assemblages and domestic hearths, which show the development of human occupations at the beginnings of the Upper Pleistocene in Central Spain.

Palynological and anthracological analyses conducted have provided in turn key information about vegetation dynamics and wood uses developed at the beginnings of the Upper Pleistocene, a period of time still characterised by scarce and fragmentary palaeovegetational information in central Spain.

Pollen data have shown the progressive installation of an open landscape in the area in accordance with the global scale increasingly colder conditions.

Based on these previous data this work focuses on the potential resources that such vegetal environments can provide to the dietary, subsistence and uses of territory by the Neanderthal community settled there. The taxa

identified by pollen and charcoal analyses are grouped into four categories (food, medicinal use, manufacturing and firewood), in order to know the range of uses that neanderthals may have made from plants. Charcoal data revealed the use of wood from different plant communities which demonstrates the potential of woody plant resources that such open environments hosted inside.

On the other hand the studies on oral dental microwear have proved that Neanderthal not only consumed meat, but seafood, fish and some cooked vegetables were also present in his diet.

Correlations between climate change on paleoecosystems and Neanderthal subsistence patterns have been established, showing how flexible was the Neanderthal diet and his ability of adaptation to changes in food resources over time.

POSTER

**21. ARCHÉOZOOLOGIE DES NÉANDERTALIENS DU ROC DE MARSAL : ENTRE SUBSISTANCE ET ACTIVITÉS TECHNIQUES**

*Castel, Jean-Christophe - (Muséum de Genève) jean-christophe.castel@ville-ge.ch*

*Soulier, Marie-Cécile - (Trent Universitx & Université de Toulouse) mariecsoulier@gmail.com*

*Chauvière, François-Xavier - (OPAN Neuchâtel, Suisse) francois-xavier.chauviere@ne.ch*

*Discamps, Emmanuel - (University of Bergen & Université de Bordeaux) ediscamps@gmail.com*

The Roc-de-Marsal cave (Campagne, Dordogne, France) presents an important stratigraphic sequence for the Middle Palaeolithic, with lithic assemblages attributed to the Denticulate Mousterian, Typical Mousterian and Quina Mousterian. This communication compares the archaeozoological data obtained for the Typical Mousterian and Quina Mousterian assemblages, two techno-complexes that are distinguished by important differences in their lithic industries. The large number of faunal remains discovered allows an exploration of the impact of this technical diversification on the methods of game exploitation.

Nearly 36,000 animal remains were analysed (7000 identified). Reindeer was the most abundant species in all the layers, with a small proportion of horse. Other species were present, but of marginal importance. The bone surfaces were well preserved, and many traces of human

activity could be observed, while evidence of consumption by carnivores was rare.

To compare the subsistence behaviours of the different Neanderthal groups that occupied the Roc-de-Marsal cave, we present a chronological comparison of the strategies employed in hunting game and the methods of butchery employed.

Although the overall similarities are clear, there are differences in the details that illustrate variability in the behaviour of Neanderthal populations. These observed differences are discussed to distinguish those representing a response to natural constraints (the health of the prey, etc.) and those that may relate to cultural traditions.

The bone material collected at Roc-de-Marsal is characterised by the abundance of anthropic marks not related to butchery. There is a very high proportion of *retouches*, but also various kinds of superficial marks, blunt tips and series of notches along the edges of some diaphyses.

These indicate that the animals were not used solely for food and that their exploitation gave rise to varied activities in the cave, and may be compared with the other types of archaeological data.

---

## POSTER

### 22. THE SITE OF TATA (HUNGARY) REVISITED. MORPHO-FUNCTIONAL RESULTS SUGGEST HAFTING OF NEANDERTAL'S MICROLITHIC TOOLS

Borel, Antony - (UMR7194 - Département de Préhistoire, Muséum national d'Histoire naturelle) borel@mnhn.fr

Moncel, Marie-Hélène - (UMR7194 - Département de Préhistoire, Muséum national d'Histoire naturelle- CNRS) moncel@mnhn.fr

Several Western and Central European archaeological sites from the Marine Isotopic Stage (MIS) 5 to 3 yielded lithic artifacts odd by their small size (less than 30 mm long) into the Neanderthal world. However, the European Prehistory lacks a thorough study of these small artifacts to understand their potential function and to investigate Neanderthal capabilities, behaviours and conception of their tool kit.

We propose here a morpho-functional (morphometrics and usewear analysis) approach of the microlithic artifacts from Tata (Hungary), dated from the MIS 5, from 116

$\pm 1.6$  Kya to  $70 \pm 2$  Kya (U/Th), to understand how and for what purpose these tools were used. The open-air site of Tata yielded an extensive microlithic assemblage (more than 10,000 pieces) mainly made of local raw material: silicites-radiolarites (88 %), quartz and quartzite.

A sequential experimentation was carried out with local radiolarite in order to build a reference set of traces. The observation with a magnification glass (40x) of a sample of 7615 archaeological stone artifacts lead to the selection of 100 artifacts made of siliceous rocks with traces which could be due or intended to use. Both experimental and archaeological artifacts were observed with a reflected light microscope (50-500x) and a stereomicroscope (6.3-80x).

Morphometrics data consisted in the mass, length, width and thickness of each artifact selected for usewear analysis. Log shape ratios were used to gain insights into the variation of shape in the sample. The relationships between shapes and the presence of use traces were analyzed as well as the relation between shape and size and shape and mass with use traces.

The analysis of the archaeological sample resulted in the identification of 57 pieces with traces of use or hafting and 43 with indeterminate or no traces. The used artifacts have statistically significant larger dimensions than pieces with indeterminate or no traces. The tests on log shape ratios showed no significant difference of shape related to use. The primary mode of use identified was a transverse motion (N = 22) but some tools were also used in longitudinal mode (N = 9) and in percussive motion (N = 3). Hafting traces were identified on 24 flakes but only 6 pieces could be interpreted with a sufficient reliability score. The results were also crossed with previous typo-technological study of the assemblage.

In conclusion, the overall outline of the tools was probably not of great interest for the human (Neanderthal) from Tata. However, it seems that they were looking for artifacts with at least one sharp edge opposite a back, likely for better prehension or hafting. They used their production (pebble tools, raw and retouched flakes) hand held or hafted for several activities. The reason why they produced so small artifacts remains unknown as large pebbles were also available and the proportions among the studied sample, morphometric tests and usewear analysis showed that the smallest artifacts may not be the most frequently used.

POSTER

**23. TRANSPORTS OF STONE ARTEFACTS: INSIGHTS FROM LANGEDOCIAN LATE MIDDLE PALAEO-LITHIC ASSEMBLAGES**

*Lebègue, Frédéric - (UMR 7194, Muséum National d'Histoire Naturelle de Paris - UPVD, CNRS.) fred.lebague@gmail.com*

Raw material procurement and stone artefact handling strategies are key data sets for the study of Middle Palaeolithic hominin behaviour. Moreover, recent technological studies on Western Europe Mousterian assemblages underline the strong fragmentation of the *chaînes opératoires* and their close relationship with the mobile character of the Neandertal populations. These show also a more diversified nature of transported lithic items that what was commonly described for thirty years in the technological analysis. Ongoing research on the Langedocian Late Middle Palaeolithic provides new insights on the transport patterns of lithic objects made on non-local materials no matter the geographic scale.

This study integrates lithic technology and raw material data retrieved from the recent reassessment of the main regional Middle Palaeolithic series, which widely benefits from the last ten years progresses in cartography and detailed petrographic analysis of the Mediterranean north-western corner lithic resources. Based on fine-grained techno-economical analyses, the present contribution is specially focused on spatial fragmentation of the non-local and exotic materials reduction sequences and the identification of their transporting forms towards the diverse regional landscapes.

Data obtained on the languedocian assemblages, coming mostly from cave and rockshelter sites, confirm as well as add to the results of other works, conducted in the Aquitaine region, the Liguria or the nearby Rhône valley. They highlight the ubiquitous and continuous transport of stone artefacts of a wide variety of forms, despite the decrease in quantity and proportion of distant origin materials. Beside the usual Levallois flakes and retouched tools (scrapers), mobile toolkits regularly include different kinds of cortical or non-cortical flakes, thus not only desired end-products - among which very thin and sharp flakes, reshaping flakes, large thick flakes transformable into tools or cores - and already preformed cores. The transport, the exploitation and the passing through of cores upon 80 to 100 km as well as tool maintenance processes are widely documented in the Mediterranean area, both in coastal and hinterland sites, by refitting and different sets of byproducts (small

flakes, retouching flakes, fragments and chunks). Rather than specialized objects or specific tools, the toolkits of the Middle Palaeolithic groups seem to be composed by general purpose or multipurpose artefacts forming easily transportable and versatile reserves of raw material. Illustrating the Neanderthals abilities to anticipate their technical needs, the size of the imported equipment, as his composing and maintenance degree (resharpening/recycling) varies depending on the provisioning strategies, the planned activities on the site, but also on the techno-economical organization of the lithic techno-complexes (Quina, Levallois, ...).

Our results, matching with observations recently made on Middle Palaeolithic assemblages of other regions, underline the large scale of lithic artefacts moved by Neandertals, occasionally upon distances of 100km or more. This less stringent tool blanks selection criteria than usually assumed, illustrated by the transport and the use of all types of usable products (irregular flakes, 'wastes', ...) testifies to both the high flexibility of the raw material procurement strategies and the role of mobility in structuring Mousterian lithic assemblages.

The Italian Peninsula seems to be playing an important role in the debate on the cultural occurrences connected to Neanderthals. Its particular geographical position, as a peripheral appendix of the European continent, gives origin to a territory constrained in a long and narrow strip of land which, differently from the vast plains of Northern Europe, acts as a *cul de sac* in the population dynamics of humans and animals.

At the same time, the highly variable and fragmented landscapes, sprouting from a great geomorphological variety (Apennine Chain - coastal areas), create the conditions for a wide range of resources and for a mosaic-like peopling of the Peninsula. From a chronological standpoint too, a narrowing of the time range of Neanderthal record is observable, particularly in Southern Italy. This is defined, in comparison to the wider European context, by a late appearance of *Levallois* in lithic industries (OIS 5) and by an early arrival of the first cultures connected to *Homo sapiens* (Uluzzian, about 45-44 kys BP).

For this reason, the study of Neanderthal communities who occupied Southern Italy during that time span provides a very interesting viewpoint for the understanding of their actual variability and complexity. Over the last decade, Middle Palaeolithic research in Italy has experienced an important methodological renewal thanks not only to the diffusion of technological approach in

lithic studies, but also to the broader attention paid to behavioural expressions of these human groups: exploitation strategies of the territory and of the mineral and food resources, spatial organization, mobility within territories, stone tool production, fire technology, symbolic expressions, etc.

Investigations carried out by Research Unit in "Prehistory and Anthropology" of the University of Siena fit within this framework of methodological renewal and focus the on key sites located in different regions of Central-Southern Italy.

This work wants to present and compare the results obtained over the last few years from the sites of Cala dei Santi (Southern Tuscany), Castelcivita, Molare and Grotta Grande (Campania), Oscuruscuito and Santa Croce (Apulia), with the aim of shedding light on Neanderthals' behavioural variability.

Different types of human settlements can be found both in caves and rock-shelters during the Middle Palaeolithic (e.g., camp-sites, seasonal occupations, short settlements, etc.). Distinguishing these types of occupations is not an easy task. Furthermore, the palimpsest character documented in the most of the archaeological sites difficult still more the interpretation of them. Nevertheless, data from multidisciplinary studies can help making approaches and characterizing in a more accurate way these accumulations.

Level III of Teixoneres Cave (Moià, Barcelona, Spain) has provided a significant record belonging to the Late Pleistocene (MIS 3). It corresponds to a palimpsest alternating human and carnivorous activities. The stratigraphic sequence, spanning more than 7 m high, is dated between  $100.3 \pm 6.1$  ka and ca. 14-16 ka BP.

The multidisciplinary works carried out on Level III assemblage since 2007 showed a significant biological dynamic related to carnivore activities, mainly bears and hyenas. This constant dynamic was perturbed occasionally by the presence of human groups, with an occupational model based on the use of the cave as an occasional shelter by small groups of Neanderthals during very short periods of time. This was mainly demonstrated by:

- (1) the reduced dimensions and the thinness of the hearths and the limited spatial extension of the activity areas related to them (discrete areas);
- (2) the high diversity of large mammals and low integrity of their skeletons;
- (3) the low number of anthropogenic bone damage (cutmarks, burning damage and intentional bone breakage);
- (4) high carnivore damage;
- (5) presence of characteristic remains of carnivore dens (immature individuals, coprolites, etc.);
- (6) the diversity of allochthonous stone raw materials;
- (7) the fragmented character of the lithic operative chains realized on allochthonous raw materials in opposition of the complete reduction sequences realized on local stones (basically the quartz).

A multiproxy palaeoecological approach based on studies of pollen, charcoal, small vertebrates (amphibians, squamates and small mammals)- and large-mammal dental wear indicates temperate and humid conditions for Level III (López-García et al. 2012). More recently, the identification of few remains of cold-adapted ungulates, such as woolly mammoth and woolly rhinoceros –which does not fit with the previous climatic interpretation–, suggests the occurrence of climatic shifts during the sedimentary formation of this unit. The presence, in the same level, of both cold and temperate taxa clearly supports that Level III correspond to a palimpsest of several occupations. Moreover, the new results obtained from the zooarchaeological and taphonomic analysis of small preys such as the leporid remains corroborate the expeditious character of the human occupation patterns (Rufà 2013). In addition, tooth microwear study on ungulates permits to identify a succession of short and seasonal events (Sánchez Hernández 2013) and allow to distinguish a higher intensity of human activities at the lower part of the palimpsest of Level III. Studying the hu-

man occupational pattern provides a framework focused on understanding the Neanderthal groups' behaviour in a territory. The aim of this study is to characterize the short-term occupations and value the human-carnivore interactions at Teixoneres Cave level III and by extension in the European Middle Palaeolithic.

ORAL

## 26. LAS CALLEJUELAS (MONTEAGUDO DEL CASTILLO, TERUEL): A HIGH-ALTITUDE SITE OCCUPIED DURING THE OIS 5

*Utrilla Miranda, Pilar - (Universidad de Zaragoza) utrilla@unizar.es*

*Domingo Martínez, Rafael - (Universidad de Zaragoza) rdomingo@unizar.es*

*Torres Pérez-Hidalgo, Trinidad de - (Universidad Politécnica de Madrid) trinidad.torres@upm.es*

*Ortiz Menéndez, José Eugenio - (Universidad Politécnica de Madrid) joseeugenio.ortiz@upm.es*

Las Callejuelas is an open-air, high-altitude (1450 m) site located in a strategic area in the Sierra de Gúdar – Maestrazgo region. It occupies the margins of a small ravine that serves as a corridor to canalize the faunal displacements and links two different biotopes: a dry, semi-step-pic zone in the southern area and an endorreic, more humid valley in the northern slope. Even today, the region presents severe challenges for the human life: it is one of the coolest in the Iberian Peninsula, with a continental, dry climate influenced by the notable altitude and its location in the heart of the Iberian range.

There, groups of Neanderthal people hunted Bovidae and horses as well as some Cervidae. The coarse and small-sized lithic industry is based mainly in non-canonical endscrapers and perforators that have been knapped on low-quality raw materials.

Recently, some teeth have been dated by racemization, with interesting and coherent results: the upper part of the stratigraphy has been dated in 116 ky, the middle part in 122 ky and the lower part in 135 ky. The site was occupied during the OIS 5, in coincidence with some of the human presences in Bolomor and Cuesta de la Bajada, with whom Las Callejuelas shares technological similitudes. The human occupation of the site during the interglacial period is well suited with the extreme climate that characterizes the region and its condition of open-air butchery camp.

ORAL

## 27. PERSISTENCE AND EVOLUTION OF NEANDERTAL BEHAVIOR IN THE ARBREDA CAVE DURING THE UPPER PLEISTOCENE SOLER, JOAQUIM - (UNIVERSITAT DE GIRONA) JOAQUIM.SOLER@GMAIL.COM

*Soler, Narcís - (Universitat de Girona) narcis.soler@udg.edu*

The Neandertals occupied the Arbreda cave (located in Serinyà, NE Iberian Peninsula) since the beginning of the Upper Pleistocene until their disappearance around 40.000 bp. Although most occupations have low spatial and vertical resolution, there are no other sites in the region with wider or even similar chronological limits. Therefore the evidences provided by this site could contribute to describe the evolution of the Neandertal behavior in the long term scale.

More than 30.000 lithic artifacts and good preserved faunal remains distributed in a 4 meters deep stratigraphy have been documented. They have been chronologically framed by Uranium series results for the bottom, which we introduce for first time in this paper, and radiocarbon results for the top.

The archaeological remains of their occupations in the Arbreda cave confirm the commonly admitted idea about the persistence of their technological traditions, which only seem to evolve slightly at the end of the sequence just before the arrival of the Archaic Aurignacian. However several components and choices of their technological behavior may be considered unreasonable if analyzed only under the actual and dominant economic logic, which is commanded by the idea of productivity. In opposition to that evidence for technological stability, the way in which the cave was occupied differs significantly between the beginning of the Upper Pleistocene and the interruption of the Mousterian traditions. This evolution should be explained in relation to the alternating uses of the cave between the *Homo neanderthalensis* and the *Ursus speleaeus*, whose remains are absent in the bottom of the Mousterian sequence but omnipresent at the end.

In order to study the Neandertal behavior in the long term scale, the evidences discovered in the Mousterian levels of the Arbreda cave show the need to combine the ideas of the technological stability, occupational variability and economic singularities. A better understanding of those phenomena might be obtained with more spatial and temporal resolution. Therefore the Mouste-

rian sequence of the Arbreda cave should be enlightened with the evidence provided by the sites with true occupational resolution, which are fortunately present in different landscapes of Catalonia.

Neanderthal behavior is a much-debated topic in current archeological and paleoanthropological research, mostly due to the particular role of Neanderthals in the discussion about the emergence of modern behavior. Neanderthal behavioral patterns have been too often approached from the study of low-resolution lithic and faunal assemblages, which tend to reduce the range of variability by merging together different activity events. This time-averaging problem may yield an inaccurate picture of Neanderthal behaviors. High resolution assemblages in which palimpsest dissection is a feasible endeavor are therefore particularly suitable for approaching the behavioral variability of Neanderthals. This high-resolution approach is enhanced when the analysis of archeological remains is coupled with a detailed spatial perspective allowing to put activities in context.

Our approach to Neanderthal behavior is based on the study of level M of Abric Romaní (Capellades, Spain). This level, dated to c. 51-55 kyr BP, can be considered as a good example of a high-resolution and spatially-controlled assemblage even if some data suggest that it is an archeological palimpsest. The analysis of different types of archeological remains (including wood imprints) with a multidisciplinary approach is focused on identifying activity events and defining activity areas through spatial distributions and refittings.

The results of this study have allowed to show the behavioral variability of level M dwellers, especially concerning lithic technology. Besides characterizing provisioning and reduction strategies, lithic analysis will emphasize the importance of intrasite artifact transport and recycling in assemblage formation. On the other hand, the faunal remains indicate that humans were the main agent in assemblage formation as in the rest of the archaeological layers of the stratigraphic sequence. Different hearth-focused activity areas have been identified, some of them connected by refits, which opens the possibility to scrutinize the temporal relationship between the spatial units forming level M.

The focus on the high-resolution events forming an archeological assemblage highlights the variability of Neanderthal behavior in the short term. Moreover, the comparison between level M and other layers of the Abric Romaní sequence suggests that some behavioral patterns change according to factors acting at long-term temporal scales. The example of level M illustrates how

Neanderthal behavior is conditioned by different factors operating at different temporal scales and underscores the importance of temporal issues in the debate on behavioral variability.

*Molina Hernández, Francisco Javier - (U. de Alicante) jamonite@gmail.com*

*Vidal Matutano, Paloma (U. de Valencia) - p.vidal.mat@gmail.com*

El Salt is a Middle Palaeolithic site situated at the headwaters of the Serpis River (Alcoy, Spain). It is an open air place at the foot of a 38 meter-high cliff, located in a mountainous region of Alicante. It is near abundant flint sources and it occupies a strategic position at the confluence of two rivers with different biotopes and a freshwater spring system. This archaeological site is currently being the subject of a multidisciplinary research project mainly focused on the disappearance of Neanderthals and the earliest Upper Palaeolithic evidences of the Iberian Mediterranean.

In this communication geoarchaeological, chronological and paleoanthropological data from its Middle Palaeolithic sequence are presented. Alongside with those of other sites, they cast doubts on the hypothesis of survival of Iberian Neanderthals south of the Ebro River.

Our multidisciplinary perspective is oriented to the integration of geoarchaeological techniques (chronostratigraphy, geomorphology, paleobotany, geochemistry and micromorphology) and lithic and faunal studies in order to approach Neanderthal occupations at a high temporal resolution of analysis.

From the base of the sequence (SU XII) up to SU IX (around 50 thousand years ago) data show a pattern

of frequent but of short duration human occupations. These are materialized in a complex archaeological palimpsest in which site abandonment periods have been identified through archaeostratigraphic, micromorphologic and of biomarker analysis. Combustion structures are abundant in this part of the sequence, and their spatial distribution in relation to other archaeological remains indicates that they were a focus of human activity. From SU VIII up to SU lower V, human impact as reflected on artifact and faunal remains shows decline, coinciding with the end of Heinrich 5 event.

The base of SU V (around 47 thousand years ago), which is the uppermost and archaeologically poorest layer of the entire sequence, yielded teeth from the upper maxilla of a young adult individual. It is identified as a Neanderthal in a clearly Mousterian context. These fossils possibly represent some of the last Neanderthals of the region. There is no other evidence of Neanderthal presence in the area after this date.

This evidence -the latest Middle Palaeolithic of El Salt- is overlaid by a thick archaeologically sterile deposit. A similar discontinuity pattern has been attested at the nearby site of Cova Beneito, as well as in other Iberian sites.

These preliminary results from El Salt point to a gradual decrease of Neanderthal presence since 50 thousand years ago, coinciding with a paleoenvironmental shift towards driest conditions. The impact produced by such shift on regional human dynamic needs to be further investigated, but all data seem to indicate some degree of regional depopulation prior to the instalment of the earliest Upper Palaeolithic groups.

## POSTER SESSION 3

## POSTER

### 30. SYMBOLIC CHARACTER PRODUCTIONS IN THE MOUSTÉRIAN SITE OF LA ROCHE-COTARD IN LANGEAIS (INDRE-ET-LOIRE, FRANCE).

*Marquet, Jean-Claude - (CITERES/LAT/UMR 7324) jcmarquet@wanadoo.fr*

*Lorblanchet, Michel - (CNRS) michel.lorblanchet@wanadoo.fr*

The site of La Roche-Cotard is located on the right side of the Loire valley about twenty kilometers downstream from Tours. The cave, probably discovered in 1846, following the extraction of materials in front of the cave,

was excavated in 1912 to give mousterian industry. Researches start again in 1975 during 3 years and then from 2008 till now.

The first retaking of excavations in 1975 allowed the discovery, in front of the entrance of the cave, at the foot of the chalk cliff limestone, of a bit of beach of Loire river on which Neandertal have lit a fire, left mousterian industry and a protofigurine called by M. Lorblanchet the "mask of La Roche-Cotard" (Marquet and Lorblanchet, *Paleo* n°12/2000 and *Antiquity* 77/298/2003). A very low shelter was also found, containing some pieces of lithic industry and developments of blocks on the ground.

The second resumption of excavations in 2008 allowed the discovery of a small cave shelter filled with sediments and whose entrance was completely obscured by deposits on the slope. The imposing stratigraphy also revealed evidence of occupation by Neandertal. But these renewed excavations especially allowed to continue working within the main cavity.

Thorough examination of the walls, made with help of M. Lorblanchet, P. Paillet and E. Man-Estier, allowed to recognize, without any chronological hypothesis then preferred, three panels of traces using fingers or using an instrument giving the same type of traces, and a panel of punctuations.

These traces are visible because there were material removal on the wall of limestone weathered chalk covered with a thin film of clay and silt. On one of the panels, there is a circular representation; another triangular area is completely covered with parallel, organized, rhythmic, applied traces; a third rectangular panel has yet parallel tracks. On the other hand, four red ocher stains, three were discovered in a hidden place of a narrow tunnel and another one in the same tunnel near a wide crack.

The geometric size and morphological studies of deposits of all four loci of the site, as well as numerous bones datings from the  $^{14}\text{C}$  and sediments by the OSL method permit to show that after the occupation of the cave by hyenas which followed that one of Neandertal, the entrance of the cavity was completely obscured and that it was reopened only in 1846 or even in 1912.

No direct dating of plots is obviously possible. However, their local alteration, very strong in some areas (friction due to furs?), much more lighter elsewhere (draught?), datings of bones and sediments just in front of panels and naturally the shutting of the entrance of the cave after occupation by Neandertal allow to exclude a recent age for these plots.

Mask, tracks and traces of paint in an inaccessible cavity for *Homo sapiens* until 1846 (geometry of deposits and not any Upper Paleolithic tool discovered in the four loci) give the site of La Roche-Cotard a great interest at a moment when we reconsider seriously the question about competency of Neandertal.

---

POSTER

**31. THE EARLY MIDDLE PALAEOLITHIC OF THE CANTABRIAN CORNICHE AND THE AQUITAIN BASIN. A TECHNO-ECONOMIC STUDY OF PREHISTORIC SETTLEMENTS FROM CANTABRIA AND PERIGORD.**

*Djema, Hélène - (Conseil général du Val-d'Oise UMR 7041 ArScAn) helene.djema@free.fr*

In this study, the author considers the advances in the archaeological, anthropological and chrono-climatical domains to understand the place which occupies the ancient middle Palaeolithic (M.I.S.9 to 6) in the technical evolution of the past societies.

By revising the theoretical models of the technical evolution, it turns out that the question of the cultural phenomenon is situated in the heart of the problematic. Also, the purpose of the analysis is to enrich the documentation and to pursue the reflection on the existing relations between the cultural phenomenon and the technical data of the first neandertalians. The comparative techno-economic approach seems to answer in part of those expectations. Six lithics assemblages are studied : Petit Bost, Combe Brune III, Vaufrey cave, El Hondal, La Verde and El Castillo cave.

The study of those six lithics assemblages from Perigord and Cantabria supports the idea that the cultural phenomenon would be a process of progressive complexity, a process of "individuation" according to Gilbert Simondon's terms, of which "Moustérien" constitute a particular case.

The first neandertalians' comportemental strategies are certainly complex. Their technical systems are not strong marker pens of cultural entities. It is necessary to wait for news discoveries and fall on sites rich in information about these ethnocultural aspects. One day we will put in evidence of others comprtemental strategies, certainly more complex than what we imagine and propose more realistic scenarios on the meaning of the variability but also on the evolutionary processes of those technical systems.

Recent research have shown that Neanderthal's subsistence and hunting strategies were much more complex than those of passive scavengers. Further discoveries in European and Levant Middle Palaeolithic contexts might suggest the growing importance of throwing systems in hunting equipments.

In an attempt to better understand Neanderthal behaviours connected with the production of stone tools possibly linked with the manufacture of hunting weapons, convergent stone tools from the Middle Palaeolithic sites of Abri du Maras (Ardèche, France) and Baume-Vallée (Haute-Loire, France) were examined to establish how they were produced and their possible use.

A multi-analytical approach has been followed using technological analysis; morphometry and macro-use wear analysis.

From a corpus of 162 pointed tools, Levallois points have been compared to triangular flakes to identify the operational schemes involved. Tip cross-sectional area (TCSA) value has been calculated to testy the penetration degree of stone-tips. Moreover a low power approach with a binocular microscope Olympus SZ-PT (10–63 magnification) was used to observe impact fractures and hafting traces.

Technological studies at Abri du Maras have shown that pointed tools, issued from several knapping methods (Levallois, Discoid), were mostly unretouched Levallois points obtained by five main recurrent or preferential operational schemes (OS), (unipolar convergent OS, unipolar longitudinal OS, bipolar OS, centripetal OS and peripheral-orthogonal). Whereas at Baume-Vallée convergent and Quina scrapers, extensively retouched, represented the largest portion.

The morphometric TCSA values for the corpus of points have indicated low values compared to ethnographic darts, arrow tips and experimental thrusting spear data. Moreover TCSA values fell well within the expected values observed for experimental throwing spear and dart tips.

Preliminary macro use-wear analysis on a small sample of artefact showed evidence of possibly diagnostic impact fractures on their tip (step termination, burin-like fractures and spin-off) presumably connected with throwing activities.

The initial results from Abri du Maras and Baume-Vallée show a technological purpose to produce convergent tool shape using several reduction sequences, nonetheless relationship between shape and function cannot be easily established. At Abri du Maras TCSA values match the range proposed for throwing spears and dart tips and the existence of impact fractures suggest that even being multi-functional tools, either hafted or used as hand tools, a small sample of convergent artefacts may have functioned as projectile points, probably connected with hunting activities.

Stone tool projectile technology has generally been linked to the early African modern humans, therefore plausible evidences of Neanderthal projectile weapons at Abri du Maras during European Middle Palaeolithic, although being sporadic, should be able to question on current Neanderthal behaviours.

**33. THE GRAJAS CAVE OF ARCHIDONA (MÁLAGA, SPAIN). ONE EXAMPLE OF HUMAN OCCUPATION IN CAVES IN THE LATE MIDDLE PLEISTOCENE IN THE SOUTH OF IBERIAN PENÍNSULA.**

*Toro Moyano, Isidro - (Museo Arqueológico de Granada) isidro.toro@juntadeandalucia.es*

*Jiménez Arenas, Juan Manuel - (Departamento de Prehistoria y Arqueología Universidad de Granada) jumajia@ugr.es*

Las Grajas cave of Archidona (Málaga, Spain) represent one of the oldest examples of human occupation in caves in the south of the Iberian peninsula. Levels belonging to the late middle Pleistocene offers us a interesting portrait of environmental conditions and how interact and use resources by groups of hunter-gathered equipped with a Mousterian lithic technology aspect, typical of early middle Paleolithic.

POSTER

**34. NEW INSIGHTS INTO NEANDERTHAL DIET USING THE FAECAL BIOMARKER APPROACH**

*Sistiaga, Ainara - (Universidad de La Laguna, Massachusetts Institute of Technology) msistiag@ull.es*

*Summons, Roger E. - (Massachusetts Institute of Technology) rsummons@mit.edu*

*Mallol, Carolina - (Universidad de La Laguna) cmallol@ull.es*

*Galván, Bertila - (Universidad de La Laguna) bgalván@ull.es*

Neanderthal dietary interpretations have, until now, been based on indirect evidence and may disregard the role of plants as a food source. At present, there is some ambivalence in the paleodietary information available from the fossil record. While zooarchaeological and stable isotope data portray Neanderthals as prime carnivores, evidence of plant intake from dental calculus and paleobotanical remains warn us about the possible importance of plants in the hominin diet. Thus, our current view of Neanderthals diet does not provide information about the relative amounts of different kinds of foods that contributed most to their diets. What were Neanderthals' regular meals.

GC-MS analyses were carried out using a sensitive and selective detection method, that is, multiple reaction monitoring (MRM). We used precursor-product mass spectrometric transitions for sterol and stanols in combination with gas chromatographic retention times to establish the composition of steroidal lipids isolated from combustion structures from El Salt Middle Paleolithic site Unit X.

The sediment samples belong to the stratigraphic unit under current excavation (S.U. X) and are associated with archaeological remains and sedimentary facies were excavated, sampled and documented according to a methodology geared to the identification of human occupation episodes. The selected combustion features belong to diachronous archaeological facies association.

Our gas chromatography-mass spectrometry results from El Salt (Spain), a Middle Palaeolithic site dating to ca. 50,000 yr. BP, represents the oldest positive identification of human faecal matter. Our study demonstrates that Neanderthals, like anatomically modern humans, exhibit a high rate of conversion of cholesterol to coprostanol related to the presence of necessary gut bacteria. Analysis of five sediment samples from different occupation floors suggests that Neanderthals predominantly consumed meat, as indicated by high coprostanol propor-

tions, but also had significant plant intake, as shown by the presence of 5 $\beta$ -stigmastanol. This study highlights the potential of the biomarker approach in Pleistocene contexts as a provider of direct palaeodietary information and supports the opportunity for further research into cholesterol metabolism throughout human evolution.

*de Lumley, Marie-Antoinette (UPVD-CERP-MNHN) lumley@mnhn.fr*

*Régis Vézian (UPVD-CERP-MNHN)*

The cave of Le Portel-Ouest (Loubens, France) is the only site in Ariège that contains a stratigraphic sequence that extends from the Middle Paleolithic to the Upper Paleolithic. Between 1949 and 1985, 33 human remains were discovered (dental, cranial and postcranial remains) in successive Mousterian layers dating from the end of IOS 3 (44 ky). This study aims to establish the taxonomic affinities of Le Portel's hominid fossils from dental elements.

The series of Le Portel-Ouest is composed by twenty three teeth (12 deciduous and 11 permanent), representing a minimum of 5 individuals. Dental remains are compared with a Neandertal and Modern Human samples. Coronary dimensions and non-metric characters of the outer enamel surface (OES) and the enamel-dentine junction (EDJ) are considered (data from  $\mu$ CT-scan).

The external metric analysis reveals low coronary dimensions (M-D; V-L) of deciduous and permanent teeth from Le Portel-Ouest. On the other hand, some of the non-metric morphological features of OES and EDJ have clear similarities with Neandertal teeth. Several of non-metric features, characteristics of Neandertals, were observed on both the deciduous and permanent teeth of the same dental class. However, lower definitive incisors are less taxonomically discriminating.

Thus, the occlusal morphology of deciduous and permanent teeth from Portel-Ouest presents some affinities with Neandertals. The Neandertal occlusal morphology combined with especially coronary reduced dimensions has been already reported for Neandertal individuals from Hortus (Hérault, France), which has a geographical and chronological proximity to Le Portel-Ouest.

### 36. UPDATING THE WESTERN LANGUEDOC AND ROUSSILLON MOUSTERIAN WORLD

*Saos, Thibaud - (CERP UPVD UMR 7194) saos@cerptautavel.com*

*Magniez, Pierre - (CERP UPVD UMR 7194) magniez@cerptautavel.com*

*Moigne, Anne-Marie - (CERP MNHN UMR 7194) moigne@mnhn.fr*

*Gregoire, Sophie - (CERP UPVD UMR 7194) gregoire@cerptautavel.com*

The Languedoc-Roussillon french region contains numerous and rich mousterian sequences mostly revealed by old excavations, and the findings were recently reviewed by university works in different fields (paleontology, technology, petrography,...). These studies confirmed the great potential and interest of these sites in the aim of characterizing the regional mediterranean Mousterian.

However, this pluridisciplinary studies are almost curbed by gaps, particularly on levels dating or confuse stratigraphic context of remains discovery, and the extensive exploitation of those old collections requires a field back to validate archeostratigraphic and chronostratigraphic results.

It's the aim of the multiannual PCR (Research Collective Program) "The western Languedoc and Roussillon Mousterian world" supported by French Culture Ministry, started in 2013 with four key sites (Tournal cave, Crouzade cave, Ramandils cave, Montou cave) and now extended to the entire region, which first results will be submitted for discussing the status of this regional area in the global mousterian sphere.

*Moloney, Norah - (Museo Nacional de Ciencias Naturales (CSIC), C/José Gutiérrez Abascal, 2, 28006 - Madrid - SPAIN) tcfa305@ucl.ac.uk*

Azokh Cave is a Middle Pleistocene to Holocene site located in Nagorno Karabagh (Lesser Caucasus). The geographic region forms a corridor linking Africa, Europe and Asia, and was important for early hominin and other animal expansion. Azokh Cave is part of a karstic system with several fossiliferous chambers located 850 m a. s. l and 200 m above the nearby village of Azokh. The main entrance, Azokh 1, is a large cave that has two geological sequences (lower and upper) with nine geo-archaeological units of which only the upper ones (Units I to V) have a significant archaeological record. The faunal remains and lithic artefacts present in these units indicate different kinds of human involvement, for example for occupation or animal exploitation.

The lithic artefacts presented here were recovered from Unit V, Unit III and Unit II during 2002 – 2012 excavation seasons. The available chronological data indicates an age between 293 – 100 Ka for these units. The study sample consists of 1199 artefacts: cores, simple and retouched flakes, flake fragments and fragments, some of which may be considered as debris. The Logical Analytical System (LAS) and aspects established by Anglo-Saxon and French schools form the theoretical and methodological framework of lithic analysis, used in this study. Different local and non-local raw materials were exploited in all units for the production of lithic artefacts, although the range of raw materials is more varied in Unit II. Local chert, flint and basalt were used most commonly, probably due to their easy accessibility. Limestone, jasper and sandstone, from local and non-local sources, are present in small quantities in Units V and II. Obsidian is the only raw material that possibly originates from more distant sources. Flint and chert appear to have been preferentially exploited for flake tool production in all units, but the toolmakers show a preference for better quality raw material (flint, basalt, obsidian) for retouched pieces in Units V and II, and for Levallois production in Unit II. The operational chain is incomplete and artefacts found in the cave are primarily end-products dominated by flake-tools. The assemblage of Unit V is composed primarily of

simple, unretouched flakes with a minimal presence of retouched flakes and cores. The Unit II lithic assemblage includes a substantial Levallois component, although with fewer cores and retouched flakes. Unit III contains a small number of flakes and flake fragments.

While it is still difficult to assign the Unit V assemblage to a techno-typological group or complex (i.e. Acheulean, Mousterian or other local techno-complexes such as the Kudarian), the Unit II assemblage is clearly associated with the Mousterian techno-complex.

### 38. UNDO KLDE - MIDDLE AND UPPER PALEOLITHIC CAVE SITE ("SIMA DE LOS HUESOS" OF GEORGIA)

*Tushabramishvili, Nikoloz - (Ilia State University) nikoloz\_tushabramishvili@iliauni.edu.ge*

*Javakhishvili, Zurab - (Ilia State University) zurab\_javakhishvili@iliauni.edu.ge*

*Elashvili, Mikheil - (Ilia State University) mikheil\_elashvili@iliauni.edu.ge*

*Mamiashvili, Vaja - (Ilia State University) vazha.mamiashvili.1@iliauni.edu.ge*

*Gabekhadze, Bachana - (Ilia State University) bachana.gabekhadze.1@iliauni.edu.ge*

*Dvalishvili, David - (Akaki Tsereteli State University) dato1686@mail.ru*

The unique cave site Undo Klde is situated in the karstic region of Western Georgia, in Upper Imereti, which is one of the richest and well-known by the Paleolithic sites regions. The uniqueness of the site is: Temporary camp-site of hunters; Presence of the MP and UP layers which are in contact with each other; Presence of the deep karstic pit at the end of the corridor; Paleontological and Anthropological materials on the bottom of the pit; The evidence of the earthquake in Paleolithic Age.

**Methods.** All kind of common multidisciplinary researches have been used for study of the cave. The elevator was installed to study the 50 m deep karstic pit.

**Stratigraphy.** For the present time 8 lithological layers have been determined in the cave. 7 of them contain the materials of different ages and cultures: Medieval, Upper Paleolithic and Middle Paleolithic.

**Middle Paleolithic stone industry.** The percent of the tools is quite high. Most of the tools are the elongated Mousterian points. Other materials are represented by

some flakes and elongated blades. The materials belong to the levallois facies.

**Faune.** 99% (12 ind.) belong to *Ursus* sp. Big number of *Ursus* sp broken remains have been found just under the big rocks.

**Microfaune.** The microfauna is represented by *Arvicola* sp. and *Microtus* sp.

**Paleoanthropology.** The fragment of the human tooth was found during the sieving of the sediments of the Middle Palaeolithic layer.

**Karstic Pit.** At the end of the Cave horizontal corridor (length-80 m) a rather deep (48 m) natural karstic pit has been discovered, which is rich with faunal and anthropological remains. The pit is extremely difficult to reach as it is situated at the end of a long and narrow passageway. It is rather probable that animal and human remains were intentionally thrown or fallen into the pit.

*Ursus* sp. *Canis lupus*, *Cervus elaphus*, *Capreolus capreolus* and some other species have been identified. Besides, human remains were found there too. The study of the bone materials show us that part of them appeared in the pit after mortality.

We would like to note that we could not find any archaeological material in the pit.

**Rock Art.** The engraved marks were found deeply inside on the wall of the cave. It can be considered as the unique and the oldest trace in the region of the Rock Art. We have one more Cave site in the region with Middle and Upper Paleolithic Layers without sterile layer between them. Undo Cave is giving us more possibilities to understand human behaviours and the problems of Middle to Upper Paleolithic transition.

Conclusions:

1. The cave was used by Middle and Upper Paleolithic hunters as a temporary camp;
2. The cave periodically was used by the cave-bears.
3. Possibly, the part of them was killed by the fallen rocks (result of earth-quake).
4. The cave was used for some kind of initial rituals;
5. The layer with big number of *Ursus spelaeus* remains

possible correlated with the Bondi Cave layers where are confirmed the results of paleo-volcanism and paleo-earthquake.

*María Haber-Uriarte - (Dept of Prehistory, Archaeology, Ancient and Mediaeval History and Historiographical Techniques, Faculty of Letters, Murcia University, Campus Universitario de La Merced, Calle Santo Cristo 1, 30001 Murcia, Spain) mariahaber@pi-ma.es*

*Ortega-Rodrigáñez, Jon - (Dept of Zoology and Physical Anthropology, Biology Faculty, Murcia University, Campus Universitario de Espinardo Edificio 20, 30100 Murcia, Spain) ventepalportus@yahoo.es*

Articulated skeletons of two Neanderthal adults and a child excavated in this cave system were positioned before rigor mortis occurred because both a woman and the child were found with flexed knees and elbows, their hands against their faces. Nearby finds suggest attention was paid to the deceased. Scattered remains of at least another six individuals may have been afforded less attention.

Systematic excavation began in 1994 and despite finding scattered Neanderthal teeth and bone fragments before 2005 only then did deeply-lying bones in anatomical connexion appear, though technical problems had to be overcome in order to extract from a heavily-cemented rock tumble more articulated skeletal parts which by 2008 corresponding to three Neanderthals lying above one another: from above downwards SP96 ("Paloma"), SP97 ("Paloma's child"), and SP92 to which may belong a mandible cemented in articulation with the maxillae, extracted by a spelaeologist in 1991.

SP96 ("Paloma") was a 16-20 year-old woman of short stature, lying on her left side (head West, ankles East). Her skeletal parts lay connected anatomically, including

shoulder and pelvic girdles, flexed knees and elbows, both hands held against her crushed skull. Cranium, mandible, and >70 different bones are present, including all major limb bones. Laboratory removal of adherent breccia with vibroscalpels continues. A metacarpal gave a direct U-series date of 54,100±3850 BP (APSLP-1), in broad agreement with other dates from the excavation (Walker *et al.*, 2012, *Quaternary International* 259: 7-21). CAT scanning, undertaken to enable virtual reconstruction, has rendered visible also bones hidden in hard sediment cemented to the SP97 child's forehead, resembling SP96's manual arrangement. Found with knees and arms flexed, this Neanderthal child has cranium, mandible and >34 different bones. SP92 is represented by 60 different bones excluding the 1991 crushed mandible and cranial fragment which if they belonged to would accord with its W-E orientation because its articulated foot bones lay at E. The three skeletons lack cut-marks or traces of burning, though charred articulated horse ankle bones were excavated close to them, as were two unburnt articulated leopard paws, evidence of flint-knapping and Mousterian artifacts. There was no burial pit.

Were rocks thrown in disorderly fashion over the bodies (a family group?) to prevent disturbance by leopards or hyaenas? A hyaena tooth comes from the site. A burnt leopard temporal bone from the site suggests Neanderthal dominance. Articulated skeletal parts of humans and leopards imply Neanderthals deterred scavengers. Arranging cadavers before rigor mortis set in implies attention paid to flexing the elbows and knees of the dead. Regourdou, Shanidar 7 and Skhul 4 and 7 were Mousterian skeletons found with flexed elbows and hands against the face, though knee flexion is more widespread (A. Defleur, 1993, *Les sépultures moustériennes*, CNRS, esp. p. 233). The contrast is intriguing between the three articulated skeletons and scattered remains of other Neanderthal individuals found at the site (including some burnt bones). Layers under excavation below the articulated skeletons have provided Mousterian artifacts and burnt animal bones but as yet lack human remains.
